# A Modified Multiple OLS ( $\mathrm{m}^{2} \mathrm{OLS}$ ) Algorithm for Signal Recovery in Compressive Sensing 

Samrat Mukhopadhyay ${ }^{1}$, Student Member, IEEE, Siddhartha Satpathi ${ }^{2}$, and Mrityunjoy Chakraborty ${ }^{3}$, Senior Member, IEEE

#### Abstract

Orthogonal least square (OLS) is an important sparse signal recovery algorithm in compressive sensing, which enjoys superior probability of success over other well known recovery algorithms under conditions of correlated measurement matrices. Multiple OLS (mOLS) is a recently proposed improved version of OLS which selects multiple candidates per iteration by generalizing the greedy selection principle used in OLS and enjoys faster convergence than OLS. In this paper, we present a refined version of the mOLS algorithm where at each step of iteration, we first preselect a submatrix of the measurement matrix suitably and then apply the mOLS computations to the chosen submatrix. Since mOLS now works only on a submatrix and not on the overall matrix, computations reduce drastically. Convergence of the algorithm, however, requires to ensure passage of true candidates through the two stages of preselection and mOLS based selection successively. This paper presents convergence conditions for both noisy and noise free signal models. The proposed algorithm enjoys faster convergence properties similar to mOLS, at a much reduced computational complexity.

## Index Terms

Compressive Sensing, mOLS, restricted isometry property

## I. Introduction

Signal recovery in compressive sensing (CS) requires evaluation of the sparsest solution to anderdetermined set of equations $\boldsymbol{y}=\boldsymbol{\Phi} \boldsymbol{x}$, where $\boldsymbol{\Phi} \in \mathbb{R}^{m \times n}(m \ll n)$ is the so-called measurement matrix and $\boldsymbol{y}$ is the $m \times 1$ observation vector. It is usually presumed that the sparsest solution is $K$-sparse, i.e., not more than $K$ elements of $\boldsymbol{x}$ are non-zero, and also that the sparsest solution is unique which can be ensured by maintaining every $2 K$ columns of $\Phi$ as linearly independent. There exist a popular class of algorithms in literature called greedy algorithms, which obtain the sparsest $\boldsymbol{x}$ by iteratively constructing the support set of $\boldsymbol{x}$ (i.e., the set of indices of non-zero elements in $\boldsymbol{x}$ ) via some greedy principles. Orthogonal Matching Pursuit(OMP) [1] is a prominent algorithm in this category, which, at each step of iteration, enlarges a partially constructed support set by appending a column of $\Phi$ that is most strongly correlated with a residual vector, and updates the residual vector by projecting $\boldsymbol{y}$ on the column space of the sub-matrix of $\Phi$ indexed by the updated support set, and then taking the projection error. Tropp and Gilbert [1] have shown that OMP can recover the original sparse vector from a few measurements with exceedingly high probability when the measurement matrix has i.i.d Gaussian entries. OMP was extended by Wang et al [2] to the generalized orthogonal matching pursuit (gOMP)where at the indentification stage, multiple columns are selected based on the correlation of the columns of matrix $\Phi$ with the residual vector, which allows gOMP to enjoy faster convergence compared to OMP.

It has, however, been shown recently by Soussen et al [3] that the probability of success in OMP reduces sharply as the correlation between the columns of $\Phi$ increases, and for measurement matrices with correlated entries, another greedy algorithm, namely, the Orthogonal Least Squares (OLS) [4] enjoys much higher probability of recovery of the sparse signal than OMP. OLS is computationally similar to OMP except for a more expensive greedy selection step. Here, at each step of iteration, the partial support set already evaluated is augmented by an index $i$ which minimizes the energy (i.e., the $l_{2}$ norm) of the resulting residual vector.

An improved version of OLS called multiple OLS (mOLS) has been proposed recently by Wang et al [5], where unlike OLS, a total of $L(L>1)$ indices are appended to the existing partial support set by suitably generalizing the greedy principle used in OLS. As $L$ indices are chosen each time, possibility of selection of multiple "true" candidates in each iteration increases and thus, the probability of convergence in much fewer iterations than OLS becomes significantly high.

In this paper, we present a refinement of the mOLS algorithm, named as modified mOLS ( $\mathrm{m}^{2} \mathrm{OLS}$ ), where, at each step of iteration, we first pre-select a total of, say, $N$ columns of $\Phi$ by evaluating the correlation between the columns of $\Phi$ with the current residual vector and choosing the $N$ largest (in magnitude) of them. The steps of mOLS are then applied to this pre-selected set of columns. Here the preselection strategy is identical to the identification strategy of gOMP so that chances of selection of multiple "true" candidates in the pre-selected set is expected to be high. Furthermore, as the mOLS subsequently

[^0]works on this preselected set of columns and not on the entire matrix $\boldsymbol{\Phi}$, to determine a subset of $L$ columns $(L<N)$, computational costs reduce drastically compared to conventional mOLS. This is also confirmed by our simulation studies. Derivation of conditions of convergence for the proposed algorithm is, however, tricky, as it requires to ensure simultaneous passage of at least one true candidate from $\boldsymbol{\Phi}$ to the pre-selected set and then, from the pre-selected set to the mOLS determined subset at every iteration step. This paper presents convergence conditions of the proposed algorithm for the cases of both noise free and noisy observations. It also presents the computational steps of an efficient implementation of both mOLS and $\mathrm{m}^{2}$ OLS, and brings out the computational superiority of $\mathrm{m}^{2}$ OLS over mOLS analytically. Detailed simulation results in support of the claims made are also presented.

## II. Preliminaries

The following notations have been used throughout the paper :' $t$ ' in superscript indicates transposition of matrices / vectors. $\boldsymbol{\Phi} \in \mathbb{R}^{m \times n}$ denotes the measurement matrix $(m<n)$ and the $i$ th column of $\boldsymbol{\Phi}$ is denoted by $\boldsymbol{\phi}_{i}, i=1,2, \cdots, n$. All the columns of $\boldsymbol{\Phi}$ are assumed to have unit $l_{2}$ norm, i.e., $\left\|\phi_{i}\right\|_{2}=1$, which is a common assumption in the literature [1], [5]. $\mathcal{H}$ denotes the set of all the indices $\{1,2, \cdots, n\} . K$ indicates the sparsity level of $\boldsymbol{x}$, i.e., not more than $K$ elements of $\boldsymbol{x}$ are non-zero. $T$ denotes the true support set of $\boldsymbol{x}$, i.e., $T=\left\{i \in \mathcal{H} \mid[\boldsymbol{x}]_{i} \neq 0\right\}$. For any $S \subseteq \mathcal{H}, \boldsymbol{x}_{S}$ denotes the vector $\boldsymbol{x}$ restricted to $S$, i.e., $\boldsymbol{x}_{S}$ consists of those entries of $\boldsymbol{x}$ that have indices belonging to $S$. Similarly, $\boldsymbol{\Phi}_{S}$ denotes the submatrix of $\boldsymbol{\Phi}$ formed with the columns of $\boldsymbol{\Phi}$ restricted to the index set $S$. If $\boldsymbol{\Phi}_{S}$ has full column rank of $|S|(|S|<m)$, then the Moore-Penrose pseudo-inverse of $\boldsymbol{\Phi}_{S}$ is given by $\boldsymbol{\Phi}_{S}^{\dagger}=\left(\boldsymbol{\Phi}_{S}^{t} \boldsymbol{\Phi}_{S}\right)^{-1} \boldsymbol{\Phi}_{S}^{t} . \mathbf{P}_{S}=\boldsymbol{\Phi}_{S} \boldsymbol{\Phi}_{S}^{\dagger}$ denotes the orthogonal projection operator associated with $\operatorname{span}\left(\boldsymbol{\Phi}_{S}\right)$ and $\mathbf{P} \stackrel{\perp}{S}=\boldsymbol{I}-\mathbf{P}_{S}$ denotes the orthogonal projection operator on the orthogonal complement of $\operatorname{span}\left(\boldsymbol{\Phi}_{S}\right)$. For any set $S \subseteq \mathcal{H}$, the matrix $\mathbf{P}_{S}^{\perp} \boldsymbol{\Phi}$ is denoted by $\boldsymbol{A}_{S}$. For a given sparsity order $K$ and a given matrix $\boldsymbol{\Phi}$, it can be shown that there exists a real, positive constant $\delta_{K}$ such that $\Phi$ satisfies the following "Restricted Isometry Property (RIP)" for all $K$-sparse $\boldsymbol{x}$ :

$$
\left(1-\delta_{K}\right)\|\boldsymbol{x}\|_{2}^{2} \leq\|\boldsymbol{\Phi} \boldsymbol{x}\|_{2}^{2} \leq\left(1+\delta_{K}\right)\|\boldsymbol{x}\|_{2}^{2} .
$$

The constant $\delta_{K}$ is called the restricted isometry constant (RIC)[6] of the matrix $\boldsymbol{\Phi}$ for order $K$. Clearly, it is the minimum such constant for which the RIP is satisfied. Note that if $\delta_{K}<1, \boldsymbol{x} \neq \mathbf{0}$ for a $K$-sparse $\boldsymbol{x}$ implies $\|\boldsymbol{\Phi} \boldsymbol{x}\|_{2} \neq 0$ and thus, $\boldsymbol{\Phi} \boldsymbol{x} \neq \mathbf{0}$, meaning every $K$ columns of $\boldsymbol{\Phi}$ are linearly independent. The RIC gives a measure of near unitariness of $\boldsymbol{\Phi}$ (smaller the RIC is, closer $\Phi$ will be to being unitary). Convergence conditions of recovery algorithms in CS are usually given in terms of upper bounds on the RIC.

## III. Proposed Algorithm

Input: measurement vector $\boldsymbol{y} \in \mathbb{R}^{m}$, sensing matrix $\boldsymbol{\Phi} \in \mathbb{R}^{m \times n}$; sparsity level $K$; number of indices preselected $N$; number of indices chosen in identification step, $L(L \leq N, L \leq K)$, prespecified residual threshold $\epsilon$;
Initialize: counter $k=0$, residue $\boldsymbol{r}^{0}=\boldsymbol{y}$, estimated support set, $T^{0}=\emptyset$, set selected by preselection step $S^{0}=\emptyset$,
While $\left(\left\|\boldsymbol{r}^{k}\right\|_{2} \geq \epsilon\right.$ and $\left.k<K\right)$
$k=k+1$
Preselect: $S^{k}$ is the set containing indices corresponding to the $N$ largest absolute entries of $\boldsymbol{\Phi}^{t} \boldsymbol{r}^{k-1}$
Identify: $h^{k}=\underset{\Lambda \subset S^{k}:|\Lambda|=L}{\arg \min } \sum_{i \in \Lambda}\left\|\mathbf{P}_{T^{k-1} \cup\{i\}}^{\perp} \boldsymbol{y}\right\|_{2}^{2}$
Augment: $T^{k}=T^{k-1} \cup h^{k}$
Estimate: $\boldsymbol{x}^{k}=\underset{\boldsymbol{u}: \boldsymbol{u} \in \mathbb{R}^{n}, \operatorname{supp}(\boldsymbol{u})=T^{k}}{\arg \min }\|\boldsymbol{y}-\boldsymbol{\Phi} \boldsymbol{u}\|_{2}$
Update: $\boldsymbol{r}^{k}=\boldsymbol{y}-\boldsymbol{\Phi} \boldsymbol{x}^{k}$
(Note : Computation of $\boldsymbol{x}^{k}$ for $1 \leq k \leq K$ requires every $L K$ columns of $\boldsymbol{\Phi}$ to be linearly independent which is guaranteed by the proposed RIC bound)
End While

Output: estimated support set $\hat{T}=\underset{\Lambda:|\Lambda|=K}{\arg \max }\left\|\boldsymbol{x}_{\Lambda}^{k}\right\|_{2}$ and $K$-sparse signal $\hat{\boldsymbol{x}}$
satisfying $\hat{\boldsymbol{x}}_{\hat{T}}=\boldsymbol{\Phi}_{\hat{T}}^{\dagger} \boldsymbol{y}, \hat{\boldsymbol{x}}_{\mathcal{H} \backslash \hat{T}}=\mathbf{0}$
TABLE I: Proposed m²OLS Algorithm

The proposed $\mathrm{m}^{2}$ OLS algorithm is described in Table. It any $k$-th step of iteration $(k \geq 1)$, assume a residual signal vector $\boldsymbol{r}^{k-1}$ and a partially constructed support set $T^{k-1}$ have already been computed ( $\boldsymbol{r}^{0}=\boldsymbol{y}$ and $T^{0}=\emptyset$ ). In the preselection stage, $N$ columns of $\boldsymbol{\Phi}$ are identified that have largest (in magnitude) correlations with $\boldsymbol{r}^{k-1}$ by picking up the $N$ largest absolute
entries of $\boldsymbol{\Phi}^{t} \boldsymbol{r}^{k-1}$, and the set $S^{k}$ containing the corresponding indices is selected. This is followed by the identification stage, where $\sum_{i \in \Lambda}\left\|\mathbf{P}_{T^{k-1} \cup\{i\}}^{\perp} \boldsymbol{y}\right\|_{2}^{2}$ is evaluated for all subsets $\Lambda$ of $S^{k}$ having $L$ elements, and selecting the subset $h^{k}$ for which this is minimum. This is the greedy selection stage, which is carried out in practice [5] by computing $\frac{\left|\phi_{p^{t}} r^{k-1}\right|}{\left\|\mathbf{P}_{T^{k-1}}^{\perp} \phi_{i}\right\|_{2}}$ for all $i \in S^{k}$ and selecting the indices corresponding to the $L$ largest of them. The partial support set is then updated to $T^{k}$ by taking set union of $T^{k-1}$ and $h^{k}$, and the residual vector is updated to $\boldsymbol{r}^{k}$ by computing $\mathbf{P}_{T^{k}}^{\perp} \boldsymbol{y}$.

Note that in conventional mOLS algorithm, at a $k$-th step of iteration $(k \geq 1)$, one has to compute $\frac{\left|\boldsymbol{\phi}_{i}^{t} \boldsymbol{r}^{k-1}\right|}{\left\|\mathbf{P}_{T^{k-1}}^{\perp} \boldsymbol{\phi}_{i}\right\|_{2}}$ for all $i \in \mathcal{H} \backslash T^{k-1}$, involving a total of $n-(k-1) L$ columns, i.e., $\phi_{i}$ 's. In contrast, in the proposed $\mathrm{m}^{2} \mathrm{OLS}$ algorithm, the above computation is restricted only to the preselected set of $N$ elements, which results in significant reduction of computational complexity.

## A. Lemmas (Existing)

The following lemmas will be useful for the analysis of the proposed algorithm.
Lemma 3.1 (Monotonicity, Lemma 1 of [7]). If a measurement matrix satisfies RIP of orders $K_{1}, K_{2}$ and $K_{1} \leq K_{2}$, then $\delta_{K_{1}} \leq \delta_{K_{2}}$.
Lemma 3.2 (Consequence of RIP [8]). For any subset $\Lambda \subseteq \mathcal{H}$, and for any vector $\boldsymbol{u} \in \mathbb{R}^{n}$,

$$
\left(1-\delta_{|\Lambda|}\right)\left\|\boldsymbol{u}_{\Lambda}\right\|_{2} \leq\left\|\boldsymbol{\Phi}_{\Lambda}^{t} \boldsymbol{\Phi}_{\Lambda} \boldsymbol{u}_{\Lambda}\right\|_{2} \leq\left(1+\delta_{|\Lambda|}\right)\left\|\boldsymbol{u}_{\Lambda}\right\|_{2}
$$

Lemma 3.3 (Proposition 3.1 in [8]). For any $\Lambda \subseteq \mathcal{H}$, and for any vector $\boldsymbol{u} \in \mathbb{R}^{m}$

$$
\left\|\boldsymbol{\Phi}_{\Lambda}^{t} \boldsymbol{u}\right\|_{2} \leq \sqrt{1+\delta_{|\Lambda|}}\|\boldsymbol{u}\|_{2}
$$

Lemma 3.4 (Lemma 1 of [7]). If $\boldsymbol{x} \in \mathbb{R}^{n}$ is a vector with support $S_{1}$, and $S_{1} \cap S_{2}=\emptyset$, then,

$$
\left\|\boldsymbol{\Phi}_{S_{2}}^{t} \boldsymbol{\Phi} \boldsymbol{x}\right\|_{2} \leq \delta_{\left|S_{1}\right|+\left|S_{2}\right|}\|\boldsymbol{x}\|_{2}
$$

Lemma 3.5 (Lemma 3 of [9]). If $I_{1}, I_{2} \subset \mathcal{H}$ such that $I_{1} \cap I_{2}=\emptyset$ and $\delta_{\left|I_{2}\right|}<1$, then, $\forall \boldsymbol{u} \in \mathbb{R}^{n}$ such that supp $(\boldsymbol{u}) \subseteq I_{2}$,

$$
\left(1-\left(\frac{\delta_{\left|I_{1}\right|+\left|I_{2}\right|}}{1-\delta_{\left|I_{1}\right|+\left|I_{2}\right|}}\right)^{2}\right)\|\boldsymbol{\Phi} \boldsymbol{u}\|_{2}^{2} \leq\left\|\boldsymbol{A}_{I_{1}} \boldsymbol{u}\right\|_{2}^{2} \leq\left(1+\delta_{\left|I_{1}\right|+\left|I_{2}\right|}\right)\|\boldsymbol{\Phi} \boldsymbol{u}\|_{2}^{2}
$$

and,

$$
\left(1-\frac{\delta_{\left|I_{1}\right|+\left|I_{2}\right|}}{1-\delta_{\left|I_{1}\right|+\left|I_{2}\right|}}\right)\|\boldsymbol{u}\|_{2}^{2} \leq\left\|\boldsymbol{A}_{I_{1}} \boldsymbol{u}\right\|_{2}^{2} \leq\left(1+\delta_{\left|I_{1}\right|+\left|I_{2}\right|}\right)\|\boldsymbol{u}\|_{2}^{2}
$$

## IV. Signal Recovery USing m ${ }^{2}$ OLS ALGORITHM

In this section, we obtain convergence conditions for the proposed $\mathrm{m}^{2} \mathrm{OLS}$ algorithm. In particular, we derive conditions for selection of at least one correct index at each iteration, which guarantees recovery of a $K$-sparse signal by the $\mathrm{m}^{2} \mathrm{OLS}$ algorithm in a maximum of $K$ iterations.

Unlike mOLS, proving convergence is, however, trickier in the proposed $\mathrm{m}^{2} \mathrm{OLS}$ algorithm because of the presence of two selection stages at every iteration, namely, preselection and identification. In order that the proposed algorithm converges in $K$ steps or less, it is essential to ensure that at each step of iteration, at least one true support index $i$ first gets selected in $S^{k}$ and then, gets passed on from $S^{k}$ to $h^{k}$. In the following, we present the convergence conditions for $\mathrm{m}^{2} \mathrm{OLS}$ in two cases, with and without the presence of measurement noise. For the noiseless measurement model the measurement vector $\boldsymbol{y}$ satisfies $\boldsymbol{y}=\boldsymbol{\Phi} \boldsymbol{x}$, with a unique $K$-sparse vector $\boldsymbol{x}$. For the noisy measurement model, the measurement vector is assumed to be contaminated by an additive noise vector, i.e., $\boldsymbol{y}=\boldsymbol{\Phi} \boldsymbol{x}+\boldsymbol{e}$. The convergence conditions for noiseless and noisy cases are given in Theorems 4.1 and Theorem 4.2 below. Both these theorems use Lemma 4.1, which in turn uses the following definition : $\tilde{T}^{K}=\left\{i \in H \mid \boldsymbol{\phi}_{\boldsymbol{i}} \in \operatorname{span}\left(\boldsymbol{\Phi}_{T^{k}}\right)\right\}$. Note that $T^{k} \subseteq \tilde{T}^{K}$ and for $i \in \tilde{T}^{K},\left\|\mathbf{P}_{T^{k}}^{\perp} \boldsymbol{\phi}_{\boldsymbol{i}}\right\|_{2}=0,\left\langle\boldsymbol{\phi}_{\boldsymbol{i}}, \boldsymbol{r}^{k}\right\rangle=0$. It should be mentioned that the first result of Lemma 4.1 is not any new result, and similar result has already been discussed in the context of OLS [3], [10], and mOLS [5]. However, we provide an additional observation in the following lemma that concerns the identification step of $\mathrm{m}^{2} \mathrm{OLS}$.
Lemma 4.1. At the $(k+1)$ th iteration, the identification step chooses the set

$$
h^{k+1}=\underset{\Lambda: \Lambda \subset S^{k+1},|\Lambda|=L}{\arg \max } \sum_{i \in \Lambda} a_{i}^{2}
$$

where $a_{i}=\frac{\left|\left\langle\phi_{i}, \boldsymbol{r}^{k}\right\rangle\right|}{\left\|\mathbf{P}_{T^{k}}^{\perp} \phi_{i}\right\|_{2}}$ if $i \in S^{k+1} \backslash \tilde{T}^{K}$, and $a_{i}=0$ for $i \in S^{k+1} \cap \tilde{T}^{K}$. Further, if

$$
g^{k+1}=\underset{\Lambda: \Lambda \subset S^{k+1},|\Lambda|=L}{\arg \max } \sum_{i \in \Lambda} a_{i},
$$

then, $\sum_{i \in h^{k+1}} a_{i}=\sum_{i \in g^{k+1}} a_{i}$.
Proof. The first part of this lemma is a direct consequence of Proposition 1 of [5]. For the second part, let $l \in h^{k+1}$ be an index, so that, $a_{l} \leq a_{r}, \forall r \in h^{k+1}$ (i.e. $a_{l}=\min \left\{a_{r} \mid r \in h^{k+1}\right\}$ ). Clearly, $a_{l} \geq a_{j} \forall j \in S^{k+1} \backslash h^{k+1}$, as otherwise, if $\exists a_{j} \in S^{k+1} \backslash h^{k+1}$ so that $a_{l}<a_{j}$, we have $a_{l}^{2}<a_{j}^{2}$. Then constructing the set $H^{k+1}$ as $H^{k+1}=h^{k+1} \cup\{j\} \backslash\{l\}$, we have, $\sum_{i \in h^{k+1}} a_{i}^{2}<\sum_{i \in H^{k+1}} a_{i}^{2}$, which is a contradiction. The above means that $\forall i \in h^{k+1}, a_{i} \geq a_{j}, \forall j \in S^{k+1} \backslash h^{k+1}$. Thus, for any $S \subseteq S^{k+1},|S|=L, \sum_{i \in h^{k+1}} a_{i} \geq \sum_{i \in S} a_{i}$, and thus, $\sum_{i \in h^{k+1}} a_{i} \geq \sum_{i \in g^{k+1}} a_{i}$. Again, from the definition of $g^{k+1}, \sum_{i \in g^{k+1}} a_{i} \geq \sum_{i \in h^{k+1}} a_{i}$. This proves the desired equality.

Our main results regarding the signal recovery performance of the $\mathrm{m}^{2} \mathrm{OLS}$ algorithm is stated in the following two theorems.
Theorem 4.1. The $m^{2}$ OLS algorithm can recover a $K$ sparse vector $\boldsymbol{x} \in \mathbb{R}^{n}$ perfectly from the measurement vector $\boldsymbol{y}=$ $\boldsymbol{\Phi} \boldsymbol{x}, \boldsymbol{y} \in \mathbb{R}^{m}, m<n$ within $K$ iterations, if

$$
\begin{equation*}
\delta_{L K+N-L+1}<\frac{\sqrt{L}}{\sqrt{K+L}+\sqrt{L}} \tag{1}
\end{equation*}
$$

is satisfied by matrix $\boldsymbol{\Phi}$.
Proof. Given in Appendix A
To describe recovery performance of $\mathrm{m}^{2}$ OLS in presence of noise, we use the following performance measures [5]:

- $s n r:=\frac{\|\boldsymbol{\Phi} \boldsymbol{x}\|_{2}^{2}}{\|e\|_{2}^{2}}$,
- minimum-to-average-ratio (MAR) [11], $\kappa=\frac{\min _{j \in T}\left|x_{j}\right|}{\|\boldsymbol{x}\|_{2} / \sqrt{K}}$.

Theorem 4.2. Under the noisy measurement model, $m^{2} O L S$ is guaranteed to collect all the indices of the the true support set $T$ within $K$ iterations, if the sensing matrix $\Phi$ satisfies equation (1) and the snr satisfies the following condition:

$$
\begin{equation*}
\sqrt{s n r}>\frac{\left(1+\delta_{R}\right)(\sqrt{L}+\sqrt{K}) \sqrt{K}}{\kappa\left(\sqrt{L\left(1-2 \delta_{R}\right)}-\delta_{R} \sqrt{K}\right)} \tag{2}
\end{equation*}
$$

where $R=L K+N-L+1$.

## Proof. Given in Appendix A.

Note that the $\mathrm{m}^{2} \mathrm{OLS}$ algorithms reduces to the gOMP algorithm when $N=L$. Theorem 4.1 suggests that for $N=L$, the $\mathrm{m}^{2} \mathrm{OLS}$ algorithm can recover the true support of any $K$-sparse signal from noiseless measurements within $K$ if the sensing matrix satisfies $\delta_{N K+1}<\frac{1}{\sqrt{K / N+1}+1}$, where $N \geq 1$. Recently Wen et al [12] have established that, with $N \geq 1$, $\delta_{N K+1}<\frac{1}{\sqrt{K / N+1}}$ is a sharp sufficient condition for gOMP to exactly recover $K$-sparse signals from noiseless measurements within $K$ iterations. We see that for large $K / N$ ratio, $\sqrt{K / N+1}+1 \approx \sqrt{K / N+1}$, which shows that the bound provided in Theorem4.1 is nearly sharp when $N=L$. Moreover, in our analysis When $N>1$, and $L=1$, the bound in Theorem 4.1 reduces to $\delta_{K+N}<\frac{1}{\sqrt{K+1}+1}$, whereas, the recent paper [13] suggests the sufficient condition $\delta_{K+1}<\frac{1}{\sqrt{K+1}}$ for the OLS to recover perfectly a $K$-sparse signal from noiseless measurements within $K$ iterations. Again, the right hand side of the bound suggested in Theorem4.1 is very close to the one established in [13] for large $K$. However, the left hand side of the inequality contains $\delta_{K+N}$ in our case, which can be much larger than $\delta_{K+1}$, and thus makes our condition stricter than that of the one obtained in [13]. However, since in $\mathrm{m}^{2}$ OLS the operations of mOLS are performed on a smaller preselected set of indices to reduce computational cost, intuitively it is expected that the sensing matrix must satisfy some stricter RIP condition in order to yield recovery performance competitive to that of mOLS.

Our proof of the theorems 4.1 and 4.2 mainly follows the ideas of the analysis of gOMP [2, Theorem 4.2] and mOLS [5, Theorem 3] where sufficient conditions for recovery of signal support of a $K$-sparse signal from noisy measurements by running the algorithm no more than $K$ iterations were established. The proof uses mathematical induction, where we first find out a sufficient condition for success by $\mathrm{m}^{2} \mathrm{OLS}$ in the first iteration, and then assuming that $\mathrm{m}^{2} \mathrm{OLS}$ is successful in each of the previous $k(1 \leq k \leq K-1)$ iterations, we find out conditions sufficient for success at the $(k+1)^{\text {th }}$ iteration. However, unlike gOMP or mOLS, finding out the condition for success at any iteration for $\mathrm{m}^{2}$ OLS requires ensuring that first at least one true index is captured in the preselection step, which is identical to the gOMP identification step, and then further ensuring
that at least one of these captured true indices should be recaptured by the identification step, which is identical to the mOLS identification step. Thus any iteration of $\mathrm{m}^{2} \mathrm{OLS}$ is successful if the sufficient conditions for both these steps are satisfied. Finally, the sufficient conditions for any general iteration $k(2 \leq k \leq K)$, and the condition for iteration 1 is combined to obtain the final condition for successful recovery of support within $K$ iterations.

The steps in our proof are partly similar to the steps in the proof of Theorem 3 in Wang et al [5], and we have frequently used certain steps in the proof of Theorem 1 in the paper of Li et al [14], specifically [14, Eq.(25),(26)] and Eq. (9) of Satpathi et al [9]. However, our analysis have differed from these analysis during the analysis of first iteration of $\mathrm{m}^{2} \mathrm{OLS}$, where unlike Wang et al [2], and Li et al [14] we have given the analysis both for the cases $1 \leq N \leq K$, and $N>K$. Furthermore, in the identification step we have used Lemma 3.5 which have produced bound on $\left\|\mathbf{P}_{T^{k}}^{\perp} \boldsymbol{\phi}_{i}\right\|_{2}^{2}$ tighter than the one that follows from [5, Eq.(E.7)], which has been used in the subsequent analysis of $\mathrm{m}^{2} \mathrm{OLS}$.

## V. Comparative analysis of computational complexities of mols and m ${ }^{2}$ OLS

By restricting the steps of mOLS to a pre-selected subset of columns of $\boldsymbol{\Phi}$, the proposed $\mathrm{m}^{2} \mathrm{OLS}$ algorithm achieves considerable computational simplicity over mOLS. In this section, we analyze the computational steps involved in both mOLS and $\mathrm{m}^{2} \mathrm{OLS}$ at the $(k+1)^{\text {th }}$ iteration (i.e., assuming that $k$ iterations of either algorithm have been completed), and compare their computational costs in terms of number of floating point operations (flops) required.

## A. Computational steps of mOLS (in iteration $k+1$ )

Step 1 (Absolute correlation calculation) : Here $\left|\left\langle\phi_{i}, \boldsymbol{r}^{k}\right\rangle\right|$ is calculated $\forall i \in \mathcal{H} \backslash T^{k}$, where the vector $\boldsymbol{r}^{k}$ was precomputed at the end of the $k^{\text {th }}$ step. We initialize $\boldsymbol{r}^{0}=\boldsymbol{y}$.
Step 2 (Identification) : In this step, mOLS first calculates the ratios $\frac{\left|\left\langle\phi_{i}, \boldsymbol{r}^{k}\right\rangle\right|}{\left\|\mathbf{P}_{T_{k}^{k}}^{\perp} \phi_{i}\right\|_{2}}, \forall i \in \mathcal{H} \backslash T^{k}$. Since $\forall i \in \mathcal{H} \backslash T^{k}$, the numerator was calculated in Step 1, only the denominator needs to be calculated. However, as will be discussed later, at the end of each $k^{\text {th }}$ step, the norms $\left\|\mathbf{P}_{T^{k}}^{\perp} \boldsymbol{\phi}_{i}\right\|_{2}, i \in \mathcal{H} \backslash T^{k}$ are calculated and stored, which provides the denominators in the above ratios. This means, the above computation requires simply a division operation per ratio and a total of $(n-L k)$ divisions. This step is followed by finding the $L$ largest of the above ratios, and appending the corresponding columns to the previously estimated subset of columns, $\boldsymbol{\Phi}_{T^{k}}$, thereby generating $\boldsymbol{\Phi}_{T^{k+1}}$ (for $k=0, T^{k}=\emptyset$ and thus, $\boldsymbol{\Phi}_{T^{k}}=\emptyset$ ).
Step 3 (Modified Gram Schmidt) : This step finds an orthonormal basis for $\operatorname{span}\left(\boldsymbol{\Phi}_{T^{k+1}}\right)$. Assuming that an orthonormal basis $\left\{\boldsymbol{u}_{1}, \cdots, \boldsymbol{u}_{\left|T^{k}\right|}\right\}$ for $\operatorname{span}\left(\boldsymbol{\Phi}_{T^{k}}\right)$ has already been computed at the $k^{\text {th }}$ step, an efficient way to realize this will be to employ the well known Modified Gram Schmidt (MGS) procedure [15], which first computes $\mathbf{P}_{T^{k}}^{\perp} \boldsymbol{\phi}_{i}, i \in h^{k+1}$ using the above precomputed orthonormal basis and then, orthonormalizes them recursively, generating the orthonormal set $\left\{\boldsymbol{u}_{|T|^{k}+1}, \cdots, \boldsymbol{u}_{\left|T^{k+1}\right|}\right\}$.
Step 4 (Precomputation of orthogonal projection error norm) : At the $(k+1)^{\text {th }}$ step, after MGS is used to construct an orthonormal basis for $\operatorname{span}\left(\boldsymbol{\Phi}_{T^{k+1}}\right)$, the norms $\left\|\mathbf{P}_{T^{k+1}}^{\perp} \phi_{i}\right\|_{2}, i \in \mathcal{H} \backslash T^{k+1}$, are computed using the following recursive relation, for use in the identification step of $(k+2)^{\mathrm{th}}$ step:

$$
\begin{equation*}
\left\|\mathbf{P}_{T^{k+1}}^{\perp} \boldsymbol{\phi}_{i}\right\|_{2}^{2}=\left\|\mathbf{P}_{T^{k}}^{\perp} \boldsymbol{\phi}_{i}\right\|_{2}^{2}-\sum_{j=\left|T^{k}\right|+1}^{\left|T^{k+1}\right|}\left|\left\langle\boldsymbol{\phi}_{i}, \boldsymbol{u}_{\boldsymbol{j}}\right\rangle\right|^{2} \tag{3}
\end{equation*}
$$

Step 4 (Calculation of $\boldsymbol{r}^{k+1}$ ): Finally mOLS calculates the residual vector $\boldsymbol{r}^{k+1}$ as follows:

$$
\begin{equation*}
\boldsymbol{r}^{k+1}=\boldsymbol{r}^{k}-\sum_{j=\left|T^{k}\right|+1}^{\left|T^{k+1}\right|}\left\langle\boldsymbol{y}, \boldsymbol{u}_{j}\right\rangle \boldsymbol{u}_{j} . \tag{4}
\end{equation*}
$$

## B. Computational steps of $m^{2} O L S$ (in iteration $k+1$ )

Step 1 (Preselection): In this step, similar to mOLS, the absolute correlations $\left|\left\langle\phi_{i}, \boldsymbol{r}^{k}\right\rangle\right|$ are calculated using the vector $\boldsymbol{r}^{k}$ which is precomputed at the end of the $k^{\text {th }}$ step. Then the indices corresponding to the $N$ largest absolute correlations are selected to form the set $S^{k+1}$.
Step 2 (Identification): The identification step calculates the ratios $\frac{\left|\left\langle\phi_{i}, r^{k}\right\rangle\right|}{\left\|\mathbf{P}_{T_{k}^{k}}^{\perp} \phi_{i}\right\|_{2}}, \forall i \in S^{k+1}$, for which the numerators are already known from Step 1 and the denominators are calculated as per the following:

$$
\begin{equation*}
\left\|\mathbf{P}_{T^{k}}^{\perp} \boldsymbol{\phi}_{i}\right\|_{2}^{2}=\left\|\boldsymbol{\phi}_{i}\right\|_{2}^{2}-\sum_{j=1}^{\left|T^{k}\right|}\left|\left\langle\boldsymbol{\phi}_{i}, \boldsymbol{u}_{\boldsymbol{j}}\right\rangle\right|^{2} \tag{5}
\end{equation*}
$$

where, as in mOLS, $\left\{\boldsymbol{u}_{1}, \cdots, \boldsymbol{u}_{|T|^{k}}\right\}$ is the orthonormal basis formed for $\operatorname{span}\left(\boldsymbol{\Phi}_{T^{k}}\right)$ using MGS at step $k$. For the first step $k=0, T^{k}=\emptyset$, and thus $\left\|\mathbf{P}_{T^{0}}^{\perp} \phi_{i}\right\|_{2}=\left\|\phi_{i}\right\|_{2}, i \in \mathcal{H}$. It is assumed that the norms $\left\|\phi_{i}\right\|_{2}$ are all precomputed (taken

Fig. 1: Recovery probability vs sparsity.

Fig. 2: No. of iterations for exact recovery vs sparsity.
to be unity in this paper). This computation is followed by $N$ divisions as required to form the above ratios. Following this, the indices corresponding to the largest $L$ of the $N$ ratios are determined and the corresponding columns are appended to the previously estimated set of columns $\boldsymbol{\Phi}_{T^{k}}$ to obtain $\boldsymbol{\Phi}_{T^{k+1}}$.
Step 3 (Modified Gram Schmidt): This step is identical to the MGS step in mOLS, which generates an orthonormal basis for $\operatorname{span}\left(\boldsymbol{\Phi}_{T^{k+1}}\right)$.
Step 4 (Computation of $\boldsymbol{r}^{k+1}$ ): As in mOLS, the residual $\boldsymbol{r}^{k+1}$ is updated using Eq. (4).
Comparison between computational complexities of mOLS and $\mathbf{m}^{2}$ OLS: While certain operations like MGS, computation of absolute correlation and the residual $\boldsymbol{r}^{k}$ are same in both mOLS and $\mathrm{m}^{2}$ OLS, the major computational difference between them lies in the following : at the end of every $(k+1)^{\text {th }}$ step, the mOLS computes $\left\|\mathbf{P}_{T^{k+1}}^{\perp} \boldsymbol{\phi}_{i}\right\|_{2}^{2} \forall i \in \mathcal{H} \backslash T^{k+1}$ using recursion of the form (3). If computation of $\left|\left\langle\phi_{i}, \boldsymbol{u}_{\boldsymbol{j}}\right\rangle\right|^{2}$ has a complexity of $r$ flops, this requires a total of $(n-L(k+1))(L r+1)$ flops. Additionally, mOLS requires $(n-L k)$ divisions to compute the ratios $\frac{\left|\left\langle\phi_{i}, \boldsymbol{r}^{k}\right\rangle\right|}{\left\|\mathbf{P}_{T^{k}} \phi_{i}\right\|_{2}}, \forall i \in \mathcal{H} \backslash T^{k}$. The $\mathrm{m}^{2} \mathrm{OLS}$, on the other hand, calculates $\left|\left\langle\phi_{i}, \boldsymbol{u}_{\boldsymbol{j}}\right\rangle\right|^{2}$ only for $i \in S^{k+1}$, following (5), involving at the most just $N$ and not $(n-L k)$ columns. The summation on the RHS of (5), however, has $L k$ terms, meaning this step requires a total of $N(L k r+2)$ flops (including the $N$ divisions to compute $\frac{\left|\left\langle\phi_{i}, \boldsymbol{r}^{k}\right\rangle\right|}{\left\|\mathbf{P}_{T^{k}}^{\perp} \phi_{i}\right\|_{2}}, \forall i \in S^{k+1}$ ). Clearly, mOLS will require more computations than $\mathrm{m}^{2} \mathrm{OLS}$ as long as $1<\frac{(n-L k)(L r+2)-L(L r+1)}{N(L k r+2)} \approx \frac{n-L k-L}{N k}$, or, equivalently, for $k<\frac{n-L}{N+L}$. Thus, for large $n$ and $/$ or small $K$, as $k \leq K$, the mOLS will have significantly higher computational overhead as compared to $\mathrm{m}^{2}$ OLS at each iteration $k$ and the difference in cumulative computational cost over all iterations put together will be huge. Even when the sparsity $K$ is larger $(2 K<m)$, the actual number of iterations, say, $J$ required for convergence by both mOLS and $\mathrm{m}^{2} \mathrm{OLS}$ is usually much less than $K$ and the above difference continues. In case of large $K$ and $J$ close to $K$, the mOLS will require more computations than $\mathrm{m}^{2}$ OLS for $k$ upto certain value, beyond which $\mathrm{m}^{2}$ OLS will start having more computations and thus, the difference in cumulative computational cost between mOLS and $\mathrm{m}^{2} \mathrm{OLS}$ will start reducing with $k$. This means, for large $K$, we have a reasonably large range of $J$ for which the overall computational cost of mOLS remains substantially higher than that of $\mathrm{m}^{2} \mathrm{OLS}$. The above comparative assessment of mOLS and $\mathrm{m}^{2}$ OLS in terms of computations required is also validated by simulation studies as presented in the next section.

## VI. Simulation results

For simulation, we constructed measurement matrices with correlated entries, as used by Soussen et al [3]. For this, first a matrix $\boldsymbol{A}$ is formed such that $a_{i j}=[\boldsymbol{A}]_{i j}$ is given by $a_{i j}=n_{i j}+t_{j}$ where $n_{i j} \sim \mathcal{N}(0,1 / m)$ i.i.d. $\forall i, j, t_{j} \sim \mathcal{U}[0, \tau] \forall j$, and

Fig. 3: Mean runtime vs sparsity.

Fig. 4: Mean runtime vs sparsity (mOLS and $\mathrm{m}^{2} \mathrm{OLS}$ ) for different $L$.

Fig. 5: Mean runtime vs sparsity (mOLS and $\mathrm{m}^{2} \mathrm{OLS}$ ) for different $N$.

Fig. 6: Mean Square Error (MSE) vs SNR $(K=30)$
$\left\{n_{i j}\right\}$ is statistically independent of $\left\{t_{k}\right\}, \forall i, j, k$. The measurement matrix $\boldsymbol{\Phi}$ is then constructed from $\boldsymbol{A}$ as $\phi_{i j}=a_{i j} /\left\|\boldsymbol{a}_{j}\right\|_{2}$, where $\phi_{i j}=[\boldsymbol{\Phi}]_{i j}$ and $\boldsymbol{a}_{i}$ denotes the $i$-th column of $\boldsymbol{A}$. Note that in the construction process for $\boldsymbol{\Phi}$, the random variables $n_{i j}$ play the role of additive i.i.d. noise process, added to the elements of a rank 1 matrix, with columns $\left\{t_{i} \mathbf{1}\right\}_{i=1}^{n}$, where $\mathbf{1}$ denotes a $m \times 1$ vector with all entries equal to one. If the value of $\tau$ becomes large as compared to the variance $1 / m$ of $n_{i j}$, then the matrix $\boldsymbol{\Phi}$ resembles a rank 1 matrix with normalized columns. For all the simulations, the values of $m$, $n$ were fixed

Fig. 7: Mean Square Error (MSE) vs SNR $(K=30, N=70, L=3)$ for different values of $\epsilon$
at 500,800 respectively while the sparsity $K$ was varied. The nonzero elements of $\boldsymbol{x}$ were drawn randomly from i.i.d Gaussian distribution and $\tau$ was chosen to have values either 0 or 8 . Note that higher the value of $\tau$, more will be the correlation (taken as the absolute value of the inner product, which is a measure of coherence) between the columns of $\boldsymbol{\Phi}$. Thus, $\tau=0$ produces a matrix with uncorrelated columns while $\tau=8$ produces a matrix with reasonably correlated columns. Furthermore, different values for the window sizes for the preselection stage $(N)$ of $\mathrm{m}^{2} \mathrm{OLS}$ and the identification stages $(L)$ of both mOLS and $\mathrm{m}^{2}$ OLS were used for the simulation. Particularly, the values $\{60,70,80\}$ were used for $N$, and $\{1,3,5\}$ were used for $L$. Moreover, we used different values for $N_{g}$, the number of indices identified at the identification stage of gOMP, from the set $\{1,5,10\}$.

For each value of $K$, the gOMP, mOLS and $\mathrm{m}^{2}$ OLS were run till they converge or upto the $K$-th step of iteration, whichever is earlier, and the experiment was conducted 500 times. To evaluate the performance of the algorithms, three performance metrics were considered, namely, recovery probability, mean number of iterations $(\leq K)$ for convergence and mean runtime. Of these the recovery probability was obtained by counting the number of times out of the 500 trials each algorithm converges, while for the other two, averaging was done over the 500 trials [1]. In the first simulation exercise, the recovery probabilities are plotted against $K$. The plots, shown in Fig. 1(a) and (b) for $\tau=0$ and $\tau=8$ respectively, suggest that even for highly correlated dictionaries $(\tau=8)$, the probability of recovery exhibited by $\mathrm{m}^{2}$ OLS is identical to mOLS over the entire sparsity range considered, and both of them outmatch the recovery probability performance of gOMP. However, it is observed from Fig. 1b that for the correlated dictionary the recovery probability of the gOMP does increase with the increase of $N_{g}$. The second simulation exercise evaluates the average no. of iterations required by the two algorithms for exact recovery for each value of $K$. The corresponding results, shown in Fig. 2 a) and (b) for $\tau=0$ and $\tau=8$ respectively, reveal that for the uncorrelated case ( $\tau=0$ ), both mOLS and $\mathrm{m}^{2} \mathrm{OLS}$ algorithms require the same average number of iterations for successful recovery, and it is only under $\tau=8$ that as $K$ increases beyond a point, there is a marginal increase in the average number of iterations in $\mathrm{m}^{2} \mathrm{OLS}$ over mOLS. On the other hand gOMP requires relatively smaller number of iterations for $\tau=0$ and for $\tau=8$ the required number of iterations increase with increase in $N_{g}$. In our third exercise, we evaluated the average of total runtime for all three algorithms, against $K$. The corresponding results are shown in Fig. 3(a) and (b) and the results for mOLS and $\mathrm{m}^{2} \mathrm{OLS}$ are shown in Fig. 4 for $\tau=0$ and $\tau=8$ respectively. The figures demonstrate the superiority of the proposed $\mathrm{m}^{2}$ OLS algorithm over mOLS as well as gOMP, as the former is seen to require much less running time than mOLS for both values of $\tau$, and has runtime closer to gOMP for $\tau=0$, and less than gOMP for $\tau=8$. The results also illustrate that the runtime of $\mathrm{m}^{2} \mathrm{OLS}$ decreases with increasing $L$ while maintaining lesser runtime than mOLS. This validates the conjectures made at the end of $\mathrm{Sec} \nabla$ regarding the reduced computational overhead of $\mathrm{m}^{2}$ OLS over a large range of sparsity values. The plots also suggest that for $\tau=8$, while gOMP with large $N_{g}$ can exhibit probability of recovery performance almost as good as mOLS (as demonstrated by Fig. 1b), the runtime is significantly higher compared to $\mathrm{m}^{2}$ OLS. This is because as the plots in Fig. 2b suggest, for larger $N_{g}$ gOMP requires much larger number of iterations for convergence than mOLS and $\mathrm{m}^{2}$ OLS even when $N_{g}$ is high, making its runtime higher. We also plot in Fig. 5 runtimes for mOLS and $\mathrm{m}^{2}$ OLS for different $N$ with $L=3$ fixed. The results here demonstrate that the runtime of $\mathrm{m}^{2} \mathrm{OLS}$ can be controlled by changing the preselection step size $N$, which is intuitively expected. In our fourth exercise, we ran the mOLS and $\mathrm{m}^{2} \mathrm{OLS}$ algorithms with measurements corrupted by additive Gaussian noise with varying SNR (as defined in Sec IV). The mean square error (MSE) is computed as $\|\hat{\boldsymbol{x}}-\boldsymbol{x}\|_{2}^{2}$ where $\boldsymbol{x}$ is the original vector and $\hat{\boldsymbol{x}}$ is its estimate as produced by the algorithm. As a benchmark, the MSE of the Oracle estimator is plotted, where the Oracle estimator computes the least squares estimate of the optimal vector in presence of noise. For this experiment we consider $N=70, L=1,3,5$. The plots in Fig. 7 (a) and (b) demonstrate that for uncorrelated dictionaries $(\tau=0)$ the two algorithms exhibit almost the same performance, while for correlated dictionaries $(\tau=8), \mathrm{m}^{2} \mathrm{OLS}$ has actually a slightly better MSE performance than mOLS for different values of $L$. Also, the performance of mOLS as well
as $\mathrm{m}^{2} \mathrm{OLS}$ is for $L=1$ is the best in the low SNR region and the worst in the high SNR region. This is because when $L=1$, mOLS and $\mathrm{m}^{2}$ OLS incurs smaller error than for $L=3,5$, where larger error occurs because of selection of larger number of incorrect indices. We also experiment with the sensitivity of the MSE performances of the mOLS and $\mathrm{m}^{2}$ OLS algorithms with respect to the parameter $\epsilon$ on which the termination of the mOLS and $\mathrm{m}^{2}$ OLS algorithms depend on. We fix $N=70, L=3$, and take the values of $\epsilon$ as $\epsilon=\eta\|\boldsymbol{\nu}\|_{2}$, where $\boldsymbol{\nu}$ is the measurement noise vector, and $\eta \in\{0,100,200\}$. We observe from the Fig. 7a and 7b that for both the uncorrelated and correlated dictionaries, the MSE of $\mathrm{m}^{2}$ OLS is smaller than that of mOLS. Furthermore, early termination (high $\epsilon$ ) increases the MSE of $\mathrm{m}^{2}$ OLS in the high SNR region when $\tau=0$, whereas the MSE of mOLS increases in an even lower SNR region. Moreover, in the correlated dictionary, early termination reduces MSE of both mOLS and $\mathrm{m}^{2}$ OLS in low SNR region, and increases it for high SNR region.

## VII. CONCLUSION

In this paper we have proposed a greedy algorithm for sparse signal recovery which preselects a few ( $N$ ) possibly "good" indices according to correlation of the respective columns of the measurement matrix with a residual vector, and then uses an mOLS step to identify a subset of these indices (of size $L$ ) to be included in the estimated support set. We have carried out a theoretical analysis of the algorithm using RIP and have shown that for the noiseless signal model, if the sensing matrix satisfies the RIP condition $\delta_{L K+N-L+1}<\frac{\sqrt{L}}{\sqrt{L}+\sqrt{L+K}}$, then the $\mathrm{m}^{2} \mathrm{OLS}$ algorithm is guaranteed to exactly recover a $K$ sparse unknown vector, satisfying the measurement model, within $K$ steps. We further extended our analysis to a noisy measurement setup and worked out bounds on the measurement SNR analytically, which guarantees exact recovery of the support of the unknown sparse vector within $K$ iterations. We have also presented the computational steps of both mOLS and $\mathrm{m}^{2} \mathrm{OLS}$ in a MGS based efficient implementation and carried out a comparative analysis of their computational complexities, which showed that $\mathrm{m}^{2}$ OLS enjoys significantly reduced computational overhead compared to mOLS, especially for large $n$ and / or small $K$. Finally, through numerical simulations, we have verified that the introduction of the preselection step indeed leads to less computation time, and that the recovery performance of $\mathrm{m}^{2} \mathrm{OLS}$ in terms of recovery probability and number of iterations for success is highly competitive with mOLS for a wide range of parameter values.

## Appendix

1) Success at the first iteration: At the first iteration, the conditions for success are $S^{1} \cap T \neq \emptyset$, and $h^{1} \cap T \neq \emptyset$. In order to have these satisfied, we first observe the following:

## Lemma 1.1.

$$
\begin{align*}
\frac{1}{\sqrt{N}}\left\|\boldsymbol{\Phi}_{S^{1}}^{t} \boldsymbol{y}\right\|_{2} & \geq \frac{1}{\sqrt{K}}\left\|\boldsymbol{\Phi}_{T}^{t} \boldsymbol{y}\right\|_{2}, \quad(N \leq K)  \tag{6}\\
\left\|\boldsymbol{\Phi}_{S^{1}}^{t} \boldsymbol{y}\right\|_{2} & \geq\left\|\boldsymbol{\Phi}_{T}^{t} \boldsymbol{y}\right\|_{2}, \quad(N>K)  \tag{7}\\
\frac{1}{\sqrt{L}}\left\|\boldsymbol{\Phi}_{T^{1}}^{t} \boldsymbol{y}\right\|_{2} & \geq \frac{1}{\sqrt{K}}\left\|\boldsymbol{\Phi}_{T}^{t} \boldsymbol{y}\right\|_{2} \tag{8}
\end{align*}
$$

Proof. The proof is given in Appendix 3
Now, from (6) and (7) above,

$$
\begin{aligned}
\left\|\boldsymbol{\Phi}_{S^{1}}^{t} \boldsymbol{y}\right\|_{2} & \geq \min \left\{1, \sqrt{\frac{N}{K}}\right\}\left\|\boldsymbol{\Phi}_{T}^{t} \boldsymbol{y}\right\|_{2} \\
& =\min \left\{1, \sqrt{\frac{N}{K}}\right\}\left\|\boldsymbol{\Phi}_{T}^{t} \boldsymbol{\Phi}_{T} \boldsymbol{x}_{T}+\boldsymbol{\Phi}_{T}^{t} \boldsymbol{e}\right\|_{2} \\
& \geq \min \left\{1, \sqrt{\frac{N}{K}}\right\}\left[\left\|\boldsymbol{\Phi}_{T}^{t} \boldsymbol{\Phi}_{T} \boldsymbol{x}_{T}\right\|_{2}-\left\|\boldsymbol{\Phi}_{T}^{t} \boldsymbol{e}\right\|_{2}\right] \\
& \stackrel{(a)}{\geq} \min \left\{1, \sqrt{\frac{N}{K}}\right\}\left[\left(1-\delta_{K}\right)\|\boldsymbol{x}\|_{2}-\sqrt{1+\delta_{K}}\|\boldsymbol{e}\|_{2}\right]
\end{aligned}
$$

where the inequalities in step $(a)$ follow from Lemmas 3.2 and 3.3, respectively. If $S^{1} \cap T=\emptyset$, then,

$$
\begin{aligned}
\left\|\boldsymbol{\Phi}_{S^{1}}^{t} \boldsymbol{y}\right\|_{2} & =\left\|\boldsymbol{\Phi}_{S^{1}}^{t} \boldsymbol{\Phi}_{T} \boldsymbol{x}_{T}+\boldsymbol{\Phi}_{S^{1}}^{t} \boldsymbol{e}\right\|_{2} \\
& \stackrel{(b)}{\leq} \delta_{N+K}\|\boldsymbol{x}\|_{2}+\sqrt{1+\delta_{N}}\|\boldsymbol{e}\|_{2}
\end{aligned}
$$

where the inequalities in step $(b)$ follow from Lemmas 3.4, and 3.3, respectively. Hence $S^{1} \cap T \neq \emptyset$ is guaranteed if

$$
\begin{equation*}
\delta_{N+K}\|\boldsymbol{x}\|_{2}+\sqrt{1+\delta_{N}}\|\boldsymbol{e}\|_{2}<\min \left\{1, \sqrt{\frac{N}{K}}\right\}\left[\left(1-\delta_{K}\right)\|\boldsymbol{x}\|_{2}-\sqrt{1+\delta_{K}}\|\boldsymbol{e}\|_{2}\right] \tag{9}
\end{equation*}
$$

Again, in a similar manner as above,

$$
\begin{aligned}
\left\|\boldsymbol{\Phi}_{T^{1}}^{t} \boldsymbol{y}\right\|_{2} & \geq \sqrt{\frac{L}{K}}\left\|\boldsymbol{\Phi}_{T}^{t} \boldsymbol{y}\right\|_{2}=\sqrt{\frac{L}{K}}\left\|\boldsymbol{\Phi}_{T}^{t} \boldsymbol{\Phi}_{T} \boldsymbol{x}_{T}+\boldsymbol{\Phi}_{T}^{t} \boldsymbol{e}\right\|_{2} \\
& \geq \sqrt{\frac{L}{K}}\left[\left(1-\delta_{K}\right)\|\boldsymbol{x}\|_{2}-\sqrt{1+\delta_{K}}\|\boldsymbol{e}\|_{2}\right]
\end{aligned}
$$

If $T^{1} \cap T=\emptyset$, we have

$$
\begin{align*}
\left\|\boldsymbol{\Phi}_{T^{1}}^{t} \boldsymbol{y}\right\|_{2} & =\left\|\boldsymbol{\Phi}_{T^{1}}^{t} \boldsymbol{\Phi}_{T} \boldsymbol{x}_{T}+\boldsymbol{\Phi}_{T^{1}}^{t} \boldsymbol{e}\right\|_{2} \\
& \leq \delta_{L+K}\|\boldsymbol{x}\|_{2}+\sqrt{1+\delta_{L}}\|\boldsymbol{e}\|_{2} \tag{10}
\end{align*}
$$

Hence, given that $S^{1} \cap T \neq \emptyset, T^{1} \cap T \neq \emptyset$ is guaranteed, if

$$
\begin{equation*}
\delta_{L+K}\|\boldsymbol{x}\|_{2}+\sqrt{1+\delta_{L}}\|\boldsymbol{e}\|_{2}<\sqrt{\frac{L}{K}}\left[\left(1-\delta_{K}\right)\|\boldsymbol{x}\|_{2}-\sqrt{1+\delta_{K}}\|\boldsymbol{e}\|_{2}\right] \tag{11}
\end{equation*}
$$

Since, $N \geq L$ and $K \geq L$ (by assumption), we have $\delta_{N+K} \geq \delta_{L+K}$, and $\sqrt{\frac{L}{K}} \leq \min \left\{1, \sqrt{\frac{N}{K}}\right\}$. Therefore, a sufficient condition for simultaneous satisfaction of (9) and (11) (i.e., for success at first iteration) can be stated as follows:

$$
\delta_{N+K}\|\boldsymbol{x}\|_{2}+\sqrt{1+\delta_{N}}\|\boldsymbol{e}\|_{2}<\sqrt{\frac{L}{K}}\left[\left(1-\delta_{K}\right)\|\boldsymbol{x}\|_{2}-\sqrt{1+\delta_{K}}\|\boldsymbol{e}\|_{2}\right]
$$

or, equivalently,

$$
\begin{equation*}
\Leftrightarrow\|\boldsymbol{x}\|_{2}\left(\sqrt{L}\left(1-\delta_{K}\right)-\sqrt{K} \delta_{N+K}\right)>\|\boldsymbol{e}\|_{2}\left(\sqrt{K} \sqrt{1+\delta_{N}}+\sqrt{L} \sqrt{1+\delta_{K}}\right) . \tag{12}
\end{equation*}
$$

Note that as the RHS of (12) is positive, satisfaction of the above first requires the LHS to be positive.

- Noiseless case: For this, we have $e=0$. The inequality (12) then leads to

$$
\delta_{N+K}<\sqrt{\frac{L}{K}}\left(1-\delta_{K}\right)
$$

Since, $\delta_{K}<\delta_{N+K}$, the above is satisfied if the following condition holds:

$$
\begin{align*}
\delta_{N+K} & <\sqrt{\frac{L}{K}}\left(1-\delta_{K+N}\right) \\
\Leftrightarrow & \delta_{N+K}<\sqrt{L} /(\sqrt{L}+\sqrt{K}) . \tag{13}
\end{align*}
$$

- Noisy case (i.e. $\|e\|_{2}>\mathbf{0}$ ): For this, first the LHS of (12) must be positive which is guaranteed under (13). Subject to this, we need to condition the ratio $\frac{\|x\|_{2}}{\|e\|_{2}}$ appropriately so that (12) is satisfied. Note that since $\delta_{N+K} \geq \max \left\{\delta_{N}, \delta_{K}\right\}$, (12) is ensured under the following condition:

$$
\|\boldsymbol{x}\|_{2}\left(\sqrt{L}\left(1-\delta_{N+K}\right)-\sqrt{K} \delta_{N+K}\right)>\|\boldsymbol{e}\|_{2} \sqrt{1+\delta_{N+K}}(\sqrt{K}+\sqrt{L})
$$

The above leads to the following condition on $\frac{\|x\|_{2}}{\|e\|_{2}}$ for the first iteration to be successful under noisy observation

$$
\begin{equation*}
\frac{\|\boldsymbol{x}\|_{2}}{\|\boldsymbol{e}\|_{2}}>\frac{\sqrt{1+\delta_{N+K}}(\sqrt{L}+\sqrt{K})}{\sqrt{L}-(\sqrt{L}+\sqrt{K}) \delta_{N+K}} \tag{14}
\end{equation*}
$$

2) Success at $(k+1)^{\text {th }}$ iteration: We assume that in each of the previous $k(k<K)$ iterations, at least one correct index was selected, meaning, if $\left|T \cap T^{k}\right|=c_{k}$, then $c_{k} \geq k$. Let $c_{k}<K$. Also define $m_{k}:=\left|S^{k} \cap T \backslash T^{k}\right|, k \geq 1$, meaning, $m_{i} \geq 1,1 \leq i \leq k$. For success of the $(k+1)^{t h}$ iteration, we require $S^{k+1} \cap T \backslash T^{k} \neq \emptyset$, and $h^{k+1} \cap T \backslash T^{k} \neq \emptyset$ simultaneously, as this will ensure selection of at least one new true index at the $(k+1)$-th iteration.
Condition to ensure $S^{k+1} \cap T \backslash T^{k} \neq \emptyset$ : First consider the set $\mathcal{H} \backslash\left(T \backslash T^{k}\right)$. If $\left|\mathcal{H} \backslash\left(T \backslash T^{k}\right)\right|<N$, then, the condition $S^{k+1} \cap T \backslash T^{k} \neq \emptyset$ is satisfied trivially. We therefore consider cases where $\left|\mathcal{H} \backslash\left(T \backslash T^{k}\right)\right| \geq N$, for which we define the following:

- $W^{k+1}:=\underset{S \subset \mathcal{H} \backslash\left(T \backslash T^{k}\right):|S|=N}{\arg \max }\left\|\boldsymbol{\Phi}_{S}^{t} \boldsymbol{r}^{k}\right\|_{2}$.
- $\alpha_{N}^{k}:=\min _{i \in W^{k+1}}\left|\left\langle\boldsymbol{\phi}_{i}, \boldsymbol{r}^{k}\right\rangle\right|$.
- $\beta_{1}^{k}:=\max _{i \in T \backslash T^{k}}\left|\left\langle\phi_{i}, \boldsymbol{r}^{k}\right\rangle\right|$.

Clearly, $S^{k+1} \cap T \backslash T^{k} \neq \emptyset$, if $\beta_{1}^{k}>\alpha_{N}^{k}$. It is easy to see that

$$
\alpha_{N}^{k} \leq \frac{\left\|\boldsymbol{\Phi}_{W^{k+1}}^{t} \boldsymbol{r}^{k}\right\|_{2}}{\sqrt{N}}=\frac{\left\|\boldsymbol{\Phi}_{W^{k+1} \backslash T^{k}}^{t} \boldsymbol{r}^{k}\right\|_{2}}{\sqrt{N}}
$$

since $\boldsymbol{r}^{k}$ is orthogonal to the columns of $\boldsymbol{\Phi}_{T^{k}}$. Now, using the derivation of [9, Eq.(9)], it is straightforward to derive that

$$
\begin{equation*}
\boldsymbol{r}^{k}=\boldsymbol{\Phi}_{T \cup T^{k}} \boldsymbol{x}_{T \cup T^{k}}^{\prime}+\mathbf{P}_{T^{k}}^{\perp} \boldsymbol{e} \tag{15}
\end{equation*}
$$

where we have expressed the projection $\mathbf{P}_{T^{k}} \boldsymbol{\Phi}_{T \backslash T^{k}} \boldsymbol{x}_{T \backslash T^{k}}$ as a linear combination of the columns of $\boldsymbol{\Phi}_{T^{k}}$, i.e., as $\boldsymbol{\Phi}_{T^{k}} \boldsymbol{u}_{T^{k}}$ for some $\boldsymbol{u}_{T^{k}} \in \mathbb{R}^{L k}$, and,

$$
\boldsymbol{x}_{T \cup T^{k}}^{\prime}=\left[\begin{array}{c}
\boldsymbol{x}_{T \backslash T^{k}} \\
-\boldsymbol{u}_{T^{k}}
\end{array}\right]
$$

Then, using the expression for $\boldsymbol{r}^{k}$ from Eq. (15) and using steps similar to the analysis for [14, Eq.(26)], it follows that

$$
\begin{equation*}
\alpha_{N}^{k} \leq \frac{1}{\sqrt{N}}\left(\delta_{N+L k+K-c_{k}}\left\|\boldsymbol{x}_{T \cup T^{k}}^{\prime}\right\|_{2}+\sqrt{1+\delta_{N}}\|\boldsymbol{e}\|_{2}\right) \tag{16}
\end{equation*}
$$

On the other hand,

$$
\beta_{1}^{k} \geq \frac{1}{\sqrt{K-c_{k}}}\left\|\boldsymbol{\Phi}_{T \backslash T^{k}}^{t} \boldsymbol{r}^{k}\right\|_{2}
$$

Again, using the expression for $\boldsymbol{r}^{k}$ from Eq. (15) and steps similar to the analysis for [14, Eq.(25)] it follows that,

$$
\begin{equation*}
\beta_{1}^{k} \geq \frac{\left(1-\delta_{L k+K-c_{k}}\right)\left\|\boldsymbol{x}_{T \cup T^{k}}^{\prime}\right\|_{2}-\sqrt{1+\delta_{L k+K-c_{k}}}\|\boldsymbol{e}\|_{2}}{\sqrt{K-c_{k}}} \tag{17}
\end{equation*}
$$

Then, from (16) and (17), it follows that $S^{k+1} \cap T \neq \emptyset$ if

$$
\begin{equation*}
\frac{\left(\left(1-\delta_{L K-L+1}\right)\left\|\boldsymbol{x}_{T \cup T^{k}}^{\prime}\right\|_{2}-\sqrt{1+\delta_{L K-L+1}}\|\boldsymbol{e}\|_{2}\right)}{\sqrt{K-c_{k}}}>\frac{\left(\delta_{N+L K-L+1}\left\|\boldsymbol{x}_{T \cup T^{k}}^{\prime}\right\|_{2}+\sqrt{1+\delta_{N}}\|\boldsymbol{e}\|_{2}\right)}{\sqrt{N}} \tag{18}
\end{equation*}
$$

where we have used the fact that $1 \leq k \leq c_{k}$ and $k \leq K-1$, implying, $L k+K-c_{k} \leq(L-1) k+K \leq(L-1)(K-1)+K=$ $L K-L+1$, and the monotonicity of the RIC.

Condition to ensure $h^{k+1} \cap T \backslash T^{k} \neq \emptyset$ : First consider the set $S^{k+1} \backslash\left(T \backslash T^{k}\right)$. If $\left|S^{k+1} \backslash\left(T \backslash T^{k}\right)\right|<L$, then the condition $h^{k+1} \cap T \backslash T^{k} \neq \emptyset$ is satisfied trivially. Therefore, we consider cases where $\left|S^{k+1} \backslash\left(T \backslash T^{k}\right)\right| \geq L$. Then, using the definition of $a_{i}, i \in S^{k+1}$ as given in Lemma 4.1 we define the following:

- $V^{k+1}=\underset{S \subset S^{k+1} \backslash\left(T \backslash T^{k}\right):|S|=L}{\arg \max } \sum_{i \in S} a_{i}$.
- $u_{1}^{k}:=\max _{i \in S^{k+1} \cap T \backslash T^{k}} a_{i} \equiv \max _{i \in S^{k+1} \cap T} a_{i}$.
- $v_{L}^{k}=\min _{i \in V^{k+1}} a_{i}$.

From Lemma 4.1, $u_{1}^{k}>v_{L}^{k}$ will ensure $h^{k+1} \cap T \backslash T^{k} \neq \emptyset$. Now,

$$
\begin{aligned}
u_{1}^{k} & =\max _{i \in S^{k+1} \cap T} a_{i}=\max _{i \in\left(S^{k+1} \cap T\right) \backslash \tilde{T}_{K}} a_{i} \\
& \geq \max _{i \in\left(S^{k+1} \cap T\right) \backslash \tilde{T}^{K}}\left|\left\langle\boldsymbol{\phi}_{i}, \boldsymbol{r}^{\boldsymbol{k}}\right\rangle\right|\left(\text { since }\left\|\mathbf{P}_{T^{k}}^{\perp} \boldsymbol{\phi}_{\boldsymbol{i}}\right\|_{2} \leq\left\|\boldsymbol{\phi}_{\boldsymbol{i}}\right\|_{2}=1\right) \\
& \geq \max _{i \in T}\left|\left\langle\boldsymbol{\phi}_{i}, \boldsymbol{r}^{\boldsymbol{k}}\right\rangle\right| \quad\left(\text { from the definition of } S^{k+1} \text { and } \tilde{T}^{K}\right) \\
& \geq \frac{\left\|\boldsymbol{\Phi}_{T \backslash T^{k}}^{t} \boldsymbol{r}^{k}\right\|_{2}}{\sqrt{K-c_{k}}}\left(\text { since }\left\langle\boldsymbol{\phi}_{i}, \boldsymbol{r}^{\boldsymbol{k}}\right\rangle=0 \text { for } i \in T^{k}\right) .
\end{aligned}
$$

Now, recalling that $\boldsymbol{r}^{k}=\boldsymbol{\Phi}_{T \cup T^{k}} \boldsymbol{x}_{T \cup T^{k}}^{\prime}+\mathbf{P}_{T^{k}}^{\perp} \boldsymbol{e}$ and using steps similar to those used for [14] Eq.(25)] we have,

$$
\begin{aligned}
\left\|\boldsymbol{\Phi}_{T \backslash T^{k}}^{t} \boldsymbol{r}^{k}\right\|_{2} & \geq\left(1-\delta_{L k+K-c_{k}}\right)\left\|\boldsymbol{x}_{T \cup T^{k}}^{\prime}\right\|_{2}-\sqrt{1+\delta_{L k+K-c_{k}}}\|\boldsymbol{e}\|_{2} \\
& \geq\left(1-\delta_{L K-L+1}\right)\left\|\boldsymbol{x}_{T \cup T^{k}}^{\prime}\right\|_{2}-\sqrt{1+\delta_{L K-L+1}}\|\boldsymbol{e}\|_{2},
\end{aligned}
$$

Thus,

$$
\begin{equation*}
u_{1}^{k} \geq \frac{1}{\sqrt{K-c_{k}}}\left[\left(1-\delta_{L K-L+1}\right)\left\|\boldsymbol{x}_{T \cup T^{k}}^{\prime}\right\|_{2}-\sqrt{1+\delta_{L K-L+1}}\|\boldsymbol{e}\|_{2}\right] . \tag{19}
\end{equation*}
$$

On the other hand

$$
\begin{align*}
v_{L}^{k} & =\min _{i \in V^{k+1}} a_{i} \\
& \leq \frac{1}{\sqrt{L}} \sqrt{\sum_{i \in V^{k+1}} a_{i}^{2}} \\
& \leq \frac{1}{\sqrt{L}} \sqrt{\sum_{i \in S^{k+1} \backslash\left(T \backslash T^{k}\right)} a_{i}^{2}}\left(\because V^{k+1} \subset S^{k+1} \backslash\left(T \backslash T^{k}\right)\right) \\
& =\frac{1}{\sqrt{L}} \sqrt{\sum_{i \in S^{k+1} \backslash T} a_{i}^{2}} \\
& \leq \frac{\frac{1}{\sqrt{L}}\left\|\boldsymbol{\Phi}_{S^{k+1} \backslash T^{t}} \boldsymbol{r}^{k}\right\|_{2}}{\min _{i \in S^{k+1} \backslash\left(T \cup \tilde{T}^{K}\right)}\left\|\mathbf{P}_{T^{k}}^{\perp} \boldsymbol{\phi}_{i}\right\|_{2}} . \tag{20}
\end{align*}
$$

Now, $\phi_{i} \forall i \in H$ can be written as $\boldsymbol{\Phi} \boldsymbol{\nu}_{i}$, where $\boldsymbol{\nu}_{i}$ is the $i$-th column of the $n \times n$ identity matrix. Then, noting that $\operatorname{supp}\left(\boldsymbol{\nu}_{i}\right)=\{i\}$ with $|\{i\}|=1$, for $i \in S^{k+1} \backslash\left(T \cup \tilde{T}^{K}\right)$,

$$
\begin{align*}
& \left\|\mathbf{P}_{T^{k}}^{\perp} \boldsymbol{\phi}_{i}\right\|_{2}^{2}=\left\|\boldsymbol{A}_{T^{k}} \boldsymbol{\nu}_{i}\right\|_{2}^{2} \\
& \stackrel{\text { Lemma }}{\geq} \sqrt{3.5}\left(1-\left(\frac{\delta_{L k+1}}{1-\delta_{L k+1}}\right)^{2}\right)\left\|\boldsymbol{\phi}_{i}\right\|_{2}^{2} \\
& \geq\left(1-\left(\frac{\delta_{L K-L+1}}{1-\delta_{L K-L+1}}\right)^{2}\right), \tag{21}
\end{align*}
$$

since, $\left\|\phi_{i}\right\|_{2}=1$ and $k \leq K-1$ (note that application of Lemma 3.5 requires $\delta_{1}<1$, which is trivially satisfied by the proposed sufficient condition (1). Also, using the expression for $\boldsymbol{r}^{k}$ from Eq. (15) and using steps similar to the ones used to obtain [14, Eq.(26)], we obtain

$$
\begin{aligned}
\left\|\boldsymbol{\Phi}_{S^{k+1} \backslash T}^{t} \boldsymbol{r}^{k}\right\|_{2} & \leq \delta_{L k+K+N-m_{k+1}-c_{k}}\left\|\boldsymbol{x}_{T \cup T^{k}}^{\prime}\right\|_{2}+\sqrt{1+\delta_{N-m_{k+1}}}\|\boldsymbol{e}\|_{2} \\
& \leq \delta_{N+L K-L+1}\left\|\boldsymbol{x}_{T \cup T^{k}}^{\prime}\right\|_{2}+\sqrt{1+\delta_{N+L K-L+1}}\|\boldsymbol{e}\|_{2},
\end{aligned}
$$

Then, noting that $\delta_{L K-L+1}<\delta_{L K+N-L+1}$,

$$
\begin{equation*}
v_{L}^{k}<\frac{\delta_{L K+N-L+1}\left\|\boldsymbol{x}_{T \cup T^{k}}^{\prime}\right\|_{2}+\sqrt{1+\delta_{L K+N-L+1}}\|\boldsymbol{e}\|_{2}}{\sqrt{L\left(1-\left(\frac{\delta_{L K+N-L+1}}{1-\delta_{L K+N-L+1}}\right)^{2}\right)}} . \tag{22}
\end{equation*}
$$

In order to ensure that the denominator of the RHS of above remains real, we need $\delta_{L K+N-L+1}<1 / 2$. This is seen to be satisfied trivially by the proposed sufficient condition (11). For brevity, let us also denote $L K+N-L+1$ by $R$.

From Eq. (19), and Eq. (22), a sufficient condition to ensure $h^{k+1} \cap T \neq \emptyset$ is given by

$$
\begin{equation*}
\frac{1}{\sqrt{K-c_{k}}}\left[\left(1-\delta_{R}\right)\left\|\boldsymbol{x}_{T \cup T^{k}}^{\prime}\right\|_{2}-\sqrt{1+\delta_{R}}\|\boldsymbol{e}\|_{2}\right] \geq \frac{\delta_{R}\left\|\boldsymbol{x}_{T \cup T^{k}}^{\prime}\right\|_{2}+\sqrt{1+\delta_{R}}\|\boldsymbol{e}\|_{2}}{\sqrt{L\left(1-\left(\frac{\delta_{R}}{1-\delta_{R}}\right)^{2}\right)}} . \tag{23}
\end{equation*}
$$

Thus, from Eq (18) and Eq (23), a sufficient condition for success at the $(k+1)^{\text {th }}$ iteration will be as follows :

$$
\begin{align*}
\frac{1}{\sqrt{K-c_{k}}}\left[\left(1-\delta_{R}\right)\left\|\boldsymbol{x}_{T \cup T^{k}}^{\prime}\right\|_{2}-\sqrt{1+\delta_{R}}\|\boldsymbol{e}\|_{2}\right] & \geq \max \left\{\frac{1}{\sqrt{N}}, \frac{1}{\sqrt{L\left(1-\left(\frac{\delta_{R}}{1-\delta_{R}}\right)^{2}\right)}}\right\} \\
& \times\left(\delta_{R}\left\|\boldsymbol{x}_{T \cup T^{k}}^{\prime}\right\|_{2}+\sqrt{1+\delta_{R}}\|\boldsymbol{e}\|_{2}\right) \tag{24}
\end{align*}
$$

Since $L\left(1-\left(\frac{\delta_{R}}{1-\delta_{R}}\right)^{2}\right)<L \leq N$, the above sufficient condition for success at the $k+1$-th step boils down to the following

$$
\begin{equation*}
\frac{1}{\sqrt{K-c_{k}}}\left[\left(1-\delta_{R}\right)\left\|\boldsymbol{x}_{T \cup T^{k}}^{\prime}\right\|_{2}-\sqrt{1+\delta_{R}}\|\boldsymbol{e}\|_{2}\right] \geq \frac{\delta_{R}\left\|\boldsymbol{x}_{T \cup T^{k}}^{\prime}\right\|_{2}+\sqrt{1+\delta_{R}}\|\boldsymbol{e}\|_{2}}{\sqrt{L\left(1-\left(\frac{\delta_{R}}{1-\delta_{R}}\right)^{2}\right)}} \tag{25}
\end{equation*}
$$

We now derive sufficient conditions for success at $k^{\text {th }}$ step, $(k \geq 2)$, in the noiseless and noisy measurement scenarios.

- For the noiseless case, putting $e=0$ in both sides of the inequality in Eq (25), we obtain a sufficient condition for success in the noiseless case as:

$$
\frac{1}{\sqrt{K-c_{k}}}\left(1-\delta_{R}\right) \geq \frac{\delta_{R}}{\sqrt{L\left(1-\left(\frac{\delta_{R}}{1-\delta_{R}}\right)^{2}\right)}}
$$

Using $\gamma:=\frac{\delta_{R}}{1-\delta_{R}}$, the above condition is seen to be satisfied if the following holds:

$$
\begin{align*}
\sqrt{L\left(1-\gamma^{2}\right)} & >\gamma \sqrt{K-c_{k}} \\
\Leftrightarrow \gamma & <\sqrt{\frac{L}{L+K-c_{k}}} \\
\Leftrightarrow \delta_{L K+N-L+1} & <\frac{\sqrt{L}}{\sqrt{L}+\sqrt{L+K-c_{k}}} . \tag{26}
\end{align*}
$$

The above condition is ensured for all $k \geq 2$, if the following condition is satisfied,

$$
\begin{equation*}
\delta_{L K+N-L+1}<\frac{\sqrt{L}}{\sqrt{L}+\sqrt{L+K}}(<1 / 2) \tag{27}
\end{equation*}
$$

- For the noisy case, Eq. (25) is satisfied if the following is satisfied:

$$
\begin{equation*}
\frac{\left\|\boldsymbol{x}_{T \cup T^{k}}^{\prime}\right\|_{2}}{\|\boldsymbol{e}\|_{2}} \geq \frac{\sqrt{(1+\gamma)(1+2 \gamma)}\left(\sqrt{K-c_{k}}+\sqrt{L\left(1-\gamma^{2}\right)}\right)}{\sqrt{L\left(1-\gamma^{2}\right)}-\gamma \sqrt{K-c_{k}}} \tag{28}
\end{equation*}
$$

with the condition in Eq. (26) assumed to hold. The above lower bound can be simplified further by noting that

$$
\begin{aligned}
& \text { RHS of }(24)< \\
& \sqrt{(1+\gamma)(1+2 \gamma)} \frac{\sqrt{K}+\sqrt{L\left(1-\gamma^{2}\right)}}{\sqrt{L\left(1-\gamma^{2}\right)}-\gamma \sqrt{K}} \\
& =\sqrt{\frac{1}{1-\delta_{R}} \cdot \frac{1+\delta_{R}}{1-\delta_{R}} \cdot \frac{\sqrt{K\left(1-\delta_{R}\right)+\sqrt{L\left(1-2 \delta_{R}\right)}}}{1-\delta_{R}}} \frac{\sqrt{L\left(1-2 \delta_{R}\right)}-\delta_{R} \sqrt{K}}{1-\delta_{R}} \\
& =\frac{\sqrt{1+\delta_{R}}}{1-\delta_{R}} \frac{\sqrt{K}\left(1-\delta_{R}\right)+\sqrt{L\left(1-2 \delta_{R}\right)}}{\sqrt{L\left(1-2 \delta_{R}\right)}-\delta_{R} \sqrt{K}} \\
& <\frac{\sqrt{1+\delta_{R}}(\sqrt{K}+\sqrt{L})}{\sqrt{L\left(1-2 \delta_{R}\right)}-\delta_{R} \sqrt{K}},
\end{aligned}
$$

since $\sqrt{L\left(1-2 \delta_{R}\right)}<\sqrt{L}\left(1-\delta_{R}\right)$. Thus, a modified condition for success at the $(k+1)^{t h}$ iteration which also implies (28) is given by

$$
\begin{equation*}
\frac{\left\|\boldsymbol{x}_{T \cup T^{k}}^{\prime}\right\|_{2}}{\|\boldsymbol{e}\|_{2}}>\frac{\sqrt{1+\delta_{R}}(\sqrt{K}+\sqrt{L})}{\sqrt{L\left(1-2 \delta_{R}\right)}-\delta_{R} \sqrt{K}} \tag{29}
\end{equation*}
$$

Next, from the definition of $\kappa$ (section IV),

$$
\begin{aligned}
\left\|\boldsymbol{x}_{T \cup T^{k}}^{\prime}\right\|_{2} & \geq\left\|\boldsymbol{x}_{T \backslash T^{k}}\right\|_{2} \geq\left|T \backslash T^{k}\right| \min _{j \in T}\left|x_{j}\right| \\
& =\|\boldsymbol{x}\|_{2} \cdot \kappa \cdot \sqrt{\frac{K-c_{k}}{K}}>\frac{\|\boldsymbol{x}\|_{2} \cdot \kappa}{\sqrt{K}}
\end{aligned}
$$

since $\min _{j \in T \backslash T^{k}}\left|x_{j}\right| \geq \min _{j \in T}\left|x_{j}\right|$ and $c_{k}<K$. Combining with Eq. 29, we obtain a sufficient condition for successful recovery at the $k$-th step, $k \geq 2$ in the noisy measurement scenario as

$$
\begin{equation*}
\frac{\|\boldsymbol{x}\|_{2}}{\|\boldsymbol{e}\|_{2}}>\frac{\sqrt{1+\delta_{R}}(\sqrt{K}+\sqrt{L}) \sqrt{K}}{\kappa\left(\sqrt{L\left(1-2 \delta_{R}\right)}-\delta_{R} \sqrt{K}\right)} \tag{30}
\end{equation*}
$$

along with the condition in Eq (27).
3) Condition for overall success: The condition for overall success is obtained by combining the conditions for success for $k=1$ and for $k \geq 2$, and is given below.

- For the noiseless scenario, a sufficient condition for overall success has to comply with both the conditions in Eq (13) and Eq (27). Since $R-(N+K)=(L-1)(K-1) \geq 0$, as both $L, K$ are positive integers, we see that the condition in Eq (27) implies the condition in Eq (13). Thus the condition in Eq (27) serves as a sufficient condition for overall success in noiseless scenario. This proves Theorem 4.1
- For the noisy case, the conditions given by (14) and (30), along with the conditions given by (13), and (27) are sufficient. Of these, we have already seen that (27) implies (13). On the other hand, it is easy to check that the numerator of the RHS of (30) is larger than that of the RHS of (14). Further,

$$
\left(1-2 \delta_{L K+N-L+1}\right)-\left(1-\delta_{N+K}\right)^{2}=-\delta_{N+K}^{2}+2\left(\delta_{N+K}-\delta_{N+L K-L+1}\right)<0
$$

which implies that the denominator of the RHS of (30) is smaller than that of the RHS of (14). Moreover, by definition, $\kappa<1$. The overall implication of these is that the condition in (30) implies the condition in (14). Finally, noting that $\|\boldsymbol{\Phi} \boldsymbol{x}\|_{2} \leq \sqrt{1+\delta_{K}}\|\boldsymbol{x}\|_{2}<\sqrt{1+\delta_{L K+N-L+1}}\|\boldsymbol{x}\|_{2}$, the condition stated in Theorem (4.2), along with the condition in Theorem (4.1) are sufficient for overall successful recovery. This proves Theorem 4.2.
Proof. Let $N \leq K$. Then, according to the definition of $S^{1}$ (with $\boldsymbol{r}^{0}$ given by $\boldsymbol{y}$ ), we have for all $\Lambda \subset T$ such that $|\Lambda|=N$,

$$
\left\|\boldsymbol{\Phi}_{S^{1}}^{t} \boldsymbol{y}\right\|_{2}^{2} \geq\left\|\boldsymbol{\Phi}_{\Lambda}^{t} \boldsymbol{y}\right\|_{2}^{2}
$$

Since there are $\binom{K}{N}$ such subsets of $T$, labelled, $\Lambda_{i}, 1 \leq i \leq\binom{ K}{N}$, we have

$$
\begin{equation*}
\binom{K}{N}\left\|\boldsymbol{\Phi}_{S^{1}}^{t} \boldsymbol{y}\right\|_{2}^{2} \geq \sum_{i=1}^{\binom{K}{N}}\left\|\boldsymbol{\Phi}_{\Lambda_{i}}^{t} \boldsymbol{y}\right\|_{2}^{2} \tag{31}
\end{equation*}
$$

Now, take any $j \in T$, and note that it appears in one of the $\Lambda_{i}$ 's in exactly $\binom{K-1}{N-1}$ different ways. Thus, from the summation in Eq. (31), we find,

$$
\begin{gathered}
\binom{K}{N}\left\|\boldsymbol{\Phi}_{S^{1}}^{t} \boldsymbol{y}\right\|_{2}^{2} \geq\binom{ K-1}{N-1}\left\|\boldsymbol{\Phi}_{T}^{t} \boldsymbol{y}\right\|_{2}^{2} \\
\Longrightarrow\left\|\boldsymbol{\Phi}_{S^{1}}^{t} \boldsymbol{y}\right\|_{2}^{2} \geq \frac{N}{K}\left\|\boldsymbol{\Phi}_{T}^{t} \boldsymbol{y}\right\|_{2}^{2}
\end{gathered}
$$

from which Eq. (6) follows.
Now, let $N>K$. Then, we can take any subset $\Sigma \subset\{1,2, \cdots, n\}$, such that $|\Sigma|=N$ and $T \subset \Sigma$. Then, from definition, $\left\|\boldsymbol{\Phi}_{S^{1}}^{t} \boldsymbol{y}\right\|_{2}^{2} \geq\left\|\boldsymbol{\Phi}_{\Sigma}^{t} \boldsymbol{y}\right\|_{2}^{2} \geq\left\|\boldsymbol{\Phi}_{T}^{t} \boldsymbol{y}\right\|_{2}^{2}$ from which Eq. (7) follows.
To prove Eq. (8), first note that $\boldsymbol{T}^{\mathbf{0}}=\emptyset$ and thus, $\mathbf{P}_{T^{0} \cup\{i\}}^{\perp} \boldsymbol{y}=\mathbf{P}_{\{i\}}^{\perp} \boldsymbol{y}=\boldsymbol{y}-\frac{\left\langle\boldsymbol{y}, \phi_{i}\right\rangle}{\left\|\phi_{i}\right\|_{2}^{2}} \boldsymbol{\phi}_{i}=\boldsymbol{y}-\left\langle\boldsymbol{y}, \boldsymbol{\phi}_{i}\right\rangle \boldsymbol{y}$ (since $\|\boldsymbol{\phi}\|_{2}=1$ ), which means, $\left\|\mathbf{P}_{T^{0} \cup\{i\}}^{\perp} \boldsymbol{y}\right\|_{2}^{2}=\left\langle\mathbf{P}_{T^{0} \cup\{i\}}^{\perp} \boldsymbol{y}, \boldsymbol{y}\right\rangle=\|\boldsymbol{y}\|_{2}^{2}-\left|\left\langle\boldsymbol{y}, \boldsymbol{\phi}_{i}\right\rangle\right|^{2}$. This means that $T^{1}$ consists of indices corresponding to the largest $L$ absolute values $\left|\left\langle\boldsymbol{\phi}_{i}, \boldsymbol{y}\right\rangle\right|^{2}$, for $i \in S^{1}$. But since $S^{1}$ consists of indices corresponding to the $N$ largest absolute values $\left|\left\langle\boldsymbol{\phi}_{i}, \boldsymbol{y}\right\rangle\right|^{2}$ with $i \in\{1,2, \cdots, n\}=: \mathcal{H}$, and since $N \geq L$, we have, $\min _{i \in T^{1}}\left|\left\langle\boldsymbol{\phi}_{i}, \boldsymbol{y}\right\rangle\right|^{2} \geq \max _{i \in \mathcal{H} \backslash T^{1}}\left|\left\langle\boldsymbol{\phi}_{i}, \boldsymbol{y}\right\rangle\right|^{2}$. Since, $L \leq K$, for each $\Gamma \subset T$, such that $|\Gamma|=L$, we have

$$
\left\|\boldsymbol{\Phi}_{T^{1}}^{t} \boldsymbol{y}\right\|_{2}^{2} \geq\left\|\boldsymbol{\Phi}_{\Gamma}^{t} \boldsymbol{y}\right\|_{2}^{2}
$$

Since there are $\binom{K}{L}$ such subsets, we can write

$$
\binom{K}{L}\left\|\boldsymbol{\Phi}_{T^{1}}^{t} \boldsymbol{y}\right\|_{2}^{2} \geq \sum_{\Gamma: \Gamma \subset T,|\Gamma|=L}\left\|\boldsymbol{\Phi}_{\Gamma}^{t} \boldsymbol{y}\right\|_{2}^{2}
$$

Now any index $i \in T$ is contained in exactly $\binom{K-1}{L-1}$ of such $L$ cardinality subsets. Hence

$$
\binom{K}{L}\left\|\boldsymbol{\Phi}_{T^{1}}^{t} \boldsymbol{y}\right\|_{2}^{2} \geq\binom{ K-1}{L-1}\left\|\boldsymbol{\Phi}_{T}^{t} \boldsymbol{y}\right\|_{2}^{2},
$$

from which Eq. (8) follows.
