Linear time algorithm for quantum 2SAT

Itai Arad[∗] Miklos Santha† Aarthi Sundaram‡ Shengyu Zhang§

Abstract

A canonical result about satisfiability theory is that the 2-SAT problem can be solved in linear time, despite the NP-hardness of the 3-SAT problem. In the quantum 2-SAT problem, we are given a family of 2-qubit projectors Π_{ij} on a system of n qubits, and the task is to decide whether the Hamiltonian $H = \sum \prod_{ij}$ has a 0-eigenvalue, or it is larger than $1/n^{\alpha}$ for some $\alpha = O(1)$. The problem is not only a natural extension of the classical 2-SAT problem to the quantum case, but is also equivalent to the problem of finding the ground state of 2-local frustration-free Hamiltonians of spin $\frac{1}{2}$, a well-studied model believed to capture certain key properties in modern condensed matter physics. While Bravyi has shown that the quantum 2-SAT problem has a classical polynomial-time algorithm, the running time of his algorithm is $O(n⁴)$. In this paper we give a classical algorithm with linear running time in the number of local projectors, therefore achieving the best possible complexity.

1 Introduction

Various formulations of the satisfiability problem of Boolean formulae arguably constitute the center piece of classical complexity theory. In particular, a great amount of attention has been paid to the SAT problem, in which we are given a formula in conjunctive normal form $(CNF)^{-1}$ $(CNF)^{-1}$ $(CNF)^{-1}$ and the task is to find a satisfying assignment if there is one, or prove that none exists when the formula is unsatisfiable. In the case of the k-SAT problem, where k is a positive integer, in each clause the number of literals is at most k. While k-SAT is an NP-complete problem $[Coo71, Kar72, Lev73]$ $[Coo71, Kar72, Lev73]$ $[Coo71, Kar72, Lev73]$ when $k \geq 3$, the problem 2-SAT is well-known to be efficiently solvable.

Polynomial time algorithms for 2-SAT come in various flavors. Let us suppose that the input formula has n variables and m clauses. The algorithm of Krom $[Krod7]$ based on the resolution principle and on transitive closure computation decides if the formula is satisfiable in time $O(n^3)$ and finds a satisfying assignment in time $O(n^4)$. The limited backtracking technique of Even, Itai and Shamir [\[EIS76\]](#page-19-3) has linear time complexity in m , as well as the elegant procedure of Aspvall, Plass and Tarjan [\[APT79\]](#page-18-1) based on computing strongly connected components in a graph. A particularly simple randomized procedure of complexity $O(n^2)$ is described by Papadimitriou [\[Pap91\]](#page-19-4).

 $1A$ formula in CNF is a conjunction of *clauses*, where each clause is a disjunction of *literals* (variables or negated variables).

For our purposes the Davis-Putnam procedure [\[DP60\]](#page-19-5) is of singular importance. This is a resolution-principle based general SAT solving algorithm, which with its refinement due to Davis, Putnam, Logemann and Loveland [\[DLL62\]](#page-18-2), forms even today the basis for the most efficient SAT solvers. While on general SAT instances it works in exponential time, on 2-SAT formulae it is of polynomial complexity.

The high level description of the procedure for 2-SAT is relatively simple. Let us suppose that our formula ϕ contains only clauses with two literals. Pick an arbitrary unassigned variable x_i and assign $x_i = 0$. The formula is simplified: a clause $(\bar{x}_i \vee x_j)$ becomes true and therefore can be removed, and a clause $(x_i \vee x_j)$ forces $x_j = 1$. This can be, in turn, propagated to other clauses to further simplify the formula until a contradiction is found or no more propagation is possible. If no contradiction is found and the propagation stops with the simplified formula ϕ_0 , then we recurse on the satisfiabilty of ϕ_0 . Otherwise, when at some point the propagation assigns two different values to the same variable, we reverse the choice made for x_i , and propagate the new choice $x_i = 1$. If this leads to contradiction we declare ϕ unsatisfiable, otherwise we recurse on the result of this propagation, the simplified formula ϕ_1 .

There is a deep and profound link between k -SAT, arguably the central problem of complexity theory, and k-local Hamiltonians, the central objects of condensed matter physics. A k-local Hamiltonian on *n* qubits is an Hermitian operator of the form $H = \sum_{i=1}^{m} H_i$, where each H_i is by itself an Hermitian operator acting non-trivially on at most k qubits. Local Hamiltonians model the local interactions between quantum spins. Of central importance is the minimal eigenstate of the Hamiltonian, known as the ground state, and its associated eigenvalue, known as the ground energy. The ground state governs much of the low temperature physics of the system, such as quantum phase transitions and collective quantum phenomena [\[Sac07,](#page-19-6) [VLRK03\]](#page-19-7). Finding the ground state of a local Hamiltonian shares important similarities with the k-SAT problem: in both problems we are trying to find a global minimum of a set of local constraints. Moreover, with the advent of quantum information theory and quantum complexity theories, it has become clear that the complexity of finding the ground state and its energy is intimately related to its entanglement structure. In recent years, much attention has been devoted into understanding this structure, revealing a rich an intricate behaviour such as area laws [\[ECP10\]](#page-19-8) and topological order [\[Kit03\]](#page-19-9).

The connection between classical k -SAT and quantum local Hamiltonian was formalized by Kitaev $[KSVO2]$ who introduced the k-local Hamiltonian problem: one is given a k-local Hamiltonian H, along with two constants $a < b$ such that $b - a > 1/n^{\alpha}$ for some constant α . It is promised that the ground energy of H is at most a (the YES case) or is at least b (the NO case), and the task is to decide which case holds. Broadly speaking, given a quantum state $|\psi\rangle$, the energy of a local term $\langle \psi | H_i | \psi \rangle$ is a measure of how much $|\psi\rangle$ "violates" H_i , hence the ground energy is the quantum analog of the minimal number of violations in a classical k -SAT. Therefore, in spirit, the k -local Hamiltonian problem corresponds to MAX-k-SAT, and indeed Kitaev has shown [\[KSV02\]](#page-19-10) that 5 local Hamiltonian is QMA-complete, where the complexity class QMA is the quantum analogue of classical class MA, the probabilistic version of NP.

The problem quantum k-SAT, the quantum analogue of k-SAT, is a close relative of the k-local Hamiltonian problem. Here we are given a k -local Hamiltonian that is made of k -local projectors, $H = \sum_{i=1}^{m} Q_i$, and we are asked whether the ground energy is 0 or it is larger than $b = 1/n^{\alpha}$ for some constant α . Notice that the YES case, the energy of all projectors at the ground state is necessarily 0, since by definition, projectors are non-negative operators. Classically, this corresponds to a perfectly satisfiable formula. Physically, this is an example of a frustration-free Hamiltonian, in which the global ground state is also a ground state of every local term. Bravyi [\[Bra06\]](#page-18-3) has shown that quantum k-SAT was QMA_1 -complete for $k \geq 4$, where QMA_1 stands for QMA with one-sided error (i.e., on YES instances the verifier accepts with probability 1). The QMA_1 -completeness of quantum 3-SAT was recently proven by Nagaj [\[GN13\]](#page-19-11).

This paper is concerned with the quantum 2-SAT problem, which we will also denote simply by Q2SAT. The major result concerning this problem is due to Bravyi [\[Bra06\]](#page-18-3), who has proven that it belongs to the complexity class P. More precisely, he has proven that Q2SAT can be decided by a deterministic algorithm in time $O(n^4)$, together with a ground state that has a polynomial classical description.

The main result of this paper is a new algorithm for Q2SAT with a running time that is linear in m, the number of local terms in the Hamiltonian (which is upperbounded by $O(n^2)$). In this case, the Hamiltonian is given as a sum of 2-qubits projectors; each projector is defined on a 4 dimensional Hilbert space and can therefore be of rank 1, 2 or 3. Our algorithm is the extension of the Davis-Putnam procedure for Q2SAT. Structurally, it is based on a product-state theorem, which may be of independent interest. The theorem asserts that in the YES case of a Q2SAT problem that contains only rank-1 and rank-2 projectors, there always exists a ground state in the form of a tensor product of single-qubit states.

To illustrate the main idea of our algorithm, let us suppose that the input contains only projectors of rank at most two. It is worth considering a system of only rank-1 projectors, as any rank-2 projector can be written as a sum of two rank-1 projectors. Consider, for example, qubits 1 and 2 and a rank-1 projector $\Pi_{12} = |\psi\rangle\langle\psi|$ over these qubits. The product-state theorem implies that it suffices to search for product ground state. Thus on the first two qubits, we are looking for states $|a\rangle, |b\rangle$ such that such that $(\langle a|\otimes \langle b|\rangle \cdot |\psi\rangle = 0$. In other words, we look for a product state $|a\rangle \otimes |b\rangle$ which is perpendicular to $|\psi\rangle$. Assume that we have assigned qubit 1 with the state $|a\rangle$ and we are looking for a state $|b\rangle$ for qubit 2. One crucial point, which enables us to solve Q2SAT efficiently, is that just like in the classical case, there are only two possibilities: (i) for any $|b\rangle$, the state $|a\rangle \otimes |b\rangle$ is perpendicular to $|\psi\rangle$, or (ii) there is only one state $|b\rangle$ (up to an overall complex phase), for which $(|a\rangle \otimes |b\rangle) \cdot |\psi\rangle = 0$. The first case happens if and only if $|\psi\rangle$ is by itself a product state of the form $|\psi\rangle = |a^{\perp}\rangle \otimes |\xi\rangle$, where $|a^{\perp}\rangle$ is perpendicular to $|a\rangle$ and $|\xi\rangle$ is arbitrary. If the second case happens, we say that state $|a\rangle$ propagates to state $|b\rangle$ by the constraint state $|\psi\rangle$. The above dichotomy enables us to propagate a product state $|s\rangle$ on part of the system until we either reach a contradiction, or find that no further propagation is possible and we are left with a smaller Hamiltonian H_s . This smaller Hamiltonian consists of a subset of the original projectors, without introducing new projectors. It turns out that once an edge is checked for potential propagation, then no matter whether a propagation happens along the edge, the edge can be safely removed without changing the satisfiability. Thus the satisfiability of the original Hamiltonian H is the same as that of the smaller Hamiltonian H_s .

We still need to specify how the state $|a\rangle$ is chosen to initialize the propagation. An idea is to begin with projectors $|\psi\rangle\langle\psi|$ for which $|\psi\rangle$ is a product state $|\alpha\rangle\otimes|\beta\rangle$. In such cases a product state solution must either have $|\alpha^{\perp}\rangle$ at the first qubit or $|\beta^{\perp}\rangle$ at the second. To maintain a linear running time, we propagate these two choices simultaneously until one of the propagations stops without contradiction, in which case the corresponding qubit assignment is made final. If both propagations end with contradiction, the input is rejected.

The more interesting case of the algorithm happens when we have only entangled rank-1 projectors. What should our initial state be then? We make an arbitrary assignment (say, $|0\rangle$) to any

$$
\bigotimes_{i} \mathbb{R} \Rightarrow \bigotimes_{i} \bigotimes_{j} \mathbb{R} \Rightarrow \bigotimes_{i} \bigotimes_{j} \big
$$

Figure 1: Handling a contradicting cycle: we first slide the (i, j) edge along the loop until we get a double edge with a 'tail'. We then use a structure lemma to deduce that at least one of these edges can be written as a product projector.

of the still unassigned qubits and propagate this choice. If the propagation ends without contradiction, we recurse. If a contradiction is found then we confront a challenging problem. In the classical case we could reverse our choice, say $x_0 = 0$, and try the other possibility, *i.e.* $x_i = 1$. But in the quantum case we have an infinite number of potential assignment choices. The solution is found by the following observation: Whenever a contradiction is reached, it can be attributed to a cycle of entangled projectors in which the assignment has propagated from qubit i along the cycle and returned to it with another value. We call this a *contradicting cycle*. Then using the techniques of 'sliding', which was introduced in Ref. [\[JWZ11\]](#page-19-12), one can show that this cycle is equivalent to a system of one double edge and a 'tail' (see Fig. [1\)](#page-3-0). Using a simple structure lemma, we are guaranteed that at least one of the projectors of the double edge can be turned into a product state projector, which, as in the previous stage, give us two possible free choices.

Let us state here that our algorithm works in the algebraic model of computation: we suppose that every arithmetic operation on complex numbers can be done in unit time. There are several ways to work in a more realistic model. Bravyi [\[Bra06\]](#page-18-3) suggests considering bounded degree algebraic numbers, in which case the length of the representations and the cost of the operations should be analyzed. Another possibility would be to consider complex numbers with bounded precision in which case exact computation is no more possible and therefore an error analysis should be made. By choosing a more convenient computational model, we disregard these issues.

Classically Davis-Putnam [\[DP60\]](#page-19-5) and DPLL algorithms [\[DLL62\]](#page-18-2) are widely-used heuristics, forming the basis of today's most efficient solvers for general SAT. For quantum k-SAT, it could also be a good heuristic if we try to find product-state solutions, and in that respect our algorithm makes the first-step exploration.

2 Preliminaries

For a one-qubit state $|\alpha\rangle = \alpha_0|0\rangle + \alpha_1|1\rangle$, its perpendicular state is $|\alpha^{\perp}\rangle \stackrel{\text{def}}{=} \alpha_1|0\rangle - \alpha_0|1\rangle$. Any bipartite pure quantum state $|\psi\rangle$ in a two-qubit system (a, b) can be written as $|\psi\rangle = \lambda_0 |\alpha_0\rangle |\beta_0\rangle +$ $\lambda_1|\alpha_0\rangle|\beta_1\rangle$, where $\lambda_0, \lambda_1 \geq 0$ are *Schmidt coefficients*, $\{|\alpha_0\rangle, |\alpha_1\rangle\}$ is an orthonormal basis of \mathbb{C}^2_a , the space of qubit a, and $\{|\beta_0\rangle, |\beta_1\rangle\}$ is an orthonormal basis of \mathbb{C}^2_b , the space of qubit b. This is the *Schmidt decomposition* of $|\psi\rangle$.

Two quantum pure states $|\psi_0\rangle$ and $|\psi_1\rangle$ are indistinguishable by any quantum operation if they differ by a global phase only. In this case, we say that $|\psi_0\rangle$ and $|\psi_1\rangle$ are the same and write $|\psi_0\rangle = |\psi_1\rangle$. In a similar sense, when we say that there is a unique state $|\psi\rangle$ satisfying certain conditions such as $\langle \theta | \psi \rangle = 0$, we also mean the uniqueness up to a global phase.

A 2-local Hamiltonian on an *n*-qubit system is a Hermitian operator $H = \sum_{k=1}^{m} H_k$, where each H_k acts nontrivially on at most 2 qubits. The *ground energy* of a Hamiltonian is its smallest eigenvalue and a ground state is an eigenvector corresponding to the smallest eigenvalue. The subspace of the ground states is called the ground space. A Hamiltonian is frustration-free if the ground state of H is also a ground state of each H_k . By shifting the energy spectrum, we can assume without loss of generality that all the H_k have ground energy 0, thus a frustration-free Hamiltonian also has ground energy 0. In this paper, we refer to a ground state that is a tensor product of singlequbit states as a *product ground state*. We can view each H_k as a constraint on two qubits, and say that a state $|\psi\rangle$ satisfies H_k if $\langle \psi | H_k | \psi \rangle = 0$. Thus a Hamiltonian $H = \sum_k H_k$ is frustration-free if all the H_k can be simultaneously satisfied, corresponding to the classical satisfiability problem of finding an assignment to satisfy all constraints simultaneously. In this sense, we call a ground state of a frustration-free Hamiltonian a solution of that Hamiltonian.

This paper describes an efficient algorithm for deciding whether a 2-local Hamiltonian is frustrationfree and finding a ground state for frustration-free 2-local Hamiltonians. A couple of assumptions can be made without loss of generality.

- 1. We can assume that each H_k (acting on qubits i and j) is a projector onto some subspace (of \mathbb{C}^4 for qubits i and j). Indeed, assume that the spectral decomposition of H_k is $H_k =$ $\sum_{\ell:\lambda_\ell>0}\lambda_\ell\Pi_{k,\ell}$, where λ_ℓ is an eigenvalue and $\Pi_{k,\ell}$ is the projector onto the corresponding eigenspace, then $|\psi\rangle$ satisfies H_k if and only if $|\psi\rangle$ satisfies $\sum_{\ell:\lambda_\ell>0} \Pi_{k,\ell}$.
- 2. We can assume that different H_k 's act nontrivially on different subsystems. If both $H_k = \Pi_V$ and $H_{k'} = \Pi_{V'}$ act on the same subsystem, then we can replace $H_k + H_{k'}$ with $\Pi_{V \cap V'}$.
- 3. We can assume that each H_k acts on exactly two qubits, since if H_k acts nontrivially on only one qubit i, then there is exactly one assignment $|\alpha\rangle$ of that qubit satisfying this H_k , and the problem reduces to finding a state in the remaining qubits to satisfy the remaining constraints.[2](#page-4-0)

 $\sum_{(i,j)\in E} \Pi_{ij}$ of projectors, where each Π_{ij} projects onto a subspace of $\mathbb{C}_i^2 \otimes \mathbb{C}_j^2$, and $\text{rank}(\Pi_k) \in$ With these standard assumptions and preprocessing done, we face a 2-local Hamiltonian $H =$ $\{1, 2, 3\}$ is the dimension of this subspace. The 2-local Hamiltonian problem is the following one:

Input: An undirected graph $G = (V, E)$ given in the adjacency lists, and a set $\{\Pi_{ij} : (i, j) \in E\}$, where each Π_{ij} is a projector onto a subspace, with dimension 1, 2 or 3, of the space $\mathbb{C}_i^2 \otimes \mathbb{C}_j^2$. Each projector Π_{ij} of rank k can be given by description of k linearly independent states which span the subspace that Π_{ij} projects onto.

Task: Decide whether $H = \sum_{(i,j)\in E} \prod_{ij}$ is frustration-free. If yes, output a ground state; if no, output "unsatisfiable".

The graph G is called the *constraint graph* of the 2-local Hamiltonian H . We sometimes view rank-3 projectors Π_{ij} onto subspace $span\{|\psi_1\rangle, |\psi_2\rangle, |\psi_3\rangle\}$, as three parallel edges between vertices i and j, each with a rank-1 constraint $|\psi_k\rangle\langle\psi_k|, k = 1, 2, 3$. Similarly rank-2 projectors can be viewed as two rank-1 constraints with two parallel edges. So there may be two or three edges between

²Technically, we can use Propagation $(i, |\alpha\rangle, 1)$, a procedure given in Section [4.1](#page-11-0) to remove all single-qubit H_k 's in linear time.

a pair (i, j) of vertices, and when our algorithm removes one edge, there may still be one or two edges left between i and j.

For a rank-1 constraint $\Pi_{ij} = |\psi\rangle\langle\psi|$ on qubits i and j, we call the corresponding edge entangled if the constraint state is entangled, and product if the constraint state is product. No matter the constraint state $|\psi\rangle$ is entangled or not, a state $|\alpha\rangle_i$ (at qubit i) propagates along edge (i, j) with constraint state $|\psi\rangle_{ij}$ to a state $|\beta\rangle_j$ (at qubit j) if $|\beta\rangle_j$ is the unique state to make $\langle \psi | \alpha \beta \rangle = 0$.

For a graph $G = (V, E)$ and two sets $U, U' \subseteq V$, denote $E(U, U') = \{(i, j) : i \in U, j \in U'\}$, and $E(U) = E(U, U) = \{(i, j) : i, j \in U\}$. For a single-qubit state $|\phi\rangle$ and a vertex $i \in V$, we use subscript i in $|\phi\rangle_i$ to emphasize that the state is in the space \mathbb{C}_i at qubit i. Similarly, state $|\phi\rangle_{ij}$ is at qubits i, j .

We will need the following fact about 2-dimensional subspaces in $\mathbb{C}^2 \otimes \mathbb{C}^2$, which, excluding the efficient construction part, is a special case of Proposition 1.4 in [\[Par04\]](#page-19-13).

Lemma 1 Any 2-dimensional subspace V in 2-qubit space $\mathbb{C}^2 \otimes \mathbb{C}^2$ contains at least one product state, which can be found in constant time.

Proof Take a basis $\{|\psi\rangle, |\phi\rangle\}$ of the two-dimensional subspace V^{\perp} , the orthogonal complement of V. We know the existence of a product state $|\alpha\rangle \otimes |\beta\rangle$ orthogonal to both $|\psi\rangle$ and $|\phi\rangle$, and the task is to find it. Expanding $|\psi\rangle = \sum_{ij} \psi_{ij} |ij\rangle$, $|\phi\rangle = \sum_{ij} \phi_{ij} |ij\rangle$, and $|\alpha\rangle = \sum_{i} \alpha_{i} |i\rangle$, $|\beta\rangle = \sum_{i} \beta_{i} |i\rangle$.

If one of $|\psi\rangle$ and $|\phi\rangle$ is a product state, say $|\phi\rangle = |\gamma\rangle \otimes |\delta\rangle$ is a product state, then the matrix $[\phi_{ij}]_{i,j\in\{1,2\}}$ is singular. In this case, we take $|\alpha\rangle = |\gamma^{\perp}\rangle$. Decompose $|\psi\rangle$ in the basis of $\{|\gamma\rangle, |\gamma^{\perp}\rangle\}$ as $|\psi\rangle = |\gamma\rangle \otimes |\epsilon\rangle + |\gamma^{\perp}\rangle \otimes |\theta\rangle$. If $\theta = 0$, then any $|\beta\rangle$ makes $|\alpha\rangle \otimes |\beta\rangle$ inside V. If θ is nonzero, then $|\beta\rangle = |\theta^{\perp}\rangle$ makes $|\alpha\rangle \otimes |\beta\rangle$ inside V.

If both $|\psi\rangle$ and $|\phi\rangle$ are entangled, then for any $|\alpha\rangle$, each of $|\psi\rangle$ and $|\phi\rangle$ as a constraint gives a unique state $|\beta\rangle$ to make $|\alpha\rangle \otimes |\beta\rangle$ orthogonal to the constraint state. To satisfy both constraints, these two $|\beta\rangle$'s should be the same. Thus, we look for vector $|\alpha\rangle$ such that the vector $\sum_{ij} \psi_{ij} \alpha_i^* |\hat{j}\rangle$ is proportional to the vector $\sum_{ij} \phi_{ij} \alpha_i^* |j\rangle$, in which case we choose $|\beta\rangle$ to be the unit vector orthogonal to them. In matrix notation, we are looking for a vector $\left[\alpha^*\right]$ such that $\left[\psi\right] \cdot \left[\alpha^*\right] \propto \left[\phi\right] \cdot \left[\alpha^*\right]$. This can happen if and only if $\lbrack \alpha^* \rbrack$ is an eigenvector of the matrix $\lbrack \phi \rbrack^{-1} \cdot \lbrack \psi \rbrack$ – but we know that every full-rank 2×2 matrix has an eigenvector, and this eigenvector can be found in a constant time. \Box

Our algorithm is based crucially on the following product state theorem, which says that any frustration-free Hamiltonian composed of rank-1 and rank-2 projectors has a product ground state. This strengthens a result by Bravyi [\[Bra06\]](#page-18-3), which proved the existence of product ground state for frustration-free Hamiltonians which are composed of rank-1 projectors only and the constraints satisfy a technical condition of "completeness". We will use the following known fact to prove the product state theorem. An genuinely entangled state in an n-qubit system is a pure state that is not a product state with respect to any bi-partition of the n qubits. Theorem 1 of Ref. $[CCD+11]$ $[CCD+11]$ reads as follows.

Theorem 2 Given an n-qubit state $|\psi\rangle$ that is genuinely entangled and any 2-local frustration-free Hamiltonian H having $|\psi\rangle$ as its ground state, there always exists a product state of single qubits also in the ground space of H for $n \geq 3$.

Our product state theorem is stated as follows,

Theorem 3 If a given 2-local Hamiltonian $H = \sum_{k} \Pi_{k}$, where each Π_{k} is a projector of rank at most 2, is frustration-free, then there exists a product state $\otimes_{i\in V}|\phi_i\rangle$ satisfying H.

Proof Consider a frustration-free Hamiltonian H made of 2-qubit projectors of rank 1 and rank 2, and let $|\psi\rangle$ be its ground state. Generally, $|\psi\rangle$ can be written as a product state

$$
|\psi\rangle = |\psi^{(1)}\rangle \otimes |\psi^{(2)}\rangle \otimes \cdots \otimes |\psi^{(r)}\rangle ,
$$

where each $|\psi^{(i)}\rangle$ is a genuinely entangled state defined on a subset $S^{(i)}$ of qubits. Let $H^{(i)}$ be the Hamiltonian that is the sum of all the projectors whose support is in $S^{(i)}$. Clearly, $|\psi^{(i)}\rangle$ is a ground state of $H^{(i)}$.

Note that in Theorem [2,](#page-5-0) if the Hamiltonian is made of rank-1 and rank-2 projectors, the conclusion also holds for $n = 2$ qubits. This is a direct consequence of Lemma [1.](#page-5-1) Indeed, if H is defined on two qubits and is made of a rank-1 or rank-2 projector then the dimension of its ground space is at least 2, and by Lemma [1](#page-5-1) it contains a product state.

Therefore, for subsets $S^{(i)}$ with two or more qubits, we can use the above corollary to deduce that $H^{(i)}$ also has a ground state $|\phi^{(i)}\rangle$ which is a product state of one qubit states:

$$
|\phi^{(i)}\rangle \stackrel{\text{def}}{=} |\phi_1^{(i)}\rangle \otimes |\phi_2^{(i)}\rangle \otimes \cdots \tag{1}
$$

When $S^{(i)}$ has only one qubit, we define $|\phi^{(i)}\rangle \stackrel{\text{def}}{=} |\psi^{(i)}\rangle$.

We now claim that the state $|\phi\rangle \stackrel{\text{def}}{=} |\phi^{(1)}\rangle \otimes \cdots \otimes |\phi^{(r)}\rangle$, which is a product of one-qubit states, is a ground state of H . To prove this we need to show that this state is in the ground space of every projector Π_k in H. If the support of Π_k is inside one of the S_i subsets, then by definition $\Pi_k|\phi^{(i)}\rangle=0$ and therefore also $\Pi_k|\phi\rangle=0$. Assume then that Π_k is supported on a qubit from $S^{(i)}$ and a qubit from $S^{(j)}$ with $i \neq j$. We now consider 3 cases:

- 1. If both $S^{(i)}$ and $S^{(j)}$ contain only one qubit then $\Pi_k|\phi^{(i)}\rangle \otimes |\phi^{(j)}\rangle = \Pi_k|\psi^{(i)}\rangle \otimes |\psi^{(j)}\rangle = 0$.
- 2. If $S^{(i)}$ is made of one qubit but $S^{(j)}$ has two or more qubits, then consider at the reduced $\text{density matrix of } |\psi\rangle \text{ on the two qubits of } \Pi_k. \text{ It is of the form } \rho^{(i)} \otimes \rho^{(j)} \text{ where } \rho^{(i)} = |\psi^{(i)}\rangle\langle\psi^{(i)}|$ is of rank 1 (because $|S^{(i)}| = 1$) and $\rho^{(j)}$ of rank 2 (because $|\psi^{(j)}\rangle$ is genuinely entangled). Since $0 = \langle \psi | \Pi_k | \psi \rangle = Tr(\Pi_k \rho^{(i)} \otimes \rho^{(j)})$, it follows that $\Pi_k \rho^{(i)} \otimes \rho^{(j)} = 0$ and therefore Π_k annihilates the subspace $|\psi^{(i)}\rangle \otimes \mathbb{C}^2$ of the two qubits that it acts on, and in particular it annihilates $|\phi^{(i)}\rangle \otimes |\phi^{(j)}\rangle$ since $|\phi^{(i)}\rangle = |\psi^{(i)}\rangle$.
- 3. The third case in which both $S^{(i)}$ and $S^{(j)}$ contain two or more qubits cannot happen. Indeed, in such case the reduced density matrix of $|\psi\rangle$ on the support of Π_k is of the form $\rho^{(i)} \otimes \rho^{(j)}$ when now both $\rho^{(i)}$ and $\rho^{(j)}$ are rank 2 matrices. But then $\rho^{(i)} \otimes \rho^{(j)}$ is necessarily supported on the whole Hilbert space of the two qubits of Π_k , and therefore it *cannot* be annihilated by a rank-1 or a rank-2 projector.

This completes the proof of the theorem. \Box

3 Algorithm

3.1 Sketch

Let us first give a high-level description of a linear-time algorithm for the quantum 2SAT problem. The input is an *n*-qubit 2-local Hamiltonian $H = \sum_{(i,j)\in E} \prod_{ij}$ together with the linked lists of the constraint graph $G = (V, E)$. The algorithm has mainly three parts.

<u>Part 1</u>: The first part is to remove all rank-3 projectors. A rank-3 projector on qubits (i, j) determines a unique state $|\psi\rangle_{ij}$ in these two qubits. A propagation of the state to the adjacent vertices solves part of the graph.

Part 2: The second part of the algorithm is to remove product constraints—including both rank-1 product constraint and product constraints in rank-2 projections. For a state $|\alpha\rangle_i$ in qubit i, a constraint state $|\psi_{ij}\rangle$ on an edge (i, j) , we say that the state $|\alpha\rangle_i$ in qubit i propagates along edge (i, j) with constraint state $|\psi_{ij}\rangle$ if there is a unique state $|\beta\rangle_j$ at qubit j to make $\langle \psi_{ij} | \alpha \beta \rangle = 0$. Denote this by $|\alpha\rangle_i \stackrel{|\psi_{ij}\rangle}{\longrightarrow} |\beta\rangle_j$. Starting from a state $|\alpha\rangle_i$ in qubit i, we can let the state propagate on the graph. During the propagation, it may happen that some qubit j is assigned two different states (along two different routes from vertex i to vertex j), in which case we say that the propagation finds a contradiction. A propagation stops when it finds a contradiction, or when no propagation can happen along any edge. If a propagation stops without finding a contradiction, then the problem is solved on the subsystem that the propagation covers, and it can be showed (Lemma [8\)](#page-11-1) that the subsystem is detached from the rest and thus can be safely removed, and the algorithm can recursively solve the rest of the graph.

Note that a product constraint $|\alpha\rangle_i \otimes |\beta\rangle_j$ is satisfied by another product state $|\alpha'\rangle_i \otimes |\beta'\rangle_j$ if and only if $\langle \alpha | \alpha' \rangle = 0$ or $\langle \beta | \beta' \rangle = 0$. Therefore any product state solution either has $| \alpha^{\perp} \rangle$ in qubit i or $|\beta^{\perp}\rangle$ in qubit j. We will propagate from $|\alpha^{\perp}\rangle$ in qubit i and also propagate from $|\beta^{\perp}\rangle$ in qubit j . Assuming that the system has a solution, at least one of the two propagation will end without finding a contradiction and solve part of the system. To avoid wasting too much time on the incorrect propagation, we perform the two propagations simultaneously, on two copies of graph G, and stop both propagations once one of them stops without finding a contradiction.

Part 3: After the previous steps, the graph is left with entangled edges only. The third part of the algorithm aims to satisfy all these constraints. Note that an entangled constraint on edge (i, j) can propagate any state from one end i to the other end. Thus starting from an arbitrary state in an arbitrary node, the propagation either finds a solution for the entire system (or the connected component that the starting node belongs to, if the graph is unconnected at the moment), or finds a contradiction. In the latter case, it turns out that one can efficiently identify two nodes k and j and two candidate states $|\psi_k\rangle$ and $|\psi_j\rangle$, such that either $|\psi_k\rangle$ is correct for qubit k or $|\psi_j\rangle$ is correct for qubit j. Trying both candidates (again by simultaneous propagations) finishes the algorithm.

Remarks:

- 1. In previous work [\[Bra06,](#page-18-3) [JWZ11\]](#page-19-12), the second step was to remove rank-2 projectors. As mentioned in Section [1,](#page-0-1) their procedure has a cost of $\Theta(n^2)$ in the worst case. In contrast, our algorithm does not explicitly remove rank-2 projectors. We instead treat a rank-2 projector as two independent rank-1 projectors, and handle them through a unified algorithm and analysis for the rank-1 projectors. The correctness of this approach is based crucially on Theorem [3,](#page-5-2) which says that any frustration-free 2-local Hamiltonian of rank-1 and rank-2 projectors has a product ground state.
- 2. One may wonder why we need to handle rank-3 projections separately. By Lemma [1,](#page-5-1) a rank-3 projection can be represented by three rank-1 constraint state $|\psi_1\rangle$, $|\psi_2\rangle$, $|\psi_3\rangle$ with the first two both being product states. Then wouldn't the product constraint removal in the next Part 2 of algorithm remove these two constraints? The reason that this does not work is that

the product ground state exists only for Hamiltonians of rank-1 and rank-2 projections. The Part 2 and Part 3 of algorithm work only if a product ground state guarantees to exist.

3.2 The main algorithm

Next we give a more detailed and formal description for the algorithm solving Q2SAT. The main algorithm is given in box Algorithm [1.](#page-8-0)

Algorithm 1 $Q2SATSolver(H)$ **input**: A 2-local Hamiltonian $H = \sum_{(i,j)\in E} \Pi_{ij}$. output: A state $|\psi\rangle$ satisfying H if H is satisfiable, or "unsatisfiable" if H is unsatisfiable. global variables: (1) s_0 and s_1 , two *n*-element arrays. (2) *n* linked lists containing the graph and constraint information. (V_{ent}, E_{ent}) = Rank3Removal(H). \triangleright Remove rank-3 projectors. for each product constraint $|\alpha\rangle_u \otimes |\beta\rangle_v$ do . Remove product constraints. Remove this product constraint. Parallel Propagation $(u,|\alpha^{\perp}\rangle,v,|\beta^{\perp}\rangle).$ end for \triangleright Only rank-1 entangled constraints remain. for each remaining vertex i do \triangleright Handle rank-1 entangled constraints. ProbePropagation $(i, |0\rangle)$. end for if $\otimes_{i=1}^n s_0(i)$ satisfies the original input Hamiltonian H then $\qquad \qquad \triangleright$ Final verification $\text{Output } |\psi\rangle = \Big(\otimes_{(i,j)\in E_{ent}, i < j} s_0(i)\Big) \otimes \Big(\otimes_{i\in V-V_{ent}} s_0(i)\Big) \text{ as a ground state of } H.$ else Output "Unsatisfiable". end if

Now let us give a step-by-step explanation of the algorithm. For variables, s_0 and s_1 are two arrays with n elements, and they are global variables shared by all subprocedures. The array s_0 records the (part of the) solution found, and different procedures fill out different parts of the array s_0 . The array s_1 appears in procedure ParallelPropagation, where two propagations are running simultaneously with their partial solutions written in s_0 and s_1 respectively. The correct solution, no matter written in s_0 or s_1 , would be copied to s_0 . But for ParallelPropagation to work, s_1 should be updated to be the same as s_0 every time before Algorithm ParallelPropagation is called. Across all these calls, the accumulative time cost can be easily maintained to within $O(|V|)$ by using some time-step pointers.

Algorithm Q2SATSolver(H) starts by invoking procedure Rank3Removal to remove all rank-3 projectors in linear time. Each rank-3 projector Π_{ij} leaves only one possible solution for the qubits (i, j) . This state may force some adjacent qubits to be in a certain state, which may in turn force the state of some of their neighbors. This propagation ends up solving part of the system, leaving the remaining task to be satisfying a leftover Hamiltonian made of rank-1 and rank-2 projectors.

 ${\bf Lemma} \; {\bf 4} \; \; On \; an \; input \; H=\sum_{(i,j)\in E} \Pi_{ij}, \; the \; procedure \; Rank3Removal(H) \; has \; the \; following \; prop$ erties.

- 1. If Rank3Removal outputs "unsatisfiable", then H is unsatisfiable.
- 2. If Rank3Removal does not output "unsatisfiable", then it outputs a set $E_{ent} \subseteq E$ of edges and the set V_{ent} of vertices covered by E_{ent} . It also writes two-qubit entangled states $\{s_0(i) : (i,j) \in$ E_{ent} and one-qubit states $\{s_0(i): i \in V' - V_{ent}\}$ into s_0 as part of solution, where $V_{ent} \subseteq V' \subseteq V$ V. The procedure removes edges in $E(V) - E(V_1)$ where $V_1 = V - V'$, leaving the Hamiltonian $H_1 = \sum_{(i,j) \in E(V_1)} \prod_{ij}$ containing only rank-1 and rank-2 projectors over V_1 . In addition, H is satisfiable if and only if H_1 is satisfiable. More specifically, if H_1 is satisfied by some state $|\psi\rangle_{V_1}$, then H is satisfied by $\left(\otimes_{i:(i,j)\in E_{ent},i$
- 3. The running time of Rank3Removal(H) is at most $O(|F|)$, where F is the set of removed edges, with $|F| \leq |E|$ in the first case and $|F| = |E(V) - E(V_1)|$ in the second case above.

Algorithm Rank3Removal and the proof of Lemma [4](#page-8-1) are given in Section [4.2.](#page-13-0)

The next step of the algorithm removes all product edges by calling procedure ParallelPropagation $(u,|\alpha^\perp\rangle,v,|\beta^\perp\rangle)$ if the edge constraint is $|\alpha\rangle_u\otimes|\beta\rangle_v.$ In general, the algorithm ParallelPropagation $(u_0, |\alpha_0\rangle, u_1, |\alpha_1\rangle)$ is invoked when any ground state $\otimes_{i=1}^n |\psi_i\rangle$ of the current leftover Hamiltonian should either satisfy that $|\psi_{u_0}\rangle = |\alpha_0\rangle$ or that $|\psi_{u_1}\rangle = |\alpha_1\rangle$. The algorithm solves part of the system and reduces the system to the remaining part. Formally, it has the following property.

Lemma 5 Consider a Hamiltonian $H_1 = \sum_{(i,j) \in E(V_1)} \Pi_{ij}$ with $s_0(i) =$ <code>nilstate</code> for all $i \in V_1.$ For two vertices $u_0, u_1 \in V_1$, assume that there is a product ground state $\otimes_{i \in V_1} |\theta_i\rangle$ of H_1 s.t.

$$
|\theta_{u_0}\rangle = |\alpha_0\rangle \text{ or } |\theta_{u_1}\rangle = |\alpha_1\rangle. \tag{2}
$$

Then the procedure ParallelPropagation $(u_0, |\alpha_0\rangle, u_1, |\alpha_1\rangle)$ writes single-qubit states $|\alpha_i\rangle$ in s₀(i) for vertices $i \in V'_1$ for some subset $V'_1 \subseteq V_1$, with one of u_0 and u_1 in V'_1 . The procedure also removes all edges in $E(V_1) - E(V_2)$ where $V_2 = V_1 - V'_1$. The reduced Hamiltonian is $H_2 = \sum_{(i,j) \in E(V_2)} \prod_{ij}$, with the property that H_1 is satisfiable if and only if H_2 is satisfiable. If $|\psi\rangle_{V_2}$ is a solution of H_2 , then $(\otimes_{i\in V'_1} s_0(i)) \otimes |\psi\rangle_{V_2}$ is a solution of H_1 . The running time of this procedure is $O(|E(V_1)-E(V_2)|)$.

Algorithm ParallelPropagation and the proof of Lemma [5](#page-9-0) are presented in Section [4.3.](#page-15-0)

After removing all product constraints, the remaining constraints are entangled rank-1 projectors. Now we will try any state on any vertex and let it propagate. If it does not happen to be correct, then we obtain two candidates for two vertices, with the guarantee that at least one of the two is correct. In this way, we achieve the following property.

Lemma 6 Consider a frustration-free Hamiltonian $H_2 = \sum_{(i,j) \in E(V_2)} \Pi_{ij}$, where each Π_{ij} is a rank-1 projector onto an entangled state and the graph $(V_2, E(V_2))$ is connected. Assume that $s_0(i)$ = nilstate for all $i \in V_2$. For any $u \in V_2$ and any state $|\theta\rangle_u$, the procedure ProbePropagation $(u, |\theta\rangle_u)$ finds a product solution $\otimes_{i\in V_2} |\alpha_i\rangle$ for H_2 in time at most $O(|E(V_2)|)$.

We defer Algorithm ProbePropagation and the proof of Lemma [6](#page-9-1) to Section [4.4.](#page-16-0) With the above lemmas, it is not hard to prove the following theorem, which asserts the correctness and efficiency of our main algorithm.

Theorem 7 Consider any Q2SAT instance $H = \sum_{(i,j)\in E} \prod_{ij}$.

1. If H is frustration-free, the algorithm $Q2SATSolver(H)$ outputs a ground state

$$
\big(\otimes_{(i,j)\in E_{ent}, i
$$

of H, where $E_{ent} \subseteq \{(i,j): \text{rank}(\Pi_{ij})=3\}$, and V_{rest} contains the vertices not covered by $E_{ent}.$

2. If H is not frustration-free, the algorithm $Q2SATSolver(H)$ outputs "unsatisfiable".

In any case, the running time of the algorithm is $O(|E|)$.

Proof Since the last step of the algorithm verifies the correctness of the state $\otimes_{i=1}^n s_0(i)$, no unsatisfiable Hamiltonian can fool the algorithm to output a state with nonzero energy. Namely, if H is unsatisfiable, then the algorithm outputs "unsatisfiable" for sure.

Now we assume that H has a 0 energy ground state. By item 1 of Lemma [4,](#page-8-1) the procedure Rank3Removal does not output "unsatisfiable". Thus by item 2 of Lemma [4,](#page-8-1) the procedure Rank3Removal outputs a subset E_{ent} of edges and a subset V_{ent} of vertices. There is also a subset V' sandwiched between V_{ent} and V , and $V_1 = V - V'$. The procedure removes all edges in $E(V) - E(V_1)$ and reduces the problem to finding a ground state for $H_1 = \sum_{(i,j) \in E(V_1)} \prod_{ij}$, which contains only projectors over V_1 with rank at most 2. Indeed, Lemma [4](#page-8-1) also says that if H_1 is satisfied by some state $|\psi\rangle_{V-V'}$, then H is satisfied by $(\otimes_{i:(i,j)\in E_{ent},i$ This is exactly the record in s_0 as outputted in the last if branch of Algorithm Q2SATSolver(H), conditioned that the algorithm computes a ground state of H_1 .

After removing all rank-3 constraints, the Hamiltonian has only rank-1 and rank-2 projections. Then Theorem [3](#page-5-2) implies that it suffices to search for a product ground state.

The algorithm then moves to handling product constraints. If there is a product constraint $|\alpha\rangle_u \otimes |\beta\rangle_v$ in qubits (u, v) , then any product state solution $\otimes_{i \in V_1} |\theta_i\rangle$ has either $|\theta_u\rangle = |\alpha^{\perp}\rangle$ or $|\theta_v\rangle = |\beta^{\perp}\rangle$. By Lemma [5,](#page-9-0) the line ParallelPropagation $(u,|\alpha^{\perp}\rangle, v,|\beta^{\perp}\rangle)$ finds a partial solution and reduces the task to a smaller Hamiltonian H_2 on V_2 . Repeat this until all product edges are removed, reducing Hamiltonian to $H_{2,final}$ on $V_{2,final}$.

After removing all product constraints, the graph becomes a collection of connected components, with all constraints being entangled. The algorithm tries state $|0\rangle$ on an arbitrary vertex i. By Lemma [6,](#page-9-1) the procedure ProbePropagation $(i,|0\rangle)$ finds the solution for the entire component. Repeat this for all the components and we finally solve the problem.

The cost of Rank3Removal is $O(|E - E(V_1)|)$ by Lemma [4.](#page-8-1) The costs of the first and the second for loops are $O(|E(V_1) - E(V_{2,final})|)$ (by Lemma [5\)](#page-9-0) and $O(|E(V_{2,final})|)$ (by Lemma [6\)](#page-9-1) respectively. (To be more rigorous, each should also include the cost for enumerating. For example, the first for loop enumerates all the product edges. But this can be easily done in time $O(|E|)$ simply by scanning all edges and execute the **for** body only for those satisfying the **for** condition.) Thus the overall cost is $O(|E|)$, as claimed. \square

4 Subprocedures

In this section we give all subprocedures of the main algorithm, together with proofs of their properties as stated in the lemmas in the previous section.

4.1 Edge examination lemma and Propagation algorithm

Before presenting all the subprocedures that appeared in the main algorithm, let us first give a property commonly needed in those procedures. It roughly says that once we try to propagate from an node i to a neighbor node j, then the constraint Π_{ij} becomes useless no matter whether the propagation happens or not. In the lemma, we will use the language that H is satisfiable by a state $|\psi\rangle_U$ on qubits in set $U \subseteq V$, which means that there is a ground state of H with the component on U being $|\psi\rangle_U$.

Lemma 8 For any state $|\alpha\rangle_i$ at qubit i and any projector Π_{ij} , define $H' = H - \Pi_{ij}$, then exactly one of the following three cases happens.

- 1. There exists a unique state $|\beta\rangle_j$ at qubit j s.t. $|\alpha\rangle_i \otimes |\beta\rangle_j$ satisfies the constraint Π_{ij} . In this case, the state $|\alpha\rangle_i$ propagates to state $|\beta\rangle_i$ at vertex j. H is satisfiable by $|\alpha\rangle_i$ if and only if H' is satisfiable by $|\alpha\rangle_i \otimes |\beta\rangle_j$.
- 2. The product state $|\alpha\rangle_i \otimes |\beta\rangle_j$ satisfies the constraint Π_{ij} for any $|\beta\rangle_j$ at qubit j. In this case, the state $|\alpha\rangle_i$ does not propagate to vertex j by this constraint state. H is satisfiable by $|\alpha\rangle_i$ if and only if H' is satisfiable by $|\alpha\rangle_i$.
- 3. No state $|\beta\rangle_j$ at qubit j makes the product state $|\alpha\rangle_i \otimes |\beta\rangle_j$ to satisfy the constraint Π_{ij} . In this case, the state $|\alpha\rangle_i$ does not propagate to vertex j by this constraint state, and H is not satisfiable by $|\alpha\rangle_i$.

Proof (of Lemma [8\)](#page-11-1) We divide the proof into four cases according to Π_{ij} .

- 1. rank $(\Pi_{ij}) = 1$ and Π_{ij} is projector onto a product state $|a\rangle_i \otimes |b\rangle_j$. If $|\alpha\rangle_i = |a^{\perp}\rangle_i$, then any state $|\beta\rangle_j$ satisfies Π_{ij} , and case 2 happens: $|\alpha\rangle_i$ does not propagate to j by this constraint. H is satisfiable by $|\alpha\rangle_i$ if and only if H' is satisfiable by $|\alpha\rangle_i$, since the only difference between H and H' is Π_{ij} , which is already satisfied by $|\alpha\rangle_i$. If $|\alpha\rangle_i \neq |a^{\perp}\rangle_i$, then there exists a unique state $|\beta\rangle_j$ satisfying Π_{ij} , namely $|\beta\rangle_j = |b^{\perp}\rangle_j$, and case 1 happens: $|\alpha\rangle_i$ propagates to $|b^{\perp}\rangle_j$. H is satisfiable by $|\alpha\rangle_i$ if and only if H' is satisfiable by $|\alpha\rangle_i \otimes |b^{\perp}\rangle_j$.
- 2. rank $(\Pi_{ij}) = 1$ and Π_{ij} is projector onto an entangled state $|\psi\rangle$. Decompose $|\psi\rangle$ in the bases $|\alpha\rangle_i$ and $|\alpha^{\perp}\rangle_i$: $|\psi\rangle = \lambda_0 |\alpha\rangle_i \otimes |b\rangle_j + \lambda_1 |\alpha^{\perp}\rangle_i \otimes |c\rangle_j$ with both λ_0 and λ_1 nonzero. Then there is a unique state $|\beta\rangle_j$ satisfying Π_{ij} , namely $|\beta\rangle_j = |b^{\perp}\rangle_j$. Case 1 happens.
- 3. rank $(\Pi_{ij}) = 2$. Suppose Π_{ij} projects onto subspace $span{\psi_1}, \psi_2$, and view this as two rank-1 constraints. Consider what happens for the first constraint only—by previous two items we know that exactly one of the three cases happens. (1) Case 1 happens for the first constraint. Check whether the unique state at qubit j also satisfies the second constraint. If yes, then case 1 happens for Π_{ij} , and if no, then case 3 happens for Π_{ij} . (2) Case 2 happens for the first constraint. Then this constraint can be dropped and Π_{ij} reduces to just one constraint (the second one), and the lemma reduces to rank-1 case. (3) Case 3 happens for the first constraint. Then regardless of what the second constraint is, there is no solution to Π_{ij} , thus case 3 happens for Π_{ij} .
- 4. rank $(\Pi_{ij}) = 3$. There is only one state $|\phi\rangle$ satisfying the constraint. If $|\phi\rangle$ is a product state $|a\rangle_i \otimes |b\rangle_j$, then case 1 happens if $|\alpha\rangle_i = |a\rangle_i$, and case 3 happens if $|\alpha\rangle_i \neq |a\rangle_i$. If $|\phi\rangle$ is an entangled state, then case 3 happens.

 \Box

The algorithm Rank3Removal and some of the later algorithms need a procedure that propagates from a single-qubit solution. The following algorithm Propagation takes a node u and an assignment $|\theta\rangle_u$ that is known to be part of a correct solution, and propagates to the rest of the graph.

Algorithm 2 Propagation $(u, \vert \theta \rangle_u, must)$ Set $s_0(u) = |\theta\rangle_u$ and traverse the graph by BFS starting at u. During the BFS: for each edge (i, j) in the travesal do Remove edge (i, j) from G and Π_{ij} from H. if the state $|\alpha\rangle_i$ stored in $s_0(i)$ propagates along edge (i, j) to $|\beta\rangle_j$ at qubit j then if $s_0(j)$ = nilstate then $s_0(j) = |\beta\rangle_j,$ Put j into the BFS queue (to traverse its neighbors in future) else if $s_0(j) \neq |\beta\rangle_j$ and $must = 1$ then Output "unsatisfiable" and terminate the whole program else if $s_0(j) \neq |\beta\rangle_j$ and $must = 0$ then return 1 (and terminate this procedure Propagation) end if end if end for return 0

Before stating the proof of Lemma [9,](#page-12-0) some explanations regarding the algorithm Propagation are given.

- 1. The traversal is by Breadth First Search (BFS), with the following modifications. When processing a node i, as in BFS, all its neighbors will be checked. But different than BFS which puts every neighbor that has not been visited into the queue, here we put a neighbor j into the queue only when $s_0(j) = \text{nilstate}$ and a propagation happens from i to j.
- 2. Sometimes we need to *virtually run* the procedure Propagation in the following sense. Instead of really removing the edges and writing in $s₀$, we add some mark to comment out the edge and write in s_0 with a special mark. In this way, if we need to revoke the execution, we can undo the edge removal and s_0 writing in the same amount of time as the running time of this procedure Propagation.

The procedure has the following property.

Lemma 9 Assume that before calling the procedure Propagation, $s_0(i) = |\theta_i\rangle$ for $i \in V'$, and $s_0(i) = s_0(j) = |\theta_{ij}\rangle$ for $(i, j) \in E_{ent}$, $s_0(i) = \text{nilstate}$ for all other i, s.t. any 0-energy state (if existing) of a given Hamiltonian $H = \sum_{(i,j) \in E} \prod_{ij}$ has $|\theta_i\rangle$ as the component at qubit i, $\forall i \in V'$, and has $|\theta_{ij}\rangle$ as the component at qubits (i, j) , $\forall (i, j) \in E_{ent}$. Then procedure Propagation $(u, |\theta \rangle_u)$, where $u \in V'$, has the following properties.

1. If the procedure outputs "unsatisfiable", then H is unsatisfiable. The procedure removes a set $F \subseteq E$ of edges.

2. If the procedure does not output "unsatisfiable", then it removes a set $F \subseteq E$ of edges, reducing $H = \sum_{(i,j)\in E} \Pi_{ij}$ to $H' = \sum_{(i,j)\in E-F} \Pi_{ij}$. The procedure also writes some states $|\theta\rangle_v$ into $s_0(v)$ for a subset V'' of vertices v, with the property that

$$
H \text{ is satisfiable by } \left(\otimes_{(i,j)\in E_{ent}, i < j} s_0(i) \right) \otimes \left(\otimes_{i\in V'} s_0(i) \right)
$$
\n
$$
\Leftrightarrow H \text{ is satisfiable by } \left(\otimes_{(i,j)\in E_{ent}, i < j} s_0(i) \right) \otimes \left(\otimes_{i\in V' \cup V''} s_0(i) \right)
$$
\n
$$
\Leftrightarrow H' \text{ is satisfiable.}
$$

3. The running time of the procedure on $H = \sum_{(i,j)\in E} \prod_{ij}$ is at most $O(|F|)$.

Proof (of Lemma [9\)](#page-12-0) Recall that a propagation from $|\alpha\rangle_i$ at qubit i to qubit j along the edge (i, j) happens only if there is a unique state $|\beta\rangle_j$ at qubit j to satisfy Π_{ij} . Thus as long as $|\alpha\rangle_i$ is part of a correct solution, then the qubit j is forced to have $|\beta\rangle_j$ in the same solution. In general, as long as s_0 records correct components of a 0-energy state, then all the new assignments are forced to be those assigned states. Those states form a necessary condition for H to be satisfied.

If H is satisfiable, then the propagation can never find a contradiction and thus does not output "unsatisfiable". Indeed, if the procedure outputs "unsatisfiable", it goes to the else if branch, which means to have found a contradiction at some vertex j.

For the second item, the necessary condition is already argued as above, and it remains to prove that if H' is satisfiable, so is H. Indeed, define $V_1 = \{v : v$ is traversed in the BFS starting at u} and $V_2 = V - V_1$. If the procedure finishes with no contradiction found, then all constraints within V_1 are already satisfied and all the corresponding edges are safely removed by Lemma [8.](#page-11-1) In addition, by BFS, all the crossing edges, *i.e.* those connecting V_1 and V_2 , are also visited and thus removed. Thus V_1 and V_2 are separated in H', which implies that satisfying H' is sufficient to satisfying H.

Since each edge, once traversed in BFS, is removed, the total cost of the procedure is in the same order of the number of removed edges, namely $O(|F|)$. \Box

4.2 Algorithm Rank3Removal

The algorithm Rank3Removal is given in the box Algorithm [3.](#page-14-0)

Now we prove Lemma [4.](#page-8-1)

Proof (of Lemma [4\)](#page-8-1) The rank-3 projector Π_{ij} determines a unique state $|\psi\rangle_{ij}$ in qubits (i, j) . We consider two possible cases of this state. In the first case, $|\psi\rangle_{ij}$ is a product state $|\alpha\rangle_i \otimes |\beta\rangle_j$. Thus the qubits i and j are fully determined to be $|\alpha\rangle$ and $|\beta\rangle$, respectively. We can write these answers into $s_0(i)$ and $s_0(j)$, and then let them propagate on the graph. The correctness of the propagation is guaranteed by Lemma [9.](#page-12-0)

The second case is when $|\psi\rangle_{ij}$ is an entangled state. Now we consider each neighbor k of i or j. For illustration, consider the case that k is the neighbor of j. The following case-by-case analysis is not hard to be verified.

- 1. $\Pi_{ik} = |\phi\rangle\langle\phi|$ and $|\phi\rangle$ is entangled. Then there is no solution for the system (i, j, k) .
- 2. $\Pi_{jk} = |\phi\rangle\langle\phi|$ and $|\phi\rangle_{jk} = |\beta\rangle_{j} \otimes |\gamma\rangle_{k}$. Then the only possible solution for the system (i, j, k) is $|\psi\rangle_{ij} \otimes |\gamma^{\perp}\rangle_k$.

Algorithm 3 Rank3Removal

 $E_{ent} = \emptyset; V_{ent} = \emptyset; V' = \emptyset.$ for each rank-3 projector Π_{ij} do Remove the edge (i, j) from G and Π_{ij} from H; $V' = V' \cup \{i, j\}.$ Suppose that the only valid state for (i, j) is $|\psi\rangle_{ij}$. if $|\psi\rangle_{ij} = |\alpha\rangle_i \otimes |\beta\rangle_j$ for some $|\alpha\rangle_i$ and $|\beta\rangle_j$ then $\qquad \qquad \qquad \triangleright |\psi\rangle_{ij}$ is a product state $s_0(i) = |\alpha\rangle; s_0(j) = |\beta\rangle;$ Propagation $(i, |\alpha\rangle, 1)$; Propagation $(j, |\beta\rangle, 1)$. else $\triangleright |\psi\rangle_{ij}$ is an entangled state $E_{ent} = E_{ent} \cup \{(i,j)\}; \, V_{ent} = V_{ent} \cup \{i,j\};$ $s_0(i) = |\psi\rangle; s_0(j) = |\psi\rangle;$ for each $t \in \{i, j\}$ and each $k \in N(t)$ do Remove the edge (t, k) from G and Π_{tk} from H. if $\Pi_{tk} = \Pi_t \otimes |\gamma\rangle\langle\gamma|$ then if $s_0(k)$ = nilstate then \triangleright visit k for the first time $s_0(k) = |\gamma^{\perp}\rangle.$ Propagation $(k,|\gamma^\perp\rangle,1)$. else if $s_0(k) \neq |\gamma^{\perp}\rangle$ then \triangleright Find a contradiction Output "unsatisfiable" and terminate the whole program. end if else \triangleright No solution for k Output "unsatisfiable" and terminate the whole program. end if end for end if end for return $(V_{ent}, E_{ent});$

- 3. Π_{jk} is of rank 2. Then similarly, the only possibility that (i, j, k) is satisfiable is Π_{jk} = $\mathbb{C}_i^2 \otimes |\gamma\rangle_k \langle \gamma|_k$, in which case the solution for the system (i, j, k) is again $|\psi\rangle_{ij} \otimes |\gamma^{\perp}\rangle_k$.
- 4. Π_{ik} is of rank 3. Then the system (i, j, k) is not satisfiable.

Summarizing these cases, one can see that there is a solution for the system (i, j, k) if and only if $\Pi_{jk} = \Pi_j \otimes |\gamma\rangle\langle\gamma|$ for some rank-1 or rank-2 projector Π_j on qubit j and some rank-1 projector $|\gamma\rangle\langle\gamma|$ on qubit k. In this case, the only possible assignment for qubit k is $|\gamma^{\perp}\rangle$. So we write this solution $|\gamma^{\perp}\rangle$ into $s_0(k)$, unless $s_0(k)$ has already been assigned a solution $|\delta\rangle \neq |\gamma^{\perp}\rangle$, in which case we can conclude that H is not satisfiable. This explains the inner for loop.

When no contradiction is found, we solved part of the system. The qubits in V_{ent} are paired up into (i, j) 's, with an entangled two-qubit state $|\psi\rangle_{ij}$ for each pair (i, j) stored in $s_0(i)$. (When we output the solution in the main algorithm, we only output $s_0(i)$. But in the procedure Rank3Removal we also write $|\psi\rangle_{ij}$ into $s_0(j)$. This is because if qubit j is later assigned a different state, this stored $|\psi\rangle_{ij}$ enables us to detect a contradiction). The qubits in $V' - V_{ent}$ have product solutions, which are written into s_0 by the first if branch as well as the Propagation procedures. The states stored in $\{s_0(i): i \in V'\}$ form the only possible solution for V', thus the satisfiability of H reduces to that of H_1 , which is H restricted in $V_1 = V - V'$.

Since once an edge is visited, it is removed, no edge is visited twice. Since processing each edge takes constant time, the overall running time of the procedure is of the same order as the number of removed edges. \square

4.3 Algorithm ParallelPropagation

The procedure ParallelPropagation is given in Algorithm [4.](#page-15-1) This procedure is invoked in the following situation: There exists one product ground state s.t. either the component in qubit u_0 is $|\alpha_0\rangle$ or the component in qubit u_1 is $|\alpha_1\rangle$. This procedure checks which is the case by simultaneously propagating $|\alpha_0\rangle$ from qubit u_0 and $|\alpha_1\rangle$ from qubit u_1 (on two different copies of G). For the "correct" state $|\alpha_b\rangle$, its propagation solves part of the graph and makes the remaining task independent of the solved part. In this way, the cost of this procedure is at most twice the size of (i.e. number of edges within) the solved part.

Algorithm 4 ParallelPropagation $(u_0,|\alpha_0\rangle, u_1,|\alpha_1\rangle)$

Copy the new content of s_0 to s_1 .

Virtually run f_0 = Propagation $(u_0, |\alpha_0\rangle, 0)$ on H and, at the same time, virtually run f_1 = Propagation $(u_1, |\alpha_1\rangle, 0)$ on a copy of H (with s_1 taking place of s_0) in parallel, noting the following.

(Call them propagation 0 and propagation 1, respectively.)

if both propagations stop with a contradiction then

Output "unsatisfiable" and terminate the whole program.

else

Suppose propagation j is the first propagation that stops without finding a contradiction. $s_0(u_i) = |\alpha_i\rangle$.

Propagation $(u_i, |\alpha_i\rangle, 1)$ (with elements written in s_0).

end if

First we enumerate some explanations regarding the details of algorithm ParallelPropagation.

- 1. In the first line, we copy the so-called "new content" of s_0 to s_1 . We actually just want to copy s_0 to s_1 , but a naive copy may take $O(n)$ time and invoking ParallelPropagation many times would make this cost too much. To get this done in linear time (over all executions of ParallelPropagation), we can use another array to record the elements of s_0 in the order of them being written. (Namely, use an array s which contains n elements, with the t -th one being $(i_t, |\phi_t\rangle)$, where $s_0(i_t)$ is the t-th element written in s_0 , and $|\phi_t\rangle$ is the content of $s_0(i_t)$.) Maintain a time step T for s_1 indicating how many elements of s_1 have been written. Whenever we need to copy s_0 to s_1 , we just need to copy the new content—the part beyond T in s —to s_1 .
- 2. Since we do not know which propagation is correct before seeing one stopping without a contradiction, we should keep a record of the modifications (on G and on s_i) and allow ourselves to *undo* the modifications made by the *wrong* propagation. This can be done by adding a "temp" mark when writing an element of s_0 and s_1 and when removing the edges in G. Later after we know which propagation i is the right one, we remove the temp mark of these elements in s_i and really remove the corresponding edges in G , and wipe out the elements in s_{1-i} with temp mark (by assigning back their previous value nilstate). That is why we need to *virtually* run Propagation.
- 3. We have two propagations, called propagation 0 and propagation 1, both virtually running Algorithm Propagation, with propagation i writing in s_i . It is important that the two propagations run simultaneously, meaning that we traverse one edge of propagation 0 and then traverse one edge of propagation 1. The reason is that if we run the two propagations sequentially, it is possible that the first one takes a long time and finally finds a contradiction, while the second one stops quickly without finding a contradiction. Then we waste a lot of time to find out which of the two candidates is correct. Running two propagations in parallel avoids this problem.

Next we prove Lemma [5.](#page-9-0)

Proof (of Lemma [5\)](#page-9-0) Without loss of generality let us assume that propagation 0 stops first without finding a contradiction. By Lemma [9,](#page-12-0) the propagation finds part fo the correct solution and reduces H_1 to some smaller Hamiltonian H_2 on a subset V_2 of vertices.

The cost of the algorithm comes from different parts. Suppose the first propagation that stops without finding a contradiction is propagation 0 and it takes time t . Since the propagation stops after exploring all edges adjacent to the explored vertices (without finding any new propagation opportunity), the cost is $t = O(|E(V_1')| + |E(V_1', V_1 - V_1')|) = O(|E(V_1) - E(V_2)|)$. Propagation 1 takes time at most t since it is forced to stop at time t if it has not stopped by itself already. Then we need to undo the changes made by propagation 1 on s_1 and its copy of H, and confirm the changes made by propagation 0 on s_0 , which combine to take time at most 2t. Thus in total it takes time $4t = O(|E(V_1) - E(V_2)|)$. □

4.4 Algorithm ProbePropagation

The procedure ProbePropagation is given in Algorithm [5.](#page-17-0) With the parameters $(u, |\alpha\rangle_u)$, the procedure takes a vertex u and a candidate $|\alpha\rangle$ for qubit u, and checks whether it is indeed part of a valid solution by a BFS propagation.

If $|\alpha\rangle_u$ happens to be part of a correct solution, then the procedure uses Propagation $(u, |\alpha\rangle, 1)$ to solve part of the system. If in general $|\alpha\rangle_u$ is not part of a correct solution, then the it is used as a probe to find out some useful information. More precisely, if a contradiction is found at some vertex j, the procedure returns two candidates $j, (|\psi_i\rangle_i)$ and $k, (|\psi_k\rangle_k)$, with the guarantee that at least one of the two candidates is part of a valid solution (if H is satisfiable at all).

Before proving Lemma [6,](#page-9-1) we need a constraint sliding lemma.

Lemma 10 Suppose that there are two rank-1 constraints, $|\psi_1\rangle_{ab}$ on qubits (a, b) and $|\psi_2\rangle_{ac}$ on qubits (a, c). If $|\psi_1\rangle_{ab}$ is entangled, then there is another rank-1 constraint $|\psi_3\rangle_{bc}$ on qubits (b, c) s.t. the solution space for the system (a, b, c) satisfying $\{|\psi_1\rangle_{ab}, |\psi_2\rangle_{ac}\}$ is the same as that satisfying $\{|\psi_1\rangle_{ab}, |\psi_3\rangle_{bc}\}.$ If in addition $|\psi_2\rangle_{ac}$ is entangled, then so is $|\psi_3\rangle_{bc}$.

Proof Consider the Schmidt decomposition of $|\psi_1\rangle_{ab}: |\psi_1\rangle_{ab} = \lambda_1|\alpha_0\rangle_a|\beta_0\rangle_b + \lambda_2|\alpha_1\rangle_a|\beta_1\rangle_b$ where $\langle \alpha_0 | \alpha_1 \rangle = \langle \beta_0 | \beta_1 \rangle = 0$, and both λ_1 and λ_2 are nonzero as $|\psi_1\rangle_{ab}$ is entangled. Define a non-singular transformation T on qubit a by $T(\lambda_1|\alpha_0\rangle) = |\beta_1\rangle$ and $T(\lambda_2|\alpha_1\rangle) = -|\beta_0\rangle$. Then $T|\psi_1\rangle_{ab} = |\beta_1\rangle_a |\beta_0\rangle_b - |\beta_0\rangle_a |\beta_1\rangle_b$ is the unique anti-symmetric state. Let V be the solution subspace (in $\mathbb{C}_a^2 \otimes \mathbb{C}_b^2 \otimes \mathbb{C}_c^2$) for the constraints $\{ |\psi_1\rangle_{ab}, |\psi_2\rangle_{ac} \}$, then TV is the solution subspace for the constraints $\{T|\psi_1\rangle_{ab}, T|\psi_2\rangle_{ac}\}$. Since $T|\psi_1\rangle_{ab}$ is the anti-symmetric subspace, any solution is symmetric between a and b. Thus if we replace the constraint $T|\psi_2\rangle_{ac}$ by the same state on qubits (b, c) , then the solution space remains the same, *i.e.* the solution spaces for $\{T|\psi_1\rangle_{ab}, T|\psi_2\rangle_{ac}\}$ and $\{T|\psi_1\rangle_{ab}, T|\psi_2\rangle_{bc}\}\$ are the same. Now we apply the inverse T^{-1} on qubit a, which does not affect the constraint state $(T|\psi_2\rangle)_{bc}$ since the action T^{-1} is not on the qubits b and c. The solution space of the original system is the one satisfying $\{|\psi_1\rangle_{ab}, |\psi_3\rangle_{bc}\}$, where $|\psi_3\rangle = T|\psi_2\rangle$. Finally note that the single-qubit operation T does not remove the entanglement in $|\psi_2\rangle_{ac}$, thus $|\psi_3\rangle = T|\psi_2\rangle$ is also entangled. \square

Virtually run flag = Propagation $(u, |\alpha\rangle, 0)$. Record the BFS tree T. if $flag = 0$ then **Propagation** $(u, |\alpha\rangle, 1)$ (with real edge removal and s₀ writing) else \triangleright a contradiction found Suppose that the contradiction occurs during a propagation along edge (i, j) . Find the dominator k of i and j on the BFS tree T . Let p_1 be the path from k to j on T: $k \to u_1 \to \cdots \to u_s \to j$. Let p_2 be the path from k to i on T, followed by edge (i, j) : $k \to v_1 \to \cdots \to v_t \to i \to j$. Slide the constraint along p_1 to find a rank-1 projector $|\psi_1\rangle\langle\psi_1|$ on (k, j) . Slide the constraint along p_2 to find a rank-1 projector $|\psi_2\rangle \langle \psi_2|$ on (k, j) . Let Π be the rank-2 projector on the subspace $span{\{\psi_1, \psi_2\}}$ in qubits (k, j) . Use Lemma [1](#page-5-1) on Π to find a product state $|\alpha\rangle_k \otimes |\beta\rangle_j$. Parallel Propagation $(k,|\alpha^{\perp}\rangle, j,|\beta^{\perp}\rangle).$ end if

Now we are ready to prove Lemma [6.](#page-9-1)

Proof (of Lemma [6\)](#page-9-1) By Lemma [3,](#page-5-2) there is a product ground state. Recall that for an entangled constraint $|\psi\rangle_{ij}$, any state at qubit i propagates to a unique state at qubit j. Thus if $|\theta\rangle_u$ happens to be part of a correct solution, then this propagates to the entire graph to find the solution.

Now consider the general case that $|\theta\rangle_u$ is not part of a correct solution. Then starting from $|\theta\rangle_u$ in qubit u, the propagation finds a contradiction at some vertex j. The contradiction happens because there is some vertex k from which two vertex-disjoint routes p_1 and p_2 lead to the same vertex j with different assignments $|\theta_1\rangle_j$, $|\theta_2\rangle_j$ for j. The vertex k and the two routes can be found from the BFS tree as specified in the algorithm. Now for the first route $p_1 : k \to u_1 \to \cdots \to u_s \to j$, apply Lemma [10](#page-17-1) on qubits (u_1, u_2, k) to get an entangled constraint on (k, u_2) , and again apply Lemma [10](#page-17-1) on qubits (u_2, u_3, k) to get an entangled constraint on (k, u_3) , and so on, until we finally get an entangled constraint $|\psi_1\rangle\langle\psi_1|$ on (k, j) . Lemma [10](#page-17-1) guarantees that if we propagate directly from k to j by the new constraint $|\psi_1\rangle\langle\psi_1|$, we will get the same state $|\theta_1\rangle_i$ as obtained by propagation from k along the route p_1 to j. Make a similar sequence of sliding along route r_2 to find another entangled constraint $|\psi_2\rangle\langle\psi_2|$ on (k, j) , and propagation directly from k to j by this new constraint $|\psi_2\rangle\langle\psi_2|$ gives state $|\theta_2\rangle_j$. Since $|\theta_1\rangle_j \neq |\theta_2\rangle_j$, the two states $|\psi_1\rangle$ and $|\psi_2\rangle$ are distinct.

By Lemma [10,](#page-17-1) any solution to the constraints on p_1 and p_2 needs to also satisfy these two new constraints $|\psi_1\rangle\langle\psi_1|$ and $|\psi_2\rangle\langle\psi_2|$ on (k, j) . Since $|\psi_1\rangle$ and $|\psi_2\rangle$ are distinct, they span a two-dimensional subspace V, which by Lemma [1](#page-5-1) contains a product state $|\phi\rangle_{kj} = |\alpha\rangle_k \otimes |\beta\rangle_j$. The corresponding rank-1 constraint $|\phi\rangle\langle\phi|$ is derived from the original constraints on the loop as in the above process, thus any ground state of H needs to satisfy this product constraint. The last step of ParallelPropagation $(k,|\alpha^{\perp}\rangle, j,|\beta^{\perp}\rangle)$ then finds the solution for the entire graph. (Note that we did not add this new constraint $|\phi\rangle\langle\phi|$ into the Hamiltonian. We just used it to find out two candidates $|\alpha^{\perp}\rangle_k$ and $|\beta^{\perp}\rangle_j$ such that any product ground state must have at least one of them.)

The BFS tree is constructed in linear time and thus the dominator k and the two routes p_1 and p_2 can be found in linear time. The sliding takes the time equal to the length of the route. Note that all the constraints are entangled (except the newly constructed $|\phi\rangle\langle\phi|$, which is not part of the given Hamiltonian). Therefore the last step of ParallelPropagation takes time linear in the size of the given Hamiltonian, thus overall it takes linear time. \Box
