Abstract

We describe a new class of positive linear discrete-time switching systems for which the problems of stability or stabilizability can be resolved constructively. The systems constituting this class can be treated as a natural generalization of systems with the so-called independently switching state vector components. Distinctive feature of such systems is that their components can be arbitrarily ‘re-connected’ in parallel or in series without loss of the ‘constructive resolvability’ property for the problems of stability or stabilizability of a system. It is shown also that, for such systems, the individual positive trajectories with the greatest or the lowest rate of convergence to the zero can be built constructively.

1. Introduction

A linear discrete-time system

$$x(n+1) = A(n)x(n), \quad x(n) \in \mathbb{R}^N, \quad (1)$$

is called *switching* provided that the $(N \times N)$ -matrices $A(n)$, for each n , may arbitrarily take values from some set \mathcal{A} . System (1) is called (asymptotically) *stable* if, for each sequence of matrices $A(n) \in \mathcal{A}$, $n = 0, 1, \dots$, the corresponding solution $x(n)$ tends to zero.

The asymptotic stability of switching system (1) is equivalent to the exponential convergence to zero of each sequence $\{X(n)\}$ of the matrix products $X(n) = A(n) \cdots A(1)A(0)$ [1–8], which in turn is equivalent to the inequality

$$\rho(\mathcal{A}) < 1. \quad (2)$$

Here, the quantity $\rho(\mathcal{A})$, called [9] the *joint spectral radius* of the matrix set \mathcal{A} , is defined as follows:

$$\rho(\mathcal{A}) = \limsup_{n \rightarrow \infty} \left\{ \|A_n \cdots A_1\|^{1/n} : A_i \in \mathcal{A} \right\}, \quad (3)$$

where $\|\cdot\|$ is an arbitrary norm on \mathbb{R}^N .

For switching systems that are not stable, one may pose the question about the existence of at least one sequence of matrices $A(n) \in \mathcal{A}$, $n = 0, 1, \dots$, such that $A(n) \cdots A(1)A(0) \rightarrow 0$, that is, about *stabilization* of a system. It is known [4, 10–13] that system (1) can be stabilized if the following inequality holds:

$$\check{\rho}(\mathcal{A}) < 1, \quad (4)$$

where the quantity $\check{\rho}(\mathcal{A})$, called the *lower spectral radius* [4] of the matrix set \mathcal{A} , is as follows:

$$\check{\rho}(\mathcal{A}) = \liminf_{n \rightarrow \infty} \left\{ \|A_n \cdots A_1\|^{1/n} : A_i \in \mathcal{A} \right\}. \quad (5)$$

Inequalities (2) and (4) might seem to give an exhaustive answer to the questions on stability or stabilizability of a switching system. This is indeed the case from the theoretical point of view. However, in practice it is often difficult to use these criteria since the computation of the limits in (3) and (5) in a closed formula form is generally impossible, which implies the need to make use of approximate computational methods. Besides, at now there are no a priori estimates for the rate of convergence of the limits (3) and (5), and the required amount of computations rapidly increases in n and the dimension of a system, which exacerbates the difficulty in the usage of computational methods.

In this regard, we would like to note the following problems of stability and stabilizability of linear switching systems, which are not new per se, but are remaining to be relevant.

Problem 1. *How to describe the classes of switching systems (or equivalently, the classes of matrix sets \mathcal{A}), for which the joint spectral radius (3) could be constructively calculated?*

Problem 2. *How to describe the classes of switching systems (or equivalently, the classes of matrix sets \mathcal{A}), for which the lower spectral radius (5) could be constructively calculated?*

There is another circumstance that hampers the investigation of stability and stabilizability of system (1). This circumstance is barely mentioned in the theory of convergence of matrix products but is of crucial importance in the control theory. The point is that, in the control theory, systems in general are composed not of a single block but of a number

of interconnected blocks. When these blocks are linear and functioning asynchronously each of them is described by the equation

$$x_{\text{out}}(n+1) = A_i(n)x_{\text{in}}(n), \quad (6)$$

where $x_{\text{in}}(\cdot) \in \mathbb{R}^{N_i}$, $x_{\text{out}}(\cdot) \in \mathbb{R}^{M_i}$, and the matrices $A_i(n)$, for each n , may arbitrarily take values from some set \mathcal{A}_i of $(N_i \times M_i)$ -matrices, where $i = 1, 2, \dots, Q$ and Q is the total amount of blocks in the system.

Figure 1: An example of a series-parallel connection of controllers of a system

In this case it is natural to pose the question about stability or stabilizability not for isolated blocks or controllers (6), but for a system as a whole, whose blocks may be connected in parallel or in series, or in a more complicated way, represented by some directed graph with blocks of the form (6) placed on its edges, see Fig. 1. Unfortunately, under such a connection of blocks, the classes of matrices describing the transient processes of a system as a whole became very complicated and their properties are practically not investigated. As a rule, even in the cases when the dimensions of the input-output vectors coincide with each other and hence the question about stability or stabilizability of a single block may be somehow answered, after a series-parallel connection of such blocks, it is often impossible to answer the question about the stability of the whole system or, at the best, it is very difficult to get the desired answer. So, the following problem is also urgent:

Problem 3. *How to describe the classes of switching systems for which the question about stability or stabilizability can be constructively answered not only for an isolated switching block (1) or (6) but also for any series-parallel connection of such blocks?*

At last, let us consider one more aspect of the problem of constructive stability or stabilizability of the switching systems.

The joint spectral radius (3), as well as the lower spectral radius (5), provide only characterization of stability or stabilizability of a system ‘as a whole’. They describe the limiting behavior of the ‘multiplicatively averaged’ norms of the matrix products, $\|A_n \cdots A_1\|^{1/n}$. If one is interested in the study of stability of a system, in typical situations, e.g. for the so-called *irreducible* classes of matrices \mathcal{A} , for each vector $x \in \mathbb{R}^N$ and each sequence of matrices $\{A(n)\}$ the following estimate holds

$$\|A_n \cdots A_1 x\| \leq C_x \rho^n(\mathcal{A}) \|x\|,$$

where the ‘constant’ C_x is bounded uniformly in x , and moreover, for some x and sequences $\{A(n)\}$ this constant is separated from zero, see, e.g., [2]. In the case when one

is interested in the study of stabilizability of a system, in typical situations *there exists* a sequence of matrices $\{A(n)\}$ such that, for each vector x , the following estimate is valid:

$$\|A_n \cdots A_1 x\| \leq \check{C}_x \check{\rho}^n(\mathcal{A}) \|x\|.$$

At the same time often there arise the problem to find, for a given initial vector x , a sequence of matrices that would ensure the slowest or fastest ‘decrease’ of the vectors $A(n) \cdots A(1)x$. More precisely, let us consider a function $\nu(x) \equiv \nu(x_1, x_2, \dots, x_N)$ which is non-decreasing in each coordinate x_i of the vector $x = (x_1, x_2, \dots, x_N)$ and defined for all $x_1, x_2, \dots, x_N \geq 0$. Such a function will be called *coordinate-wise monotone*, while in the case when it is strictly increasing in each variable x_i it will be called *strictly coordinate-wise monotone*. For example, each of the norms

$$\|x\|_1 = \sum_i |x_i|, \quad \|x\|_2 = \sqrt{\sum_i |x_i|^2}, \quad \|x\|_\infty = \max_i |x_i|,$$

is a coordinate-wise monotone function. Moreover, the norms $\|x\|_1$ and $\|x\|_2$ are strictly coordinate-wise monotone whereas the norm $\|x\|_\infty$ is coordinate-wise monotone but not strictly coordinate-wise monotone.

If the set of matrices \mathcal{A} is finite and consists of K elements then to find the value of

$$\max_{A \in \mathcal{A}} \nu(Ax)$$

it is needed, in general, to compute K times the values of the function $\nu(\cdot)$, and then to find their maximum. Similarly, to find the value of

$$\max_{A_{i_j} \in \mathcal{A}} \nu(A_{i_n} \cdots A_{i_1} x) \tag{7}$$

one need, in general, to compute K^n times the values of the function $\nu(\cdot)$, and then to find their maximum, which leads to an exponential in n growth of the number of required computations. Therefore, it is reasonable to put the following problem:

Problem 4. *Given a coordinate-wise monotone function $\nu(\cdot)$ and a vector $x \neq 0$. How to describe the classes of switching systems (or equivalently, the classes of matrix sets \mathcal{A}), for which the number of computations of the function $\nu(\cdot)$ needed to find the quantity (7) would be less than K^n ? It is desirable that the required number of computations would be of order Kn .*

Clearly, there can be posed a similar problem about minimization of the quantity $\nu(A_{i_n} \cdots A_{i_1} x)$.

In connection with this, our aim is to describe one class of asynchronous blocks or controllers (1), rather simple and natural in applications, for which one can obtain affordable answers to Problems 1–4.

In Section 2, we recall some facts from the theory of matrix products.

2. Sets of matrices with constructively computable spectral characteristics

One of classes of matrix sets whose characteristics (3) and (5) may be constructively calculated is the so-called class of non-negative matrix sets with independent row uncertainty [14]. Recall the related definitions.

In accordance with [14], a set of $N \times M$ -matrices \mathcal{A} is called a *set with independent row uncertainty*, or an *IRU-set*, if it consists of all the matrices

$$A = \begin{pmatrix} a_{11} & a_{12} & \cdots & a_{1M} \\ a_{21} & a_{22} & \cdots & a_{2M} \\ \cdots & \cdots & \cdots & \cdots \\ a_{N1} & a_{N2} & \cdots & a_{NM} \end{pmatrix},$$

each row $a_i = (a_{i1}, a_{i2}, \dots, a_{iM})$ of which belongs to some set of M -rows $\mathcal{A}^{(i)}$, $i = 1, 2, \dots, N$. An IRU-set of matrices will be referred to as non-negative if all its matrices are non-negative, which is equivalent to the non-negativity of all the strings composing the sets \mathcal{A}_i . The totality of all IRU-sets of non-negative $(N \times M)$ -matrices will be denoted by $\mathcal{U}(N, M)$.

Example 1. Let the sets of rows $\mathcal{A}^{(1)}$ and $\mathcal{A}^{(2)}$ be as follows:

$$\mathcal{A}^{(1)} = \{(a, b), (c, d)\}, \quad \mathcal{A}^{(2)} = \{(\alpha, \beta), (\gamma, \delta), (\mu, \nu)\}.$$

Then the IRU-set \mathcal{A} consists of the following matrices:

$$A_{11} = \begin{pmatrix} a & b \\ \alpha & \beta \end{pmatrix}, \quad A_{12} = \begin{pmatrix} a & b \\ \gamma & \delta \end{pmatrix}, \quad A_{13} = \begin{pmatrix} a & b \\ \mu & \nu \end{pmatrix}, \\ A_{21} = \begin{pmatrix} c & d \\ \alpha & \beta \end{pmatrix}, \quad A_{22} = \begin{pmatrix} c & d \\ \gamma & \delta \end{pmatrix}, \quad A_{23} = \begin{pmatrix} c & d \\ \mu & \nu \end{pmatrix}.$$

If a set \mathcal{A} is compact, which is equivalent to the compactness of each set of rows $\mathcal{A}^{(1)}, \mathcal{A}^{(2)}, \dots, \mathcal{A}^{(N)}$, then the following quantities are well defined:

$$\rho_{\min}(\mathcal{A}) = \min_{A \in \mathcal{A}} \rho(A), \quad \rho_{\max}(\mathcal{A}) = \max_{A \in \mathcal{A}} \rho(A).$$

As is shown in [15, 16], for non-negative compact IRU-sets of matrices \mathcal{A} , the following equalities hold

$$\rho(\mathcal{A}) = \rho_{\max}(\mathcal{A}), \quad \check{\rho}(\mathcal{A}) = \rho_{\min}(\mathcal{A}), \quad (8)$$

whereas for arbitrary sets of matrices, as is noted in [16, Example 1], equalities (8) are not valid.

For finite IRU-sets of matrices \mathcal{A} , the quantities $\rho_{\min}(\mathcal{A})$ and $\rho_{\max}(\mathcal{A})$ can be constructively calculated, and therefore due to (8), for finite IRU-sets of non-negative matrices, the quantities $\rho(\mathcal{A})$ and $\check{\rho}(\mathcal{A})$ are also can be constructively calculated. An efficient computational algorithm for finding the quantities $\rho_{\min}(\mathcal{A})$ and $\rho_{\max}(\mathcal{A})$ for various IRU-sets of matrices \mathcal{A} is proposed in [17].

Another example of classes of matrices, for which the quantities (3) and (5) can be constructively calculated, is given by the so-called *linearly ordered* sets of non-negative matrices $\mathcal{A} = \{A_1, A_2, \dots, A_n\}$, that is, such sets of matrices for which the inequalities $0 \leq A_1 \leq A_2 \leq \dots \leq A_n$ hold, where the inequalities are meant element-wise. For this class of matrices, the validity of equalities (8) follows from the known relations between the spectral radii of comparable non-negative matrices [18, Corollary 8.1.19]. The totality of all linearly ordered sets of $(N \times M)$ -matrices will be denoted by $\mathcal{L}(N, M)$.

It should be noted that controllers or blocks whose behavior is covered by equations (1) or (6) with IRU-sets of matrices are rather common asynchronous controllers in the control theory which perform the so-called *independent coordinate-wise correction of the state vectors*. The controllers whose behavior is covered by equation (1) with linearly ordered sets of matrices are a kind of *amplifiers with ‘matrix’ coefficients of amplification* varying in time.

2.1. Hourglass alternative

In [16], it was observed that the proofs of equalities (8) for the IRU-sets of matrices, as well as for the linearly ordered sets of matrices, may be obtained by the same scheme, as a corollary of some general principle, which we now describe in more detail.

For vectors $x, y \in \mathbb{R}^N$, we write $x \geq y$ ($x > y$), if all coordinates of the vector x are not less (strictly greater, respectively), than the corresponding coordinates of the vector y . Similar notation will be applied to matrices.

A set of positive matrices \mathcal{A} is called \mathcal{H} -set [16], if for some matrix $\tilde{A} \in \mathcal{A}$ and vectors u, v the equality $\tilde{A}u = v$ holds and also there are valid the following assertions:

- H1: either $Au \geq v$ for all $A \in \mathcal{A}$ or there exists a matrix $\bar{A} \in \mathcal{A}$ such that $\bar{A}u \leq v$ and $\bar{A}u \neq v$;
- H2: either $Au \leq v$ for all $A \in \mathcal{A}$ or there exists a matrix $\bar{A} \in \mathcal{A}$ such that $\bar{A}u \geq v$ and $\bar{A}u \neq v$.

Assertions H1 and H2 have a simple geometrical interpretation. Imagine that the sets $\{x : x \leq v\}$ and $\{x : x \geq v\}$ form the lower and upper bulbs of some stylized hourglass with the neck at the point v . Then, according to Assertions H1 and H2, either all the ‘grains’ Au fill one of the bulbs (upper or lower), or there remains at least one grain in the other bulb (lower or upper, respectively). In [16], such an interpretation gave reason to call Assertions H1 and H2 the *hourglass alternative*.

2.2. \mathcal{H} -sets of matrices

Let us ascertain some general properties of \mathcal{H} -sets of matrices. We first notice that not every set of positive matrices is an \mathcal{H} -set, see an example in [16]. Introduce the operations of Minkowski addition and multiplication for sets of matrices:

$$\begin{aligned}\mathcal{A} + \mathcal{B} &:= \{A + B : A \in \mathcal{A}, B \in \mathcal{B}\}, \\ \mathcal{A}\mathcal{B} &:= \{AB : A \in \mathcal{A}, B \in \mathcal{B}\},\end{aligned}$$

and also the operation of multiplication of a set of matrices by a number:

$$t\mathcal{A} = \mathcal{A}t := \{tA : t \in \mathbb{R}, A \in \mathcal{A}\}.$$

The Minkowski addition of sets of matrices corresponds to the parallel coupling of two independently operating asynchronous controllers, while the Minkowski multiplication corresponds to the serial connection of such asynchronous controllers.

Clearly, the operation of addition is *admissible* if the matrices from the sets \mathcal{A} and \mathcal{B} are of the same size, while the operation of multiplication is *admissible* if the sizes of the matrices from sets \mathcal{A} and \mathcal{B} are matched: dimension of the rows of the matrices from \mathcal{A} is the same as dimension of the columns of the matrices from \mathcal{B} . There is no problem with matching of sizes when one considers sets of square matrices of the same size.

Theorem 1 (see [16]). *The following is true:*

- (i) $\mathcal{A} + \mathcal{B} \in \mathcal{H}(N, M)$, if $\mathcal{A}, \mathcal{B} \in \mathcal{H}(N, M)$;
- (ii) $\mathcal{A}\mathcal{B} \in \mathcal{H}(N, Q)$, if $\mathcal{A} \in \mathcal{H}(N, M)$ and $\mathcal{B} \in \mathcal{H}(M, Q)$;
- (iii) $t\mathcal{A} = \mathcal{A}t \in \mathcal{H}(N, M)$, if $t > 0$ and $\mathcal{A} \in \mathcal{H}(N, M)$.

By Theorem 1 the totality of sets of square matrices $\mathcal{H}(N, N)$ is endowed with additive and multiplicative group operations, but itself is not a group, neither additive nor multiplicative. However, after adding the zero additive element $\{0\}$ and the identity multiplicative element $\{I\}$ to $\mathcal{H}(N, N)$, the resulting totality $\mathcal{H}(N, N) \cup \{0\} \cup \{I\}$ becomes a semiring [19].

The fact that the totality $\mathcal{H}(N, N)$ has the group operations of addition and multiplication means that, by connecting in a serial-parallel manner independently operating asynchronous controllers that satisfy the axioms H1 and H2, we again obtain an asynchronous controller satisfying the axioms H1 and H2.

Remark 1. Theorem 1 implies that any finite sum of any finite products of sets of matrices from $\mathcal{H}(N, N)$ is again a set of matrices from $\mathcal{H}(N, N)$. Moreover, for any integers $n, d \geq 1$, all the polynomial sets of matrices

$$P(\mathcal{A}_1, \mathcal{A}_1, \dots, \mathcal{A}_n) = \sum_{k=1}^d \sum_{i_1, i_2, \dots, i_k \in \{1, 2, \dots, n\}} p_{i_1, i_2, \dots, i_k} \mathcal{A}_{i_1} \mathcal{A}_{i_2} \cdots \mathcal{A}_{i_k}, \quad (9)$$

where $\mathcal{A}_1, \mathcal{A}_1, \dots, \mathcal{A}_n \in \mathcal{H}(N, N)$ and the scalar coefficients p_{i_1, i_2, \dots, i_k} are positive, belong to the set $\mathcal{H}(N, N)$.

With the help of polynomials (9) one can construct not only the elements of the set $\mathcal{H}(N, N)$ but also the elements of arbitrary sets $\mathcal{H}(N, M)$, by taking the arguments $\mathcal{A}_1, \mathcal{A}_1, \dots, \mathcal{A}_n$ from the sets $\mathcal{H}(N_i, M_i)$ with arbitrary matrix sizes $N_i \times M_i$. One must only ensure that the products $\mathcal{A}_{i_1} \mathcal{A}_{i_2} \cdots \mathcal{A}_{i_k}$ are admissible and determine the sets of matrices of dimension $N \times M$.

We have presented above two types of non-trivial \mathcal{H} -sets of matrices, the sets of matrices with independent row uncertainty and the linearly ordered sets of positive matrices. In this connection, let us denote by $\mathcal{H}_*(N, M)$ the totality of all sets of $(N \times M)$ -matrices which can be obtained as admissible finite sums of finite products of the sets of positive matrices with independent rows uncertainty or the sets of linearly ordered positive matrices. In other words, $\mathcal{H}_*(N, M)$ is the totality of all sets of matrices that can be represented as the values of polynomials (9) with the arguments taken from the sets of the matrices belonging to $\mathcal{U}(N_i, M_i) \cup \mathcal{L}(N_i, M_i)$.

Now, the main result about the spectral properties of the \mathcal{H} -sets of matrices can be formulated as follows:

Theorem 2 (see [16]). *Let $\mathcal{A} \in \overline{\mathcal{H}}(N, N)$. Then equalities (8) hold.*

As a matter of fact, in [16] there are proved a number of more profound results, but we will not delve into the intricacies.

3. Main result

Theorems 1 and 2, and Remark 1 imply the following statement:

Theorem 3. *Given a closed system (1) formed by a series-parallel connection of blocks (6) (i.e. represented by some directed graph with blocks placed on its edges) corresponding to some \mathcal{H} -sets of non-negative matrices \mathcal{A}_i , $i = 1, 2, \dots, Q$. Then the question of the stability (stabilizability) of such a system can be constructively resolved by finding a matrix that maximizes (minimizes) the quantity $\rho(A)$ over the set of matrices \mathcal{A} , where \mathcal{A} is the Minkowski polynomial sum (9) of the sets of matrices \mathcal{A}_i , $i = 1, 2, \dots, Q$, corresponding to the structure of coupling of the related blocks.*

4. Construction of individual maximizing and minimizing sequences

4.1. One-step maximization

We first consider the problem of maximizing the function $\nu(Ax)$ over all A from the set \mathcal{A} , which is assumed to be compact. By Assertion H2 of the hourglass alternative, for any matrix $\tilde{A} \in \mathcal{A}$, either $Ax \leq \tilde{A}x$ for all $A \in \mathcal{A}$ or there exists a matrix $\bar{A} \in \mathcal{A}$ such that $\bar{A}x \geq \tilde{A}x$ and $\bar{A}x \neq \tilde{A}x$. This together with the compactness of the set \mathcal{A} implies the existence of a matrix $A^{(max)} \in \mathcal{A}$ such that, for all $A \in \mathcal{A}$, the following inequality holds:

$$Ax \leq A^{(max)}x. \quad (10)$$

Let us notice that the matrix $A^{(max)}$ depends on the vector x , and therefore, when needed we will write $A^{(max)} = A_x^{(max)}$. Moreover, the matrix $A_x^{(max)}$ is generally determined by the vector x non-uniquely.

Theorem 4. *Let \mathcal{A} be a compact \mathcal{H} -set of non-negative $(N \times N)$ -matrices, $\nu(\cdot)$ be a coordinate-wise monotone function, and $x \in \mathbb{R}^N$, $x \geq 0$, be a vector.*

- (i) *Then the maximum of the function $\nu(Ax)$ over $A \in \mathcal{A}$ is attained at the matrix $A^{(max)} = A_x^{(max)}$, that is,*

$$\max_{A \in \mathcal{A}} \nu(Ax) = \nu(A_x^{(max)}x).$$

- (ii) *If the maximum of the function $\nu(Ax)$ over $A \in \mathcal{A}$ is attained at a matrix $A_0 \in \mathcal{A}$ and the function $\nu(\cdot)$ is strictly coordinate-wise monotone, then $A_0x = A_x^{(max)}x$.*

Proof. Assertion (i) directly follows from inequality (10) and the coordinate-wise monotonicity of the function $\nu(\cdot)$.

To prove Assertion (ii) let us notice that

$$A_0x \leq A_x^{(max)}x.$$

If here $A_0x \neq A_x^{(max)}x$ than at least one coordinate of the vector $A_x^{(max)}x$ should be strictly greater than the respective coordinate of the vector A_0x . Then, due to the strict coordinate-wise monotonicity of the function $\nu(\cdot)$, the following inequality holds:

$$\nu(A_0x) < \nu(A_x^{(max)}x),$$

which contradicts to the assumption that the maximum of the function $\nu(Ax)$ over $A \in \mathcal{A}$ is attained at the matrix $A_0 \in \mathcal{A}$. Therefore, $A_0x = A_x^{(max)}x$, and Assertion (ii) is proved. \square

Remark 2. If the function $\nu(\cdot)$ is coordinate-wise monotone but not strictly coordinate-wise monotone then, in general, Assertion (ii) of Theorem 4 is not valid.

Remark 3. The construction of the matrix $A^{(max)}$ does not depend on the function $\nu(\cdot)$.

4.2. Multi-step maximization: solution of Problem 4

We turn now to the question of determining the quantity (7) for some $n > 1$ and $x \in \mathbb{R}^N$, $x \geq 0$. With this aim in view, let us construct sequentially the matrices $A_i^{(max)}$, $i = 1, 2, \dots, n$, as follows:

- the matrix $A_1^{(max)}$, depending in the vector $x_0 = x$, is constructed in the same way as was done in the previous section: $A_1^{(max)} = A_{x_0}^{(max)}$;
- if the matrices $A_i^{(max)}$, $i = 1, 2, \dots, k$, have already constructed then the matrix $A_{k+1}^{(max)}$, depending on the vector

$$x_k = A_k^{(max)} \dots A_1^{(max)}x,$$

is constructed to maximize the function

$$\nu(AA_k^{(max)} \dots A_1^{(max)}x) = \nu(Ax_k)$$

over all $A \in \mathcal{A}$ in the same manner as was done in the previous section. So, the matrix $A_{k+1}^{(max)}$ is defined by the equality $A_{k+1}^{(max)} = A_{x_k}^{(max)}$.

By definition of the matrices $A_i^{(max)}$ then, in view of (10), for all $A \in \mathcal{A}$ there are valid the inequalities

$$\begin{aligned} Ax &\leq A_1^{(max)}x, \\ AA_1^{(max)}x &\leq A_2^{(max)}A_1^{(max)}x, \\ &\dots \\ AA_{n-1}^{(max)} \dots A_1^{(max)}x &\leq A_n^{(max)} \dots A_1^{(max)}x, \end{aligned}$$

which implies

$$A_n \dots A_1x \leq A_n^{(max)} \dots A_1^{(max)}x \tag{11}$$

for all $A_n, \dots, A_1 \in \mathcal{A}$.

Theorem 5. Let \mathcal{A} be a compact \mathcal{H} -set of non-negative $(N \times N)$ -matrices, $\nu(\cdot)$ be a coordinate-wise monotone function, and $x \in \mathbb{R}^N$, $x \geq 0$, be a vector.

- (i) Then the maximum of the function $\nu(A_n \cdots A_1 x)$ over $A_1, \dots, A_n \in \mathcal{A}$ is attained at the set of matrices $A_1^{(max)}, \dots, A_n^{(max)}$, that is,

$$\max_{A_n, \dots, A_1 \in \mathcal{A}} \nu(A_n \cdots A_1 x) = \nu(A_n^{(max)} \cdots A_1^{(max)} x).$$

- (ii) Let \mathcal{A} be a compact \mathcal{H} -set of positive matrices. If the maximum of the function $\nu(A_n \cdots A_1 x)$ over $A_n, \dots, A_1 \in \mathcal{A}$ is attained at a set of matrices $\tilde{A}_1, \dots, \tilde{A}_n$ and the function $\nu(\cdot)$ is strictly coordinate-wise monotone, then

$$\tilde{A}_i \cdots \tilde{A}_1 x = A_i^{(max)} \cdots A_i^{(max)} x, \quad i = 1, 2, \dots, n. \quad (12)$$

Proof. Assertion (i) directly follows from inequality (11) and the coordinate-wise monotonicity of the function $\nu(\cdot)$.

To prove Assertion (ii) let us observe that

$$\begin{aligned} \tilde{A}_1 x &\leq A_1^{(max)} x, \\ \tilde{A}_2 \tilde{A}_1 x &\leq A_2^{(max)} A_1^{(max)} x, \\ &\dots \\ \tilde{A}_n \tilde{A}_{n-1} \cdots \tilde{A}_1 x &\leq A_n^{(max)} \cdots A_1^{(max)} x, \end{aligned}$$

If here equalities (12) are not valid for some $i = i_0$ but valid for all $i < i_0$ then at least one coordinate of the vector $A_{i_0}^{(max)} x$ is strictly greater than the respective coordinate of the vector $\tilde{A}_{i_0} x$. Then, due to the positivity of the matrices from the set \mathcal{A} , for each $j \geq i_0$ there is valid the equality

$$\tilde{A}_j \tilde{A}_{j-1} \cdots \tilde{A}_1 x \leq A_j^{(max)} \cdots A_1^{(max)} x,$$

where at least one coordinate of the vector $A_j^{(max)} \cdots A_1^{(max)} x$ is strictly greater¹ than the respective coordinate of the vector $\tilde{A}_j \tilde{A}_{j-1} \cdots \tilde{A}_1 x$. Then, due to the strict coordinate-wise monotonicity of the function $\nu(\cdot)$, for $j = n$ we obtain the inequality

$$\nu(A_0 x) < \nu(A_x^{(max)} x)$$

contradicting to the assumption that the maximum of the function $\nu(A_n \cdots A_1 x)$ over $A_n, \dots, A_1 \in \mathcal{A}$ is attained at the set of matrices $\tilde{A}_1, \dots, \tilde{A}_n$. Therefore, equalities (12) should be valid for all $i = 1, 2, \dots, n$, and Assertion (ii) is proved. \square

Remark 4. The construction of each subsequent matrix $A_i^{(max)}$ is ‘positional’, or what is the same, it is made in accordance with the ‘principles of dynamic programming’, that is, only based on the information known up to this step. At the same time, this construction does not depend on the function ν , and hence on the complexity of its calculation!

¹This argument ‘fails’, if we assume that the matrices constituting the set \mathcal{A} are only non-negative.

Acknowledgments

The work was carried out at the Kotelnikov Institute of Radio-engineering and Electronics, Russian Academy of Sciences, and was funded by the Russian Science Foundation, Project No. 16-11-00063.
