Abstract

We consider a parabolic-parabolic Keller-Segel system of chemotaxis model with singular sensitivity $u_t = \Delta u - \chi \nabla \cdot (\frac{u}{v} \nabla v), v_t = k\Delta v - v + u$ under homogeneous Neumann boundary conditions in a smooth bounded domain $\Omega \subset \mathbb{R}^n$ $(n \geq 2)$, with $\chi, k > 0$. It is proved that for any $k > 0$, the problem admits global classical solutions, whenever $\chi \in \left(0, -\frac{k-1}{2} + \frac{1}{2}\sqrt{(k-1)^2 + \frac{8k}{n}}\right)$. The global solutions are moreover globally bounded if $n \leq 8$. This shows an exact way the size of the diffusion constant k of the chemicals v effects the behavior of solutions.

Keywords: Chemotaxis; Logarithmic sensitivity; Boundedness

1 Introduction

In this paper, we consider the parabolic-parabolic chemotaxis system with singular sensitivity

$$
\begin{cases}\n u_t = \Delta u - \chi \nabla \cdot (\frac{u}{v} \nabla v), & x \in \Omega, \quad t \in (0, T), \\
 v_t = k \Delta v - v + u, & x \in \Omega, \quad t \in (0, T), \\
 \frac{\partial u}{\partial \nu} = \frac{\partial v}{\partial \nu} = 0, & x \in \partial\Omega, \quad t \in (0, T), \\
 (u(x, 0), v(x, 0)) = (u_0(x), v_0(x)), & x \in \Omega,\n\end{cases}
$$
\n(1.1)

where $\chi, k > 0$, Ω is a smooth bounded domain in \mathbb{R}^n $(n \geq 2)$, $\frac{\partial}{\partial \nu}$ denotes the derivation with respect to the outer normal of $\partial\Omega$, and the initial datum $u_0 \in C^0(\overline{\Omega})$, $u_0(x) \geq 0$ on $\overline{\Omega}$, $v_0 \in W^{1,q}(\Omega)$ $(q > n)$, $v_0(x) > 0$ on $\overline{\Omega}$.

The classical Keller-Segel system of chemotaxis model was introduced by Keller and Segel $[9]$ in 1970 to describe the cells (with density u) move towards the concentration gradient of a chemical substance v produced by the cells themselves. Various forms of sensitivity

functions can be chosen to model different types of chemotaxis mechanisms. Among them $\phi(v) = \frac{\chi}{v}$ was selected in [\(1.1\)](#page-0-0) largely due to the Weber-Fechner's law for cellular behaviors, where the subjective sensation is proportional to the logarithm of the stimulus intensity $[6]$. With $\phi(v) = \frac{\chi}{v}$, the cellular movements are governed by the taxis flux $\frac{\chi \nabla v}{v}$, which may be unbounded when $v \approx 0$. In the model [\(1.1\)](#page-0-0), the values of the chemotactic sensitivity coefficient χ and the chemicals diffusion constant k play significant roles to determine the behavior of solutions. Obviously, either small $\chi > 0$ or large $k > 0$ benefits the global boundedness of solutions.

Recall the known results in the field with $k = 1$. At first consider the parabolic-elliptic analogue of (1.1) , namely, the second parabolic equation in (1.1) is replaced by the elliptic equation $0 = \Delta v - v + u$. It was known that all radial classical solutions are global-in-time if either $n \geq 3$ with $\chi < \frac{2}{n-2}$, or $n = 2$ with $\chi > 0$ arbitrary [\[11\]](#page-8-2). When $0 < \phi(v) < \frac{\chi}{v^l}$ $\frac{\chi}{v^l}$ with $l \geq 1, \chi > 0$, there is a unique and globally bounded classical solution if $\chi < \frac{2}{n}$ ($l = 1$) or $\chi < \frac{2}{n} \cdot \frac{l^{l}}{(l-1)^{(l-1)}} \gamma^{(l-1)}$ $(l > 1)$, with $\gamma > 0$ depending on Ω and u_0 [\[3\]](#page-8-3). Next consider the parabolic-parabolic case. All solutions of (1.1) are global in time when either $n = 1$ [\[13\]](#page-8-4), or $n = 2$ and $\chi < \frac{5}{2}$ under the radial assumption, while $\chi < 1$ under the non-radial assumption [\[1,](#page-8-5) [12\]](#page-8-6). For $n \geq 2$, [\(1.1\)](#page-0-0) possesses global classical solutions if $0 < \chi < \sqrt{\frac{2}{n}}$, and moreover, $\chi < \sqrt{\frac{n+2}{3n-4}}$ ensures the global existence of weak solutions [\[19\]](#page-9-0). Certain radial weak solutions have been constructed when $\chi < \sqrt{\frac{n}{n-2}}$ [\[15\]](#page-8-7). Following, the global boundedness of solutions has been obtained for $\chi < \sqrt{\frac{2}{n}}$ [\[2\]](#page-8-8). Refer to [\[4,](#page-8-9) [10,](#page-8-10) [21\]](#page-9-1) for the results on more general chemotaxis models.

Recently, under somewhat complicated conditions, Wang [\[16\]](#page-8-11) established classical global solutions to the problem, a similar model to (1.1) ,

$$
\begin{cases}\nu_t = \nabla \cdot (\nabla u - \frac{\chi u}{v + c} \nabla v), & x \in \Omega, \quad t \in (0, T), \\
v_t = k \Delta v - \alpha v + \beta u, & x \in \Omega, \quad t \in (0, T), \\
\frac{\partial u}{\partial \nu} = \frac{\partial v}{\partial \nu} = 0, & x \in \partial \Omega, \quad t \in (0, T), \\
(u(x, 0), v(x, 0)) = (u_0(x), v_0(x)), & x \in \Omega,\n\end{cases}
$$

with $\chi, c, k, \alpha, \beta > 0$. In the present paper, motivated by Winkler [\[19\]](#page-9-0) and Fujie [\[2\]](#page-8-8), we will prove the global existence-boundedness of classical solutions to (1.1) , with simplified conditions. That is the following theorem.

Theorem 1 Let $n \geq 2$, $u_0 \in C^0(\overline{\Omega})$, $v_0 \in W^{1,q}(\Omega)$ $(q > n)$ with $u_0 \geq 0$, $v_0 > 0$ on $\overline{\Omega}$. Then, for <u>any k > 0</u>, there exists a global classical solution to [\(1.1\)](#page-0-0), provided $\chi \in$ $\left(0, -\frac{k-1}{2} + \frac{1}{2}\right)$ $\frac{1}{2}\sqrt{(k-1)^2+\frac{8k}{n}}$. Moreover, the solution is globally bounded under $n \leq 8$.

Remark [1](#page-1-0) Theorem 1 shows in what way the size of $k > 0$ (the diffusion strength of the chemicals v) effects the behavior of solutions to (1.1) . It is interesting to observe that when $n = 2$ the global existence-boundedness of solutions is independent of the size of $k > 0$, since $-\frac{k-1}{2}+\frac{1}{2}$ $\frac{1}{2}\sqrt{(k-1)^2+\frac{8k}{n}}\equiv 1$ with $n=2$. Quite differently, when $n\geq 3$ the contribution of $k > 0$ is significant that the range of χ for global existence-boundedness of solutions will be enlarged (shrunk) as $k > 0$ is degreasing (increasing). The arbitrariness of $k > 0$ yields the "maximal" range with $\chi \in (0,1)$ or the "minimal" range with $\chi \in (0, \frac{2}{n})$. That is to say for any $\chi \in (0,1)$ (close to 1), there is $k > 0$ (small) such that the classical solution of (1.1) is globally bounded. On the other hand, for any $k > 0$ (large), there is $\chi \in (0, \frac{2}{n})$ to ensure the global boundedness. Finally, it is pointed out that if $k = 1$, the required range of χ in Theorem [1](#page-1-0) becomes $0 < \chi < \sqrt{\frac{2}{n}}$, which coincides with those in [\[2,](#page-8-8) [19\]](#page-9-0).

Remark 2 Now compare our results for the parabolic-parabolic chemotaxis model [\(1.1\)](#page-0-0) with those for the corresponding parabiotic-elliptic model, which can be thought as a special case of (1.1) with the diffusion constant of the chemicals v sufficiently large $[3]$. Just as mentioned in Remark [1,](#page-1-1) letting $k > 0$ be arbitrarily large results in the "minimal" permitted range with $0 < \chi < \frac{2}{n}$. This does agree those obtained for the parabolic-elliptic model in [\[11\]](#page-8-2).

2 Preliminaries

In this section we introduce the local existence of classical solutions to [\(1.1\)](#page-0-0) with required estimates involving χ and k, as well as some technical lemmas for the global boundedness as preliminaries.

Lemma 2.1 Let $n \geq 2$, $u_0 \in C^0(\overline{\Omega})$, $v_0 \in W^{1,q}(\Omega)$ $(q > n)$ with $u_0 \geq 0$, $v_0 > 0$ on $\overline{\Omega}$. Then, for any $k, \chi > 0$, there exists $T_{\text{max}} \in (0, \infty]$, such that [\(1.1\)](#page-0-0) has a unique nonnegative solution $u \in C^0([0,T_{\max}); C^0(\Omega)) \times C^{2,1}(\overline{\Omega} \times (0,T_{\max}))$ and $v \in C^0([0,T_{\max}); C^0(\Omega)) \times$ $C^{2,1}(\overline{\Omega}\times(0,T_{\max}))\times L^{\infty}_{\text{loc}}([0,T); W^{1,q}(\Omega)),$ where either $T_{\max} = \infty$, or $T_{\max} < \infty$ with $\lim_{t\to T_{\text{max}}} ||u(\cdot, t)||_{L^{\infty}(\Omega)} + ||v(\cdot, t)||_{W^{1,q}(\Omega)} = \infty.$

Proof. For $k > 0$, it is known from Lemma 2.2 in [\[2\]](#page-8-8) that there is $\eta > 0$, such that $\inf_{x \in \Omega} v(x, t) \geq \eta > 0$ for all $t > 0$. Consequently, the local existence lemma can be obtained by the classical parabolic theory, refer to Theorem 3.1 in [\[17\]](#page-8-12).

The following lemma is crucial to establish the global existence-boundedness conclusions of the paper. Denote $r_{\pm}(p) = (p-1)[\frac{p\chi(1-k)+2k}{p(k-1)^2+4k} \pm \frac{2\sqrt{k^2-p\chi k(k-1)-p\chi^2k}}{p(k-1)^2+4k}]$ $\frac{-p_{\mathcal{K}}(k-1)-p_{\mathcal{K}}(k)}{p(k-1)^2+4k}$. Throughout the paper, for simplicity, denote $T = T_{\text{max}}$.

Lemma 2.2 Let (u, v) solve (1.1) with $k > 0$ and $\chi \in \left(0, -\frac{k-1}{2} + \frac{1}{2}\sqrt{(k-1)^2 + \frac{8k}{n}}\right)$. If

$$
||v(\cdot,t)||_{L^{p-r}(\Omega)} \le c, \quad t \in (0,T)
$$
\n(2.1)

with $p < \frac{k}{[\chi^2 - \chi(1-k)]_+}$, $r \in (r_{-}(p), r_{+}(p))$, and $c > 0$, then Z Ω $u^p v^{-r} dx \leq \tilde{c}, \quad t \in (0, T)$ (2.2) with some $\tilde{c} > 0$.

Proof. It is known via a simple computation with (1.1) that

$$
\frac{d}{dt} \int_{\Omega} u^p v^{-r} dx = p \int_{\Omega} u^{p-1} v^{-r} [\Delta u - \chi \nabla (\frac{u}{v} \nabla v)] dx - r \int_{\Omega} u^p v^{-r-1} (k \Delta v - v + u) dx
$$
\n
$$
= -p \int_{\Omega} \nabla (u^{p-1} v^{-r}) \cdot (\nabla u - \chi \frac{u}{v} \nabla v) dx + rk \int_{\Omega} \nabla (u^p v^{-r-1}) \cdot \nabla v dx
$$
\n
$$
+ r \int_{\Omega} u^p v^{-r} dx - r \int_{\Omega} u^{p+1} v^{-r-1} dx
$$
\n
$$
= -p(p-1) \int_{\Omega} u^{p-2} v^{-r} |\nabla u|^2 dx + [pr + prk + p(p-1)\chi] \int_{\Omega} u^{p-1} v^{-r-1} \nabla u \cdot \nabla v dx
$$
\n
$$
- [r(r+1)k + pr\chi] \int_{\Omega} u^p v^{-r-2} |\nabla v|^2 dx + r \int_{\Omega} u^p v^{-r} dx - r \int_{\Omega} u^{p+1} v^{-r-1} dx
$$
\n
$$
\leq \int_{\Omega} \left[\frac{p[(p-1)\chi + r + rk]^2}{4(p-1)} - pr\chi - r(r+1)k \right] u^p v^{-r-2} |\nabla v|^2 dx
$$
\n
$$
+ r \int_{\Omega} u^p v^{-r} dx - r \int_{\Omega} u^{p+1} v^{-r-1} dx
$$

by Young's inequality. Denote

$$
f(r; p, \chi, k) = \frac{p[(p-1)\chi + r + rk]^2}{4(p-1)} - pr\chi - r(r+1)k,
$$

and rewrite as the quadric expression in r

$$
4(p-1)f(r;p,\chi,k) = [p(k-1)^2 + 4k]r^2 + [2p(p-1)\chi(k-1) - 4(p-1)k]r + p(p-1)^2\chi^2.
$$

We know

$$
\Delta_r = 4(p-1)^2 [p\chi(k-1) - 2k]^2 - 4(p-1)^2 p\chi^2 [p(k-1)^2 + 4k]
$$

= 16(p-1)² [k² - p\chi(k-1) - p\chi^2k] > 0

whenever $p < \frac{k}{[x^2 + \chi(k-1)]_+}$. Consequently, $f(r; p, \chi, k) < 0$ for any $r \in (r-(p), r+(p))$. This yields

$$
\frac{d}{dt} \int_{\Omega} u^p v^{-r} dx \le r \int_{\Omega} u^p v^{-r} dx - r \int_{\Omega} u^{p+1} v^{-r-1} dx, \quad t \in (0, T). \tag{2.3}
$$

Due to $\int_{\Omega} u^p v^{-r} \leq (\int_{\Omega} u^{p+1} v^{-r-1})^{\frac{p}{p+1}} (\int_{\Omega} v^{p-r})^{\frac{1}{p+1}},$ we obtain [\(2.2\)](#page-2-0) from [\(2.3\)](#page-3-0) and [\(2.1\)](#page-2-1). \Box

Lemma 2.3 Let (u, v) satisfy the second equation of [\(1.1\)](#page-0-0) with $k > 0$, $1 \le q \le p \le \infty$, n $\frac{n}{2}(\frac{1}{q}-\frac{1}{p})$ < 1. Then there exists $C > 0$, such that

$$
||v(\cdot,t)||_{L^{p}(\Omega)} \leq C(1+\sup_{s\in(0,t)}||u(\cdot,s)||_{L^{q}(\Omega)}), \quad t\in(0,T)
$$
\n(2.4)

Proof. Noticing $v(\cdot, t) = e^{t(k\Delta - 1)}v_0 + \int_0^t e^{(t-s)(k\Delta - 1)}u(\cdot, s)ds$ for $t > 0$, by the standard smoothing estimates for the heat semigroup under homogeneous Neumann boundary condi-tions [\[20\]](#page-9-2), we can obtain for $q \leq p$ that

$$
||v(\cdot,t)||_{L^{p}(\Omega)} \leq ||e^{t(k\Delta-1)}v_{0}||_{L^{p}(\Omega)} + \int_{0}^{t} ||e^{(t-s)(k\Delta-1)}u(\cdot,s)||_{L^{p}(\Omega)}ds
$$

\n
$$
\leq C_{1}||v_{0}(x)||_{L^{\infty}(\Omega)} + C_{2} \sup_{s \in (0,t)} ||u(\cdot,s)||_{L^{q}(\Omega)} \int_{0}^{t} (1 + [k(t-s)])^{-\frac{n}{2}(\frac{1}{q} - \frac{1}{p})} e^{-(\lambda_{1} + \frac{1}{k})[k(t-s)]} ds
$$

\n
$$
\leq C_{1}||v_{0}(x)||_{L^{\infty}(\Omega)} + \frac{C_{2}}{k} \sup_{s \in (0,t)} ||u(\cdot,s)||_{L^{q}(\Omega)} \int_{0}^{\infty} (1 + \alpha)^{-\frac{n}{2}(\frac{1}{q} - \frac{1}{p})} e^{-\lambda_{1}\alpha} d\alpha, \quad t \in (0,T),
$$

where $C_1, C_2 > 0$, λ_1 is the first nonzero eigenvalue of $-\Delta$ under the Neumann boundary condition. This proves (2.3) . \Box

Instead of the choice of $r = \frac{p-1}{2}$ in [\[2\]](#page-8-8), we deal with the more complicated form $r =$ $(p-1)\frac{[p\chi(1-k)+2k]}{p(1-k)^2+4k}$ to describe the effect of the chemicals diffusion rate k, and denote $h(p) \triangleq$ $h(p; \chi, k) = \frac{p\chi(1-k)+2k}{p(1-k)^2+4k}$. For such $h(p)$, we have the following lemma.

Lemma 2.4 Let $k > 0$, $\chi \in \left(0, -\frac{k-1}{2} + \frac{1}{2}\right)$ $\frac{1}{2}\sqrt{(k-1)^2+\frac{8k}{n}}$, and $p \in (1, \frac{k}{[\chi^2+\chi(k-1)]_+})$. Then $h(p) \in (0,1)$.

Proof. We have $h'(p) = \frac{2k(1-k)[2\chi-(1-k)]}{[p(1-k)^2+4k]^2}$.

If
$$
k = 1
$$
, then $h(p) \equiv \frac{1}{2}$.
\nIf $k > 1$, then $h'(p) < 0$, and so
\n $0 < \frac{\chi}{2\chi + k - 1} = h(\frac{k}{\chi^2 - \chi(1 - k)} - 0) = h(\frac{k}{[\chi^2 - \chi(1 - k)]_+} - 0) < h(p) < h(1 + 0) = \frac{2k + \chi(1 - k)}{(1 - k)^2 + 4k} < \frac{2k}{(1 + k)^2} < 1$.

Now suppose $0 < k < 1$.

If $0 < \chi < \frac{1-k}{2}$, then $h'(p) < 0$, and so $0 < \frac{\chi}{1-k} = \lim_{p \to \infty}$ $p\chi(1-k)+2k$ $\frac{p\chi(1-k)+2k}{p(1-k)^2+4k} < h(p) < h(1+0) = \frac{2k+\chi(1-k)}{(1-k)^2+4k} < \frac{1}{2}$ $\frac{1}{2}$; If $\chi = \frac{1-k}{2}$, then $h(p) \equiv \frac{1}{2}$ $\frac{1}{2}$; If $\frac{1-k}{2} < \chi \leq 1-k$, then $h'(p) > 0$, and so $\frac{1}{2} < \frac{2k + \chi(1-k)}{(1+k)^2} = h(1+0) < h(p) < \lim_{p \to \infty}$ $p\chi(1-k)+2k$ $\frac{p\chi(1-k)+2k}{p(1-k)^2+4k} = \frac{\chi}{1-k} \leq 1;$ If $1-k < \chi <$ $\frac{-(k-1)+\sqrt{(k-1)^2+\frac{8k}{n}}}{2}$, then $h'(p) > 0$, and so $0 < \frac{1-k^2}{(1+k)}$ $\frac{1-k^2}{(1+k)^2} < \frac{2k+\chi(1-k)}{(1+k)^2} = h(1+0) < h(p) < h(\frac{k}{\chi^2-\chi(1-k)}-0) = \frac{\chi}{2\chi+k-1} < 1.$ The proof is complete. \square

Denote $c_0 = \inf_{p \in (1, \frac{n}{2}]} h(p)$ and $c^0 = \sup_{p \in (1, \frac{n}{2}]} h(p)$ with $n \ge 3$. By Lemma [2.4](#page-4-0) and its proof, $c_0, c^0 \in (0, 1)$. The following lemma with c_0 and c^0 will play an important role for estimating the bound of u by the involved iteration in the next section.

Lemma 2.5 Let $k > 0$, $\chi \in (0, -\frac{k-1}{2} + \frac{1}{2}\sqrt{(k-1)^2 + \frac{8k}{n}})$, then $f(x) \triangleq \frac{n[(1-c^0)x+c^0-c_0]+2c_0x}{(n-2x)(1-c_0)}$ $x > 0$ for $x \in (1, \frac{n}{2})$ $\frac{n}{2}$, provided $n \leq 8$.

Proof. It suffices to show $g(x) \triangleq 2(1 - c_0)x^2 + [2c_0 - n(c^0 - c_0)x + n(c^0 - c_0) > 0$ in $(1, \frac{n}{2})$ $\frac{n}{2}$. The case of $c_0 = c^0 \in (0, 1)$ is trivial.

Now suppose $0 < c_0 < c^0 < 1$. We have $\Delta_g = [2c_0 - n(c^0 - c_0)]^2 - 8n(1 - c_0)(c^0 - c_0) =$ $[n(c^0-c_0)]^2 + (4c_0-8)n(c^0-c_0) + 4c_0^2 < 0$, and hence $g(x) > 0$, whenever $4-2c_0-4\sqrt{1-c_0} <$ $n(c^0-c_0) < 4-2c_0+4\sqrt{1-c_0}.$

If $n(c^0 - c_0) \leq 4 - 2c_0 - 4\sqrt{1 - c_0}$, then $\Delta_g > 0$. Due $n(c^0 - c_0) - 2c_0 < 4(1 - c_0) 4\sqrt{1-c_0} < 0$, we know that both the two roots of $g(x)$ must be negative. With $g(1+0) = 2$, we obtain $g(x) > 0$.

If $n(c^0 - c_0) \geq 4 - 2c_0 + 4\sqrt{1 - c_0}$, then $\Delta_g > 0$, and the two roots of $g(x)$ satisfy $x_2 \geq x_1 > 0$. Together with $g(1+0) = 2$ and $g(\frac{n}{2})$ $(\frac{n}{2}) = \frac{n^2}{2}$ $\frac{a^2}{2}(1-c^0) + nc_0 > 0$, the positivity of $g(x)$ for $x \in (1, \frac{n}{2})$ $\frac{n}{2}$ requires that the minimal point of $g(x)$ satisfies $\frac{n(c^0-c_0)-2c_0}{4(1-c_0)} < 1$, i.e., $n(c^0 - c_0) + 2c_0 < 4$, by Vieta's formulas. This contradicts the case $n(c^0 - c_0) \ge$ $4-2c_0+4\sqrt{1-c_0}$. So, the case itself should be excluded to ensure $g(x) > 0$ in $(1, \frac{n}{2})$ $\frac{n}{2}$. Rewrite the case as $c^0 \geq \frac{(n-2)c_0+4+4\sqrt{1-c_0}}{n} \triangleq \alpha(c_0)$ with $c_0 \in (0,1)$. We have $c^0 \geq \alpha(c_0) >$ $\min\{\alpha(0), \alpha(1)\} = \min\{\frac{n+2}{n}, \frac{8}{n}\}.$ Thus, we would get a contradiction that $c^0 > 1$, whenever $n \leq 8.$

3 Proof of main result

We deal with the proof of the main result of the paper in this section.

Proof of Theorem [1.](#page-1-0)

We at first show that the local solutions ensured by Lemma [2.1](#page-2-2) should be global.

Assume $p > q$. By the Hölder inequality, we have

$$
\int_{\Omega} u^q dx = \int_{\Omega} (u^p v^{-r})^{\frac{q}{p}} v^{\frac{rq}{p}} dx \le \left(\int_{\Omega} u^p v^{-r} dx \right)^{\frac{q}{p}} \left(\int_{\Omega} v^{\frac{rq}{p-q}} dx \right)^{\frac{p-q}{p}}, \quad 0 < t < T. \tag{3.1}
$$

Let $p \leq \frac{k}{[x^2 + x(k-1)]_+}$. We know from [\(2.3\)](#page-3-0) in the proof of Lemma [2.2](#page-2-3) with $r \in$ $(r_-(p), r_+(p))$ that d

$$
\frac{d}{dt} \int_{\Omega} u^p v^{-r} dx \le r \int_{\Omega} u^p v^{-r} dx, \quad t \in (0, T),
$$

and hence

$$
\int_{\Omega} u^p v^{-r} dx \le C, \quad t \in (0, T)
$$
\n(3.2)

with $C = C(t) > 0$. Notice $\chi \in \left(0, -\frac{k-1}{2} + \frac{1}{2}\right)$ $\frac{1}{2}\sqrt{(k-1)^2 + \frac{8k}{n}}$ with $p < \frac{k}{[\chi^2 + \chi(k-1)]_+}$ admits $p > \frac{n}{2}$.

Take $q \in (\frac{n}{2})$ $(\frac{n}{2}, p) \subset (1, \min\{p, \frac{n(p-r)}{[n-2r]_+})\}$ $\frac{n(p-r)}{[n-2r]+}$). Then $\frac{n}{2}(\frac{1}{q} - \frac{p-q}{rq}) < 1$. By Lemma [2.3,](#page-3-1) we have with $C_1 > 0$ that

$$
||v||_{\frac{rq}{p-q}} \le C_1 (1 + \sup_{s \in (0,t)} ||u||_q), \quad 0 < t < T.
$$
\n(3.3)

Combining (3.1) – (3.3) yields

$$
\int_{\Omega} u^q dx \le C_2 \left(1 + \left(\sup_{s \in (0,t)} \int_{\Omega} u^q dx\right)^{\frac{r}{p}}\right), \quad t \in (0,T),
$$

and hence $\int_{\Omega} u^q dx \leq C_3$ for $t \in (0,T)$, where $C_2 = C_2(t) = \tilde{C}_2 e^{rt}$ with $\tilde{C}_2 > 0$, $C_3 = C_3(t) >$ 0, and $\frac{r}{p} < \frac{p-1}{p} < 1$ by Lemma [2.4.](#page-4-0) Now we can follow the proof of Lemma 3.4 in [\[19\]](#page-9-0) to obtain the global existence of solutions for (1.1) .

Next, we prove the solutions established above are also globally bounded if $n \leq 8$. We should verify that $\int_{\Omega} u^q dx < C$ with some $q > \frac{n}{2}$ and $C > 0$ [\[19\]](#page-9-0).

The case of $n = 2$ is simple. Take

$$
\begin{cases} p \in \left(1, \frac{k}{[\chi^2 + \chi(k-1)]_+}\right), \\ r = (p-1)h(p). \end{cases}
$$

Then $1 - \frac{1}{p-r} < 1$. By Lemma [2.3](#page-3-1) with the L¹-conservation of u, we have

$$
||v||_{L^{p-r}} \leq C_4, \quad t \in (0, T)
$$

with time-independent $C_4 > 0$. By Lemma [2.2,](#page-2-3)

$$
\int_{\Omega} u^p v^{-r} dx \le C_5, \quad t \in (0, T)
$$
\n(3.4)

with some $C_5 > 0$. We deduce from (3.1) , (3.3) and (3.4) that there exists $q > 1$, such that $||u||_q \leq C_6$ for $t \in (0,T)$ with $C_6 = C_6(k) > 0$.

Now consider the case of $3 \le n \le 8$. We should fix the assumption (2.1) with some $p > \frac{n}{2}$ and the constant independent of t there. We will do it via an iteration procedure based of Lemma [2.5.](#page-4-1)

1 ◦ Take

$$
\begin{cases} p_0 \in \left(1, \min\left\{\frac{k}{\lfloor \chi^2 + \chi(k-1) \rfloor_+}, \frac{n(1-c_0) + 2c_0}{(n-2)(1-c_0)}\right\}\right), \\ r_0 = (p_0 - 1)h(p_0). \end{cases} \tag{3.5}
$$

Then $p_0 - r_0 \leq p_0 - (p_0 - 1)c_0 = (1 - c_0)p_0 + c_0 < \frac{n}{n-2}$, i.e., $\frac{n}{2}(1 - \frac{1}{p_0 - r_0}) < 1$. By Lemma [2.3](#page-3-1) with the L^1 -conservation of u, we have

$$
||v||_{L^{p_0-r_0}} \leq C_7, \quad t \in (0,T),
$$

and hence

$$
\int_{\Omega} u^{p_0} v^{-r_0} dx \le C_8, \quad t \in (0, T)
$$
\n(3.6)

by Lemma [2.2,](#page-2-3) with some $C_7, C_8 > 0$. We know from [\(3.1\)](#page-5-0), [\(3.3\)](#page-6-0) and [\(3.6\)](#page-7-0) that $||u||_{q_0} \le C_9$ for $t \in (0, T)$ with $C_9 > 0$. If $p_0 > \frac{n}{2}$, take $q_0 \in (\frac{n}{2})$ $(\frac{n}{2}, p_0) \subset (1, \min\{p_0, \frac{n(p_0-r_0)}{[n-2r_0]_+}]$ $\frac{n(p_0-r_0)}{[n-2r_0]_+}\big\}\Big).$

2° Assume $p_0 \leq \frac{n}{2}$ $\frac{n}{2}$. Take

$$
\begin{cases} p_1 \in (p_0, \min\left\{\frac{k}{[\chi^2 + \chi(k-1)]_+}, \frac{n[(1-c^0)p_0 + c^0 - c_0] + 2c_0p_0}{(n-2p_0)(1-c_0)}\right\}),\\ r_1 = (p_1 - 1)h(p_1), \end{cases}
$$

where the well-definedness of the interval for p_1 is ensured by Lemma [2.5.](#page-4-1) A simple calculation shows

$$
p_1 - r_1 \le (1 - c_0)p_1 + c_0 < \frac{n[(1 - c^0)p_0 + c^0]}{n - 2p_0} \le \frac{n(p_0 - r_0)}{n - 2p_0} = \frac{n\frac{n(p_0 - r_0)}{n - 2r_0}}{n - \frac{2n(p_0 - r_0)}{n - 2r_0}},
$$

i.e., $\frac{n}{2}(\frac{1}{\frac{n(p_0-r_0)}{n-2r_0}}-\frac{1}{p_1-r_1})$ < 1. By Lemma [2.3](#page-3-1) with $p_0 \leq \frac{n}{2}$, there is $q_0 \in (1, \frac{n(p_0-r_0)}{n-2r_0})$ $\frac{(p_0-r_0)}{n-2r_0}$) such that

$$
||v||_{p_1-r_1} < C_{10}, \quad t \in (0, T),
$$

and thus

$$
\int_{\Omega} u^{p_1} v^{-r_1} dx \le C_{11}, \quad t \in (0, T) \tag{3.7}
$$

by Lemma [2.2,](#page-2-3) with some C_{10} , $C_{11} > 0$. It follows from (3.1) , (3.3) and (3.7) that $||u||_{q_1} \le C_{12}$ for $t \in (0, T)$ with $C_{12} > 0$. If $p_1 > \frac{n}{2}$ $\frac{n}{2}$, take $q_1 \in (\frac{n}{2})$ $(\frac{n}{2}, p_1) \subset (1, \min\{p_1, \frac{n(p_1-r_1)}{[n-2r_1]_+})\}$ $\frac{n(p_1-r_1)}{[n-2r_1]_+}\}$.

3° Assume $p_{l-1} \leq \frac{n}{2}, l = 1, 2, 3, \dots$. Take

$$
\begin{cases} p_l \in \left(p_{l-1}, \min\left\{ \frac{k}{[\chi^2 + \chi(k-1)]_+}, \frac{n[(1-c^0)p_{l-1} + c^0 - c_0] + 2c_0p_{l-1}}{(n-2p_{l-1})(1-c_0)} \right\} \right), \\ r_l = (p_{l-1} - 1)h(p_{l-1}), \end{cases} \tag{3.8}
$$

where the interval for p_l is well defined due to Lemma [2.5.](#page-4-1) Repeat the procedure in $2°$, we deduce with $q_l \in (1, \min\{p_l, \frac{n(p_l - r_l)}{[n-2r_l]_+}$ $\frac{n(p_l - r_l)}{[n-2r_l]_+}$) that $||u||_{q_l} \leq C_{13}$, $0 < t < T$, with some $C_{13} > 0$. Noticing $\frac{n[(1-c^0)p_{l-1}+c^0-c_0]+2c_0p_{l-1}}{(n-2p_{l-1})(1-c_0)} \to \infty$ as $l \to \infty$ by Lemma [2.5,](#page-4-1) we can realize $p_l > \frac{n}{2}$ $\frac{n}{2}$ after finite steps. Let $q = q_l \in (\frac{n}{2})$ $(\frac{n}{2}, p_l)$ to get $\int_{\Omega} u^q dx \leq C_{14}$ for all $t \in (0, T)$ with $C_{14} > 0$. It is mentioned that for any fixed $k > 0$, the constants C_i , $i = 5, \ldots, 14$, are all independent of $t \in (0,T)$ here.

Based on the above estimate $||u(\cdot, t)||_{L^q(\Omega)}$ with $q > \frac{n}{2}$, uniform for $t \in (0, T)$, we conclude the global boundedness of u by coping the related arguments in $[19]$ for that to the case of $k = 1.$ \Box

Remark 3 Notice $p_0 < \frac{k}{[\chi^2 + \chi(k-1)]_+}$ in [\(3.5\)](#page-6-2) with $\chi \in (0, -\frac{k-1}{2} + \frac{1}{2}\sqrt{(k-1)^2 + \frac{8k}{n}})$ admits $p_0 > \frac{n}{2}$ $\frac{n}{2}$. Moreover, a simple computation shows $p_0 < \frac{n(1-c_0)+2c_0}{(n-2)(1-c_0)}$ $p_0 > \frac{n}{2}$. Moreover, a simple computation shows $p_0 < \frac{n(1-c_0)+2c_0}{(n-2)(1-c_0)}$ $p_0 < \frac{n(1-c_0)+2c_0}{(n-2)(1-c_0)}$ $p_0 < \frac{n(1-c_0)+2c_0}{(n-2)(1-c_0)}$ in [\(3.5\)](#page-6-2) ensures $\frac{n(1-c_0)+2c_0}{(n-2)(1-c_0)} > \frac{n}{2}$ whenever $n = 3, 4$. Therefore, the Steps 2° and 3° in the proof of Theorem 1 are unneces for $n = 3, 4$ there. In addition, it should be pointed out that $c^0 = c_0 = \frac{1}{2}$ $\frac{1}{2}$ if $k = 1$, and thus the requirement $n \leq 8$ itself can be removed away for the global boundedness of solutions with $k = 1$.
