An Approximation Algorithm for Maximum Internal Spanning Tree

Zhi-Zhong Chen[*]   Youta Harada[†]   Lusheng Wang[‡]

Abstract

Given a graph G, the *maximum internal spanning tree problem* (MIST for short) asks for computing a spanning tree T of G such that the number of internal vertices in T is maximized. MIST has possible applications in the design of cost-efficient communication networks and water supply networks and hence has been extensively studied in the literature. MIST is NP-hard and hence a number of polynomial-time approximation algorithms have been designed for MIST in the literature. The previously best polynomial-time approximation algorithm for MIST achieves a ratio of $\frac{3}{4}$. In this paper, we first design a simpler algorithm that achieves the same ratio and the same time complexity as the previous best. We then refine the algorithm into a new approximation algorithm that achieves a better ratio (namely, $\frac{13}{17}$) with the same time complexity. Our new algorithm explores much deeper structure of the problem than the previous best. The discovered structure may be used to design even better approximation or parameterized algorithms for the problem in the future.

Keywords: Approximation algorithms, spanning trees, path-cycle covers.

1   Introduction

The *maximum internal spanning tree problem* (MIST for short) requires the computation of a spanning tree T in a given graph G such that the number of internal vertices in T is maximized. MIST has possible applications in the design of cost-efficient communication networks [17] and water supply networks [1]. Unfortunately, MIST is clearly NP-hard because the problem of finding a Hamiltonian path in a given graph is NP-hard [5] and can be easily reduced to MIST. MIST is in fact APX-hard [9] and hence does not admit a polynomial-time approximation scheme.

Since MIST is APX-hard, it is of interest to design polynomial-time approximation algorithms for it that achieve a constant ratio as close to 1 as possible. Indeed, Prieto and Sliper [12] presented a polynomial-time approximation algorithm for MIST achieving a ratio of $\frac{1}{2}$. Their algorithm is based on local search. By slightly modifying Prieto and Sliper's algorithm, Salamon and Wiener [17] then obtained a faster (linear-time) approximation algorithm achieving the same ratio. Salamon and Wiener [17] also considered two special cases of MISP. More specifically, they [17] designed a polynomial-time approximation algorithm for the special case of MIST restricted to claw-free graphs that achieves a ratio of $\frac{2}{3}$, and also designed a polynomial-time approximation algorithm for the special case of MIST restricted to cubic graphs that achieves a ratio of $\frac{5}{6}$. Salamon [15] later proved that the approximation algorithm in [17] indeed achieves a performance ratio of $\frac{3}{r+1}$ for the special case of MIST restricted to r-regular graphs. Based on local optimization, Salamon [16]

further came up with an $O(n^4)$-time approximation algorithm for the special of MIST restricted to graphs without leaves that achieves a ratio of $\frac{4}{7}$. The algorithm in [16] was subsequently simplified and re-analyzed by Knauer and Spoerhase [7] so that it runs faster (in cubic time) and achieves a better ratio (namely, $\frac{3}{5}$) for (the general) MIST. Li $et\ al.$ [8] even went further by showing that a deeper local search than those in [7] and [16] can achieve a ratio of $\frac{2}{3}$ for MIST. Recently, Li and Zhu [9] came up with a polynomial-time approximation algorithm for MIST that achieves a ratio of $\frac{3}{4}$. Unlike the other previously known approximation algorithms for MIST, the algorithm in [9] is based on a simple but crucial observation that the maximum number of internal vertices in a spanning tree of a graph G can be bounded from above by the maximum number of edges in a triangle-free path-cycle cover of G.

In the weighted version of MIST (WMIST for short), each vertex of the given graph G has a nonnegative weight and the objective is to find a spanning tree T of G such that the total weight of internal vertices in T is maximized. Salamon [16] designed an $O(n^4)$-time approximation for WMIST that achieves a ratio of $\frac{1}{2\Delta-3}$, where Δ is the maximum degree of a vertex in the input graph. Salamon [16] also considered the special case of WMIST restricted to claw-free graphs without leaves, and designed an $O(n^4)$-time approximation algorithm for the special case that achieves a ratio of $\frac{1}{2}$. Subsequently, Knauer and Spoerhase [7] proposed a polynomial-time approximation algorithm for (the general) WMIST that achieves a ratio of $\frac{1}{3} - \epsilon$ for any constant $\epsilon > 0$.

In the parameterized version of MIST (PMIST for short), we are asked to decide whether a given graph G has a spanning tree with at least a given number k of internal vertices. PMIST and its special cases and variants have also been extensively studied in the literature [1, 2, 3, 4, 10, 11, 12, 13, 14]. The best known kernel for PMIST is of size $2k$ and it leads to the fastest known algorithm for PMIST with running time $O(4^k n^{O(1)})$ [11].

In this paper, we first give a new approximation algorithm for MIST that is simpler than the one in [9] but achieves the same approximation ratio and time complexity. In more details, the time complexity is dominated by that of computing a maximum triangle-free path-cycle cover in a graph. We then show that the algorithm can be refined into a new approximation algorithm for MIST that has the same time complexity as the algorithm in [9] but achieves a better ratio (namely, $\frac{13}{17}$). To obtain our algorithm, we use three new main ideas. The first main idea is to bound the maximum number of internal vertices in a spanning tree of a graph G by the maximum number of edges in a $special$ (rather than general) triangle-free path-cycle cover of G. Roughly speaking, we can figure out that certain vertices in G must be leaves in an optimal spanning tree of G, and hence we can require that the degrees of these vertices be at most 1 when computing a maximum triangle-free path-cycle cover $\mathcal{C}$ of G. In this sense, $\mathcal{C}$ is special and can have significantly fewer edges than a maximum (general) triangle-free path-cycle cover of G, and hence gives us a tighter upper bound. The second idea is to carefully modify $\mathcal{C}$ into a spanning tree T by local improvement. Unfortunately, we can not always guarantee that the number of internal vertices in T is at least $\frac{13}{17}$ times the number of edges in $\mathcal{C}$. Our third idea is to show that if this unfortunate case occurs, then an optimal spanning tree of G cannot have so many internal vertices. These ideas may be used to design even better approximation or parameterized algorithms for MIST in the future.

The remainder of this paper is organized as follows. Section 2 gives basic definitions that will be used in the remainder of the paper. Section 3 presents a simple approximation algorithm for MIST that achieves a ratio of $\frac{3}{4}$. The subsequent sections are devoted to refining the algorithm so that it achieves a better ratio.

2 Basic Definitions

Throughout this chapter, a graph means a simple undirected graph (i.e., it has neither parallel edges nor self-loops).

Let G be a graph. We denote the vertex set of G by $V(G)$, and denote the edge set of G by $E(G)$. For a subset U of $V(G)$, $G - U$ denotes the graph obtained from G by removing the vertices in U (together with the edges incident to them), while $G[U]$ denotes $G - (V(G) \setminus U)$. We call $G[U]$ the *subgraph of G induced by U*. For a subset F of $E(G)$, $G - F$ denotes the graph obtained from G by removing the edges in F. An edge e of G is a *bridge* of G if $G - \{e\}$ has more connected components than G, and is a *non-bridge* otherwise. A vertex v of G is a *cut-point* if $G - \{v\}$ has more connected components than G.

Let v be a vertex of G. The *neighborhood* of v in G, denoted by $N_G(v)$, is $\{u \mid \{v, u\} \in E(G)\}$. The *degree* of v in G, denoted by $d_G(v)$, is $|N_G(v)|$. If $d_G(v) = 0$, then v is an *isolated* vertex of G. If $d_G(v) \leq 1$, then v is a *leaf* of G; otherwise, v is a *non-leaf* of G. We use $L(G)$ to denote the set of leaves in G.

Let H be a subgraph of G. $N_G(H)$ denotes $\bigcup_{v \in V(H)} N_G(v) \setminus V(H)$. A *port* of H is a $u \in V(H)$ with $N_G(u) \setminus V(H) \neq \emptyset$. When H is a path, H is *dead* if neither endpoint of H is a port of H, while H is *alive* otherwise. H and another subgraph H' of G are *adjacent* in G if $V(H) \cap V(H') = \emptyset$ but $N_G(H) \cap V(H') \neq \emptyset$ (or equivalently, $N_G(H') \cap V(H) \neq \emptyset$).

A *cycle* in G is a connected subgraph of G in which each vertex is of degree 2. A *path* in G is either a single vertex of G or a connected subgraph of G in which exactly two vertices are of degree 1 and the others are of degree 2. A vertex v of a path P in G is an *endpoint* of P if $d_P(v) \leq 1$, and is an *internal vertex* of P if $d_P(v) = 2$. The *length* of a cycle or path C is the number of edges in C and is denoted by $|C|$. A *k-cycle* is a cycle of length k, while a *k-path* is a path of length k. A *tree* (respectively, *cycle*) *component* of G is a connected component of G that is a tree (respectively, cycle). In particular, if a tree component T of G is indeed a path (respectively, k-path), then we call T a *path* (respectively, *k-path*) *component* of G.

A *tree-cycle cover* (TCC for short) of G is a subgraph H of G such that $V(H) = V(G)$ and each connected component of H is a tree or cycle. Let H be a TCC of G. H is a *Hamiltonian path* (respectively, *cycle*) of G if H is a path (respectively, cycle), and is a *spanning tree* of G if H is a tree. H is a *path-cycle cover* (PCC for short) of G if each tree component of H is a path. H is a *path cover* of G if H has only path components. A *triangle-free* TCC (TFTCC for short) of G is a TCC without 3-cycles. Similarly, a *triangle-free* PCC (TFPCC for short) of G is a PCC without 3-cycles. A TFPCC of G is *maximum* if its number of edges is maximized over all TFPCCs of G. For convenience, let $t(n, m)$ denote the time complexity of computing a maximum TFPCC in a graph with n vertices and m edges. It is known that $t(n, m) = O(n^2 m^2)$ [6].

Suppose that G is connected. The *weight* of a spanning tree T of G, denoted by $w(T)$, is the number of non-leaves in T. We use $opt(G)$ to denote the maximum weight of a spanning tree of G. An *optimal spanning tree* (OST for short) of G is a spanning tree T of G with $w(T) = opt(G)$.

3 A Simple 0.75-Approximation Algorithm

Throughout the remainder of this paper, G means a connected graph for which we want to find an OST. Moreover, T denotes an OST of G. For convenience, let $n = |V(G)|$ and $m = |E(G)|$.

3.1 Reduction Rules

We want to make G smaller (say, by deleting one or more vertices or edges from G) without decreasing $opt(G)$. For this purpose, we define two *strongly safe* operations on G below. Here, an operation on G is *strongly safe* if performing it on G does not change $opt(G)$.

Operation 1. If $|V(G)| > 3$ and $E(G)$ contains two edges $\{u_1, v\}$ and $\{u_2, v\}$ such that both u_1 and u_2 are leaves of G, then delete u_2.

Operation 2. If for a non-bridge $e = \{u_1, u_2\}$ of G, $G - \{u_i\}$ has a connected component K_i with $u_{3-i} \notin V(K_i)$ for each $i \in \{1, 2\}$, then delete e. (*Comment:* When $|V(K_1)| = |V(K_2)| = 1$, Li and Zhu [9] showed that Operation 2 is strongly safe.)

Figure 1: Operations 1 through 4, where the wavy curve is a path and each dotted edge and the vertex enclosed by a dotted circle will be deleted.

Lemma 3.1 [9] *Operation 1 is strongly safe.*

Lemma 3.2 *Operation 2 is strongly safe.*

PROOF. If $e \notin E(T)$, we are done. So, assume that $e \in E(T)$. Obviously, at least one vertex v_1 of K_1 is adjacent to u_1 in T because T is connected. So, $\{u_2, v_1\} \subseteq N_T(u_1)$. Similarly, $\{u_1, v_2\} \subseteq N_T(u_2)$ for some vertex v_2 of K_2. Moreover, since e is a non-bridge of G, $G - \{u_1, u_2\}$ has a connected component K_3 (other than K_1 and K_2) with $\{u_1, u_2\} \subseteq N_G(K_3)$. Since T is connected, u_1 or u_2 is adjacent to a vertex v_3 of K_3 in T. We assume that $v_3 \in N_T(u_1)$; the other case is similar. Then, after deleting e from T, only u_2 may become a new leaf. If u_2 becomes a leaf in $T - \{e\}$, then all vertices of K_3 must belong to the component tree of $T - \{e\}$ containing u_1 and hence adding an arbitrary edge $\{u_2, v_4\}$ of G with $v_4 \in V(K_3)$ to $T - \{e\}$ yields a new OST of G. So, we may assume that u_2 does not become a leaf in $T - \{e\}$. Then, since e is a non-bridge of G, G must have an edge $\{x_1, x_2\}$ such that for each $i \in \{1, 2\}$, x_i belongs to the component tree of $T - \{e\}$ containing u_i. Now, adding the edge $\{x_1, x_2\}$ to $T - \{e\}$ yields a new OST of G. □

An operation on G is *weakly safe* if performing it on G yields one or more graphs $G_1, \ldots, G_k$ such that (1) $|V(G)| \geq \sum_{i=1}^{k} |V(G_i)|$, $|E(G)| \geq \sum_{i=1}^{k} |E(G_i)|$, and $|V(G)| + |E(G)| > \sum_{i=1}^{k} |V(G_i)| + \sum_{i=1}^{k} |E(G_i)|$, (2) $opt(G) \leq \sum_{i=1}^{k} opt(G_i) + c$ for some nonnegative integer c, and (3) given a spanning tree T_i for each G_i, a spanning tree T of G with $w(T) \geq \sum_{i=1}^{k} w(T_i) + c$ can be computed in linear time. Note that the last two conditions in the definition imply that $opt(G) = \sum_{i=1}^{k} opt(G_i) + c$.

Operation 3. If G has a bridge $e = \{u_1, u_2\}$ such that for each $i \in \{1, 2\}$, u_i is a cut-point in the connected component G_i of $G - e$ with $u_i \in V(G_i)$, then obtain G_1 and G_2 as the connected components of $G - e$.

Operation 4. If G has a cut-point v such that one connected component K of $G - \{v\}$ has at least two but at most 8 vertices, then obtain G_1 from $G - V(K)$ by adding a new vertex u and a new edge $\{v, u\}$.

The number 8 in the definition of Operation 4 is not essential. It can be chosen at one's discretion as long as it is a constant. We here choose the number 8, because it will be the smallest number for the proofs of several lemmas in this paper to go through.

Lemma 3.3 *Operation 3 is weakly safe.*

PROOF. First, we want to show that $opt(G) \leq opt(G_1) + opt(G_2)$. Consider an $i \in \{1, 2\}$. Since u_i is a cut-point in G_i, $d_T(u_i) \geq 3$. Thus, the degree of u_i in $T - \{e\}$ is at least 2. So, one component tree of $T - \{e\}$ is a spanning tree of G_1, the other is a spanning tree of G_2, and their total weights equals $w(T)$. Thus, $opt(G) \leq opt(G_1) + opt(G_2)$.

Next, suppose that for each $i \in \{1, 2\}$, T_i is a spanning tree of G_i. Since u_i is a cut-point in G_i, $d_{T_i}(u_i) \geq 2$. So, using e to connect T_1 and T_2 into a single tree yields a spanning tree of G whose weight is $w(T_1) + w(T_2)$. □

Lemma 3.4 *Operation 4 is weakly safe.*

PROOF. Let K' be the graph obtained from $G[V(K) \cup \{v\}]$ by adding a new vertex u' and a new edge $\{u', v\}$. Let $c = opt(K') - 1$.

First, we want to show that $opt(G) \leq opt(G_1) + c$. Since v is a cut-point of G, $d_T(v) \geq 2$. Let T_1 be the spanning tree of G_1 obtained from $T - V(K)$ by adding u and the edge $\{v, u\}$. Further let T' be the spanning tree of K' obtained from $T[\{v\} \cup V(K)]$ by adding u' and edge $\{u', v\}$. Clearly, $w(T) = w(T_1) + w(T') - 1 \leq opt(G_1) + c$. Thus, $opt(G) \leq opt(G_1) + c$.

Next, suppose that T_1 is a spanning tree of G_1. Let T' be an OST of K'. We can obtain a spanning tree $\tilde{T}$ of G from T_1 by first deleting u, next adding $T'[V(K)]$, and further adding new edges to connect v to those vertices of $V(K)$ that are adjacent to v in T'. Obviously, $u \in L(T_1)$, $u' \in L(T')$, $v \notin L(T_1)$, $v \notin L(T')$, the degree of each vertex x of T_1 other than v and u in $\tilde{T}$ is $d_{T_1}(x)$, and the degree of each vertex y of T' other than v and u' in $\tilde{T}$ is $d_{T'}(y)$. Thus, $w(\tilde{T}) = w(T_1) + w(T') - 1 = w(T_1) + c$. □

An operation on G is *safe* if it is strongly or weakly safe on G.

3.2 The Algorithm

As in [9], the algorithm is based on a lemma which says that G has a path cover $\mathcal{P}$ such that $opt(G)$ is bounded from above by the number of edges in $\mathcal{P}$. We next state the lemma in a stronger form and give an extremely simple proof.

Lemma 3.5 *Given a spanning tree $\tilde{T}$ of G, we can construct a path cover $\mathcal{P}$ of G such that $|E(\mathcal{P})| \geq w(\tilde{T})$ and $d_{\mathcal{P}}(v) \leq 1$ for each leaf v of $\tilde{T}$.*

PROOF. We simply construct $\mathcal{P}$ from $\tilde{T}$ by first rooting $\tilde{T}$ at an arbitrary non-leaf and then for each non-leaf u of $\tilde{T}$, deleting all but one edge between u and its children. □

Now, the outline of the algorithm is as follows.

1. Whenever there is an $i \in \{1, 2\}$ such that Operation i can be performed on G, then perform Operation i on G.

2. Whenever there is an $i \in \{3, 4\}$ such that Operation i can be performed on G, then perform the following steps:

(a) Perform Operation i on G. Let $G_1, \ldots, G_k$ be the resulting graphs.

(b) For each $j \in \{1, \ldots, k\}$, compute a spanning tree T_j of G_j recursively.

(c) Combine $T_1, \ldots, T_k$ into a spanning tree $\tilde{T}$ of G such that $w(\tilde{T}) \geq \sum_{i=1}^{k} w(T_i) + c$.

(d) Return $\tilde{T}$.

3. If $|V(G)| \leq 8$, then compute and return an OST of G in $O(1)$ time.

4. Compute a maximum TFPCC $\mathcal{C}$ of G. (*Comment:* By Lemma 3.5, $opt(G) \leq |E(\mathcal{C})|$.)

5. Perform a preprocessing on $\mathcal{C}$ without decreasing $|E(\mathcal{C})|$.

6. Transform $\mathcal{C}$ into a spanning tree $\tilde{T}$ of G such that $w(\tilde{T}) \geq \frac{3}{4}|E(\mathcal{C})|$.

7. Return $\tilde{T}$.

Only Steps 5 and 6 are unclear. So, we detail them below. First, Step 5 is done by performing the next three operations until none of them is applicable.

Operation 5. If $\mathcal{C}$ has a dead path component P such that $2 \leq |P| \leq 4$ and $G[V(P)]$ has an alive Hamiltonian path Q, then replace P by Q.

Operation 6. If an endpoint u of a path component P of $\mathcal{C}$ is adjacent to a vertex v of a cycle C of $\mathcal{C}$ in G, then combine P and C into a single path by replacing one edge incident to v in C with the edge $\{u, v\}$.

Operation 7. If an endpoint u_1 of a path component P_1 of $\mathcal{C}$ is adjacent to an internal vertex u_2 of another path component P_2 in G such that one edge e' incident to u_2 in P_2 satisfies that combining P_1 and P_2 by replacing e' with the edge $\{u_1, u_2\}$ yields two paths Q_1 and Q_2 with $\max\{|Q_1|, |Q_2|\} > \max\{|P_1|, |P_2|\}$, then replace P_1 and P_2 by Q_1 and Q_2. (*Comment:* For each $i \in \{5, 6, 7\}$, Operation i does not change the maximality of $\mathcal{C}$. So, due to the maximality of $\mathcal{C}$, no endpoint of a path component P_1 of $\mathcal{C}$ is adjacent to an endpoint of another path component P_2 in G.)

Figure 2: The possible cases of Operation 5, where each filled circle is a port, each dotted edge will be deleted, and each bold edge will be added.

Lemma 3.6 *Immediately after Step 5, the following statements hold:*

1. $\mathcal{C}$ is a maximum TFPCC of G and hence has at least $opt(G)$ edges.

2. If a path component P of $\mathcal{C}$ is of length at most 3, then P is alive.
Figure 3: Operations 6 and 7, where each wavy line or curve is a path, each dotted edge will be deleted, and each bold edge will be added.

   3. If an endpoint v of a path component P of $\mathcal{C}$ is a port of P, then each vertex in $N_G(v) \setminus V(P)$ is an internal vertex of a path component Q of $\mathcal{C}$ with $|Q| \geq 2|P| + 2$.

PROOF. We prove the statements separately as follows.

   Statement 1: Immediately before Step 5, $\mathcal{C}$ has is a maximum TFPCC of G. Since Operations 5 through 7 keep $\mathcal{C}$ being a TFPCC without changing the number of edges in $\mathcal{C}$, Statement 1 holds.

   Statement 2: Let P be a path component of $\mathcal{C}$ with $|P| \leq 3$. If $|P| \leq 1$, then P is alive because otherwise G would be disconnected. So, $|P| = 2$ or 3. Let u_1 and u_2 be the endpoints of P. For a contradiction, assume that P is dead. Then, since G is connected, P has at least one internal vertex x adjacent to a vertex $x' \in V(G) \setminus V(P)$ in G. If $\{u_1, u_2\} \in E(G)$, then $G[V(P)]$ has a Hamiltonian path Q in which x is an endpoint, contradicting the fact that Operation 5 cannot be performed on $\mathcal{C}$. So, we assume that $\{u_1, u_2\} \notin E(G)$. Now, if $|P| = 2$, then Operation 1 can be performed on G, a contradiction. Thus, we further assume that $|P| = 3$. Then, since Operation 4 cannot be performed on G, the other internal vertex y (than x) of P is adjacent to a vertex $y' \in V(G) \setminus V(P)$ in G. Now, if $G[V(P)]$ is not P itself, then Operation 5 can be performed on $\mathcal{C}$, a contradiction; otherwise, Operation 2 or 3 can be performed on G, a contradiction. Note that it does not matter whether $x' = y'$ or not.

   Statement 3: Suppose that an endpoint v of a path component P of $\mathcal{C}$ is a port. Consider an arbitrary $u \in N_G(v) \setminus V(P)$. Since Operation 6 is not applicable on $\mathcal{C}$, u appears in a path component Q of $\mathcal{C}$. Then, by the comment on Operation 7, u is an internal vertex of Q. Let u_1 and u_2 be the endpoints of Q. For each $i \in \{1, 2\}$, let Q_i be the path from u to u_i in P. Then, $|Q| = |Q_1| + |Q_2|$. Moreover, since Operation 7 cannot be applied on $\mathcal{C}$, $|P| + |Q_i| + 1 \leq |Q|$ for each $i \in \{1, 2\}$. Thus, $2|P| + 2 \leq |Q|$.   □

   We next detail Step 6. First, for each path component P of $\mathcal{C}$ with $1 \leq |P| \leq 3$, we select one edge $e_P \in E(G)$ connecting an endpoint of P to a vertex not in P, and add e_P to an initially empty set M. Such e_P exists by Statement 2 in Lemma 3.6. Moreover, by Statement 3 in Lemma 3.6, the endpoint of e_P not in P appears in a path component Q of $\mathcal{C}$ with $|Q| \geq 4$. So, for two path components P_1 and P_2 in $\mathcal{C}$, $e_{P_1} \neq e_{P_2}$. Consider the graph H obtained from $\mathcal{C}$ by adding the edges in M. Each connected component of H is a cycle of length at least 4 or a tree. Suppose that we modify H by performing the following three steps in turn:

- Whenever H has two cycles C_1 and C_2 such that some edge $e = \{u_1, u_2\} \in E(G)$ satisfies $u_1 \in V(C_1)$ and $u_2 \in V(C_2)$, delete one edge of C_1 incident to u_1 from H, delete one edge of C_2 incident to u_2 from H, and add e to H.

- Whenever H has a cycle C, choose an edge $e = \{u, v\} \in E(G)$ with $u \in V(C)$ and $v \notin V(C)$, delete one edge of C incident to u from H, and add e to H.

- Whenever H has two connected components C_1 and C_2 such that some edge $e = \{u_1, u_2\} \in E(G)$ satisfies $u_1 \in V(C_1)$ and $u_2 \in V(C_2)$, add e to H.

7

Step 6 is done by obtaining $\tilde{T}$ as the final modified H. Obviously, for each cycle C of $\mathcal{C}$, at least $|C| - 1 \geq \frac{3}{4}|C|$ vertices of C are internal vertices of $\tilde{T}$. Moreover, for each path component P of $\mathcal{C}$ with $|P| \geq 4$, at least $|P| - 1 \geq \frac{3}{4}|P|$ vertices of P are internal vertices of $\tilde{T}$. Furthermore, for each path component P of $\mathcal{C}$ with $1 \leq |P| \leq 3$, at least $|P|$ vertices of P are internal vertices of $\tilde{T}$. So, $\tilde{T}$ has at least $\frac{3}{4}|E(\mathcal{C})|$ internal vertices. Obviously, all steps of the algorithm excluding Steps 2b and 4 can be done in $O(|E(G)|^2)$ time. Now, we have the following theorem:

Theorem 3.7 *The algorithm achieves an approximation ratio of $\frac{3}{4}$ and runs in $O(m^2) + t(n, m)$ time.*

In the sequel, we consider how to improve the algorithm. The first idea is to introduce more safe reduction rules (cf. Section 4). The second idea is to compute a better upper bound on $opt(G)$ than that given by a maximum TFPCC (cf. Section 5). The third idea is to perform a more sophisticated preprocessing on $\mathcal{C}$ (cf. Section 6). The last idea is to transform $\mathcal{C}$ into a spanning tree of G more carefully (cf. Section 7).

4   More Safe Reduction Rules

In addition to the four safe reduction rules in Section 3.1, we further introduce the following rules.

Operation 8. If for four vertices u_1, ..., u_4, $N_G(u_3) = N_G(u_4) = \{u_1, u_2\}$, $G - \{u_2\}$ has a connected component K with $u_1 \notin V(K)$, then delete the edge $e = \{u_2, u_3\}$.

Operation 9. If for five vertices u_1, ..., u_5, $N_G(u_3) = N_G(u_4) = N_G(u_5) = \{u_1, u_2\}$, then delete the edge $e = \{u_2, u_3\}$.

Operation 10. If for two vertices u and v of G, $G - \{u, v\}$ has a connected component K with $|V(K)| \leq 6$ such that $V(G) \neq V(K) \cup \{u, v\}$ and $G[V(K) \cup \{u, v\}]$ has a Hamiltonian path P from u to v, then delete all edges of $G[V(K) \cup \{u, v\}]$ that do not appear in P.

Operation 11. If G has an edge $e = \{u_1, u_2\}$ with $d_G(u_1) = d_G(u_2) = 2$, then obtain G_1 from G by merging u_1 and u_2 into a single vertex $u_1 u_2$.

Figure 4: Operations 8 through 11, where the wavy line is a path and each dotted edge will be deleted.

Lemma 4.1 *Operation 8 is strongly safe.*

PROOF.   If $e \notin E(T)$, we are done. So, assume that $e \in E(T)$. Obviously, at least one vertex v of K is adjacent to u_2 in T because T is connected. So, $\{u_3, v\} \subseteq N_T(u_2)$. For each $i \in \{2, 3\}$, let T_i be the component tree of $T - \{e\}$ in which u_i appears. If $u_4 \in V(T_3)$, then u_4 is a leaf of T and hence adding the edge $\{u_2, u_4\}$ to $T - \{e\}$ clearly yields a spanning tree $\tilde{T}$ of G with $|L(\tilde{T})| = |L(T)|$. So, we assume $u_4 \in V(T_2)$. If $u_1 \in V(T_3)$, then u_4 is a leaf of T and hence adding

the edge $\{u_1, u_4\}$ to $T - \{e\}$ clearly yields a spanning tree $\tilde{T}$ of G with $|L(\tilde{T})| = |L(T)|$. Otherwise, u_3 is a leaf of T and hence adding the edge $\{u_1, u_3\}$ to $T - \{e\}$ clearly yields a spanning tree $\tilde{T}$ of G with $|L(\tilde{T})| = |L(T)|$. $\qquad\square$

Lemma 4.2 *Operation 9 is strongly safe.*

PROOF. If $e \notin E(T)$, we are done. So, assume that $e \in E(T)$. Obviously, $\{u_4, u_5\} \cap L(T) \neq \emptyset$. Moreover, if for some $i \in \{4, 5\}$, $u_i \in L(T)$ and $\{u_2, u_i\} \in E(T)$, then the proof of Lemma 4.1 shows that T can be transformed into a spanning tree $\tilde{T}$ such that $|L(\tilde{T})| \leq |L(T)|$ and $e \notin E(\tilde{T})$. Thus, we may assume that $u_5 \in L(T)$, $\{u_1, u_4\} \in E(T)$, and $\{u_1, u_5\} \in E(T)$. Obviously, either $N_T(u_3) = \{u_2\}$ or $N_T(u_3) = \{u_1, u_2\}$. In the latter case, adding the edge $\{u_2, u_5\}$ to $T - \{e\}$ clearly yields a spanning tree $\tilde{T}$ of G, and $|L(\tilde{T})| = |L(T)|$ holds for $u_5 \in L(T)$. So, we assume the former case. Let $e' = \{u_1, u_5\}$. Then, adding the edges $\{u_1, u_3\}$ and $\{u_2, u_5\}$ to $T - \{e, e'\}$ clearly yields a spanning tree $\tilde{T}$ of G with $|L(\tilde{T})| = |L(T)|$. $\qquad\square$

Lemma 4.3 *Operation 10 is strongly safe.*

PROOF. Operation 10 is clearly strongly safe if $V(G) = V(K) \cup \{u, v\}$. So, we assume that $V(G) \neq V(K) \cup \{u, v\}$. Since K is a connected component, the degree of each vertex $x \notin V(K)$ in $T - V(K)$ is $d_T(x)$ unless $x \in \{u, v\}$. Let $u \sim_T v$ be the path between u and v in T.

Let S be the set of internal vertices of $u \sim_T v$. Since K is a connected component of $G - \{u, v\}$, either $S \cap V(K) = \emptyset$ or $S \subseteq V(K)$. Obviously, we are done if $S = V(K)$. So, we assume that $S \cap V(K)$ is either empty or contains at least one but not all vertices of K. Then, $T - \{u, v\}$ has one or more component trees in which at least one vertex of K appears. Let $T_1, \ldots, T_\ell$ be such component trees. For each $i \in \{1, \ldots, \ell\}$, $V(T_i) \subseteq V(K)$ because K is a connected component of $G - \{u, v\}$. Moreover, if $V(T_i) \neq S$, then $L(T) \cap V(T_i) \neq \emptyset$. Since $V(T_i) \neq S$ for at least one $i \in \{1, \ldots, \ell\}$, $|L(T) \cap V(K)| \geq 1$. Furthermore, if $S \cap V(K) = \emptyset$, then $|L(T) \cap V(K)| \geq \ell$.

Case 1: S is a nonempty proper subset of $V(K)$. Then, modifying $T - V(K)$ by adding the edges of P yields a new spanning tree $\tilde{T}$ of G. Clearly, $L(\tilde{T}) \setminus L(T) \subseteq \{u, v\}$. Moreover, since $V(G) \neq V(K) \cup \{u, v\}$, it is impossible that $\{u, v\} \subseteq L(\tilde{T})$. So, $|L(\tilde{T}) \setminus L(T)| \leq 1$. Consequently, $|L(\tilde{T})| \leq |L(T)|$ because $|L(T) \cap V(K)| \geq 1$.

Case 2: $S \cap V(K) = \emptyset$. Then, both u and v are of degree at least 1 in $T - V(K)$. We assume that the degree of u in $T - V(K)$ is at least as large as that of v in $T - V(K)$; the other case is similar. Let y be the neighbor of u in $u \sim_T v$. It is possible that $y = v$. Obviously, modifying $T - V(K)$ by adding the edges of P and deleting the edge $\{u, y\}$ yields a new spanning tree $\tilde{T}$ of G. Clearly, $L(\tilde{T}) \setminus L(T) \subseteq \{u, y\}$. Thus, if $L(\tilde{T}) \setminus L(T) \neq \{u, y\}$, then $|L(\tilde{T})| \leq |L(T)|$ because $|L(T) \cap V(K)| \geq 1$. Moreover, if $\ell \geq 2$, then $|L(T) \cap V(K)| \geq 2$ and in turn $|L(\tilde{T})| \leq |L(T)|$. So, we may assume that $L(\tilde{T}) \setminus L(T) = \{u, y\}$ and $\ell = 1$. Then, the degree of u in $T - V(K)$ is 1 and in turn so is v. Now, since $\ell = 1$ and $u \in L(\tilde{T}) \setminus L(T)$, v is adjacent to no vertex of K in T and hence v is a leaf of T. Therefore, no matter whether $y = v$ or not, $|L(\tilde{T})| \leq |L(T)|$ because $|L(T) \cap V(K)| \geq 1$. $\qquad\square$

Lemma 4.4 *Operation 11 is weakly safe.*

PROOF. For each $i \in \{1, 2\}$, let u_i' be the vertex in $N_G(u_i) \setminus \{u_{3-i}\}$. Possibly, $u_1' = u_2'$. If $u_1' \neq u_2'$, then $N_{G_1}(u_1 u_2) = \{u_1', u_2'\}$; otherwise, $N_{G_1}(u_1 u_2) = \{u_1'\}$.

First, we want to show that $opt(G) \leq opt(G_1) + 1$. If $e \notin E(T)$, then T contains both $\{u_1', u_1\}$ and $\{u_2', u_2\}$ and we can modify T (without decreasing $|L(T)|$) by replacing the edge $\{u_2', u_2\}$ with

e. So, we can assume that $e \in E(T)$. Then, it is clear that modifying T by merging u_1 and u_2 into a single vertex u_1u_2 yields a spanning tree of G_1 whose weight is $w(T) - 1$. Thus, $opt(G) \leq opt(G_1) + 1$.

Next, suppose that T_1 is a spanning tree of G_1. If $u_1' = u_2'$, then u_1u_2 is a leaf of T_1 and its neighbor in T_1 is u_1', and hence modifying T_1 by deleting the vertex u_1u_2 and adding the two edges $\{u_1, u_2\}$, $\{u_2, u_2'\}$ yields a spanning tree of G whose weight is $w(T_1) + 1$. So, we assume that $u_1' \neq u_2'$. Clearly, at least one of $\{u_1', u_1u_2\}$ and $\{u_2', u_1u_2\}$ is an edge of T_1. If for exactly one $i \in \{1, 2\}$, $\{u_i', u_1u_2\} \in E(T_1)$, then modifying T_1 by deleting the vertex u_1u_2 and adding the two edges e, $\{u_i', u_i\}$ yields a spanning tree of G whose weight is $w(T_1) + 1$. Otherwise, modifying T_1 by deleting the vertex u_1u_2 and adding the three edges $\{u_1', u_1\}$, e, $\{u_2, u_2'\}$ yields a spanning tree of G whose weight is $w(T_1) + 1$. $\qquad \square$

Accordingly, we need to modify Step 1 of the algorithm by choosing i from $\{1, 2, 8, 9, 10\}$ and also modify Step 2 by choosing i from $\{3, 4, 11\}$. Obviously, after the modification, Steps 1 and 2 can be done in $O(n^2m)$ time.

5 Computing a Preferred TFPCC $\mathcal{C}$

In this section, we consider how to refine Step 4. Because of Steps 1 and 3, we hereafter assume that $|V(G)| \geq 9$ and there is no $i \in \{1, \ldots, 4, 8, \ldots, 11\}$ such that Operation i can be performed on G. Then, we can prove the next lemma:

Lemma 5.1 *Suppose that C is a cycle of G with $|C| \leq 8$. Let A be the set of ports of C. Then, the following statements hold.*

1. *$|A| \geq 2$.*

2. *If $|A| = 2$, then the two vertices in A are not adjacent in C and $|C| \neq 5$.*

3. *If $|A| = 2$ and $|C| = 4$, then $G[V(C)]$ and C are the same graph.*

PROOF.   We prove the statements separately as follows.

Statement 1: Since G is connected and $|C| < 9 \leq |V(G)|$, $|A| \geq 1$. Moreover, since Operation 4 cannot be performed on G, $|A| \geq 2$.

Statement 2: Suppose that $|A| = 2$. Then, the two vertices in A cannot be adjacent in C, because otherwise Operation 10 could be performed on G. For a contradiction, assume that $|C| = 5$. Suppose that u_1, $\ldots$, u_5 are the vertices of a 5-cycle of C and appear in C clockwise in this order. Since the two vertices in A are not adjacent in C, we may assume that $A = \{u_1, u_3\}$. If $\{u_2, u_4\} \in E(G)$ or $\{u_2, u_5\} \in E(G)$, then Operation 10 can be performed on G, a contradiction. So, we assume that $\{u_2, u_4\} \notin E(G)$ and $\{u_2, u_5\} \notin E(G)$. If $\{u_1, u_4\} \in E(G)$ or $\{u_3, u_5\} \in E(G)$, then Operation 10 can be performed on G, a contradiction. Thus, we may further assume that $\{u_1, u_4\} \notin E(G)$ and $\{u_3, u_5\} \notin E(G)$. Now, $\{u_4, u_5\} \in E(G)$, $d_G(u_4) = 2$, and $d_G(u_5) = 2$. Hence, Operation 11 can be performed on G, a contradiction.

Statement 3: Suppose that $|A| = 2$ and $|C| = 4$. The two vertices in A are not adjacent in C by Statement 2, and hence $G[V(C)]$ and C are the same graph because otherwise Operation 10 could be performed on G. $\qquad \square$

To refine Step 4, our idea is to compute $\mathcal{C}$ as a *preferred* TFPCC of G. Before defining what the word "preferred" means here, we need to prove a lemma. For ease of explanation, we assume, with loss of generality, that there is a linear order (denoted by $\prec$) on the vertices of G.

Lemma 5.2 *Suppose that u_1 and u_3 are two vertices of G such that $u_1 \prec u_3$ and Condition C1 below holds. Then, G has an OST in which u_1 or u_3 is a leaf. Consequently, G has an OST in which u_1 is a leaf.*

   C1. For two vertices u_2 and u_4 in $V(G) \setminus \{u_1, u_3\}$, $N_G(u_1) = N_G(u_3) = \{u_2, u_4\}$.

PROOF.   If u_1 is a leaf of T, then we are done. So, assume that u_1 is not a leaf of T. Since Condition C1 holds, u_3 is clearly a leaf of T and we can modify T (without decreasing $w(T)$) by switching u_1 and u_3 so that u_1 becomes a leaf in T.   □

If Condition C1 in Lemma 5.2 holds for u_1 and u_3, we refer to u_2 and u_4 as the *boundary points* of the pair $p = (u_1, u_3)$, and refer to the edges incident to u_1 or u_3 as the *supports* of p.

Let Π be the set of pairs (u_1, u_3) of vertices in G satisfying Condition C1. It is worth pointing out that for each $p \in \Pi$ and each boundary point u of p, $d_G(u) \geq 3$ because otherwise Operation 4 could be performed on G.

Lemma 5.3 *No two pairs in Π share a support.*

PROOF.   Obviously, for two pairs in Π to share a support, they have to share their boundary points. However, no two pairs in Π can share their boundary points, because otherwise Operation 9 could be performed on G. So, no two pairs in Π share a support.   □

Lemma 5.4 *G has an OST in which u_1 is a leaf for each $(u_1, u_3) \in \Pi$.*

PROOF.   By Lemma 5.2, we can assume that for every $p = (u_1, u_3) \in \Pi$, $d_T(u_1) \leq 1$. In a nutshell, the proof of Lemma 5.2 shows that even if T is an OST with $d_T(u_1) \geq 2$, we can modify T without decreasing $w(T)$ so that $d_T(u_1) \leq 1$. Indeed, the modification only uses the supports of p. Now, by Lemma 5.3, a similar modification can be done independently for each other $p' \in \Pi$. Therefore, the lemma holds.   □

Now, we are ready to make two definitions. Let $\mathcal{C}$ be a TFPCC of G. $\mathcal{C}$ is *special* if for every pair $(u_1, u_3) \in \Pi$, $d_{\mathcal{C}}(u_1) \leq 1$. $\mathcal{C}$ is *preferred* if $\mathcal{C}$ is special and $|E(\mathcal{C})|$ is maximized over all special TFPCCs of G.

Lemma 5.5 *If $\mathcal{C}$ is a preferred TFPCC of G, then $opt(G) \leq |E(\mathcal{C})|$.*

PROOF.   By Lemma 5.4, G has an OST $\tilde{T}$ such that for each $(u_1, u_3) \in \Pi$, $d_{\tilde{T}}(u_1) = 1$. So, by Lemma 3.5, we can construct a path cover $\mathcal{P}$ of G with $|E(\mathcal{P})| \geq w(\tilde{T})$ such that $d_{\mathcal{P}}(u_1) \leq 1$ for every $(u_1, u_3) \in \Pi$. Thus, $\mathcal{P}$ is a special TFPCC of G. Consequently, if $\mathcal{C}$ is a preferred TFPCC of G, then $opt(G) = w(\tilde{T}) \leq |E(\mathcal{P})| \leq |E(\mathcal{C})|$.   □

Lemma 5.6 *We can compute a preferred TFPCC $\mathcal{C}$ of G in $t(2n, 2m)$ time.*

PROOF.   We construct a new graph G' from G by adding a new vertex x_p and the edge $\{u_1, x_p\}$ for each pair $p = (u_1, u_3) \in \Pi$. Obviously, if $\mathcal{C}^*$ is a preferred TFPCC of G, then adding the edges $\{x_p, u_1\}$ with $p = (u_1, u_3) \in \Pi$ to $\mathcal{C}^*$ yields a TFPCC $\mathcal{C}'$ of G' with $|E(\mathcal{C}')| = |E(\mathcal{C}^*)| + |\Pi|$.

We then compute a maximum TFPCC $\mathcal{C}'$ of G' in $t(|V(G')|, |E(G')|)$ time. By the discussion in the last paragraph, $|E(\mathcal{C}')| \geq |E(\mathcal{C}^*)| + |\Pi|$. If for some $p = (u_1, u_3) \in \Pi$, $d_{\mathcal{C}'}(x_p) = 0$, then by the maximality of $\mathcal{C}'$, $d_{\mathcal{C}'}(u_1) = 2$ and we can modify $\mathcal{C}'$ by replacing one of the edges incident to u_1 in

$\mathcal{C}'$ with the edge $\{x_p, u_1\}$. Clearly, $\mathcal{C}'$ is still a maximum TFPCC of G' after the modification. So, we can repeatedly modify $\mathcal{C}'$ in this way until $d_{\mathcal{C}'}(x_p) = 1$ for every $p = (u_1, u_3) \in \Pi$. $\mathcal{C}'$ is now a maximum TFPCC of G' such that for every $p = (u_1, u_3) \in \Pi$, $d_{\mathcal{C}'}(x_p) = 1$. Finally, we obtain $\mathcal{C}$ from $\mathcal{C}'$ by deleting the edge $\{x_p, u_1\}$ for each $p = (u_1, u_3) \in \Pi$. Clearly, $|E(\mathcal{C})| = |E(\mathcal{C}')| - |\Pi| \geq |E(\mathcal{C}^*)|$. Therefore, $\mathcal{C}$ is a preferred TFPCC of G. Since $|V(G')| \leq 2|V(G)|$ and $|E(G')| \leq 2|E(G)|$, the lemma holds. $\qquad\square$

Recall that $t(n, m) = O(n^2 m^2)$ [6]. So, Lemma 5.6 ensures that after modifying Step 4 by computing $\mathcal{C}$ as a preferred TFPCC of G, Step 4 can still be done in $t(n, m)$ time.

6 Preprocessing $\mathcal{C}$

In this section, we consider how to refine Step 5. So, suppose that we have computed a preferred TFPCC $\mathcal{C}$ of G as in Lemma 5.6. To refine Step 5, we repeatedly perform not only Operations 5 through 7 but also the following three operations on $\mathcal{C}$ until none of the six is applicable.

Operation 12. If a cycle C_1 of $\mathcal{C}$ has an edge $e_1 = \{u_1, u_1'\}$ and another cycle or path component C_2 of $\mathcal{C}$ has an edge $e_2 = \{u_2, u_2'\}$ such that $e = \{u_1, u_2\} \in E(G)$ and $e' = \{u_1', u_2'\} \in E(G)$, then combine C_1 and C_2 into a single cycle or path by replacing e_1 and e_2 with e and e'.

Operation 13. If an endpoint u_1 of a path component P_1 of $\mathcal{C}$ is adjacent to an endpoint u_2 of another path component P_2 of $\mathcal{C}$ in G, then combine P_1 and P_2 into a single path by adding the edge $\{u_1, u_2\}$.

Operation 14. If $e = \{u, v\}$ is an edge of a path component of $\mathcal{C}$ such that for some isolated vertex x of $\mathcal{C}$, $\{u, x\} \in E(G)$ and $\{v, x\} \in E(G)$, then replace e by the edges $\{u, x\}$ and $\{v, x\}$.

Figure 5: Operations 12 through 14, where each wavy line or curve is a path, each dotted edge will be deleted, and each bold edge will be added.

Lemma 6.1 *Immediately after the refined preprocessing step, the following statements hold:*

1. *$\mathcal{C}$ is a TFPCC of G and has at least $opt(G)$ edges.*

2. *If a path component P of $\mathcal{C}$ is of length at most 3, then P is alive.*

3. *If an endpoint v of a path component P of $\mathcal{C}$ is a port of P, then each vertex in $N_G(v) \setminus V(P)$ is an internal vertex of a path component Q of $\mathcal{C}$ with $|Q| \geq 2|P| + 2$.*

4. *No pair $(u_1, u_3) \in \Pi$ satisfies that u_1 appears in a cycle of $\mathcal{C}$.*

5. *If a dead path component P of $\mathcal{C}$ is of length 4, then both endpoints of P are leaves in G.*

6. *Each 4-cycle C of $\mathcal{C}$ has at least three ports.*

12

PROOF.   A *short* cycle is a cycle of length at most 7. We prove the statements separately as follows.

Statement 1: Before the refined preprocessing, $\mathcal{C}$ has at least $opt(G)$ edges by Lemma 5.5 and is a TFPCC of G. Since Operation i does not decrease the number of edges in $\mathcal{C}$ or creates a new short cycle or a vertex of degree larger than 2 in $\mathcal{C}$ for each $i \in \{5, 6, 7, 12, 13, 14\}$, Statement 1 holds.

Statement 2: Same as that of Statement 2 in Lemma 3.6.

Statement 3: Suppose that an endpoint v of a path component P of $\mathcal{C}$ is a port. Consider an arbitrary $u \in N_G(v) \setminus V(P)$. Since neither Operation 6 nor Operation 13 can be performed on $\mathcal{C}$, u is an internal vertex of a path component Q of $\mathcal{C}$. Let u_1 and u_2 be the endpoints of Q. For each $i \in \{1, 2\}$, let Q_i be the path from u to u_i in P. Then, $|Q| = |Q_1| + |Q_2|$. Moreover, since Operation 7 cannot be applied on $\mathcal{C}$, $|P| + |Q_i| + 1 \le |Q|$ for each $i \in \{1, 2\}$. Thus, $2|P| + 2 \le |Q|$.

Statement 4: Before the refined preprocessing, no pair $(u_1, u_3) \in \Pi$ satisfies that u_1 appears in a cycle of $\mathcal{C}$ because $\mathcal{C}$ is a preferred TFPCC of G. Moreover, if Operation i creates a new cycle C in $\mathcal{C}$ for some $i \in \{5, 6, 7, 12, 13, 14\}$, then $i = 12$ and C is obtained by merging two shorter cycles in $\mathcal{C}$. Thus, Statement 4 holds.

Statement 5: Let P be a dead path component of $\mathcal{C}$ with $|P| = 4$. Suppose that u_1, ..., u_5 are the vertices of P and they appear in P in this order. If all internal vertices of P are ports, then both u_1 and u_5 are leaves of G (and we are done), because otherwise Operation 5 could be performed on $\mathcal{C}$. Moreover, if at most one internal vertex of P is a port, then G would be disconnected or Operation 4 could be performed on G, a contradiction. So, we assume that exactly two internal vertices of P are ports. Now, if $\{i, j\} = \{2, 4\}$, then $\{u_1, u_5\} \notin E(G)$, $\{u_1, u_3\} \notin E(G)$, and $\{u_5, u_3\} \notin E(G)$ (because otherwise Operation 5 could be performed on $\mathcal{C}$), and in turn both u_1 and u_5 are leaves of G (and we are done) because otherwise Operation 8 or 9 could be performed on G. Thus, we may assume that $i = 2$ and $j = 3$. Then, since Operation 5 cannot be performed on $\mathcal{C}$, u_1 is a leaf of G and $\{u_1, u_2\} \cap N_G(u_5) = \emptyset$. For the same reason, $\{u_3, u_5\} \notin E(G)$ or $\{u_2, u_4\} \notin E(G)$. Indeed, $\{u_2, u_4\} \in E(G)$ because otherwise the edge $\{u_2, u_3\}$ would be deleted by Operation 2 or 3, Therefore, $\{u_3, u_5\} \notin E(G)$ and in turn u_5 is also a leaf of G.

Statement 6: Let C be a 4-cycle in $\mathcal{C}$, and A be the set of ports of C. Further let u_1, ..., u_4 be the vertices of C and assume that they appear in C clockwise in this order. By Lemma 5.1, $|A| \ge 2$. For a contradiction, assume that $|A| = 2$. Then, by Statement 3 in Lemma 5.1, $A = \{u_1, u_3\}$ or $A = \{u_2, u_4\}$. We may assume that $A = \{u_2, u_4\}$ and $u_1 \prec u_3$. Then, $N_G(u_1) = N_G(u_3) = \{u_2, u_4\}$ by Statement 3 in Lemma 5.1, and in turn $(u_1, u_3) \in \Pi$. Since the refined preprocessing of $\mathcal{C}$ does not introduce a new short cycle, C is a cycle in $\mathcal{C}$ even before the refined preprocessing. However, this contradicts the fact that $\mathcal{C}$ is a preferred TFPCC of G before the refined preprocessing. □

Obviously, the refined preprocessing (i.e., Step 5) can be done in $O(nm)$ time.

7   Transforming $\mathcal{C}$ into a Spanning Tree

In this section, we consider how to refine Step 6. So, suppose that we have just performed the refined preprocessing on $\mathcal{C}$ as in Section 6. Let Γ be the set of (ordered) pairs (P, Q) of path components of $\mathcal{C}$ such that $|P| \ge 1$ and some endpoint v of P is adjacent to a vertex u of Q in G. Note that $d_{\mathcal{C}}(u) = 2$ and $2|P| + 2 \le |Q|$ by Statement 3 in Lemma 6.1. Suppose that we obtain a subset Γ' of Γ from Γ as follows.

- For each path component P of $\mathcal{C}$ such that there are two or more path components Q of $\mathcal{C}$ with $(P, Q) \in \Gamma$, delete all but one pair (P, Q) from Γ.

Now, consider an auxiliary digraph D such that the vertices of D one-to-one correspond to the path components P of $\mathcal{C}$ with $|P| \geq 1$ and the arcs of D one-to-one correspond to the pairs in Γ'. By Statement 3 in Lemma 6.1, D is a rooted forest (in which each leaf is of in-degree 0, each root is of out-degree 0, and each vertex is of out-degree at most 1).

To transform $\mathcal{C}$ into a spanning tree of G, the idea is to modify $\mathcal{C}$ in three stages. $\mathcal{C}$ is initially a TFPCC of G and we will always keep $\mathcal{C}$ being a TFTCC of G. For each $i \in \{1, 2, 3\}$, we use $\mathcal{C}_i$ to denote the $\mathcal{C}$ immediately after the i-th stage. For convenience, we use $\mathcal{C}_0$ to denote the $\mathcal{C}$ immediately before the first stage. Moreover, for each $i \in \{1, 2, 3\}$ and each connected component C of $\mathcal{C}_i$, we use $b(C)$ to denote the number of edges $\{u, v\} \in E(\mathcal{C}_0)$ such that $\{u, v\} \subseteq V(C)$.

In the first stage, we modify $\mathcal{C}$ by performing the following step:

1. For each pair $(P, Q) \in \Gamma'$, add an arbitrary $\{u, v\} \in E(G)$ to $\mathcal{C}$ such that u is an endpoint of P and v appears in Q.

Lemma 7.1 *Each connected component of $\mathcal{C}_1$ that is not a path or cycle is a tree $\hat{T}$ satisfying Condition C2 below:*

C2. $b(\hat{T}) \geq 5$, $|L(\hat{T})| \leq b(\hat{T}) - 2$, and $w(\hat{T}) \geq \frac{4}{5} b(\hat{T})$.

PROOF. Let $\hat{T}$ be a connected component of $\mathcal{C}_1$ that is not a path or cycle. Obviously, $\hat{T}$ can be obtained from a tree component $\hat{T}_D$ of D by replacing each vertex of $\hat{T}_D$ with the corresponding path component of $\mathcal{C}$ and replacing each arc of $\hat{T}_D$ corresponding to a pair $(P, Q) \in \Gamma'$ with an edge $\{v, u\} \in E(G)$ such that v is an endpoint of P and u appears in Q. Thus, $\hat{T}$ is clearly a tree.

We next prove that $\hat{T}$ satisfies Condition C2 by induction on the number of arcs in $\hat{T}_D$. Clearly, $\hat{T}_D$ has at least one edge. In the base case, $\hat{T}_D$ has only one arc. Let (P, Q) be the pair in Γ' corresponding to the arc. $\hat{T}$ is obtained from P and Q by connecting them with an edge $\{v, u\} \in E(G)$ such that v is an endpoint of P and u appears in Q. Thus, $w(\hat{T}) = |P| + |Q| - 1$, $|L(\hat{T})| = 3$, and $b(\hat{T}) = |P| + |Q|$. Hence, by Statement 3 in Lemma 6.1, $b(\hat{T}) \geq 3|P| + 2 \geq 5$. Therefore, $|L(\hat{T})| \leq b(\hat{T}) - 2$ and $\frac{w(\hat{T})}{b(\hat{T})} = 1 - \frac{1}{b(\hat{T})} \geq \frac{4}{5}$. This shows that $\hat{T}$ satisfies Condition C2 in the base case.

Now, assume that $\hat{T}_D$ has at least two arcs. Consider an arbitrary $(P, Q) \in \Gamma'$ such that the vertex α of D corresponding to P is a leaf of $\hat{T}_D$. Let $\hat{T}'_D$ be obtained from $\hat{T}_D$ by deleting α, and $\hat{T}'$ be obtained from $\hat{T}$ by deleting the vertices of P. Since $\hat{T}'_D$ has one fewer arc than $\hat{T}_D$, the inductive hypothesis implies that $b(\hat{T}') \geq 5$, $|L(\hat{T}')| \leq b(\hat{T}') - 2$, and $w(\hat{T}') \geq \frac{4}{5} b(\hat{T}')$. Obviously, $b(\hat{T}) = b(\hat{T}') + |P|$, $|L(\hat{T})| = |L(\hat{T}')| + 1$, and $w(\hat{T}) = w(\hat{T}') + |P|$. Since $|P| \geq 1$, it is now easy to verify that $\hat{T}$ satisfies Condition C2. $\square$

Hereafter, a connected component of $\mathcal{C}$ is *good* if it is a tree $\hat{T}$ satisfying Condition C2 in Lemma 7.1 or Condition C3 below, while it is *bad* otherwise.

C3. $w(\hat{T}) \geq b(\hat{T}) = 4$ and $|L(\hat{T})| = 3$.

Lemma 7.2 *Suppose that C is a bad connected component of $\mathcal{C}_1$. Then, C is a cycle of length at least 4, a 0-path, or a 4-path whose endpoints are leaves of G. Moreover, if C is a 0-path, then the unique vertex $u \in V(C)$ satisfies that each $v \in N_G(u)$ is an internal vertex of a tree component of $\mathcal{C}_1$ and no two vertices in $N_G(u)$ are adjacent in $\mathcal{C}_1$.*

PROOF. Since C is bad, Lemma 7.1 ensures that C is a path or cycle and in turn is a connected component of $\mathcal{C}_0$. Indeed, C cannot be a path of length at least 5, because otherwise C would

14

satisfy Condition C2. Now, by Lemma 6.1, C is a cycle of length at least 4, a 0-path, or a 4-path whose endpoints are leaves of G.

Suppose that C is a 0-path. Then, C is also 0-path in $\mathcal{C}_0$. Let u be the unique vertex in C. Consider an arbitrary $v \in N_G(u)$. Since Operation 13 cannot be performed on $\mathcal{C}_0$, v is not a leaf of a tree component of $\mathcal{C}_1$. Moreover, since Operation 6 cannot be performed on $\mathcal{C}_0$, v does not appear in a cycle of $\mathcal{C}_1$. Furthermore, since Operation 14 cannot be performed on $\mathcal{C}_0$, no two vertices in $N_G(u)$ are adjacent in $\mathcal{C}_1$. $\qquad\square$

We next want to define several operations on $\mathcal{C}$ none of which will produce a new cycle or a new bad connected component in $\mathcal{C}$. An operation on $\mathcal{C}$ is *good* if it either just connects two or more connected components of $\mathcal{C}$ into a single good connected component, or modify a good connected component of $\mathcal{C}$ so that it has more internal vertices (and hence remains good).

In the second stage, we modify $\mathcal{C}$ by repeatedly performing the following operations on $\mathcal{C}$ until none of them is applicable.

Operation 15. If $\mathcal{C}$ has two cycles C_1 and C_2 such that $|C_1|+|C_2| \geq 10$ and some edge $e = \{v_1, v_2\}$ of G satisfies $v_1 \in V(C_1)$ and $v_2 \in V(C_2)$, then connect C_1 and C_2 into a single path T by deleting one edge incident to v_1 in C_1, deleting one edge incident to v_2 in C_2, and adding the edge e.

Operation 16. If $\mathcal{C}$ has a cycle C_1 of length at least 5 and a good connected component C_2 such that some edge $e = \{v, u\}$ of G satisfies $v \in V(C_1)$ and $u \in V(C_2)$, then connect C_1 and C_2 into a single tree T by deleting one edge incident to v in C_1 and adding the edge e.

Operation 17. If $\mathcal{C}$ has a cycle C of length at least 6 and a 4-path component P such that some edge $e = \{v, u\}$ of G satisfies $v \in V(C)$ and $u \in V(P)$, then connect C and P into a single tree T by deleting one edge incident to v in C and adding the edge e.

Operation 18. If $\mathcal{C}$ has a 0-path component P whose unique vertex u has two neighbors v_1 and v_2 in G such that v_1 and v_2 fall into different connected components C_1 and C_2 of $\mathcal{C}$, then connect P, C_1, and C_2 into a single connected component T by adding the edges $\{u, v_1\}$ and $\{u, v_2\}$.

Operation 19. If $\mathcal{C}$ has a good connected component C_1 and another connected component C_2 such that some leaf u of C_1 is adjacent to a vertex v of C_2 in G, then connect C_1 and C_2 into a single tree component T by deleting one edge incident to v in C_2 if C_2 is a cycle, and further adding the edge $\{u, v\}$.

Operation 20. If a cycle C of $\mathcal{C}$ has an edge $e = \{v_1, v_2\}$ such that some $u_1 \in N_G(v_1) \setminus V(C)$ and some $u_2 \in N_G(v_2) \setminus V(C)$ fall into different connected components C_1 and C_2 of $\mathcal{C}$ other than C, then connect C, C_1, and C_2 into a single tree component T by deleting e, deleting one edge incident to u_1 if C_1 is a cycle, deleting one edge incident to u_2 if C_2 is a cycle, and adding the edges $\{v_1, u_1\}$ and $\{v_2, u_2\}$.

Operation 21. If a good connected components C of $\mathcal{C}$ is not a Hamiltonian path of G but is a dead path whose endpoints are adjacent in G, then choose an arbitrary port u of C, modify C by adding the edge of G between the endpoints of C and deleting one edge incident to u in C, and further perform Operation 19.

Operation 22. If a good connected component C of $\mathcal{C}$ is not a path but has two leaves u and v with $\{u, v\} \in E(G)$, then modify C by first finding an arbitrary vertex x on the path P

between u and v in C with $d_C(x) \geq 3$, then deleting one edge incident to x in P, and further adding the edge $\{u, v\}$.

Operation 23. If $\mathcal{C}$ has a 0-path component C_1, a 4-path component P, and a connected component C_2 other than C_1 and P such that the center vertex u_3 of P is adjacent to a vertex x of C_2 in G and the unique vertex v of C_1 is adjacent to the other two internal vertices u_2 and u_4 of P (than u_3) in G, then connect C_1, P, and C_2 into a single connected component T by deleting the edge $\{u_2, u_3\}$, deleting one edge incident to x if C_2 is a cycle, and adding the edges $\{v, u_2\}$, $\{v, u_4\}$, $\{u_3, x\}$.

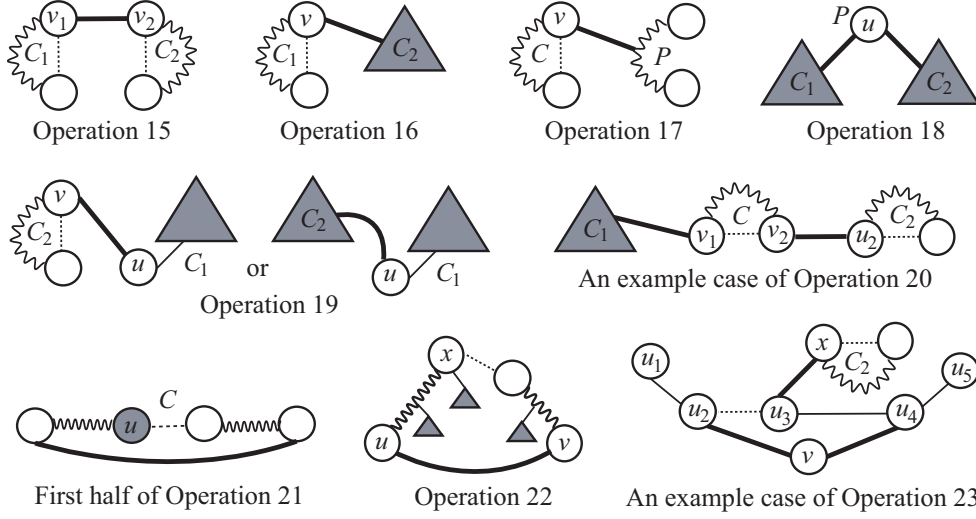

Figure 6: Operations 15 through 23, where the filled circle is a port, each wavy line or curve is a path, each filled triangle is a tree, each dotted edge will be deleted, and each bold edge will be added.

In the following proofs of Lemmas 7.3 through 7.11, $\hat{T}$ denotes the new connected component of $\mathcal{C}$ created by the corresponding operation.

Lemma 7.3 *Operation 15 is good.*

PROOF. Obviously, $w(\hat{T}) = |C_1| + |C_2| - 2$, $b(\hat{T}) = |C_1| + |C_2| \geq 10$, and $|L(\hat{T})| = 2$. Thus, $\hat{T}$ is good. □

Lemma 7.4 *Operation 16 is good.*

PROOF. Obviously, $w(\hat{T}) \geq w(C_2) + |C_1| - 1 \geq \frac{4}{5}b(C_2) + |C_1| - 1$, $b(\hat{T}) = b(C_2) + |C_1| \geq b(C_2) + 5$, and $|L(\hat{T})| \leq |L(C_2)| + 1$. Thus, $\hat{T}$ is good. □

Lemma 7.5 *Operation 17 is good.*

PROOF. Obviously, $w(\hat{T}) = |C| + 2$, $b(\hat{T}) = |C| + 4 \geq 10$, and $|L(\hat{T})| = 3$. Thus, $\hat{T}$ is good. □

Lemma 7.6 *Operation 18 is good.*

16

PROOF. Since Operation 6 cannot be applied on $\mathcal{C}_0$, neither C_1 nor C_2 is a cycle. Hence, both C_1 and C_2 are trees and in turn $\hat{T}$ is a tree. To show that $\hat{T}$ is good, we distinguish three cases as follows.

Case 1: Both C_1 and C_2 are good. In this case, $w(\hat{T}) \geq w(C_1) + w(C_2) + 1 \geq \frac{4}{5}b(C_1) + \frac{4}{5}b(C_2) + 1$, $b(\hat{T}) = b(C_1) + b(C_2) \geq 8$, and $|L(\hat{T})| \leq |L(C_1)| + |L(C_2)|$. Thus, $\hat{T}$ is clearly good.

Case 2: One of C_1 and C_2 is good. W.l.o.g., we assume that C_1 is good and C_2 is bad. Then, by Lemma 7.2, C_2 is either a 0-path or a 4-path whose endpoints are leaves of G. The former case is impossible, because Operation 13 cannot be performed on $\mathcal{C}_0$. In the latter case, $w(\hat{T}) \geq w(C_1) + 4 \geq \frac{4}{5}b(C_1) + 4$, $b(\hat{T}) = b(C_1) + 4 \geq 8$, and $|L(\hat{T})| \leq |L(C_1)| + 2$, implying that $\hat{T}$ is good.

Case 3: Both C_1 and C_2 are bad. In this case, both C_1 and C_2 are 4-paths whose endpoints are leaves of G, because Operation 13 cannot be performed on $\mathcal{C}_0$. So, $w(\hat{T}) = 7$, $b(\hat{T}) = 8$, and $|L(\hat{T})| = 4$, implying that $\hat{T}$ is good. □

Lemma 7.7 *Operation 19 is good.*

PROOF. $\hat{T}$ is clearly a tree. To show that $\hat{T}$ is good, we distinguish three cases as follows.

Case 1: C_2 is a cycle. In this case, $w(\hat{T}) = w(C_1) + |C_2| \geq \frac{4}{5}b(C_1) + |C_2|$, $b(\hat{T}) = b(C_1) + |C_2| \geq 8$, and $|L(\hat{T})| = |L(C_1)|$. So, $\hat{T}$ is clearly good.

Case 2: C_2 is good. In this case, $w(\hat{T}) \geq w(C_1) + w(C_2) + 1 \geq \frac{4}{5}b(C_1) + \frac{4}{5}b(C_2) + 1$, $b(\hat{T}) = b(C_1) + b(C_2) \geq 8$, and $|L(\hat{T})| = |L(C_1)| + |L(C_2)| - 1$. So, $\hat{T}$ is clearly good.

Case 3: C_2 is bad but not a cycle. In this case, Lemma 7.2 ensures that C_2 is either a 0-path or a 4-path whose endpoints are leaves of G. In the latter case, $w(\hat{T}) \geq w(C_1) + 4 \geq \frac{4}{5}b(C_1) + 4$, $b(\hat{T}) = b(C_1) + 4 \geq 8$, and $|L(\hat{T})| = |L(C_1)| + 1$, implying that $\hat{T}$ is clearly good. So, we assume the former case. If C_1 satisfies Condition C2, then $w(\hat{T}) = w(C_1) + 1 \geq \frac{4}{5}b(C_1) + 1$, $b(\hat{T}) = b(C_1) \geq 5$, and $|L(\hat{T})| = |L(C_1)|$, implying that $\hat{T}$ is good. Otherwise, $b(\hat{T}) = b(C_1) = 4$, $w(\hat{T}) = w(C_1) + 1 \geq b(C_1) + 1 > b(\hat{T})$, and $|L(\hat{T})| = |L(C_1)|$, implying that $\hat{T}$ is good. □

Lemma 7.8 *Operation 20 is good.*

PROOF. $\hat{T}$ is clearly a tree. To show that $\hat{T}$ is good, we distinguish three cases as follows.

Case 1: Both C_1 and C_2 are cycles. In this case, $w(\hat{T}) = |C| + |C_1| + |C_2| - 2$, $b(\hat{T}) = |C| + |C_1| + |C_2| \geq 12$, and $|L(\hat{T})| = 2$. Thus, $\hat{T}$ is clearly good.

Case 2: One of C_1 and C_2 is a cycle. W.l.o.g., we assume that C_2 is a cycle. If C_1 is good, then $w(\hat{T}) \geq w(C_1) + |C| + |C_2| - 1 \geq \frac{4}{5}b(C_1) + |C| + |C_2| - 1$, $b(\hat{T}) = b(C_1) + |C| + |C_2| \geq b(C_1) + 8 \geq 12$, and $|L(\hat{T})| \leq |L(C_1)| + 1$, implying that $\hat{T}$ is good. So, assume that C_1 is bad. Then, by Lemma 7.2, C_1 is a 0-path or 4-path whose endpoints are leaves of G. Indeed, C_1 is not a 0-path, because Operation 13 cannot be performed on $\mathcal{C}_0$. Thus, $w(\hat{T}) = |C| + |C_2| + 2$, $b(\hat{T}) = |C| + |C_2| + 4 \geq 12$, and $|L(\hat{T})| = 3$. Hence, $\hat{T}$ is good.

Case 3: Neither C_1 nor C_2 is a cycle. If both C_1 and C_2 are good, then $w(\hat{T}) \geq |C| + w(C_1) + w(C_2) \geq |C| + \frac{4}{5}b(C_1) + \frac{4}{5}b(C_2)$, $b(\hat{T}) = |C| + b(C_1) + b(C_2) \geq b(C_1) + b(C_2) + 4 \geq 12$, and $|L(\hat{T})| \leq |L(C_1)| + |L(C_2)|$, implying that $\hat{T}$ is good. Similarly, if both C_1 and C_2 are bad, then both of them are 4-paths whose endpoints are leaves of G and in turn $w(\hat{T}) = |C| + 6$, $b(\hat{T}) = |C| + 8 \geq 12$, and $|L(\hat{T})| = 4$, implying that $\hat{T}$ is good. So, we may assume that C_1 is good but C_2 is bad. Then, C_2 is a 4-path whose endpoints are leaves of G. Hence, $w(\hat{T}) \geq |C| + w(C_1) + 3 \geq |C| + \frac{4}{5}b(C_1) + 3$, $b(\hat{T}) = |C| + b(C_1) + 4 \geq b(C_1) + 8 \geq 12$, and $|L(\hat{T})| \leq |L(C_1)| + 2$. Therefore, $\hat{T}$ is good. □

17

Lemma 7.9 *Operation 21 is good.*

PROOF. By Lemma 7.7, Operation 21 is clearly good. □

Lemma 7.10 *Operation 22 is good.*

PROOF. The operation clearly decreases the number of leaves in C by 1, and is hence good. □

Lemma 7.11 *Operation 23 is good.*

PROOF. $\hat{T}$ is clearly a tree. To show that $\hat{T}$ is good, we distinguish three cases as follows.

Case 1: C_2 is a cycle. In this case, $w(\hat{T}) = |C_2| + 3$, $b(\hat{T}) = |C_2| + 4 \geq 8$, and $|L(\hat{T})| = 3$. So, $\hat{T}$ is clearly good.

Case 2: C_2 is good. In this case, $w(\hat{T}) \geq w(C_2) + 4 \geq \frac{4}{5}b(C_2) + 4$, $b(\hat{T}) = b(C_2) + 4 \geq 8$, and $|L(\hat{T})| \leq |L(C_2)| + 2$. So, $\hat{T}$ is clearly good.

Case 3: C_2 is bad. In this case, C_2 is either a 0-path or a 4-path whose endpoints are leaves of G. In the former case, $w(\hat{T}) = 4$, $b(\hat{T}) = 4$, and $|L(\hat{T})| = 3$, implying that $\hat{T}$ is clearly good. In the latter case, $w(\hat{T}) = 7$, $b(\hat{T}) = 8$, and $|L(\hat{T})| = 4$, implying that $\hat{T}$ is clearly good. □

We next show that the above operations lead to a number of useful properties of $\mathcal{C}_2$.

Lemma 7.12 *Each 4-cycle of $\mathcal{C}_2$ is adjacent to at most one other connected component of $\mathcal{C}_2$ in G.*

PROOF. Let C be a 4-cycle in $\mathcal{C}_2$. Further let v_1, ..., v_4 be the vertices of C and assume that they appear in C clockwise in this order. By Statement 6 in Lemma 6.1, C has at least three ports. Without loss of generality, we may assume that v_1 through v_3 are ports of C. Since Operation 20 cannot be performed on $\mathcal{C}_2$, there is a unique connected component C' in $\mathcal{C}_2$ such that $N_G(\{v_1, v_2\}) \setminus V(C)$ is a nonempty subset of $V(C')$. For the same reason, $N_G(\{v_2, v_3\}) \setminus V(C)$ is a nonempty subset of $V(C')$. Moreover, if v_4 is also a port of C, then for the same reason, $N_G(\{v_3, v_4\}) \setminus V(C)$ is a nonempty subset of $V(C')$. Therefore, in any case, $N_G(C) \setminus V(C) \subseteq V(C')$ and hence C is adjacent to only C' in G. □

Lemma 7.13 *No two 4-cycles of $\mathcal{C}_2$ are adjacent in G.*

PROOF. For a contradiction, assume that two 4-cycles C_1 and C_2 of $\mathcal{C}_2$ are adjacent in G. Then, by Lemma 7.12, $G[V(C_1) \cup V(C_2)]$ is a connected component of G. However, this is impossible because G is connected and $|V(G)| \geq 9$. □

Lemma 7.14 *No 4-cycle C of $\mathcal{C}_2$ is adjacent to a 4-path component of $\mathcal{C}_2$ in G.*

PROOF. For a contradiction, assume that a 4-cycle C of $\mathcal{C}_2$ is adjacent to a 4-path component P of $\mathcal{C}_2$ in G. Let v_1, ..., v_4 be the vertices of C and assume that they appear in C clockwise in this order. Let B be the set of all $u \in V(G) \setminus V(C)$ such that for some $v_i \in V(C)$, $\{u, v_i\} \in E(G)$. Since Operation 4 cannot be performed on G, $|B| \geq 2$. Moreover, by Lemma 7.12, $B \subseteq V(P)$.

Let u_1, ..., u_5 be the vertices of P and assume that they appear in P in this order. Then, P is a dead 4-path component of $\mathcal{C}_0$. So, by Statement 5 in Lemma 6.1, both u_1 and u_5 are leaves of G. Thus, $B \subseteq \{u_2, u_3, u_4\}$. Since $|C| = 4$ and C has at least three ports (by Statement 6 in

Lemma 6.1), there are two consecutive edges in C whose endpoints all are ports of C. Without loss of generality, we assume that v_1 through v_3 are ports of C.

Case 1: $\{v_2, u_3\} \in E(G)$. In this case, since both v_1 and v_3 are ports of C and Operation 12 cannot be performed on $\mathcal{C}_0$, $\{u_2, u_3, u_4\} \cap N_G(v_1) = \{u_3\}$ and $\{u_2, u_3, u_4\} \cap N_G(v_3) = \{u_3\}$, and in turn $\{u_2, u_3, u_4\} \cap N_G(v_2) = \{u_3\}$ as well. Now, since $|B| \geq 2$, G has an edge $\{v_4, u_j\}$ with $j \in \{2, 4\}$. However, we can now see that Operation 12 can be performed on $\mathcal{C}_0$, a contradiction.

Case 2: $\{v_2, u_3\} \notin E(G)$. In this case, since v_2 is a port of C, $\{v_2, u_2\} \in E(G)$ or $\{v_2, u_4\} \in E(G)$. So, $\{v_1, u_3\} \notin E(G)$ and $\{v_3, u_3\} \notin E(G)$, because Operation 12 cannot be performed on $\mathcal{C}_0$. Thus, $N_G(\{v_1, v_2, v_3\}) \cap \{u_2, u_3, u_4\}$ is either $\{u_2, u_4\}$ or $\{u_j\}$ for some $j \in \{2, 4\}$. In the latter case, since $|B| \geq 2$, $\{v_4, u_3\} \in E(G)$ or $\{v_4, u_{6-j}\} \in E(G)$, and hence Operation 10 or 12 can be performed, a contradiction. In the former case, if $\{v_4, u_3\} \in E(G)$, then Operation 12 can be performed on $\mathcal{C}_0$, a contradiction; otherwise, $N_G(v_4) \subseteq V(C) \cup \{u_2, u_4\}$ and in turn Operation 10 can be performed on G, a contradiction. $\square$

Lemma 7.15 *No 4-cycle of $\mathcal{C}_2$ is adjacent to a 5-cycle of $\mathcal{C}_2$ in G.*

PROOF.   For a contradiction, assume that a 4-cycle C_1 of $\mathcal{C}_2$ is adjacent to a 5-cycle C_2 of $\mathcal{C}_2$ in G. For each $i \in \{1, 2\}$, let $v_{i,1}, \ldots, v_{i,|C_i|}$ be the vertices of C_i and assume that they appear in C_i clockwise in this order. By Statement 6 in Lemma 6.1, C_1 has at least three ports, and in turn three ports of C_1 appear in C_1 consecutively because $|C_1| = 4$. Without loss of generality, we assume that $v_{1,1}$, $v_{1,2}$, and $v_{1,3}$ are ports of C_1.

By Lemma 7.12, $N_G(C_1) \setminus V(C_1) \subseteq V(C_2)$. Since $|C_1| + |C_2| - 1 = 8 < 9$ and Operation 4 cannot be performed on G, $|X| \geq 2$, where X is the set of vertices $v_{2,j} \in V(C_2)$ with $N_G(v_{2,j}) \setminus (V(C_1) \cup V(C_2)) \neq \emptyset$. We distinguish two cases as follows.

Case 1: X has two vertices adjacent in C_2. Without loss of generality, we assume that $\{v_{2,4}, v_{2,5}\} \subseteq X$. Then, since Operation 20 cannot be performed on $\mathcal{C}_2$, $N_G(C_1) \setminus V(C_1) \subseteq \{v_{2,2}\}$. So, Operation 4 can be performed on G, a contradiction.

Case 2: No two vertices of X are adjacent in C_2. In this case, since $|C_2| = 5$, $|X| = 2$. Without loss of generality, we assume that $X = \{v_{2,1}, v_{2,3}\}$. Then, since Operation 20 cannot be performed on $\mathcal{C}_2$, $N_G(C_1) \setminus V(C_1) \subseteq X$. Indeed, since Operation 4 cannot be performed on $\mathcal{C}_2$, $N_G(C_1) \setminus V(C_1) = X$. So, $|N_G(\{v_{1,1}, v_{1,2}\}) \setminus V(C_1)| = 1$ and $|N_G(\{v_{1,2}, v_{1,3}\}) \setminus V(C_1)| = 1$ because Operation 10 cannot be performed on G. Thus, $|N_G(\{v_{1,1}, v_{1,2}, v_{1,3}\}) \setminus V(C_1)| = 1$ because $N_G(v_{1,2}) \setminus V(C_1) \neq \emptyset$. Now, since $|N_G(C_1) \setminus V(C_1)| = 2$, $|N_G(\{v_{1,3}, v_{1,4}\}) \setminus V(C_1)| = 2$ and in turn Operation 10 can be performed on G, a contradiction. $\square$

Based on the above lemmas in this section, we are now ready to prove the next lemma:

Lemma 7.16 *Suppose that C is a connected component of $\mathcal{C}_2$. Then, C is a 4-cycle, 5-cycle, 0-path, 4-path, or good connected component. Moreover, the following statements hold:*

1. *If C is a 0-path, then its unique vertex u satisfies that for a single tree component C' of $\mathcal{C}_2$, each $v \in N_G(u)$ is an internal vertex of C', and u is a leaf of G if C' is bad.*

2. *If C is a 4-path component of $\mathcal{C}_2$, then its endpoints are leaves of G and each internal vertex u of C satisfies that each neighbor of u in G is a leaf of G, a vertex of a 5-cycle of $\mathcal{C}_2$, or an internal vertex of a 4-path component or a good connected component of C.*

3. *If C is a 4-cycle of $\mathcal{C}_2$, then each vertex u of C satisfies that each neighbor of u in G is an internal vertex of a good connected component of $\mathcal{C}_2$.*

4. If C is a 5-cycle of $\mathcal{C}_2$, then each vertex u of C satisfies that each neighbor of u in G is an internal vertex of a 4-path component of $\mathcal{C}_2$.

5. If C is a good connected component but not a Hamiltonian path of G, then each leaf u of C satisfies that each neighbor of u in G is an internal vertex of C.

PROOF. By Lemmas 7.2 through 7.11, C is a cycle of length at least 4, 0-path, 4-path, or good connected component. Indeed, C cannot be a cycle of length 6 or more, because otherwise Operation 6 could be performed on $\mathcal{C}_1$ or Operation i could be performed on $\mathcal{C}_2$ for some $i \in \{15, 16, 17\}$. We next prove the statements separately as follows.

Statement 1: Suppose that C is a 0-path. Let u be the unique vertex in C. Since Operation 18 cannot be performed on $\mathcal{C}_2$, $N_G(u) \subseteq V(C')$ for some connected component C' of $\mathcal{C}_2$. If C' is not a connected component of $\mathcal{C}_1$, then by Lemmas 7.3 through 7.11, C' is a good connected component of $\mathcal{C}_2$ and in turn each $v \in N_G(u)$ is an internal vertex of C' (because otherwise Operation 19 could be performed on $\mathcal{C}_2$). So, we may assume that C' is also a connected component of $\mathcal{C}_1$. Then, by Lemma 7.2, C' is a tree component and each $v \in N_G(u)$ is an internal vertex of C'. For a contradiction, assume that C' is bad but u is not a leaf of G. Since C' is a bad tree component of $\mathcal{C}_1$ with internal vertices, Lemma 7.2 ensures that C' is a 4-path. Let $u_1, \ldots, u_5$ be the vertices of C' and assume that they appear in C' in this order. Since u is not a leaf of G, Lemma 7.2 ensures that $N_G(u) = \{u_2, u_4\}$. Now, Operation 8 or 23 can be performed on G, a contradiction.

Statement 2: Suppose that C is a 4-path component of $\mathcal{C}_2$. Then, C is also a 4-path component of $\mathcal{C}_1$, because Operation i does not produce a new bad connected component in $\mathcal{C}$ for each $i \in \{15, \ldots, 23\}$. So, by Lemma 7.2, each endpoint of C is a leaf of G. Consider an arbitrary internal vertex u of C and an arbitrary neighbor v of u in G. Since Operation 19 cannot be performed on $\mathcal{C}_2$, v is not a leaf of a good connected component of $\mathcal{C}_2$. So, if v appears in a good connected component C' of $\mathcal{C}_2$, v must be an internal vertex of C'. Moreover, by Lemma 7.14, v cannot appear in a 4-cycle of $\mathcal{C}_2$. Thus, to finish the proof, we may assume that v appears in a bad tree component C'' of $\mathcal{C}_2$. Now, if v appears in a 0-path component of $\mathcal{C}_2$, then v is a leaf of G by Statement 1 in this lemma; otherwise, v cannot be an endpoint of another 4-path component of $\mathcal{C}_2$ because each endpoint of a 4-path component of $\mathcal{C}_2$ is a leaf of G.

Statement 3: Let C be a 4-cycle of $\mathcal{C}_2$. C cannot be adjacent to a 0-path component of $\mathcal{C}_2$ in G, because Operation 6 cannot be performed on $\mathcal{C}_0$ and neither Stage 2 nor Stage 3 produces a new cycle or a new 0-path component in $\mathcal{C}$. So, by Lemmas 7.13 through 7.15, each $v \in N_G(C)$ appears in a good connected component C' of $\mathcal{C}_2$. Indeed, v must be an internal vertex of C', because Operation 19 cannot be performed on $\mathcal{C}_2$.

Statement 4: Let C be a 5-cycle of $\mathcal{C}_2$. C cannot be adjacent to a 0-path component of $\mathcal{C}_2$ in G, because Operation 6 cannot be performed on $\mathcal{C}_0$ and neither Stage 2 nor Stage 3 produces a new cycle or a new 0-path component in $\mathcal{C}$. Moreover, since neither Operation 15 nor Operation 16 can be performed on $\mathcal{C}_2$, C cannot be adjacent to a 5-cycle or a good connected component of $\mathcal{C}_2$ in G. So, by Lemma 7.15, each $v \in N_G(C)$ appears in a 4-path component C' of $\mathcal{C}_2$. Indeed, v must be an internal vertex of C', because each endpoint of C' is a leaf of G.

Statement 5: Supppose that C is a good connected component of $\mathcal{C}_2$ but not a Hamiltonian path of G. Let u be a leaf of C. Since Operation i cannot be performed on $\mathcal{C}_2$ for each $i \in \{19, 21, 22\}$, each $v \in N_G(u)$ is an internal vertex of C. □

Finally, in the third stage, we complete the transformation of $\mathcal{C}$ into a spanning tree of G by further modifying $\mathcal{C}$ by performing the following steps:

1. For each cycle C of $\mathcal{C}$, first select an arbitrary edge $e = \{u, v\} \in E(G)$ such that $u \in V(C)$ and $v \in V(G) \setminus V(C)$, then delete one edge incident to u in C, and further add e. (*Comment:*

Since no two cycles in $\mathcal{C}_2$ are adjacent in G, v appears in a tree component of $\mathcal{C}$. Moreover, after this step, $\mathcal{C}$ has only tree components.)

2. Arbitrarily connect the connected components of $\mathcal{C}$ into a tree by adding some edges of G.

It is easy to see that for each $i \in \{15, \ldots, 23\}$, Step i can be done in $O(m)$ time. So, the second stage takes $O(nm)$ time. Since the other two stages can be easily done in $O(m)$ time, the refined Step 6 can be done $O(nm)$ time.

8   Performance Analysis

Let g_2 (respectively, g_3) be the number of internal vertices in connected components of $\mathcal{C}_2$ satisfying Condition C2 (respectively, C3), b_2 (respectively, b_3) be the total number of edges in $\mathcal{C}_0$ whose endpoints appear in the same connected components of $\mathcal{C}_2$ satisfying Condition C2 (respectively, C3), c_4 (respectively, c_5) be the number of 4-cycles (respectively, 5-cycles) in $\mathcal{C}_2$, and p_4 be the number of 4-path components in $\mathcal{C}_2$.

Lemma 8.1 *Let T_{apx} be the spanning tree of G outputted by the refined algorithm. Then, the following hold:*

1. $w(T_{apx}) \geq 3c_4 + 4c_5 + 3p_4 + g_2 + g_3 \geq 3c_4 + 4c_5 + 3p_4 + \frac{4}{5}b_2 + b_3$.

2. $opt(G) \leq 4c_4 + 5c_5 + 4p_4 + b_2 + b_3$.

3. $opt(G) \leq 3c_4 + 5c_5 + 3p_4 + 2g_2 + 2g_3$.

PROOF.   We prove the statements separately as follows.

Statement 1: Obvious.

Statement 2: Clear from the fact that $opt(G) \leq |E(\mathcal{C}_0)| \leq 4c_4 + 5c_5 + 4p_4 + b_2 + b_3$.

Statement 3: For convenience, let T' be obtained from T by rooting T at an internal vertex, and T'' be obtained from T' by removing those edges (u, v) such that some 4-cycle of $\mathcal{C}_2$ contains both u and v. Further let I' (respectively, I'') be the set of vertices in T' (respectively, T'') that have at least one child in T' (respectively, T''). Also let $J = I' \setminus I''$. Clearly, $w(T) = |I'|$. Moreover, for each 4-cycle C of $\mathcal{C}_2$, T' can contain at most three edges between the vertices of C. So, $|J| \leq 3c_4$. Furthermore, Lemma 7.16 ensures that each vertex of I' other than

- the vertices in J,

- the $3p_4$ internal vertices of 4-path components of $\mathcal{C}_2$,

- the $5c_5$ vertices of 5-cycles, and

- the $g_2 + g_3$ internal vertices of good connected components of $\mathcal{C}_2$

must have a child in T'' that is an internal vertex of a good connected component of $\mathcal{C}_2$. So, $w(T) = |I'| \leq 3c_4 + (5c_5 + 3p_4 + g_2 + g_3) + (g_2 + g_3)$. $\qquad\square$

Theorem 8.2 *The algorithm achieves an approximation ratio of $\frac{13}{17}$ and runs in $O(n^2 m) + t(2n, 2m)$ time.*

PROOF. Let T_{apx} be as in Lemma 8.1, and $r = w(T_{apx})/opt(G)$. By Lemma 8.1, $r \geq \max\{r_1, r_2\}$, where $r_1 = \frac{3c_4+4c_5+3p_4+g_2+g_3}{4c_4+5c_5+4p_4+b_2+b_3}$ and $r_2 = \frac{3c_4+4c_5+3p_4+g_2+g_3}{3c_4+5c_5+3p_4+2g_2+2g_3}$. Note that $r_1 \geq \min\left\{\frac{4}{5}, r_1'\right\}$ and $r_2 \geq \min\left\{\frac{4}{5}, r_2'\right\}$, where $r_1' = \frac{3c_4+3p_4+g_2+g_3}{4c_4+4p_4+b_2+b_3}$ and $r_2' = \frac{3c_4+3p_4+g_2+g_3}{3c_4+3p_4+2g_2+2g_3}$. So, it suffices to show that $\max\{r_1', r_2'\} \geq \frac{13}{17}$. This is done if $r_1' \geq \frac{13}{17}$. Thus, we assume that $r_1' < \frac{13}{17}$. Then, $c_4 + p_4 > 17g_2 + 17g_3 - 13b_2 - 13b_3$. Hence, $r_2' > \frac{52g_2+52g_3-39b_2-39b_3}{53g_2+53g_3-39b_2-39b_3} \geq \min\left\{\frac{52g_2-39b_2}{53g_2-39b_2}, \frac{52g_3-39b_3}{53g_3-39b_3}\right\}$. Now, since $g_2 \geq \frac{4}{5}b_2$, $\frac{52g_2-39b_2}{53g_2-39b_2} \geq \frac{13}{17}$. Moreover, since $g_3 \geq b_3$, $\frac{52g_3-39b_3}{53g_3-39b_3} \geq \frac{13}{14}$. Therefore, $r_2' > \frac{13}{17}$. The running is clearly as claimed. $\qquad\square$

Recall that $t(n, m) = O(n^2 m^2)$ [6]. So, the algorithm takes $O(n^2 m^2)$ time.
