Existence and regularity results for Fully Non Linear Operators on the model of the pseudo Pucci's operators

I. Birindelli, F. Demengel

1 Introduction

This paper is devoted to the existence and regularity of viscosity solutions for a class of degenerate operators, on the model of the pseudo p-Laplacian.

Recall that the pseudo-p-Laplacian, for $p > 1$ is defined by:

$$
\tilde{\Delta}_p u := \sum_1^N \partial_i (|\partial_i u|^{p-2} \partial_i u).
$$

When $p > 2$, it is degenerate elliptic at any point where even only one derivative $\partial_i u$ is zero.

Using classical methods in the calculus of variations, equation

$$
\tilde{\Delta}_p u = (p-1)f \tag{1.1}
$$

has solutions in $W^{1,p}$, when for example $f \in L^{p'}$. The regularity results are obtained through specific variational technics, see [\[18\]](#page-23-0), [\[11\]](#page-22-0). When $p < 2$, Lipschitz regularity is a consequence of [\[13\]](#page-22-1).

When $p > 2$ things are more delicate. Note that in [\[8\]](#page-22-2), for some fixed non negative numbers δ_i , the following widely degenerate equation was considered

$$
\sum_{i} \partial_i ((|\partial_i u| - \delta_i)_+^{p-1} \frac{\partial_i u}{|\partial_i u|}) = (p-1)f. \tag{1.2}
$$

The authors proved that the solutions of [\(1.2\)](#page-0-0) are in $W_{loc}^{1,q}$ when $f \in L_{loc}^{\infty}$. As a consequence, by the Sobolev Morrey's imbedding, the solutions are Hölder's continuous for any exponent $\gamma < 1$.

The Lipschitz interior regularity for [\(1.1\)](#page-0-1) has been very recently proved by the second author in [\[12\]](#page-22-3). The regularity obtained concerns Lipschitz continuity for viscosity solutions. Since weak solutions are viscosity solutions, (see also [\[3\]](#page-21-0)), she obtains Lipschitz continuity for weak solutions when the forcing term is in L^{∞}_{loc} .

At the same time, in [\[7\]](#page-22-4), the local Lipschitz regularity of the solutions of [\(1.2\)](#page-0-0) has been proved when either $N = 2$, $p \ge 2$ and $f \in W_{loc}^{1,p'}$ or $N \ge 3$, $p \ge 4$, and $f \in W_{loc}^{1,\infty}$. Remark that [\(1.2\)](#page-0-0) can also be written formally as

$$
\sum_{i} (|\partial_i u| - \delta_i)_+^{p-2} \partial_{ii} u = f.
$$

Hence viscosity solutions have an obvious definition, and with the methods employed in $[12]$, one can prove, in particular, that the solutions are Hölder's continuous for any exponent $\gamma < 1$. Unfortunately the Lipschitz continuity for viscosity solution of [\(1.2\)](#page-0-0) cannot be obtained in the same way.

Let us state the precise assumptions that hold in this paper and present our main result. Fix $\alpha > 0$, and for any $q \in \mathbb{R}^N$ let $\Theta_\alpha(q)$ be the diagonal matrix with entries $|q_i|^{\frac{\alpha}{2}}$ on the diagonal, and let X be a symmetric matrix.

Let F be defined on $\mathbb{R}^N \times \mathbb{R}^N \times S$, continuous in all its arguments, which satisfies $F(x, 0, M) = F(x, p, 0) = 0$ and

(H1) For any $M \in S$ and $N \in S$, $N \geq 0$, for any $x \in \overline{\Omega}$

$$
\lambda tr(\Theta_{\alpha}(q)N\Theta_{\alpha}(q)) \le F(x, q, M+N) - F(x, q, M) \le \Lambda tr(\Theta_{\alpha}(q)N\Theta_{\alpha}(q)) \tag{1.3}
$$

(H2) There exist $\gamma_F \in]0,1]$ and $c_{\gamma_F} > 0$ such that for any $(q, X) \in \mathbb{R}^N \times S$

$$
|F(x,q,X) - F(y,q,X)| \leq c_{\gamma_F}|x-y|^{\gamma_F}|q|^{\alpha}|X| \tag{1.4}
$$

(H3) There exists ω_F a continuous function on \mathbb{R}^+ such that $\omega_F(0) = 0$, and as soon as (X, Y) satisfy for some $m > 0$

$$
-m\left(\begin{array}{cc} I & 0 \\ 0 & I \end{array}\right) \leq \left(\begin{array}{cc} X & 0 \\ 0 & Y \end{array}\right) \leq m\left(\begin{array}{cc} I & -I \\ -I & I \end{array}\right) \tag{1.5}
$$

then

$$
F(x, m(x-y), X) - F(x, m(x-y), Y) \le \omega_F(m|x-y|^{\frac{\alpha+2}{\alpha+1}}) + o(m|x-y|^{\frac{\alpha+2}{\alpha+1}}) \tag{1.6}
$$

when m goes to infinity.

(H4) There exists c_F such that for any $p, q \in \mathbb{R}^N$, for all $x \in \mathbb{R}^N$, $X \in S$

$$
|F(x, p, X) - F(x, q, X)| \le c_F ||p|^\alpha - |q|^\alpha ||X| \tag{1.7}
$$

Note that the pseudo - Pucci's operators, for $0 < \lambda < \Lambda$

$$
\mathcal{M}_{\alpha}^{+}(q, X) = \Lambda tr((\Theta_{\alpha}(q)X\Theta_{\alpha}(q))^{+}) - \lambda tr((\Theta_{\alpha}(q)X\Theta_{\alpha}(q))^{-})
$$

=
$$
\sup_{\lambda I \leq A \leq \Lambda I} tr(A\Theta_{\alpha}(q)X\Theta_{\alpha}(q)).
$$

and

$$
\mathcal{M}_{\alpha}^{-}(q, X) = -\mathcal{M}_{\alpha}^{+}(q, -X)
$$

satisfy all the assumptions above.

We will also consider equations with lower order terms. Precisely, let h defined on $\mathbb{R}^N\times\mathbb{R}^N$, continuous with respect to its arguments, which satisfies on any bounded domain Ω

$$
|h(x,q)| \le c_{h,\Omega}(|q|^{1+\alpha} + 1)
$$
\n(1.8)

Our main result is the following.

Theorem 1.1. Let Ω be a bounded domain and f be continuous and bounded in Ω . Under the conditions [\(1.6\)](#page-1-0), [\(1.3\)](#page-1-1), [\(1.4\)](#page-1-2), [\(1.7\)](#page-2-0) and [\(1.8\)](#page-2-1), let u be a solution of

$$
F(x, \nabla u, D^2 u) + h(x, \nabla u) = f \quad \text{in} \quad \Omega. \tag{1.9}
$$

Then, for any $\Omega' \subset\subset \Omega$, there exists $C_{\Omega'}$, such that for any $(x, y) \in \Omega'$

$$
|u(x) - u(y)| \leq C_{\Omega'}|x - y|.
$$

This will be a consequence of the more general result Theorem [3.1](#page-6-0) in section three.

We shall construct in Section 4 a super-solution of [\(1.9\)](#page-2-2) which is zero on the boundary. Ishii's Perron method, since the comparison principle holds, leads to the following existence's result :

Theorem 1.2. Suppose that Ω is a bounded \mathcal{C}^2 domain and let F and h satisfy [\(1.3\)](#page-1-1), [\(1.6\)](#page-1-0), [\(1.7\)](#page-2-0), (H3), and [\(1.8\)](#page-2-1). Then for any $f \in \mathcal{C}(\overline{\Omega})$ there exists u a viscosity solution of

$$
\begin{cases}\nF(x, \nabla u, D^2 u) + h(x, \nabla u) = f(x) & \text{in } \Omega \\
u = 0 & \text{on } \partial\Omega\n\end{cases}
$$

Furthermore u is Lipschitz continuous in Ω .

Finally in the last section we prove that the strong maximum principle holds. Let us end this introduction by saying a few words about the principal eigenvalues and eigenfunctions, on the model of [\[4\]](#page-21-1). Indeed the regularity and existence results obtained above allow to prove the existence of a principal eigenvalue as long as the operator, F is in addition homogeneous, precisely :

For any (x, p, X) and any $s \in \mathbb{R}$ and $t \geq 0$:

$$
F(x, sp, tX) = |s|^{\alpha} t F(x, p, X).
$$

We also suppose that h is continuous with values in \mathbb{R}^N , and that $h(x,p) =$ $h(x) \cdot p|p|^{\alpha}$. Then we can define the two values

$$
\mu^+ = \{ \mu \in \mathbb{R}, \exists \varphi > 0 \text{ in } \Omega, F(x, \nabla \phi, D^2 \phi) + h(x) \cdot \nabla \phi |\nabla \phi|^\alpha + \mu \phi^{\alpha+1} \le 0 \}.
$$

and

$$
\bar{\mu}^- := \sup \{ \mu \in \mathbb{R}, \ \exists \psi < 0 \ \text{in} \ \Omega, \ F(x, \nabla \psi, D^2 \psi) + h(x) \cdot \nabla \psi |\nabla \psi|^\alpha + \mu |\psi|^\alpha \psi \ge 0 \ \}.
$$

As in previous works e.g. [\[4\]](#page-21-1), [\[2\]](#page-21-2) and [\[5\]](#page-22-5) it is easy to prove that below μ^+ the classical property of maximum principle holds, i.e. if $\tau < \bar{\mu}^+$ and u is a solution of

$$
F(x, \nabla u, D^2u) + h(x)|\nabla u|^{\alpha}\nabla u + \tau|u|^{\alpha}u \ge 0
$$

such $u \leq 0$ on $\partial\Omega$ then $u \leq 0$ in Ω . Similarly, for any $\tau < \mu^-$, the minimum principle holds.

Furthermore, one can prove the existence of $\psi^+ > 0$ and $\psi^- < 0$ solution, respectively of

$$
F(x, \nabla \psi^+, D^2 \psi^+) + \mu^+ (\psi^+)^{\alpha+1} = 0 \text{ in } \Omega, \ \psi^+ = 0 \text{ on } \partial \Omega,
$$

$$
F(x, \nabla \psi^-, D^2 \psi^-) + \mu^- |\psi^-|^{\alpha} \psi^- = 0 \text{ in } \Omega, \ \psi^- = 0 \text{ on } \partial \Omega.
$$

Thus the values μ^+ and μ^- are called "principal eigenvalues".

We will not give proofs for these last results which can be obtained arguing as in [\[5\]](#page-22-5), and using the comparison principle in Theorem [4.1](#page-16-0) and the Lipschitz a priori bounds.

Many questions concerning these very degenerate operators are still open . To name a few let us mention:

Does Alexandroff Bakelman Pucci 's inequality hold true, similarly to the cases treated in [\[14\]](#page-22-6)?

Is some Harnack inequality true (still as in $[14]$)? Even for the pseudo-p-Laplacian this is not known. Finally the further step in regularity is naturally the \mathcal{C}^1 regularity. Even in the case $f = 0$ and $N = 2$ it does not seem easy to obtain.

2 Examples

Example 1 : Let

$$
F(x, p, X) := tr(L(x)\Theta_{\alpha}(p)X\Theta_{\alpha}(p)L(x)).
$$

if $L(x)$ is a Lipschitz and bounded matrix such that $\sqrt{\lambda}$ $\leq L \leq \sqrt{\Lambda}$ then conditions [\(1.3\)](#page-1-1) and [\(1.4\)](#page-1-2) are obviously satisfied. In order to check the condition (H3), one uses the right inequality in [\(1.5\)](#page-1-3) multiplied by $\begin{pmatrix} L(x)\Theta_{\alpha}(p) \\ L(x)\Theta_{\alpha}(p) \end{pmatrix}$ $L(y)\Theta_\alpha(p)$ \setminus on the right and by its transpose on the left. Hence

$$
F(x, m(x - y), X) - F(x, m(x - y), -Y)
$$

\n
$$
\leq m^{t}(L(x) - L(y))\Theta_{\alpha}^{2}(m(x - y))(L(x) - L(y))
$$

\n
$$
\leq m^{\alpha+1}|x - y|^{2+\alpha}
$$

Let us check now condition [\(1.7\)](#page-2-0)

$$
F(x, p, X) - F(x, q, X) = tr(L(x)(\Theta_{\alpha}(p) - \Theta_{\alpha}(q))X(\Theta_{\alpha}(p) + \Theta_{\alpha}(q))L(x))
$$

$$
\leq \Lambda |X||\Theta_{\alpha}(p)^{2} - \Theta_{\alpha}(q)^{2}|
$$

which yields the result.

Example 2 : We define

$$
F(x, p, X) := a(x) \mathcal{M}_{\alpha}^{\pm}(p, X).
$$

If a is a Lipschitz function such that $a(x) \ge a_o > 0$ then conditions [\(1.3\)](#page-1-1) and [\(1.4\)](#page-1-2) are satisfied. Let us check the condition (H3).

Recall the following standard extremality property of the Pucci's operators

$$
\mathcal{M}^+(X) \le \mathcal{M}^+(-Y) + \mathcal{M}^+(X+Y) \quad \text{and} \quad \mathcal{M}^-(X) \le \mathcal{M}^-(-Y) + \mathcal{M}^+(X+Y).
$$

Using the identity

 $a(x)\mathcal{M}_{\alpha}^{\pm}(X) = \mathcal{M}^{\pm}(a(x)\Theta_{\alpha}(p)X\Theta_{\alpha}(p)) = \mathcal{M}^{\pm}(\sqrt{a(x)}\Theta_{\alpha}(p)X\Theta_{\alpha}(p)\sqrt{a(x)})$ we have

$$
\mathcal{M}^{\pm}(\sqrt{a(x)}\Theta_{\alpha}(p)X\Theta_{\alpha}(p)\sqrt{a(x)}) \leq \mathcal{M}^{\pm}(\sqrt{a(y)}\Theta_{\alpha}(p)(-Y)\Theta_{\alpha}(p)\sqrt{a(y)}) \n+ \mathcal{M}^{\pm}\left[\sqrt{a(x)}\Theta_{\alpha}(p)X\Theta_{\alpha}(p)\sqrt{a(x)} \n+ \sqrt{a(y)}\Theta_{\alpha}(p)Y\Theta_{\alpha}(p)\sqrt{a(y)})\right].
$$

Multiplying [\(1.5\)](#page-1-3), by the matrix

$$
\left(\begin{array}{cc} \sqrt{a(x)} \Theta_{\alpha}(p) & 0 \\ 0 & \sqrt{a(y)} \Theta_{\alpha}(p) \end{array} \right)
$$

on the left and on the right, one obtains that for $p = m(x - y)$,

$$
\sqrt{a(x)}\Theta_{\alpha}(p)X\Theta_{\alpha}(p)\sqrt{a(x)} + \sqrt{a(y)}\Theta_{\alpha}(p)Y\Theta_{\alpha}(p)\sqrt{a(y)}\leq m(\sqrt{a(x)} - \sqrt{a(y)})^2\Theta_{\alpha}(p)^2\leq m^{\alpha+1}|x-y|^{\alpha}\frac{(a(x) - a(y))^2}{(\sqrt{a(x)} + \sqrt{a(y)})^2}I\leq (\text{Lip }a)^2\frac{m^{\alpha+1}|x-y|^{\alpha+2}}{4a_o}I.
$$

In particular

$$
\mathcal{M}^+(\sqrt{a(x)}\Theta_\alpha(p)X\Theta_\alpha(p)\sqrt{a(x)} + \sqrt{a(y)}\Theta_\alpha(p)Y\Theta_\alpha(p)\sqrt{a(y)})
$$

$$
\leq \Lambda(\text{Lip }a)^2N\frac{m^{\alpha+1}|x-y|^{\alpha+2}}{4a_o}.
$$

Let us check finally [\(1.7\)](#page-2-0), for that, it is clear that one can suppose $a(x) = 1$, we write

$$
|\mathcal{M}_{\alpha}^{\pm}(p, X) - \mathcal{M}_{\alpha}^{\pm}(q, X)| \leq \mathcal{M}^{+}(\Theta_{\alpha}(p)X\Theta_{\alpha}(p) - \Theta_{\alpha}(q)X\Theta_{\alpha}(q))
$$

$$
= \frac{1}{2}\mathcal{M}^{+}[(\Theta_{\alpha}(p)) - \Theta_{\alpha}(q))X(\Theta_{\alpha}(p) + \Theta_{\alpha}(q))
$$

$$
+ (\Theta_{\alpha}(p) + \Theta_{\alpha}(q))X(\Theta_{\alpha}(p) - \Theta_{\alpha}(q))]
$$

$$
\leq \Lambda|\Theta_{\alpha}^{2}(p) - \Theta_{\alpha}^{2}(q)||X|
$$

3 Proof of Lipschitz regularity.

In this section we prove our main result:

Theorem 3.1. Let f and g be continuous and bounded in Ω , while F, Ω and h satisfy the hypothesis in Theorem [1.1.](#page-2-3) Suppose that u is a bounded USC sub-solution of

$$
F(x, \nabla u, D^2u) + h(x, \nabla u) \ge f \text{ in } \Omega
$$

and v is a bounded LSC super-solution of

$$
F(x, \nabla v, D^2v) + h(x, \nabla v) \le g \text{ in } \Omega.
$$

Then for any $\Omega' \subset\subset \Omega$ there exists $C_{\Omega'}$, such that for any $(x, y) \in (\Omega')^2$

$$
u(x) \le v(y) + \sup_{\Omega} (u - v) + C_{\Omega'} |x - y|.
$$

We start by recalling some general facts.

If $\psi : \mathbb{R}^N \times \mathbb{R}^N \to \mathbb{R}$, let $D_1\psi$ denotes the gradient in the first N variables and $D_2\psi$ the gradient in the last N variables.

In the proof of Theorem [3.1](#page-6-0) we shall need the following technical lemma.

Lemma 3.2. Suppose that u and v are respectively USC and LSC functions such that, for some constant $M > 1$ and for some function Φ

$$
u(x) - v(y) - M|x - x_o|^2 - M|y - x_o|^2 - \Phi(x, y)
$$

has a local maximum in (\bar{x}, \bar{y}) where ϕ is \mathcal{C}^2 .

Then for any ι , there exist X_{ι} , Y_{ι} such that

$$
(D_1\Phi(\bar{x}, \bar{y}) + 2M(\bar{x} - x_o), X_\iota) \in \bar{J}^{2,+}u(\bar{x}),
$$

$$
(-D_2\Phi(\bar{x}, \bar{y}) - 2M(\bar{y} - x_o), -Y_\iota) \in \bar{J}^{2,-}v(\bar{y})
$$

with

$$
-(\frac{1}{\iota} + |A| + 1) \begin{pmatrix} I & 0 \ 0 & I \end{pmatrix} \leq \begin{pmatrix} X_{\iota} - 2M I & 0 \ 0 & Y_{\iota} - 2M I \end{pmatrix} \leq (A + \iota A^2) + \begin{pmatrix} I & 0 \ 0 & I \end{pmatrix}
$$

and $A = D^2 \Phi(\bar{x}, \bar{y}).$

This is a direct consequence of a famous Lemma by Ishii [\[16\]](#page-23-1). For the convenience of the reader the proof of Lemma [3.2](#page-6-1) is given in the appendix. In the sequel, for some M, we will use Lemma [3.2](#page-6-1) with $\Phi(x, y) := Mg(x - y)$, where g is some functions which is \mathcal{C}^2 except at 0, to be defined later. Denoting by $H_1(x) := D^2 g(x)$, then

$$
D^2 \Phi = M \begin{pmatrix} H_1(\bar{x} - \bar{y}) & -H_1(\bar{x} - \bar{y}) \\ -H_1(\bar{x} - \bar{y}) & H_1(\bar{x} - \bar{y}) \end{pmatrix}
$$

Choosing $\iota = \frac{1}{4M|H}$ $\frac{1}{4M|H_1(x)|}$, and defining $\tilde{H}(x) := H_1(x) + \frac{2}{4|H_1(x)|}H_1^2(x)$, one has

$$
D^2\Phi + \iota(D^2\Phi)^2 = M\begin{pmatrix} \tilde{H}(\bar{x}-\bar{y}) & -\tilde{H}(\bar{x}-\bar{y}) \\ -\tilde{H}(\bar{x}-\bar{y}) & \tilde{H}(\bar{x}-\bar{y}) \end{pmatrix}.
$$

Remark that $|A| = 2M|H_1(\bar{x} - \bar{y})|$. We give some precisions on the choice of g: We will assume that g is radial, say there exists ω some continuous function on \mathbb{R}^+ , such that $g(x) = \omega(|x|)$ and ω is supposed to satisfy :

$$
\omega(0) = 0
$$
, ω is C^2 on \mathbb{R}^{+*} , $\omega(s) > 0$, $\omega'(s) > 0$ and $\omega''(s) < 0$ on $]0, 1[.$ (3.1)

For $x \neq 0$, it is well known that $Dg(x) = \omega'(|x|) \frac{x}{|x|}$ $\frac{x}{|x|}$ and

$$
D^2 g(x) = \left(\omega''(|x|) - \frac{\omega'(|x|)}{|x|}\right) \frac{x \otimes x}{|x|^2} + \frac{\omega'(|x|)}{|x|}.
$$

For $\iota \leq \frac{1}{4|D^2g(x)|}$, there exist constants $\gamma_H \in]\frac{1}{2}$ $\frac{1}{2}, \frac{3}{2}$ $\frac{3}{2}$, $\beta_H \ge \frac{1}{2}$ $\frac{1}{2}$ such that

$$
D^2 g + 2\iota (D^2 g)^2(x) = \left(\beta_H \omega''(|x|) - \gamma_H \frac{\omega'(|x|)}{|x|}\right) \frac{x \otimes x}{|x|^2} + \gamma_H \frac{\omega'(|x|)}{|x|} I. \tag{3.2}
$$

For $|x| < 1$ and $\epsilon > 0$, we shall use the following set:

$$
I(x,\epsilon) := \{ i \in [1,N], |x_i| \ge |x|^{1+\epsilon} \}.
$$

We also define the diagonal matrix $\Theta(x)$ with entries $\Theta_{ii}(x) = \begin{bmatrix} 0 & 0 & i \end{bmatrix}$ $\omega'(|x|)x_i$ $|x|$ $\begin{array}{c} \hline \end{array}$ $\frac{\alpha}{2}$.

A consequence of [\(3.2\)](#page-7-0) is the following Proposition proved in [\[12\]](#page-22-3).

Proposition 3.3 ([\[12\]](#page-22-3)). 1) If $\alpha \leq 2$, for all $x \neq 0$, $|x| < 1$, $\Theta(x)H(x)\Theta(x)$ has at least one eigenvalue smaller than

$$
N^{\frac{-\alpha}{2}} \beta_H \omega''(|x|) (\omega'(|x|))^{\alpha}.
$$
 (3.3)

2) If $\alpha > 2$, for all $x \neq 0$, $|x| < 1$, for any $\epsilon > 0$ such that $I(x, \epsilon) \neq \emptyset$, and such that

$$
\beta_H \omega''(|x|)(1 - N|x|^{2\epsilon}) + \gamma_H N|x|^{2\epsilon} \frac{\omega'(|x|)}{|x|} \le \frac{\omega''(|x|)}{4} < 0,\tag{3.4}
$$

then $\Theta(x)\tilde{H}(x)\Theta(x)$ possesses at least one eigenvalue smaller than

$$
\frac{1 - N|x|^{2\epsilon}}{\#I(x, \epsilon)} (\omega'(|x|))^\alpha \frac{\omega''(|x|)}{4} |x|^{(\alpha - 2)\epsilon}.
$$
\n(3.5)

[Proof of Theorem [3.1\]](#page-6-0) Borrowing ideas from [\[15\]](#page-23-2), [\[1\]](#page-21-3), [\[6\]](#page-22-7), for some $x_o \in B_r$ we define the function

$$
\psi(x,y) = u(x) - v(y) - \sup(u - v) - M\omega(|x - y|) - M|x - x_o|^2 - M|y - x_o|^2;
$$

M is a large constant and ω is a function satisfying [\(3.1\)](#page-7-1), both to be defined more precisely later .

If there exists M independent of $x_o \in B_r$ such that $\psi(x, y) \leq 0$ in B_1^2 , by taking $x = x_o$ and using $|x_o - y| \leq 2$ one gets

$$
u(x_o) - v(y) \le \sup(u - v) + 3M\omega(|x_o - y|).
$$

So making x_o vary we obtain that for any $(x, y) \in B_r^2$

$$
u(x) - v(y) \le \sup(u - v) + M\omega(|x - y|).
$$

This proves the theorem when ω behaves like s near zero. This can be done once the case where $\omega(s) = s^{\gamma}$ is treated for $\gamma \in]0,1[$, i.e the Hölder's analogous result.

In order to prove that $\psi(x, y) \leq 0$ in B_r^2 , suppose by contradiction that the supremum of ψ , achieved on $(\bar{x}, \bar{y}) \in \overline{B_1}^2$, is positive. If we have chosen M such that

$$
M(1-r)^2 > 4(|u|_{\infty} + |v|_{\infty}), \text{ and } M > \frac{2|u|_{\infty} + 2|v|_{\infty}}{\omega(\delta)},
$$
 (3.6)

we would get that $|\bar{x} - x_o|, |\bar{y} - x_o| < \frac{1-r}{2}$ $\frac{-r}{2}$. Hence, by [\(3.6\)](#page-8-0), \bar{x} and \bar{y} are in $B_{\frac{1+r}{2}}$ i.e. in B_1 . Furthermore, always using [\(3.6\)](#page-8-0), the positivity of the supremum of ψ leads to $|\bar{x}-\bar{y}| < \delta$.

As it is shown later the contradiction will be found by choosing δ small enough and M large enough depending on $(r, \alpha, \lambda, \Lambda, N)$.

We proceed using Lemma [3.2](#page-6-1) and so, for all $\iota > 0$ there exist X_{ι} and Y_{ι} such that

$$
(q+2M(x-xo), Xt) \in \overline{J}^{2,+}u(\bar{x}) \text{ and } (q-2M(y-xo), -Yt) \in \overline{J}^{2,-}v(\bar{y})
$$

with $q = M\omega'(|\bar{x} - \bar{y}|)\frac{\bar{x} - \bar{y}}{|\bar{x} - \bar{y}|}$ $\frac{x-y}{|\bar{x}-\bar{y}|}$. Furthermore, still using the above notations i.e. $g(x) = \omega(|x|)$, and choosing $\iota = \frac{1}{4M|D^2}$ $\frac{1}{4M|D^2g(x)|}$, for $\bar{H} = (D^2g(x) + \frac{1}{2|D^2g(x)|}D^2g(x)^2)$, we have that

$$
-(\frac{1}{\iota} + M|\bar{H}|) \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix} \leq \begin{pmatrix} X_{\iota} - (2M+1)I & 0 \\ 0 & Y_{\iota} - (2M+1)I \end{pmatrix}
$$

$$
\leq M \begin{pmatrix} \bar{H} & -\bar{H} \\ -\bar{H} & \bar{H} \end{pmatrix}.
$$
 (3.7)

From now on we will drop the ι for X and Y. Recall that $\Theta(q)$ is the diagonal matrix such that $(\Theta)_{ii}(q) = (|q_i|)^{\frac{\alpha}{2}}$.

In order to end the proof we will prove the following claims.

Claims. There exists $\hat{\tau} > 0$, such that, if δ is small enough and $|x - y| < \delta$ the matrix $\Theta(X+Y)\Theta$ has one eigenvalue μ_1 such that

$$
\mu_1(\Theta(X+Y)\Theta) \le -cM^{\alpha+1}|\bar{x}-\bar{y}|^{-\hat{\tau}} \tag{3.8}
$$

There exist $\tau_i < \hat{\tau}$ and c_i for $i = 1, \ldots, 4$ such that the four following assertions hold :

for all
$$
j \ge 2
$$
 $\mu_j(\Theta(X+Y)\Theta) \le c_1 M^{\alpha+1} |\bar{x} - \bar{y}|^{-\tau_1}$, (3.9)

$$
|F(\bar{x}, q^x, X) - F(\bar{x}, q, X)| + |F(\bar{y}, q^y, -Y) - F(\bar{y}, q, -Y)| \le c_2 M^{\alpha+1} |\bar{x} - \bar{y}|^{-\tau_2}
$$
\n(3.10)

$$
|F(\bar{x}, q, X) - F(\bar{y}, q, X)| + |F(\bar{x}, q, -Y) - F(\bar{y}, q, -Y)| \le c_3 M^{1+\alpha} |\bar{x} - \bar{y}|^{-\tau_3},
$$
\n(3.11)

$$
|h(\bar{x}, q^x)| + |h(\bar{y}, q^y)| \le c_4 M^{1+\alpha} |\bar{x} - \bar{y}|^{-\tau_4}.
$$
 (3.12)

From all these claims, by taking δ small enough depending only on c_i and τ_i , $\lambda, \Lambda, \alpha, N, r$ one gets

$$
F(\bar{x}, q^x, X) - F(\bar{y}, q^y, -Y) + h(\bar{x}, q^x) - h(\bar{y}, q^y) \le -\frac{\lambda c}{2} M^{\alpha+1} |\bar{x} - \bar{y}|^{-\hat{\tau}}.
$$

Precisely one needs to take δ such that $c_2\delta^{-\tau_2+\hat{\tau}}+c_3\delta^{\tau-\tau_3}+c_4\delta^{\tau-\tau_4}+\Lambda c_1\delta^{\tau-\tau_1}$ λc $\frac{\lambda c}{2}$. Finally, one can conclude as follows

$$
f(\bar{x}) \leq F(\bar{x}, q^x, X) + h(\bar{x}, q^x)
$$

\n
$$
\leq F(\bar{y}, q^y, -Y) + h(\bar{y}, q^y) - \frac{\lambda c}{2} M^{\alpha+1} |\bar{x} - \bar{y}|^{-\hat{\tau}}
$$

\n
$$
\leq -\frac{\lambda c}{2} M^{\alpha+1} |\bar{x} - \bar{y}|^{-\hat{\tau}} + g(\bar{y}).
$$

This contradicts the fact that f and g are bounded, as soon as δ is small or M is large enough. And then in order to get the desired result it is sufficient to prove in all cases [\(3.8\)](#page-9-0), [\(3.9\)](#page-9-1), [\(3.10\)](#page-9-2), [\(3.11\)](#page-9-3), [\(3.12\)](#page-10-0).

So to prove the claims, we will use inequality [\(3.7\)](#page-9-4) which has three important consequences for $\Theta(X + Y - 2(2M + 1)I)\Theta$:

1. As is well known the second inequality in [\(3.7\)](#page-9-4) gives $(X + Y - 2(2M + 1)I) \leq 0$, then also $\Theta(X + Y - 2(2M + 1)I)\Theta \leq 0$. In particular

> all the eigenvalues of $\Theta(X+Y)\Theta$ are less than $6M|\Theta|^2$ (3.13)

2. By Proposition [3.3,](#page-8-1) $\Theta(\bar{H})\Theta$ has a large negative eigenvalue, let e be the corresponding eigenvector. Multiplying by $\begin{pmatrix} e \end{pmatrix}$ $-e$ \setminus on the right and by its transpose on the left of (3.7) , one gets, using (3.3) that, for some positive constant c, when $\alpha \leq 2$,

$$
\mu_1(\Theta(X+Y-2(2M+1)\mathbf{I})\Theta) \le cM^{1+\alpha}\omega''(|\bar{x}-\bar{y}|)(\omega'(|\bar{x}-\bar{y}|))^{\alpha};\tag{3.14}
$$

this in particular implies that

$$
\mu_1(\Theta(X+Y)\Theta) \le cM^{1+\alpha}\omega''(|\bar{x}-\bar{y}|)(\omega'(|\bar{x}-\bar{y}|))^{\alpha} + 6M|\Theta|^2.
$$

When $\alpha \geq 2$, if [\(3.4\)](#page-8-3) holds, using [\(3.5\)](#page-8-4),

$$
\mu_1(\Theta(X+Y)\Theta) \le cM^{1+\alpha}\omega''(|\bar{x}-\bar{y}|)(\omega'(|\bar{x}-\bar{y}|))^{\alpha}|\bar{x}-\bar{y}|^{2\epsilon}+6M|\theta|^2. \tag{3.15}
$$

3. Finally, using [\(3.7\)](#page-9-4), we obtain an upper bound for $|X| + |Y|$ i.e.

$$
|X| + |Y| \le CM(|D^2g| + 1). \tag{3.16}
$$

remarking that $|\bar{H}| \leq \frac{3}{2} |D^2 g(x)|$.

We will need to detail the cases $\omega(s) \simeq s$ or $\omega(s) = s^{\gamma}$ both when $\alpha \leq 2$ or $\alpha \geq 2$.

Proofs of the claims when $\omega(r) = r^{\gamma}$ and $\alpha \leq 2$.

In this case, $\omega(s) = s^{\gamma}$, $\omega'(s) = \gamma s^{\gamma-1}$ and $\omega''(s) = -\gamma(1-\gamma)s^{\gamma-2}$, $q =$ $M\gamma|\bar{x}-\bar{y}|^{\gamma-1}\frac{\bar{x}-\bar{y}}{|\bar{x}-\bar{y}|}$ $\frac{\bar{x}-\bar{y}}{|\bar{x}-\bar{y}|}, q^x = q + 2M(\bar{x}-x_o), q^y = q - 2M(\bar{y}-x_o).$ By [\(3.14\)](#page-10-1), since $\gamma \in (0,1), \Theta(X+Y-2(2M+1)I)\Theta$ has one eigenvalue less than

$$
-\frac{\gamma(1-\gamma)}{4}M^{\alpha+1}|\bar{x}-\bar{y}|^{\gamma-2+(\gamma-1)\alpha}.
$$

While $6|\Theta|^2 \leq 6M^{\alpha}\gamma^{\alpha}|\bar{x}-\bar{y}|^{(\gamma-1)\alpha}$. Consequently, as soon as δ is small enough, $\Theta(X + Y)\Theta$ has at least one eigenvalue less than $-\frac{\gamma(1-\gamma)}{4}M^{\alpha+1}|\bar{x}$ $\bar y|^{\gamma-2+(\gamma-1)\alpha}+M|\Theta|^2\le -\tfrac{\gamma(1-\gamma)}{4}M^{\alpha+1}|\bar x-\bar y|^{\gamma-2+(\gamma-1)\alpha}+6M^{1+\alpha}\gamma^{\alpha}|\bar x-\bar y|^{(\gamma-1)\alpha}\le$ $-\gamma \frac{1-\gamma}{8} M^{\alpha+1} |\bar{x}-\bar{y}|^{\gamma-2+(\gamma-1)\alpha}$. This proves [\(3.8\)](#page-9-0) with $\hat{\tau}=2-\gamma+(1-\gamma)\alpha>\tau_1$, and $c = \gamma \frac{1-\gamma}{8}$ $\frac{-\gamma}{8}$.

Now using [\(3.13\)](#page-10-2) and the above estimate on $M|\Theta|^2$, [\(3.9\)](#page-9-1) holds with $\tau_1 =$ $(1 - \gamma)\alpha$.

Note now that

$$
|D^2g(\bar{x}-\bar{y})| \le \gamma(N-\gamma)|\bar{x}-\bar{y}|^{\gamma-2},
$$

and recall that $|\bar{H}| \leq \frac{3}{2}|D^2g|$, and then, by [\(3.16\)](#page-11-0),

$$
|X| + |Y| \le 6\gamma (N - \gamma + 3)M|\bar{x} - \bar{y}|^{\gamma - 2}.
$$
 (3.17)

Consequently [\(3.11\)](#page-9-3) holds with $\tau_2 = (2 - \gamma) + (1 - \gamma)\alpha - \gamma_F$ and $c_2 =$ $12c_{\gamma_F} \gamma^{1+\alpha}(N+3-\gamma)$ using hypothesis [\(1.4\)](#page-1-2).

To prove (3.10) we will use the following universal inequality : For any Z and T in \mathbb{R}^N

$$
||Z|^{\alpha} - |T|^{\alpha}| \le \sup(1,\alpha)|Z - T|^{\inf(1,\alpha)}(|Z| + |T|)^{(\alpha-1)^{+}} \tag{3.18}
$$

in the form

$$
||q^x|^{\alpha} - |q|^{\alpha}| \le 2^{\alpha} \sup(1,\alpha) M^{\alpha} |\bar{x} - \bar{y}|^{(\gamma - 1)(\alpha - 1)^{+}}.
$$

Hence using [\(3.17\)](#page-11-1), [\(3.10\)](#page-9-2) holds with $\tau_3 = (2 - \gamma) + (1 - \gamma)(\alpha - 1)^+$, and $c_3 = c_F 2^{1+\alpha} (\gamma + 1)^{(\alpha-1)^+}$. Finally [\(3.12\)](#page-10-0) holds with $\tau_4 = (1-\gamma)(1+\alpha)$ and $c_4 = 2c_{h,\Omega}((\gamma + 3)^{1+\alpha} + 1)$.

Proofs of the claims when $\omega(r) = r^{\gamma}$ and $\alpha \geq 2$. The function ω is the same than in the previous case. In order to use the result in Proposition [3.3](#page-8-1) we need [\(3.4\)](#page-8-3) to be satisfied. For that aim we take $\epsilon > 0$ such that $\epsilon < \inf(\frac{\gamma_F}{2}, \frac{1-\gamma}{2})$ $\frac{-\gamma}{2}$). Let

$$
\delta_N := \exp\left(\frac{-\log(2N(4-\gamma)) + \log(1-\gamma)}{2\epsilon}\right),\tag{3.19}
$$

and assume $\delta < \delta_N$. In particular, since there exists $i \in [1, N]$ such that

$$
|\bar{x}_i - \bar{y}_i|^2 \ge \frac{|\bar{x} - \bar{y}|^2}{N} \ge |\bar{x} - \bar{y}|^{2+2\epsilon},
$$

for $\alpha \geq 2$, using the definition of δ_N in [\(3.19\)](#page-12-0), $I(\bar{x}-\bar{y}, \epsilon) \neq \emptyset$. Furthermore for $|\bar{x}-\bar{y}| < \delta \leq \delta_N$

$$
\frac{1}{2}\omega''(|\bar{x}-\bar{y}|)(1-N|\bar{x}-\bar{y}|^{2\epsilon}) + \frac{3N}{2}|\bar{x}-\bar{y}|^{2\epsilon}\frac{\omega'(|\bar{x}-\bar{y}|)}{|\bar{x}-\bar{y}|}
$$
\n
$$
\leq \frac{1}{2}\omega''(|\bar{x}-\bar{y}|)
$$
\n
$$
+\frac{N}{2}|\bar{x}-\bar{y}|^{2\epsilon}(\gamma(1-\gamma)+3\gamma)|\bar{x}-\bar{y}|^{\gamma-2}
$$
\n
$$
\leq \frac{1}{4}\gamma(\gamma-1)|\bar{x}-\bar{y}|^{\gamma-2}
$$
\n
$$
= \frac{\omega''(|\bar{x}-\bar{y}|)}{4},
$$

and then [\(3.4\)](#page-8-3) is satisfied. We are in a position to apply [\(3.15\)](#page-11-2), and $\Theta(X+Y)\Theta$ has at least one eigenvalue μ_1 less than $-(\gamma \frac{1-\gamma}{4})$ $\frac{-\gamma}{4}$) $M^{\alpha+1}|\bar{x}-\bar{y}|^{\gamma-2+(\gamma-1)\alpha+\epsilon}$ + $6M|\Theta|^2$, hence

$$
\mu_1 \le -(\frac{\gamma(1-\gamma)}{4})M^{\alpha+1}|\bar{x}-\bar{y}|^{\gamma-2+(\gamma-1)\alpha+\epsilon}
$$

+ $6M^{1+\alpha}\gamma^{\alpha}|\bar{x}-\bar{y}|^{(\gamma-1)\alpha}$

$$
\le -(\frac{\gamma(1-\gamma)}{8})M^{\alpha+1}|\bar{x}-\bar{y}|^{\gamma-2+(\gamma-1)\alpha+\epsilon}
$$

for $|\bar{x}-\bar{y}| \le \delta$ small enough, hence [\(3.8\)](#page-9-0) holds with $\hat{\tau}=2-\gamma+(1-\gamma)-\epsilon$.

Note that (3.9) , (3.11) (3.10) and (3.12) have already been proved in the previous case, since the sign of $\alpha - 2$ does not play a role. Recall then that $\tau_1 = (-\gamma + 1)\alpha$, and $c_1 = 6\gamma^{1+\alpha}(N-\gamma+3)$, while $\tau_2 = (2-\gamma)+(1-\gamma)\alpha-\gamma_F < \hat{\tau}$ by the choice of ϵ , and $c_2 = 12c_{\gamma_F} \gamma^{1+\alpha}(N+3-\gamma)$.

Finally $\tau_3 = (2 - \gamma) + (\alpha - 1)(\gamma - 1)$ and $c_3 = c_F 2^{1+\alpha}(\gamma + 1)^{(\alpha-1)^+}$, and [\(3.12\)](#page-10-0) still holds with $\tau_4 = (1 - \gamma)(1 + \alpha)$.

Let us observe that in the hypothesis of Theorem [3.1](#page-6-0) we have proved that u and v satisfy, for any $\gamma \in (0,1)$,

$$
u(x) \le v(y) + \sup_{\Omega} (u - v) + c_{\gamma,r} |x - y|^{\gamma}
$$
\n(3.20)

This will be used in the next cases.

Proofs of the claims when $\omega(r) \simeq r$ and $\alpha \leq 2$. We choose $\tau \in (0, \inf(\gamma_F, \frac{1}{2}))$ $\frac{1}{2}, \frac{\alpha}{2}$ $\frac{\alpha}{2})$ and $\gamma \in (1, \frac{\tau}{\inf(\frac{1}{2}, \frac{\alpha}{2})})$. We define $\omega(s) = s - \omega_o s^{1+\tau}$, where $s < s_o = \left(\frac{1}{(1+\tau)^{1+\tau}}\right)$ $(1{+}\tau)\omega_o$ $\frac{1}{\tau}$ and ω_o is chosen so that $s_o > 1$. We suppose that $\delta^{\tau}\omega_o(1+\tau) < \frac{1}{2}$ $\frac{1}{2}$, which ensures that

for
$$
s < \delta \frac{1}{2} \le \omega'(s) < 1, \ \omega(s) \ge \frac{s}{2}
$$
. (3.21)

We suppose that

$$
M\frac{\delta\tau}{(1+\tau)} > 2 \sup u, \ M > 1 \text{ and } M(\frac{1-r}{2})^2 > 2 \sup u.
$$
 (3.22)

which implies in particular (3.6) .

Here $|D^2 g(\bar{x} - \bar{y})| \leq \frac{N-1}{|\bar{x} - \bar{y}|} + \omega_o \tau (1 + \tau) |\bar{x} - \bar{y}|^{-1+\tau} \leq (N - 1 + \omega_o \tau (1 + \tau)) |\bar{x} - \bar{y}|^{-1+\tau}$ $|\bar{y}|^{-1}, |\bar{H}| \leq \frac{3}{2} |D^2 g(\bar{x} - \bar{y})|$ and then [\(3.16\)](#page-11-0) is nothing else but

$$
|X| + |Y| \le 6M(|D^2 g(\bar{x} - \bar{y})| + 1) \le 6M(N - 1 + \omega_o \tau (1 + \tau))|\bar{x} - \bar{y}|^{-1}.
$$
 (3.23)

Furthermore $q = M\omega'(|\bar{x} - \bar{y}|)\frac{\bar{x} - \bar{y}}{|\bar{x} - \bar{y}|}$ $\frac{\bar{x}-\bar{y}}{|\bar{x}-\bar{y}|} q^x = q + 2M(\bar{x}-x_o), q^y = q - 2M(\bar{y}-x_o).$ Using [\(3.20\)](#page-13-0) in $B_{\frac{1+r}{2}}$, for all $\gamma < 1$,

$$
M|\bar{x} - x_o|^2 + M|\bar{y} - x_o|^2 + \sup(u - v) \le u(\bar{x}) - v(\bar{y}) \le \sup(u - v) + c_{\gamma, r}|\bar{x} - \bar{y}|^{\gamma}
$$

and then

$$
|\bar{y} - x_o| + |\bar{x} - x_o| \le \left(\frac{c_{\gamma, r} |\bar{x} - \bar{y}|^{\gamma}}{M}\right)^{\frac{1}{2}}.
$$
\n(3.24)

Then taking δ small enough, more precisely if $(c_{\gamma,r}\delta^{\gamma})^{\frac{1}{2}} < \frac{1}{4}$ $\frac{1}{4}$ by [\(3.21\)](#page-13-1),

$$
\frac{M}{2} \le |q| \le M, \ \frac{M}{4} \le |q^x|, |q^y| \le \frac{5M}{4} \tag{3.25}
$$

Then we derive from [\(3.14\)](#page-10-1) that $\Theta(X + Y - 2(2M + 1)I)\Theta$ has at least one eigenvalue less than

$$
-\frac{\omega_o \tau (1+\tau)}{4} M^{\alpha+1} |\bar{x}-\bar{y}|^{\tau-1} \tag{3.26}
$$

Since $M|\Theta|^2 \le M^{1+\alpha}$, [\(3.9\)](#page-9-1) holds with $\tau_1 = 0 < 1 - \tau$, and $c_1 = 6$, while [\(3.11\)](#page-9-3) is satisfied with $\tau_2 = -\gamma_F + 1 < 1 - \tau$, and $c_2 = c_{\gamma_F}(6 + 2\omega_o \tau (1 + \tau))$.

To check [\(3.10\)](#page-9-2), by [\(3.18\)](#page-11-3), [\(3.25\)](#page-14-0), [\(3.24\)](#page-14-1), and [\(3.23\)](#page-13-2)

$$
| |q_i^x|^{\alpha} - |q_i|^{\alpha} | |X_{ii}| \le (6 + 2\omega_0 \tau (1 + \tau)) M^{1 + \frac{\inf(\alpha, 1)}{2}} c_{\gamma, r}^{\frac{\sup(1, \alpha)}{2}} |\bar{x} - \bar{y}|^{\frac{\inf(1, \alpha)\gamma}{2}} |\bar{x} - \bar{y}|^{-1}.
$$

Hence, by using $\inf(1, \alpha)\gamma > 2\tau$, [\(3.10\)](#page-9-2) holds with $\tau_3 = 1 - \frac{\inf(1, \alpha)}{2}$ $\frac{1, \alpha)}{2}$ and $c_3 =$ $2c_F(6+2\omega_o\tau(1+\tau))(c_{\gamma,r})^{\frac{\alpha}{2}}$ if $\alpha \leq 1$ and $c_3 = 2c_F(6+2\omega_o\tau(1+\tau)c_{\gamma,r}^{1/2}\alpha 3^{\alpha-1})$ if $\alpha \geq 1$.

Finally $\tau_4 = 0$ and $c_4 = c_{h,\Omega}(2^{1+\alpha} + 1)$ are convenient for [\(3.12\)](#page-10-0).

Proofs of the claims when $\omega(r) \simeq r$ and $\alpha \geq 2$

In order to use the result in Proposition [3.3](#page-8-1) we need [\(3.4\)](#page-8-3) to be satisfied. For that aim we take τ and $\epsilon > 0$ such that

$$
0 < \tau < \inf\left(\frac{1}{\alpha}, \gamma_F\right), \ 1 > \gamma > \tau\alpha, \text{ and } \frac{\tau}{2} < \epsilon < \inf\left(\frac{\frac{\gamma}{2} - \tau}{\alpha - 2}, \frac{\gamma_F - \tau}{\alpha - 2}\right). \tag{3.27}
$$

Let us define ω , s_o , as in the case $\alpha \leq 2$. We suppose $\delta < \delta_N$ where

$$
\delta_N: = \inf \left(\exp \frac{\log(\omega_o(1+\tau)\tau) - \log(2N(1+\omega_o\tau(1+\tau)))}{2\epsilon - \tau}, \exp \frac{-\log(2\omega_o(1+\tau))}{\tau} \right)
$$
\n(3.28)

In particular since there exists i such that $|\bar{x}_i - \bar{y}_i|^2 \geq \frac{1}{N}$ $\frac{1}{N}|\bar{x}-\bar{y}|^2 \geq |\bar{x}-\bar{y}|^{2+2\epsilon}, \text{ by}$ $(3.28), I(\bar{x}-\bar{y}, \epsilon) \neq \emptyset$ $(3.28), I(\bar{x}-\bar{y}, \epsilon) \neq \emptyset$. Furthermore, recall that by $(3.28), 1 \geq \omega'(|\bar{x}-\bar{y}|) \geq \frac{1}{2}$ 2 and

$$
\frac{1}{2}\omega''(|\bar{x}-\bar{y}|) + \frac{N}{2}\omega_{o}\tau(1+\tau)|\bar{x}-\bar{y}|^{\tau-1+2\epsilon} + \frac{3}{2}N|\bar{x}-\bar{y}|^{2\epsilon-1}\omega'(|\bar{x}-\bar{y}|) \n\leq \frac{1}{2}\omega''(|\bar{x}-\bar{y}|) + \frac{N}{2}(\omega_{o}\tau(1+\tau)+3)|\bar{x}-\bar{y}|^{2\epsilon-1} \n\leq -\frac{1}{4}\omega_{o}(1+\tau)\tau|\bar{x}-\bar{y}|^{-1+\tau} = \frac{\omega''(|\bar{x}-\bar{y}|)}{4},
$$

and then [\(3.4\)](#page-8-3) holds. We still assume that [\(3.22\)](#page-13-3) holds.

As in the case $\alpha \leq 2$, using [\(3.20\)](#page-13-0), one has, for δ small enough, [\(3.25\)](#page-14-0) still holds.

The hypothesis [\(3.28\)](#page-14-2) ensures that $\Theta(X + Y - 2(2M + 1)I)\Theta$ has at least one eigenvalue less than

$$
-\frac{\omega_o \tau (1+\tau)}{4} M^{1+\alpha} |\bar{x}-\bar{y}|^{-1+\tau+(\alpha-2)\epsilon}
$$

and then using the fact that $\Theta(X+Y)\Theta \leq 6M|\Theta|^2 \leq 6M^{1+\alpha}$, by (3.27) and for δ small enough, [\(3.8\)](#page-9-0) holds with $\hat{\tau} = (2 - \alpha)\epsilon + 1 - \tau$ and $c = \frac{\omega_{\sigma}\tau(1+\tau)}{8}$ $\frac{1+\tau)}{8}$. Furthermore [\(3.9](#page-9-1)) holds with $\tau_1 = 0$, and $c_1 = 6$

As in the previous case, [\(3.23\)](#page-13-2) holds, and then [\(3.11\)](#page-9-3) holds with τ_2 = $1 - \gamma_F < 1 - \tau + (2 - \alpha)\epsilon$ and $c_2 = c_{\gamma_F}(6 + 2\omega_o \tau (1 + \tau))$. Now using [\(3.18\)](#page-11-3), [\(3.23\)](#page-13-2), [\(3.25\)](#page-14-0), [\(3.24\)](#page-14-1), one has

$$
||q^x|^{\alpha} - |q|^{\alpha}||X| \le \alpha (M|\bar{x} - x_o|)(\frac{5M}{4})^{\alpha - 1}M|\bar{x} - \bar{y}|^{-1} \le c_3|\bar{x} - \bar{y}|^{\frac{\gamma}{2} - 1}M^{1 + \alpha}
$$

and then [\(3.10\)](#page-9-2) holds with $\tau_3 = 1 - \frac{\gamma}{2} < 1 - \tau + (2 - \alpha)\epsilon$ and $c_3 = 2(c_{\gamma,r})(2)^{\alpha - 1}$. Note finally that

$$
|h(\bar{x}, q^x)| + |h(\bar{y}, q^y)| \le 2c_h \left(\frac{5M}{4}\right)^{1+\alpha}
$$

and then [\(3.12\)](#page-10-0) holds with $\tau_4 = 0$ and $c_4 = 2^{2+\alpha} c_h$.

4 Existence of solutions.

As it is classical, see e. g. [\[9\]](#page-22-8), the existence's Theorem [1.2](#page-2-4) will be proved once the following Propositions are known:

Proposition 4.1. Suppose that Ω is a bounded domain in \mathbb{R}^N and that F satisfies (1.3) , $(H3)$, (1.4) , (1.7) . Suppose that h is continuous and it satisfies [\(1.8\)](#page-2-1). Let u be a USC sub-solution of

$$
F(x, \nabla u, D^2u) + h(x, \nabla u) - \beta(u) \ge f \text{ in } \Omega
$$

and v be a LSC super-solution of

$$
F(x, \nabla v, D^2v) + h(x, \nabla v) - \beta(v) \le g \text{ in } \Omega
$$

where β , f and q are continuous.

Suppose that either β is increasing and $f \geq g$, or β is nondecreasing and $f > q$. If $u \leq v$ on $\partial\Omega$, then $u \leq v$ in Ω .

Proposition 4.2. Suppose that the assumptions in Proposition [4.1](#page-16-0) hold, and that f is continuous and bounded and β is increasing. If <u>u</u> is a USC subsolution, and \overline{u} is a LSC super-solution of the equation

$$
F(x, \nabla u, D^2u) + h(x, \nabla u) - \beta(u) = f, \text{ in } \Omega,
$$

such that $u = \overline{u} = \varphi$ on $\partial\Omega$. Then there exists u a viscosity solution of the equation with $\underline{u} \leq u \leq \overline{u}$ in Ω , and $u = \varphi$ on $\partial \Omega$.

The proofs of these two Propositions can be done by using the classical tools, see [\[9\]](#page-22-8).

Remark 4.3. One can get the same existence's result when $\beta = 0$, by using a standard approximation procedure and the stability of viscosity solutions.

Nevertheless the proof of Theorem [1.2](#page-2-4) requires the existence of a supersolution which is zero on the boundary when $\beta = 0$:

Proposition 4.4. Suppose that Ω is a bounded \mathcal{C}^2 domain, and that F and h satisfy the hypothesis in Proposition [4.2.](#page-16-1) Then for any f continuous and bounded, there exist a super-solution and a sub-solution of of

$$
F(x, \nabla u, D^2u) + h(x, \nabla u) = f \text{ in } \Omega
$$

which are zero on the boundary.

Proof of Proposition 4.4 :

Let us recall that the distance to the boundary d satisfies everywhere: d is semi concave or equivalently there exists C_1 such that

$$
D^2d \le C_1I.
$$

In the following lines we will make the computations as if d is \mathcal{C}^2 , it is not difficult to see that the required inequalities hold also in the viscosity sense. We now choose k large such that

$$
(k+1)(\sum_{1}^{N}|\partial_i d|^{2+\alpha})^{\frac{1+\alpha}{2+\alpha}} \ge 2C_1 N^{\frac{1+\alpha}{2+\alpha}} (1 + \text{diam }\Omega).
$$

This can be done since $\sum_{1}^{N}(\partial_{i}d)^{2} = 1 \leq (\sum_{1}^{N}|\partial_{i}d|^{2+\alpha})^{\frac{2}{2+\alpha}}N^{\frac{1+\alpha}{2+\alpha}}$. We will choose later M large and define

$$
\psi(x) = M(1 - \frac{1}{(1+d)^k}).
$$

Clearly

$$
\nabla \psi = M \frac{k \nabla d}{(1+d)^{k+1}}, \ D^2 \psi = \frac{Mk}{(1+d)^{k+2}} ((1+d)D^2 d - (k+1) \nabla d \otimes \nabla d)
$$

and then choosing k such that $\lambda(k+1)N^{-\frac{1}{2+\alpha}} \geq 3N\Lambda C_1 + 2C_h(1 + \text{diam }\Omega).$

$$
F(x, \nabla \psi, D^2 \psi) + h(x, \nabla \psi) \leq \frac{(Mk)^{\alpha+1}}{(1+d)^{k+2+(k+1)\alpha}} \left((1+d)\mathcal{M}_{\alpha}^+(\nabla d, D^2 d) \right. - (k+1)\mathcal{M}_{\alpha}^-(\nabla d, D^2 d) \right) + C_h |\nabla \psi|^{1+\alpha} \n\leq \frac{(Mk)^{\alpha+1}}{(1+d)^{k+2+(k+1)\alpha}} \left[(1+d)\Lambda C_1 \sum |\partial_i d|^{\alpha} - (k+1)\lambda \sum |\partial_i d|^{\alpha+2} \right] + C_h \frac{(Mk)^{\alpha+1}}{(1+d)^{(k+1)(1+\alpha)}} \n\leq \frac{(Mk)^{\alpha+1}}{(1+d)^{k+2+(k+1)\alpha}} (2N\Lambda C_1 - \lambda(k+1)N^{-\frac{1}{2+\alpha}}) + C_h \frac{(Mk)^{\alpha+1}}{(1+d)^{(k+1)(1+\alpha)}} \n\leq -\frac{(k+1)\lambda N^{-\frac{1}{2+\alpha}} (Mk)^{\alpha+1}}{4(1+d)^{k+2+(k+1)\alpha}}.
$$

It is clear that one can choose M large enough as soon as k is fixed as above in order that

$$
F(x, \nabla \psi, D^2 \psi) + h(x, \nabla \psi) \le -\|f\|_{\infty}.
$$

A similar computation leads to:

$$
F(x, \nabla(-\psi), D^2(-\psi)) + h(x, \nabla - \psi) \ge ||f||_{\infty}.
$$

5 The strong Maximum Principle

Theorem 5.1. Suppose that u is a supersolution of the equation $F(x, \nabla u, D^2u)$ 0 in a domain Ω and that $u \ge 0$. Then either $u > 0$ in Ω or $u \equiv 0$.

Proof. One can suppose that $u > 0$, on $B(x_1, |x_1-x_0|)$, $u(x_0) = 0$, $R = |x_1-x_0|$ and we can assume that the annulus $\frac{R}{2} \leq |x - x_1| \leq \frac{3R}{2}$ is included in Ω . Let w be defined as

$$
w(x) = m(e^{-c|x-x_1|} - e^{-cR})
$$

for some c and m to be chosen. Without loss of generality we will suppose that $x_1 = 0$ and denote $r := |x - x_1| = |x|$. We choose m so that on $r = \frac{R}{2}$ $\frac{R}{2}$, $w \leq u$. In the sequel for simplicity we replace m by 1.

One has

$$
\nabla w = \frac{-cx}{r}e^{-cr}, \ D^2 w = e^{-cr}(\frac{c^2}{r^2} + \frac{c}{r^3})(x \otimes x) - \frac{c}{r}I
$$

and then, using the usual notation $\Theta(\nabla w)$, $H := \Theta(\nabla w)D^2w\Theta(\nabla w)$, i.e.

$$
He^{c(\alpha+1)r} = \left(\frac{c}{r}\right)^{\alpha} \left(\left(\frac{c^2}{r^2} + \frac{c}{r^3}\right) \vec{i} \otimes \vec{i} - \frac{c}{r} \vec{j} \otimes \vec{j} \right)
$$

where $\vec{i} = \sum |x_i|^{\frac{\alpha}{2}} x_i e_i$ and $\vec{j} = \sum |x_i|^{\frac{\alpha}{2}} e_i$.

We need to evaluate the eigenvalues of H and in particular prove that

$$
\mathcal{M}^-(H) > 0.
$$

For that aim let us note that $(\vec{i}, \vec{j})^{\perp}$ is in the kernel of H. We introduce $a = \frac{c^2}{r^2}$ $\frac{c^2}{r^2} + \frac{c}{r^3}$ $\frac{c}{r^3}$ and $b = -\frac{c}{r}$ $\frac{c}{r}$. Then the non zero eigenvalues of $Hc^{-\alpha}e^{cr(1+\alpha)}$ are given by

$$
\mu^{\pm} = \frac{a|\vec{i}|^2 + b|\vec{j}|^2}{2} \pm \sqrt{\left(\frac{a|\vec{i}|^2 + b|\vec{j}|^2}{2}\right)^2 - ab(|\vec{i}|^2|\vec{j}|^2 - (\vec{i} \cdot \vec{j})^2)}.
$$

Note that there exist constants $c_i(N, \alpha)$ for $i = 1, \dots 4$, such that

$$
c_1(N,\alpha)\left(\frac{R}{2}\right)^{\alpha+2} \le c_1(N,\alpha)r^{\alpha+2} \le |\vec{i}|^2 \le c_2(N,\alpha)r^{\alpha+2} \le c_2(N,\alpha)\left(\frac{3R}{2}\right)^{\alpha+2}
$$
 and

and

$$
c_3(N,\alpha)\left(\frac{R}{2}\right)^{\alpha} \le c_3(N,\alpha)r^{\alpha} \le |\vec{j}|^2 \le c_4(N,\alpha)r^{\alpha} \le c_4(N,\alpha)\left(\frac{3R}{2}\right)^{\alpha}.
$$

Note that one can choose c large enough in order that for some constant $c_5(N, \alpha)$

$$
a|\vec{i}|^2 + b|\vec{j}|^2 \ge c_1(N,\alpha) \left(\frac{R}{2}\right)^{\alpha+2} \frac{c^2}{r^2} - c_4(N,\alpha) \left(\frac{3R}{2}\right)^{\alpha} \frac{c}{r}
$$

 $\ge c_5(N,\alpha)c^2.$

On the other hand one can assume c large enough in order that

$$
4|ab|(|\vec{i}|^2|\vec{j}|^2 - (\vec{i} \cdot \vec{j})^2) \le 4\frac{c^3}{r^2}c_2(N,\alpha)c_4(N,\alpha)\left(\frac{3R}{2}\right)^{2\alpha+2}
$$

$$
\le c_6(N,\alpha)c^3
$$

$$
< [(\frac{\lambda+\Lambda}{\Lambda-\lambda})^2 - 1](c_5(N,\alpha)c^2))^2
$$

$$
\le [(\frac{\lambda+\Lambda}{\Lambda-\lambda})^2 - 1] (a|\vec{i}|^2 + b|\vec{j}|^2)^2.
$$

In particular this implies

$$
\lambda \mu^{+} + \Lambda \mu^{-} = \left(\frac{a|\vec{i}|^{2} + b|\vec{j}|^{2}}{2} \right) \left((\lambda + \Lambda) + (\lambda - \Lambda) \sqrt{1 + 4 \frac{|ab| (|\vec{i}|^{2}|\vec{j}|^{2} - (\vec{i} \cdot \vec{j})^{2})}{(a|\vec{i}|^{2} + b|\vec{j}|^{2})^{2}}} \right) > 0
$$

i.e. $\mathcal{M}^-(H) > 0$. Using the comparison principle in the annulus $\{\frac{R}{2} \leq |x-x_1| \leq$ 3R $\frac{dR}{2}$ one obtains that $u \geq w$.

Observe that w touches u by below on x_o , and then, since w is \mathcal{C}^2 around x_o , by the definition of viscosity solution

$$
F(x_o, \nabla w(x_o), D^2 w(x_o)) \le 0.
$$

This contradicts the above computation.

Remark 5.2. As it is well known, the above proof can be used to see that on a point of the boundary where the interior sphere condition is satisfied, the Hopf principle holds.

 \Box

6 Appendix: Proof of Lemma [3.2](#page-6-1)

The proof of Lemma [3.2](#page-6-1) is based on the following Lemma by Ishii

Lemma 6.1 (Ishii). Let A be a symmetric matrix on \mathbb{R}^{2N} . Suppose that $U \in$ $USC(\mathbb{R}^N)$ and $V \in USC(\mathbb{R}^N)$ satisfy $U(0) = V(0)$ and, for all $(x, y) \in (\mathbb{R}^N)^2$,

$$
U(x) + V(y) \le \frac{1}{2} ({}^t x, {}^t y) A\left(\begin{array}{c} x \\ y \end{array}\right).
$$

Then, for all $\iota > 0$, there exist $X_{\iota}^U \in S$, $X_{\iota}^V \in S$ such that

$$
(0, X_t^U) \in \bar{J}^{2,+}U(0), (0, X_t^V) \in \bar{J}^{2,+}V(0)
$$

and

$$
-(\frac{1}{\iota}+|A|)\left(\begin{array}{cc}I&0\\0&I\end{array}\right)\leq\left(\begin{array}{cc}X_{\iota}^U&0\\0&X_{\iota}^V\end{array}\right)\leq(A+\iota A^2).
$$

We can now start the proof of Lemma [3.2.](#page-6-1) The second order Taylor's expansion for Φ , gives that for all $\epsilon > 0$ there exists $r > 0$ such that, for $|x - \bar{x}|^2 + |\bar{y} - y|^2 \leq r^2$,

$$
u(x) - u(\bar{x}) - \langle D_1 \Phi(\bar{x}, \bar{y}) + 2M(\bar{x} - x_o), x - \bar{x} \rangle +
$$

+
$$
v(\bar{y}) - v(y) - \langle D_2 \Phi(\bar{x}, \bar{y}) + 2M(\bar{y} - x_o), y - \bar{y} \rangle
$$

$$
\leq \frac{1}{2} ({}^t (x - \bar{x}), {}^t (y - \bar{y})) (D^2 \Phi(\bar{x}, \bar{y}) + \epsilon I) \left(\begin{array}{c} x - \bar{x} \\ y - \bar{y} \end{array} \right)
$$

+
$$
M(|x - \bar{x}|^2 + |y - \bar{y}|^2).
$$

We now introduce the functions U and V defined, in the closed ball $|x - \bar{x}|^2 +$ $|\bar{y} - y|^2 \le r^2$, by

$$
U(x) = u(x + \bar{x}) - \langle D_1 \Phi(\bar{x}, \bar{y}) + 2M(\bar{x} - x_o), x \rangle - u(\bar{x}) - M|x|^2
$$

and

$$
V(y) = -v(y + \bar{y}) - \langle D_2\Phi(\bar{x}, \bar{y}) + 2M(\bar{y} - x_o), y \rangle + v(\bar{y}) - M|y|^2
$$

which we extend by some convenient negative constants in the complementary of that ball (see [\[16\]](#page-23-1) for details). Observe first that

$$
(0, X^U) \in \overline{J}^{2,+}U(0), (0, X^V) \in \overline{J}^{2,-}V(0)
$$

is equivalent to

$$
(D_1\Phi(\bar{x}, \bar{y}) + 2M(\bar{x} - x_o), X^U + 2M\mathbf{I}) \in \overline{J}^{2,+}u(\bar{x})
$$

and

$$
(-D_2\Phi(\bar{x}, \bar{y}) - 2M(\bar{y} - x_o), -X^V - 2M\mathbf{I}) \in \overline{J}^{2,-}v(\bar{y}).
$$

We can apply Lemma [6.1,](#page-20-0) which gives that, for any $\iota > 0$, there exists (X_{ι}, Y_{ι}) such that

$$
(D_1\Phi(\bar{x}, \bar{y}) + 2M(\bar{x} - x_o), X_\iota) \in \bar{J}^{2,+}u(\bar{x})
$$

and

$$
(-D_2\Phi(\bar{x}, \bar{y}) - 2M(\bar{y} - x_o), -Y_\iota) \in \bar{J}^{2,-}v(\bar{y})
$$

Choosing ϵ such that $2\epsilon\iota|D^2\Phi(\bar{x},\bar{y})| + \epsilon + \iota(\epsilon)^2 < 1$, one gets

$$
-(\frac{1}{\iota}+|D^2\Phi|+1)\begin{pmatrix}I&0\\0&I\end{pmatrix} \leq \begin{pmatrix}X_{\iota}-2M\mathbf{I}&0\\0&Y_{\iota}-2M\mathbf{I}\end{pmatrix}
$$

$$
\leq (D^2\Phi+\iota(D^2\Phi)^2)+\begin{pmatrix}I&0\\0&I\end{pmatrix}.
$$
