Abstract

A graph Γ is said to be *symmetric* if its automorphism group $Aut(\Gamma)$ is transitive on the arc set of Γ. Let G be a finite non-abelian simple group and let Γ be a connected pentavalent symmetric graph such that $G \leq Aut(\Gamma)$. In this paper, we show that if G is transitive on the vertex set of Γ, then either $G \trianglelefteq Aut(\Gamma)$ or $Aut(\Gamma)$ contains a non-abelian simple normal subgroup T such that $G \leq T$ and (G, T) is one of 58 possible pairs of non-abelian simple groups. In particular, if G is arc-transitive, then (G, T) is one of 17 possible pairs, and if G is regular on the vertex set of Γ, then (G, T) is one of 13 possible pairs, which improves the result on pentavalent symmetric Cayley graph given by Fang, Ma and Wang in 2011.

Keywords: Symmetric graph, Cayley graph, coset graph, simple group.

2010 Mathematics Subject Classification: 05C25, 20B25.

1 Introduction

Let G be a permutation group on a set Ω and let $\alpha \in \Omega$. Denote by G_{α} the stabilizer of α in G, that is, the subgroup of G fixing the point α . We say that G is *regular* on Ω if for any two points there is a unique element of G mapping one to the other. Denote by \mathbb{Z}_n , D_n , A_n and S_n the cyclic group of order n, the dihedral group of order $2n$, the alternating group and the symmetric group of degree n , respectively. For a subgroup H of a group G, denote by $C_G(H)$ the centralizer of H in G and by $N_G(H)$ the normalizer of H in G.

Throughout this paper, all groups and graphs are finite, and all graphs are simple and undirected. For a graph Γ, we denote its vertex set and automorphism group by $V(\Gamma)$ and Aut(Γ), respectively. A graph Γ is said to be *G-vertex-transitive* for $G \leq \text{Aut}(\Gamma)$ if G acts transitively on V (Γ), G*-regular* if G acts regularly on V (Γ), and G*-symmetric* if G acts transitively on the arc set of Γ (an arc is an ordered pair of adjacent vertices). In particular, Γ is *vertex-transitive* or *symmetric* if it is Aut(Γ)-vertex-transitive or Aut(Γ) symmetric, respectively. The graph Γ is a *Cayley graph* on G if G is regular on the vertex set of Γ , and the Cayley graph is *normal* if G is a normal subgroup of $Aut(\Gamma)$.

Let G be a non-abelian simple group and let Γ be a pentavalent symmetric G-vertextransitive graph. In this paper, we show that either $G \triangleleft Aut(\Gamma)$ or $Aut(\Gamma)$ contains a non-abelian simple normal subgroup T such that $G < T$ and (G, T) is one of 58 possible pairs of non-abelian simple groups. The motivation of this investigation comes from the two extreme cases, that is, G-symmetric and G-regular.

There are two steps to study a symmetric graph Γ — the first step is to investigate the normal quotient graph for a normal subgroup of an arc-transitive group of automorphisms (see Section [2](#page-2-0) for the definition of quotient graph), and the second step is to reconstruct the original graph Γ from the normal quotient by using covering techniques. This is usually done by taking a maximal normal subgroup such that the normal quotient graph has the same valency as the graph Γ, and in this case, the normal quotient graph is called a *basic graph* of Γ. The situation seems to be somewhat more promising with 2-arctransitive graphs (a 2-arc is a directed path of length 2), and the strategy for the structural analysis of these graphs, based on taking normal quotients, was first laid out by Praeger (see [\[23,](#page-15-0) [24\]](#page-16-0)). The strategy works for locally primitive graphs, that is, vertex-transitive graphs with vertex stabilizers acting primitively on the corresponding neighbors sets (see $[25, 26]$ $[25, 26]$. For more results, refer to $[9, 20]$ $[9, 20]$ for example. For a non-abelian simple group G, the G-symmetric graphs are important basic graphs and have received wide attention. For example, Fang and Praeger $[6, 7]$ $[6, 7]$ classified G-symmetric graphs admitting G as Suzuki simple groups or Ree simple groups acting transitively on the set of 2-arcs of the graphs. For cubic G-symmetric graph, it was proved by Li [\[19\]](#page-15-5) that either G is a normal in $Aut(\Gamma)$, or $(G, Aut(\Gamma)) = (A_7, A_8), (A_7, S_8), (A_7, 2A_8), (A_{15}, A_{16})$ or $(GL(4, 2), AGL(4, 2)).$ Fang *et al* [\[3\]](#page-14-0) proved that none of the above five pairs can happen, that is, G is always normal in Aut(Γ). In this paper, we show that if Γ be a connected pentavalent G-symmetric graph, then either $G \trianglelefteq Aut(\Gamma)$ or $Aut(\Gamma)$ contains a non-abelian simple normal subgroup T such that $G < T$ and (G, T) is one of 17 possible pairs of non-abelian simple groups.

Investigation of Cayley graphs on a non-abelian simple group is currently a hot topic in algebraic graph theory. One of the most remarkable achievements is the complete classification of connected trivalent symmetric non-normal Cayley graphs on finite nonabelian simple groups. This work was began in 1996 by Li [\[19\]](#page-15-5), and he proved that a connected trivalent symmetric Cayley graph Γ on a non-abelian simple group G is either normal or $G = A_5$, A_7 , $PSL(2, 11)$, M_{11} , A_{11} , A_{15} , M_{23} , A_{23} or A_{47} . In 2005, Xu *et al* [\[32\]](#page-16-3) proved that either Γ is normal or $G = A_{47}$, and two years later, Xu *et al* [\[33\]](#page-16-4) further showed that if $G = A_{47}$ and Γ is not normal, then Γ must be 5-arc-transitive and up to isomorphism there are exactly two such graphs.

Let Γ be a connected symmetric Cayley graph Γ on a non-abelian simple group G. Fang, Praeger and Wang [\[8\]](#page-15-6) developed a general method to investigate the automorphism group $Aut(\Gamma)$, and using this, the symmetry of Cayley graphs of valency 4 or 5 has been investigated in [\[4,](#page-14-1) [5\]](#page-14-2). Now let Γ be non-normal and of valency 5. Fang *et al* [\[5\]](#page-14-2) proved that if Aut(Γ) is quasiprimitive then $(G, \text{soc}(Aut(\Gamma))) = (A_{n-1}, A_n)$, where either $n = 60 \cdot k$ with $k \mid 2^{15} \cdot 3$ and $k \neq 3, 4, 6, 8$ or $n = 10 \cdot m$ with $m \mid 8$, and if Aut(Γ) is not quasiprimitive then there is a maximal intransitive normal subgroup K of $Aut(\Gamma)$ such that the socle of Aut(Γ)/K, denoted by L, is a simple group containing $G = GK/K \cong G$ properly, where $(G, L) = (\Omega^-(8, 2), \text{PSp}(8, 2)), (A_{14}, A_{16}), (A_{n-1}, A_n)$ with $n \geq 6$ such that n is a

divisor of $2^{17} \cdot 3^2 \cdot 5$ or $\overline{G} = \overline{L}$ is isomorphic to an irreducible subgroup of PSL $(d, 2)$ for $4 \leq d \leq 17$ and the 2-part $|G|_2 > 2^d$. In this paper, we prove that $Aut(\Gamma)$ contains a non-abelian simple normal subgroup T such that $G < T$ and (G, T) is one of 13 possible pairs of non-abelian simple groups. The following is the main result of this paper.

Theorem 1.1 *Let* G *be a non-abelian simple group and* Γ *a connected pentavalent symmetric* G-vertex-transitive graph. Then either $G \trianglelefteq \text{Aut}(\Gamma)$, or $\text{Aut}(\Gamma)$ contains a non*abelian simple normal subgroup* T *such that* $G < T$ *and* $(G, T) = (\Omega_{8}^{-}(2), \text{PSp}(8, 2)),$ $(A_{14}, A_{16}), \text{ (PSL}(2, 8), A_9) \text{ or } (A_{n-1}, A_n) \text{ with } n \geq 6 \text{ and } n \mid 2^9 \cdot 3^2 \cdot 5.$

Corollary 1.2 *Let* G *be a non-abelian simple group and* Γ *a connected pentavalent* G*symmetric graph. Then either* $G \trianglelefteq Aut(\Gamma)$ *, or* $Aut(\Gamma)$ *contains a non-abelian simple normal subgroup* T *such that* $G < T$ *and* $(G, T) = (A_{n-1}, A_n)$ *with* $n = 2 \cdot 3$, $2^2 \cdot 3$, 2^4 , $2^3 \cdot 3, 2^5, 2^2 \cdot 3^2, 2^4 \cdot 3, 2^3 \cdot 3^2, 2^5 \cdot 3, 2^4 \cdot 3^2, 2^6 \cdot 3, 2^5 \cdot 3^2, 2^7 \cdot 3, 2^6 \cdot 3^2, 2^7 \cdot 3^2, 2^8 \cdot 3^2$ or $2^9 \cdot 3^2$. Moreover, if $T = A_6$, then Aut(Γ) = S₆ and if $T = A_{2^5}$, $A_{2^7 \cdot 3}$, $A_{2^7 \cdot 3^2}$, $A_{2^8 \cdot 3^2}$ or $A_{2^9 \cdot 3^2}$, then $\text{Aut}(\Gamma) = T$.

Corollary 1.3 *Let* G *be a non-abelian simple group and* Γ *a connected pentavalent symmetric* G-regular graph. Then either $G \trianglelefteq Aut(\Gamma)$, or $Aut(\Gamma)$ contains a non-abelian simple *normal subgroup T such that* $G < T$ *and* $(G, T) = (A_{n-1}, A_n)$ *with* $n = 2 \cdot 5$, $2^2 \cdot 5$, $2^3 \cdot 5$, $2 \cdot 3 \cdot 5$, $2^4 \cdot 5$, $2^3 \cdot 3 \cdot 5$, $2^4 \cdot 3^2 \cdot 5$, $2^6 \cdot 3 \cdot 5$, $2^5 \cdot 3^2 \cdot 5$, $2^7 \cdot 3 \cdot 5$, $2^6 \cdot 3^2 \cdot 5$, $2^7 \cdot 3^2 \cdot 5$ or $2^9 \cdot 3^2 \cdot 5$.

For connected symmetric cubic Cayley graphs on non-abelian simple groups, simi-lar to Corollary [1.3](#page-2-1) there are six possible pairs $(G, T) = (A_{47}, A_{48})$, $(PSL(2, 11), M_{11})$, $(M_{11}, M_{12}), (A_{11}, A_{12}), (M_{23}, M_{24})$ or (A_{23}, A_{24}) (see [\[19,](#page-15-5) Theorem 7.1.3]), and Xu *et al* [\[32,](#page-16-3) [33\]](#page-16-4) proved that only the pair $(G, T) = (A_{47}, A_{48})$ can happen and there are exactly two connected non-normal symmetric cubic Cayley graphs on A_{47} with automorphism groups A_{48} . Based on the method given in [\[32,](#page-16-3) [33\]](#page-16-4), we may show that $(G, T) = (A_9, A_{10})$ or (A_{19}, A_{20}) cannot happen in Corollary [1.3.](#page-2-1) For $(G, T) = (A_{39}, A_{40})$, with MAGMA [\[1\]](#page-14-3) we find a connected non-normal pentavalent Cayley graph on A_{39} (see Example [3.8\)](#page-14-4).

2 Preliminaries

In this section, we describe some preliminary results which will be used later. First we describe vertex stabilizers of connected pentavalent symmetric graphs.

Proposition 2.1 [\[11,](#page-15-7) Theorem 1.1] *Let* Γ *be a connected pentavalent* G*-symmetric graph* $with \ v \in V(\Gamma)$. Then $G_v \cong \mathbb{Z}_5$, D_5 , D_{10} , F_{20} , $F_{20} \times \mathbb{Z}_2$, $F_{20} \times \mathbb{Z}_4$, A_5 , S_5 , $A_4 \times A_5$, $S_4 \times S_5$, $(A_4 \times A_5) \rtimes \mathbb{Z}_2$, $\text{ASL}(2, 4)$, $\text{AGL}(2, 4)$, $\text{ALL}(2, 4)$, $\text{ATL}(2, 4)$ *or* $\mathbb{Z}_2^6 \rtimes \text{TL}(2, 4)$ *, where* F_{20} *is the Frobenius group of order* 20, $A_4 \rtimes \mathbb{Z}_2 = S_4$ *and* $A_5 \rtimes \mathbb{Z}_2 = S_5$ *. In particular,* $|G_v| = 5$ *,* $2 \cdot 5$, $2^2 \cdot 5$, $2^2 \cdot 5$, $2^3 \cdot 5$, $2^4 \cdot 5$, $2^2 \cdot 3 \cdot 5$, $2^3 \cdot 3 \cdot 5$, $2^4 \cdot 3^2 \cdot 5$, $2^6 \cdot 3^2 \cdot 5$, $2^5 \cdot 3^2 \cdot 5$, $2^6 \cdot 3 \cdot 5$, $2^6 \cdot 3^2 \cdot 5$, $2^7 \cdot 3 \cdot 5$, $2^7 \cdot 3^2 \cdot 5$ or $2^9 \cdot 3^2 \cdot 5$, respectively.

Let Γ be a graph and $N \leq \text{Aut}(\Gamma)$. The *quotient graph* Γ_N of Γ relative to N is defined as the graph with vertices the orbits of N on $V(\Gamma)$ and with two orbits adjacent if there is an edge in Γ between these two orbits.

Proposition 2.2 [\[21,](#page-15-8) Theorem 9] *Let* Γ *be a connected* G*-symmetric graph of prime valency, and let* $N \triangleleft G$ *have at least three orbits on* $V(\Gamma)$ *. Then* N *is the kernel of* G *on* $V(\Gamma_N)$ *, and semiregular on* $V(\Gamma)$ *. Furthermore,* Γ_N *is* G/N *-symmetric with* $G/N \leq$ $Aut(\Gamma_N)$.

For a group G and a prime p, denote by $O_p(G)$ the largest normal p-subgroup of G and by $\Phi(G)$ the Frattini subgroup of G, that is, the intersection of all maximal subgroups of G. By [\[29,](#page-16-5) Lemma 2.7], we have the following proposition.

Proposition 2.3 For a group G and a prime p, let $H = O_p(G)$ and $V = H/\Phi(H)$. Then G has a natural action on V, induced from the action of G on H by conjugation. If $C_G(H) \leq H$, then H is the kernel of this action of G on V, that is, $G/H \leq GL(V)$.

The following result follows from the classification of three-factor simple groups.

Proposition 2.4 [\[17,](#page-15-9) Theorem I] *Let* G *be a non-abelian simple* {2, 3, 5}*-group. Then* $G = A_5$, A_6 *or* $PSU(4, 2)$ *.*

Given a group G, its factorization $G = HD$ is said to be *maximal* if both H and D are maximal subgroups of G.

Proposition 2.5 [\[5,](#page-14-2) Lemma 3.3] *Let* T *be a simple group and* G *a non-abelian simple* subgroup such that $|T:G| = n > 1$ and $n = 2^a \cdot 3^b \cdot 5^c$ for some $0 \le a \le 9$, $0 \le b \le 2$ and $0 \leq c \leq 1$ *. If* $T = HD$ *is a maximal factorization with* $G \leq H$ *, then* T *,* G *and* $|T : G|$ *are listed in Table [1.](#page-3-0)*

Let G and E be two groups. We call an extension E of G by N a *central extension* of G if E has a central subgroup N such that $E/N \cong G$, and if further E is perfect, that is,

the derived group E' equal to E , we call E a *covering group* of G . A covering group E of G is called a *double cover* if $|E| = 2|G|$. Schur [\[28\]](#page-16-6) proved that for every non-abelian simple group G there is a unique maximal covering group M such that every covering group of G is a factor group of M (see [\[15,](#page-15-10) Kapitel V, §23]). This group M is called the *full covering group* of G, and the center of M is the *Schur multiplier* of G, denoted by $Mult(G)$.

Proposition 2.6 For $n \geq 5$, the alternating group A_n has a unique double cover $2.A_n$, *and for* $n \geq 7$ *, all subgroups of index* n *of* 2. A_n *are conjugate and isomorphic to* 2. A_{n-1} *.*

Proof: By Kleidman and Liebeck [\[18,](#page-15-11) Theorem 5.1.4], Mult $(A_n) \cong \mathbb{Z}_2$ for $n \geq 5$ with $n \neq 6, 7$, and Mult $(A_n) \cong \mathbb{Z}_6$ for $n = 6$ or 7. This implies that A_n has a unique double cover for $n \geq 5$, denoted by $2.A_n$. Since A_n has no proper subgroup of index less than n, all subgroups of index n of $2.A_n$ contain the center of $2.A_n$. Let $n \ge 7$. By [\[31,](#page-16-7) 2.7.2], 2. A_n contains a subgroup 2. A_{n-1} of index n, and since all subgroups of index n of A_n are conjugate, all subgroups of index n of 2. A_n are conjugate and isomorphic to 2. A_{n-1} . \Box

Let G be a group. For $H \leq G$, let D be a union of some double cosets of H in G such that $D^{-1} = D$. The *coset graph* $\Gamma = \text{Cos}(G, H, D)$ on G with respect to H and D is defined to have vertex set $V(\Gamma) = [G : H]$, the set of right cosets of H in G, and edge set $E(\Gamma) = \{ \{ Hq, Hdq \} \mid q \in G, d \in D \}.$ The graph Γ has valency $|D|/|H|$ and it is connected if and only if $G = \langle D, H \rangle$, that is, D and H generate G. The action of G on $V(\Gamma)$ by right multiplication induces a transitive group of automorphisms, and this group is symmetric if and only if D is a single double coset. Moreover, this action is faithful if and only if $H_G = 1$, where H_G is the largest normal subgroup of G contained in H.

Conversely, let Γ be a G-vertex-transitive graph with $G \leq Aut(\Gamma)$. By [\[27\]](#page-16-8), the graph Γ is isomorphic to a coset graph $\text{Cos}(G, H, D)$, where $H = G_v$ is the vertex stabilizer of $v \in V(\Gamma)$ in G and D consists of all elements of G mapping v to one of its neighbors. It is easy to show that $H_G = 1$ and D is a union of some double cosets of H in G satisfying $D^{-1} = D$. Assume that Γ is G-symmetric and $g \in G$ interchanges v and one of its neighbors. Then $g^2 \in H$ and $D = HgH$. Furthermore, g can be chosen as a 2-element in G, and the valency of Γ is $|D|/|H| = |H : H \cap H^g|$. For more details regarding coset graph, referee to [\[6,](#page-15-3) [21,](#page-15-8) [22,](#page-15-12) [27\]](#page-16-8).

Proposition 2.7 *Let* Γ *be a connected* G*-symmetric graph of valency* k*, and let* {u, v} *be an edge of* Γ. Then Γ *is isomorphic to a coset graph* $\text{Cos}(G, G_v, G_v, G_v, G_v)$ *, where g is a* 2-element in G such that $G_{uv}^g = G_{uv}, g^2 \in G_v, \langle G_v, g \rangle = G$, and $k = |G_v : G_v \cap G_v^g|$.

In Proposition [2.7,](#page-4-0) the 2-element g such that $g^2 \in G_v$, $\langle G_v, g \rangle = G$ and $k = |G_v|$: $G_v \cap G_v^g$, is called *feasible* to G and G_v . Feasible g can be computed by MAGMA [\[1\]](#page-14-3) when the order $|G|$ is not too large, and this is often used in Section [1.1.](#page-2-2)

3 Proof of Theorem [1.1](#page-2-2)

In this section, we always assume that G is a non-abelian simple group. Let us begin by proving a series of lemmas which will be used in the proof of Theorem [1.1.](#page-2-2)

Lemma 3.1 *Let* Γ *a connected pentavalent symmetric* G*-vertex-transitive graph with* G = A₅. Then either $G \trianglelefteq \text{Aut}(\Gamma)$, or $\Gamma = K_6$ and $\text{Aut}(\Gamma) = S_6$.

Proof: Set $A = \text{Aut}(\Gamma)$. Assume $G \nleq A$. Since $|A_5| = 2^2 \cdot 3 \cdot 5$ and Γ is a connected pentavalent symmetric G-vertex-transitive graph, we have $|V(\Gamma)| = 2^2 \cdot 3 \cdot 5$, $2 \cdot 3 \cdot 5$, $2^2 \cdot 5$, $2 \cdot 5$, $2^2 \cdot 3$ or $2 \cdot 3$. If $|V(\Gamma)| = 2^2 \cdot 3 \cdot 5$, by [\[12,](#page-15-13) Theorem 4.1], $\Gamma = \mathcal{G}_{60}$ and $A = A_5 \rtimes D_5$, implying that $G \trianglelefteq A$, contrary to the assumption $G \ntrianglelefteq A$. By [\[14,](#page-15-14) Theorems 4.1 and 4.2], there is no connected pentavalent symmetric graph of order $2 \cdot 3 \cdot 5$ or $2^2 \cdot 5$. If $|V(\Gamma)| = 2 \cdot 5$, then $\Gamma = K_{5,5}$ with $A = (S_5 \times S_5) \rtimes \mathbb{Z}_2$ where $S_5 \times S_5$ fixes the bipartite sets of Γ . Since $G = A_5 \leq S_5 \times S_5$, Γ is not G-vertex-transitive, contrary to the hypothesis that Γ is Gvertex-transitive. If $|V(\Gamma)| = 2^2 \cdot 3$, by [\[14,](#page-15-14) Theorem 4.1], Γ is the Icosahedron graph I_{12} , or $K_{6,6}$ – 6 K_2 , the complete bipartite graph of order 12 minus a one factor. If $\Gamma = K_{6,6} - 6K_2$ then $A = S_6 \times \mathbb{Z}_2$ and S_6 fixes the bipartite sets of Γ. Thus, $G = A_5 \leq A_6 \leq S_6$ and Γ is not G-vertex-transitive, a contradiction. If $\Gamma = I_{12}$ then $A = A_5 \times \mathbb{Z}_2$, implying that $G \leq A$, a contradiction. Thus, $|V(\Gamma)| = 6$. It follows that $\Gamma = K_6$ and $A = S_6$. □

Lemma 3.2 *Let* Γ *be a connected pentavalent symmetric* G*-vertex-transitive graph with* $v \in V(\Gamma)$ *. Let* $H \leq \text{Aut}(\Gamma)$ and $GH \leq \text{Aut}(\Gamma)$ *. Then* $|(HG)_v|/|G_v| = |H|/|H \cap G|$ is a divisor of $2^9 \cdot 3^2 \cdot 5$.

Proof: Since Γ is G-vertex-transitive, the Frattini argument implies $GH = G(GH)_v$ and $|H||G|/|H \cap G| = |HG| = |G(GH)_v| = |G||(GH)_v|/|G \cap (GH)_v| = |G||(GH)_v|/|G_v|,$ that is, $|H|/|H \cap G| = |(GH)_v|/|G_v|$. Since $GH \leq Aut(\Gamma)$, Proposition [2.1](#page-2-3) implies $|(GH)_v| \nvert 2^9 \cdot 3^2 \cdot 5$. It follows $|H|/|H \cap G| \nvert 2^9 \cdot 3^2 \cdot 5$. □

The *radical* of a finite group is the largest solvable normal subgroup of the group.

Lemma 3.3 *Let* Γ *be a connected pentavalent symmetric* G*-vertex-transitive graph and* R *the radical of* $Aut(\Gamma)$ *. Let* $G \neq A_5$ *and* $5 | |R|$ *. Then* $RG = R \times G$ *.*

Proof: Let $v \in V(\Gamma)$ and set $B = RG$. Since $G \cap R \trianglelefteq G$, we have $G \cap R = 1$ because the simplicity of G implies $G \nleq R$. It follows $|B| = |R||G|$, and by Lemma [3.2,](#page-5-0) $|R| =$ $|B_v|/|G_v|$ $\begin{array}{c|c|c|c|c|c} 2^9 & 3^2 & 5 \end{array}$. Since 5 $\begin{array}{c|c|c|c} |R|$, we have 5 $\begin{array}{c|c|c|c} |B_v| \end{array}$, that is, Γ is B-symmetric.

Since R is solvable, R has a Hall $\{2,3\}$ -subgroup, say H. Set $\Omega = \{H^r | r \in R\}$. By [\[13\]](#page-15-15), all Hall $\{2,3\}$ -subgroups of R are conjugate and so the conjugate action of B is transitive on Ω . Since $|R| \mid 2^9 \cdot 3^2 \cdot 5$, we have $|\Omega| = |R : N_R(H)| = 1$ or 5, and since $G \neq A_5$, the conjugate action of G on Ω is trivial. This means that G normalizes H, implying $GH \leq B$. Set $Y = GH$ and $\Delta = \{Yb | b \in B\}$. Then $|\Delta| = |B : Y| = 5$. The kernel of the right multiplication action of B on Δ is Y_B, the largest normal subgroup of B contained in Y. It follows $B/Y_B \lesssim S_5$ and so $G \leq Y_B$, as $G \neq A_5$.

Since $|G||H|/|G \cap H| = |GH| = |Y| = |G||Y_v|$, Y_v is a $\{2,3\}$ -group as H is a $\{2,3\}$ group, and hence $(Y_B)_v$ is a $\{2,3\}$ -group. Recall that Γ is B-symmetric and has valency 5. If $(Y_B)_v \neq 1$, then B_v is primitive on the neighborhood $\Gamma(v)$ of v in Γ, and then $Y_B \trianglelefteq B$ implies $5 \mid |(Y_B)_v|$, a contradiction. It follows $(Y_B)_v = 1$ and $Y_B = G(Y_B)_v = G$. In particular, $G \trianglelefteq B$ and so $B = R \times G$. □

Lemma 3.4 *Let* Γ *a connected pentavalent G*-symmetric graph with $G \leq S_9$ and $G \neq A_5$. *Then* $G \triangleleft \text{Aut}(\Gamma)$ *.*

Proof: Set $A = \text{Aut}(\Gamma)$. By the simplicity of $G, G \leq S_9$ implies $G \leq A_9$. By the Atlas [\[2,](#page-14-5) p. 37, $G = A_9$ or $G \leq A_8, A_7, A_6, A_5$, $PSL(2,8)$. Similarly, if $G \leq A_8$ then $G = A_8$ or $G \leq A_7, A_6, \text{PSL}(3, 2), A_5$; if $G \leq A_7$ then $G = A_7$ or $G \leq A_6, A_5, \text{PSL}(2, 7)$; if $G \leq A_6$ then $G = A_6$ or A_5 . Since Γ is G-symmetric with $G \neq A_5$, we have $G = A_9$, A_8 , A_7 or A_6 .

By Proposition [2.7,](#page-4-0) $\Gamma = \text{Cos}(G, G_v, G_v, G_v)$ for some feasible g, that is, a 2-element g in G satisfying $g^2 \in G_v$, $\langle G_v, g \rangle = G$ and $5 = |G_v : G_v \cap G_v^g|$. By Proposition [2.1,](#page-2-3) g has order at most 8.

For $G = A_9$, by the Atlas [\[2,](#page-14-5) p. 37] and Proposition [2.1,](#page-2-3) we have $G_v \cong \mathbb{Z}_5$, D_5 , D_{10} , F_{20} , $F_{20} \times \mathbb{Z}_2$, A_5 , S_5 , $A_4 \times A_5$ or $(A_4 \times A_5) \rtimes \mathbb{Z}_2$. By MAGMA, G has two conjugacy classes of subgroups isomorphic to $D_5, D_{10}, F_{20}, F_{20} \times \mathbb{Z}_2, A_5$ or S_5 and one conjugacy class of subgroups isomorphic to \mathbb{Z}_5 , $A_4 \times A_5$ or $(A_4 \times A_5) \rtimes \mathbb{Z}_2$.

Let $G_v \cong A_5$ or S_5 . By taking a given G_v in each conjugacy class, computation with MAGMA shows that there is no feasible q .

Let $G_v \cong D_5, D_{10}, F_{20}$ or $F_{20} \times \mathbb{Z}_2$. Then G_v has two conjugacy classes, and computation shows that there is no feasible g in one of the two classes. Take a given G_v in the other class. By MAGMA, if $G_v \cong D_5$ then there are 80 feasible g, and for each of them, the corresponding coset graph Γ is a connected pentavalent G-symmetric graph with $A = A_9 \times \mathbb{Z}_2^2$. Similarly, if $G_v \cong D_{10}$, F_{20} or $F_{20} \times \mathbb{Z}_2$ then in each case, there are 80 feasible g, and for each of them, the corresponding coset graph Γ is a connected pentavalent G-symmetric graph with $A = A_9 \times \mathbb{Z}_2$, $A_9 \rtimes \mathbb{Z}_4$ or S_9 respectively. It follows $G \trianglelefteq A$.

Let $G_v \cong \mathbb{Z}_5$, $A_4 \times A_5$ or $(A_4 \times A_5) \rtimes \mathbb{Z}_2$. Then G_v has one conjugacy class and take a given G_v in the class. By MAGMA, if $G_v \cong \mathbb{Z}_5$ then there are 120 feasible g, and for each of them, the corresponding coset graph is a connected pentavalent G-symmetric graph with $A = A_9 \times \mathbb{Z}_4$. Similarly, if $G_v \cong A_4 \times A_5$ or $(A_4 \times A_5) \rtimes \mathbb{Z}_2$ then in each case, there are 480 feasible g, and for each of them, the corresponding coset graph is a connected pentavalent G-symmetric graph with $A = A_9 \times \mathbb{Z}_2$ or S_9 respectively. It follows $G \trianglelefteq A$.

For $G = A_8$, A_7 or A_6 , similar arguments as the case $G = A_9$ give rise to $G \trianglelefteq A$. \Box

Lemma 3.5 *Let* Γ *be a connected pentavalent* G*-symmetric graph and* R *the radical of* Aut(Γ)*.* Then $RG = R \times G$.

Proof: Set $B = RG$ and $A = Aut(\Gamma)$. Since $G \cap R \leq G$, we have $G \cap R = 1$ because the simplicity of G implies $G \not\leq R$. It follows $|B| = |R||G|$. Since Γ is G-symmetric, we have 5 $\left| \begin{array}{l} |G_v| \text{ for } v \in V(\Gamma). \end{array} \right.$ By Lemma [3.2,](#page-5-0) $|R| = |B_v|/|G_v|$, and by Proposition [2.1,](#page-2-3) $|R| \left| 2^9 \cdot 3^2$.

If $G \leq A_9$, Lemmas [3.1](#page-4-1) and [3.4](#page-5-1) imply that either $G \leq A$, or $G = A_5$ and $\Gamma = K_6$ (for this case $R = 1$). Thus, $RG = R \times G$ for $G \leq A_9$. In what follows we may assume $G \nleq S_9$.

Let $\text{Syl}_2(R)$ be the set of Sylow 2-subgroups of R. Recall that $R \leq A$ and $|R| \left| 2^9 \cdot 3^2 \right|$ By Sylow's Theorem, $|\mathrm{Syl}_2(R)| = 1, 3$ or 9. Since $R \leq B$, G has a natural action on $\mathrm{Syl}_2(R)$ by conjugation, and since $G \nleq S_9$, G fixes every element in $Syl_2(R)$. Thus, G normalizes P for any $P \in \mathrm{Syl}_2(R)$. Clearly, $|P| = 2^r$ for some $0 \le r \le 9$.

Now we claim $GP = G \times P$. Set $D = PG$. Then $P \triangleleft D$ and Γ is D-symmetric. The simplicity of G implies $P \cap G = 1$. By Lemma [3.2,](#page-5-0) $|P| = |P|/|P \cap G| = |D_v|/|G_v| = 2^r$ and hence $|D_v| = 2^r \cdot |G_v|$, which implies that if $G_v \cong \mathbb{Z}_5$ then by Proposition [2.1,](#page-2-3) $D_v \cong D_5$, D_{10} , F_{20} , $F_{20} \times \mathbb{Z}_2$ or $F_{20} \times \mathbb{Z}_4$. Thus, $r \leq 5$. This is always true for other G_v by checking all other possible cases in Proposition [2.1.](#page-2-3) In particular, $r = 5$ if and only if $(G_v, D_v) \cong (A_5, \text{AZL}(2, 4))$ or $(A_4 \times A_5, \mathbb{Z}_2^6 \rtimes \text{TL}(2, 4)).$

Let $C = C_D(P)$. Then $C \le D$ and $G \cap C = G$ or 1. Suppose $G \cap C = 1$. Since P is 2-group and $D/P \cong G$ is simple, we have $P = O_2(D)$, the largest normal 2-subgroup of D. On the other hand, since $D = PG$ and $G \cap C = 1$, C is 2-group and hence $C \leq P$. Since $r \le 5$, Proposition [2.3](#page-3-1) implies $G \cong D/P \le GL(5, 2) \cong \text{PSL}(5, 2)$, and since $G \nleq S_9$, the Atlas [\[2,](#page-14-5) p. 70] implies $G = \text{PSL}(5, 2)$ because $\text{PSL}(4, 2) \cong A_8$. It follows that $r = 5$ and $(G_v, D_v) \cong (A_5, A\Sigma L(2, 4))$ or $(A_4 \times A_5, \mathbb{Z}_2^6 \rtimes \Gamma L(2, 4))$. However, by MAGMA, G has no subgroup isomorphic to $A_4 \times A_5$. Thus, $G_v \cong A_5$, and by Proposition [2.7,](#page-4-0) $\Gamma =$ $\text{Cos}(G, G_v, G_v, G_v, G_v)$ for a 2-element g such that $g^2 \in G_v$, $\langle G_v, g \rangle = G$ and $|G_v : G_v \cap G_v^g| = 5$. Again by MAGMA, G has four conjugacy classes of subgroups isomorphic to A_5 and by taking a G_v in each class, computation shows that there is no feasible g for G_v . It follows $G \cap C = G$, that is, $G \leq C$. Since $G \cap P = 1$, we have $D = P \times G$, as claimed.

Set $\Omega = \{Db \mid b \in B\}$. Then $|\Omega| = 1, 3$ or 9. By considering the right multiplication action of B on Ω , we have $B/D_B \leq S_9$, where D_B is the largest normal subgroup of B contained in D. Since $G \nleq S_9$, we have $G \leq D_B$. Thus, G is characteristic in D_B because $D = P \times G$ implies that G is characteristic in D. It follows that $G \trianglelefteq B$ as $D_B \trianglelefteq B$. Since $R \trianglelefteq B$ and $R \cap G = 1$, we have $B = RG = R \times G$. \Box

Lemma 3.6 *Let* Γ *be a connected pentavalent* X*-symmetric* G*-vertex-transitive graph with* $G \leq X$. Assume X has trivial radical. Then either $G \leq X$, or X has a non-abelian $simple\ normal\ subgroup\ T\ such\ that\ G < T\ and\ (G,T) = (\Omega_8^-(2),\text{PSp}(8,2)),\ (A_{14},A_{16}),$ $(PSL(2,8), A_9)$ *or* (A_{n-1}, A_n) *with* $n \geq 6$ *and* $n \mid 2^9 \cdot 3^2 \cdot 5$ *.*

Proof: Let $A = Aut(\Gamma)$. Let N be a minimal normal subgroup of X. Since X has trivial radical, $N = T^s$ for a positive integer s and a non-abelian simple group T. Then $NG \leq X$, and by Lemma [3.2,](#page-5-0) $|N|/|N \cap G|$ $|2^9 \cdot 3^2 \cdot 5$.

If $G = A_5$, by Lemma [3.1,](#page-4-1) either $G \leq X$ or $\Gamma = K_6$ and $A = S_6$. For the latter, $(G, T) = (A_5, A_6)$. In what follows we may assume $G \neq A_5$ and $G \nleq X$. Thus, $G \ntriangleq A$.

Suppose $N \cap G = 1$. Then $|N| = |N|/|N \cap G|$ $|2^9 \cdot 3^2 \cdot 5$, $|K| = |NG| = |N||G|$ and $K/N \cong G$. Write $K = NG$. For $v \in V(\Gamma)$, we have $K = GK_v$ and $|K| = |GK_v|$ $|G||K_v|/|G_v|$. It follows $|K_v| = |G_v||N|$. Note that $|PSU(4, 2)| = 2^6 \cdot 3^4 \cdot 5$. By Proposi-tion [2.4,](#page-3-2) $N = A_5$ or A_6 . Thus, $5 \mid |K_v|$, forcing that Γ is K-symmetric. Let $C = C_K(N)$.

Assume $C = 1$. Then $G \leq K = K/C \leq \text{Aut}(N) \leq S_6$, implying that $5 \mid |G|$ and $5^2 \nmid |K|$. On the other hand, $5^2 \nmid |N||G| = |K|$, a contradiction.

Assume $C \neq 1$. Then $C \cap N = Z(N) = 1$, and $C = C/C \cap N \cong CN/N \leq K/N \cong G$. Since $|K| = |N||G| = |N||C|$, we have $K = C \times N$. First let $C \cap G = 1$. Then $|CG| = |C||G|$. Since $CG \leq K$, $|CG|$ is a divisor of $|K| = |N||C|$, implying $|G| \cdot |N|$. Since $N \cong A_5$ or A_6 and $G \neq A_5$, we have $C \cong G \cong N = A_6$ and hence $K = C \times N \cong A_6 \times A_6$.

If $C_v = 1$ then C is regular on $V(\Gamma)$ because Γ is G-vertex-transitive. In this case, $|C||N| = |K| = |CK_v| = |C||K_v|$ and $|K_v| = |N| = |A_6| = 2^3 \cdot 3^2 \cdot 5$, which is impossible by Proposition [2.1.](#page-2-3) Thus, $C_v \neq 1$, and similarly, $N_v \neq 1$. Since Γ is K-symmetric and has valency 5, K_v is primitive on the neighborhood $N(v)$, and since $C_v \trianglelefteq K_v$ and $N_v \trianglelefteq K_v$, both C_v and N_v are transitive on $N(v)$. It follows $5 \mid |N_v|$ and $5 \mid |C_v|$, and hence $5^2 \mid |K_v|$, contrary to Proposition [2.1.](#page-2-3) Now let $C \cap G \neq 1$. Then $G \leq C$ as G is simple. Since $C \cong G$, we have $C = G$, and so $K = G \times N$. Set $L = C_X(N)$ and $M = LN$. Then $L \leq X, G \leq L$ and $M = L \times N$ because $L \cap N = Z(N) = 1$. Since $G \nleq X, G$ is a proper subgroup of L and hence $L_v \neq 1$. It follows $5 \mid |L_v|$ because Γ is X-symmetric. Since $|L||N| = |M| = |LM_v| = |L||M_v|/|L_v|$, we have $|M_v| = |L_v||N|$, which implies $5^2 |M_v|$, contrary to Proposition [2.1.](#page-2-3)

The above contradictions imply $N \cap G \neq 1$, and so $G \leq N$. Thus, $|N|/|G| = |N|/|N \cap G|$ $G \mid 2^9 \cdot 3^2 \cdot 5$. Since $G \nleq X$, G is a proper subgroup of N, yielding $5 \mid |N_v|$. It follows that Γ is *N*-symmetric. Recall that $N = T^s$ for some $s \geq 1$.

Suppose $s \geq 2$. We claim $|T| \leq 2^9 \cdot 3^2 \cdot 5$. It suffices to show $|T| \leq |N|/|G|$. Note that ļ $T \cap G = G$ or 1. If $T \cap G = G$ then $G \leq T$ and so $|G| \cdot |T|$. Since $s \geq 2$, we have $|T| \mid |N|/|G|$. If $G \cap T = 1$ then $|TG| = |T||G|$. Since $TG \leq N$, we have $|G| \mid |T|^{s-1}$ and hence $|T| \bigcup |N|/|G|$, as required. The proof also implies that if $s = 2$ then $|G| \bigcup |T|$.

Since $G \leq N$, the above claim means that both G and T are non-abelian simple $\{2,3,5\}$ -groups. Since $G \neq A_5$, Proposition [2.4](#page-3-2) implies $G = A_6$ or PSU(4, 2) and also $T = A_6$ or $PSU(4, 2)$. Since $5^2 \nmid |N|/|G|$, we have $s = 2$ and so $|G| \nmid |T|$. Note that $N = T \times T$. If both direct factors T of N are not semiregular, then 5 | $|T_v|$ for each T because Γ is N-symmetric, yielding $5^2 \mid |N_v|$, contrary to Proposition [2.1.](#page-2-3) Thus, N has a direct factor T with $T_v = 1$. Since $|G| ||T|$ and Γ is G-vertex-transitive, T is regular on $V(\Gamma)$ and so $|N_v| = |T| = |A_6|$ or $|PSU(4, 2)|$, that is, $2^3 \cdot 3^2 \cdot 5$ or $2^6 \cdot 3^4 \cdot 5$, of which both are impossible by Proposition [2.1.](#page-2-3)

The above contradictions imply $s = 1$, that is, $N = T$ is a non-abelian simple group. Thus, $G \leq T \leq X$ and $|T : G| = |N|/|G| + 2^9 \cdot 3^2 \cdot 5$. Since Γ is X-symmetric, it is also T-symmetric, that is, 5 | $|T_v|$. Furthermore, $|T|/|G| = |T_v|/|G_v|$ and $G \neq T$ ļ as $G \nleq X$. If $|T|/|G| \nvert 2^9 \cdot 3^2$, then $5 \nvert T_v|$, implying that Γ is G -symmetric. By Proposition [2.7,](#page-4-0) $\Gamma = \text{Cos}(T, T_v, T_v t T_v)$ for some feasible t, and if Γ is G-symmetric then $\Gamma = \text{Cos}(G, G_v, G_v, G_v, G_w)$ for some feasible g.

By the Frattini argument, $T = GT_v$. Let H and D be maximal subgroups of T containing G and T_v , respectively. Then $T = HD$ is a maximal factorization of T. By Proposition [2.5,](#page-3-3) (G, T) is listed in Table [1.](#page-3-0) Clearly, $(G, T) \neq (PSL(2, 7), PSU(3, 3))$ as $5 \nmid \text{PSU}(3,3)|$. To finish the proof, we only need to show $(G, T) \neq (A_6, \text{PSU}(4, 2)),$ $(A_7, \text{PSp}(6, 2)), (A_7, A_9), (A_8, \text{PSp}(6, 2)), (\text{PSL}(2, 11), M_{11}), (\text{PSL}(2, 11), M_{12}), (M_{11},$ M_{12}), (M_{23}, M_{24}) , $(PSL(2, 25), {}^{2}F_{4}(2)')$, $(PSL(2, 16), PSp(4, 4))$, $(PSL(2, 7), PSL(3, 4))$, $(PSL(2, 7), A_7)$, $(PSL(3, 2), A_8)$, $(PSL(2, 8), PSp(6, 2)), (A_8, A_{10}), (A_7, A_{10}), (A_9, P\Omega^+(8, 2))$ or $(PSp(6, 2), P\Omega^+(8, 2)).$

Suppose $(G, T) = (A_6, \text{PSU}(4, 2)), (A_7, \text{PSp}(6, 2)), (A_7, A_9)$ or $(A_8, \text{PSp}(6, 2)).$ Then $|T_v|/|G_v| = |T|/|G| \left(2^6 \cdot 3^2 \text{ and } \Gamma \text{ is } G\text{-symmetric. By Lemma 3.4, } G \leq A, \text{ a contradiction.} \right)$ $|T_v|/|G_v| = |T|/|G| \left(2^6 \cdot 3^2 \text{ and } \Gamma \text{ is } G\text{-symmetric. By Lemma 3.4, } G \leq A, \text{ a contradiction.} \right)$ $|T_v|/|G_v| = |T|/|G| \left(2^6 \cdot 3^2 \text{ and } \Gamma \text{ is } G\text{-symmetric. By Lemma 3.4, } G \leq A, \text{ a contradiction.} \right)$ Suppose $(G, T) = (PSL(2, 11), M_{11})$ or $(PSL(2, 11), M_{12})$. Then $|T_v|/|G_v| = |T|/|G|$

 $\frac{1}{2}$ $2^4 \cdot 3^2$ and Γ is G-symmetric. By the Atlas [\[2,](#page-14-5) p. 7] and Proposition [2.1,](#page-2-3) $G_v \cong \mathbb{Z}_5$, D_5

or A_5 . If $G_v \cong A_5$ then $|V(\Gamma)| = 11$, which is impossible because there is no pentavalent graph of odd order. It follows $G_v \cong \mathbb{Z}_5$ or D_5 , and hence $|V(\Gamma)| = 132$ or 66. By [\[12,](#page-15-13) Theorem 4.1] and [\[14,](#page-15-14) Theorem 4.2], $\Gamma = \mathcal{G}_{132}^1$, \mathcal{G}_{132}^2 , \mathcal{G}_{132}^3 or \mathcal{G}_{66} : $A = \text{PSL}(2, 11) \times \mathbb{Z}_2$ for $\Gamma = \mathcal{G}_{132}^1$ and $A = \text{PGL}(2, 11)$ for other cases. In all cases, $G \leq A$, a contradiction.

Suppose $(G, T) = (M_{11}, M_{12})$. Then $|T_v|/|G_v| = |T|/|G| \mid 2^2 \cdot 3$ and Γ is G-symmetric. By the Atlas [\[2,](#page-14-5) p. 18] and Proposition [2.1,](#page-2-3) $G_v \cong \mathbb{Z}_5$, D_5 , F_{20} , A_5 or S_5 , and $|T_v|$ = $|G_v||T|/|G| = 2^2 \cdot 3 \cdot 5$, $2^3 \cdot 3 \cdot 5$, $2^4 \cdot 3 \cdot 5$, $2^4 \cdot 3^2 \cdot 5$ or $2^5 \cdot 3^2 \cdot 5$, respectively. By Proposition [2.1,](#page-2-3) $(G_v, T_v) \cong (\mathbb{Z}_5, A_5)$, (D_5, S_5) , $(A_5, A_4 \times A_5)$ or $(S_5, (A_4 \times A_5) \rtimes \mathbb{Z}_2)$. By MAGMA, T has no subgroups isomorphic to $A_4 \times A_5$ or $(A_4 \times A_5) \rtimes \mathbb{Z}_2$, and G has one conjugacy class of subgroups isomorphic to \mathbb{Z}_5 or D_5 . Take a given G_v in each class: for $G_v \cong D_5$, there is no feasible g for G_v , and for $G_v \cong \mathbb{Z}_5$, there are 40 feasible g for G_v . For every such feasible g, the corresponding coset graph Γ is a connected pentavalent G-symmetric graph with $A = M_{11}$. Thus, $G \leq A$, a contradiction.

Suppose $(G, T) = (M_{23}, M_{24})$. Then $|T_v|/|G_v| = |T|/|G| \mid 2^3 \cdot 3$ and Γ is G-symmetric. By the Atlas [\[2,](#page-14-5) p. 71] and Proposition [2.1,](#page-2-3) $G_v \cong \mathbb{Z}_5$, D_5 , F_{20} , A_5 , S_5 , ASL(2, 4), AGL(2, 4), $\text{A}\Sigma\text{L}(2,4)$ or $\text{A}\Gamma\text{L}(2,4)$, and $|T_v| = |G_v||T|/|G| = 2^3 \cdot 3 \cdot 5$, $2^4 \cdot 3 \cdot 5$, $2^5 \cdot 3 \cdot 5$, $2^5 \cdot 3^2 \cdot 5$, $2^6 \cdot 3^2 \cdot 5$, $2^9 \cdot 3^2 \cdot 5$, $2^9 \cdot 3^3 \cdot 5$, $2^{10} \cdot 3^2 \cdot 5$ or $2^{10} \cdot 3^3 \cdot 5$, respectively. By Proposition [2.1,](#page-2-3) $(G_v, T_v) \cong (\mathbb{Z}_5, S_5)$, $(A_5, (A_4 \times A_5) \rtimes \mathbb{Z}_2)$, $(S_5, \text{AGL}(2, 4))$, $(S_5, S_4 \times S_5)$ or $(\text{ASL}(2, 4), \mathbb{Z}_2^6 \rtimes \text{TL}(2, 4))$. By MAGMA, T has no subgroup isomorphic to $S_4 \times S_5$, AGL $(2, 4)$ has no subgroup isomorphic to S_5 , and $\mathbb{Z}_2^6 \rtimes \text{TL}(2, 4)$ has no subgroup isomorphic to $\text{ASL}(2, 4)$ (both are subgroups of M_{24}). Furthermore, T has five conjugacy classes of subgroups isomorphic to S_5 and one conjugacy class of subgroups isomorphic to $(A_4 \times A_5) \rtimes \mathbb{Z}_2$. Take a given T_v in each class, and computation shows that T has no feasible t for each T_v , a contradiction.

Suppose $(G, T) = (PSL(2, 25), {}^2F_4(2)')$. Then $|T_v|/|G_v| = |T|/|G| \mid 2^8 \cdot 3^2$ and Γ is G-symmetric. By the Atlas [\[2,](#page-14-5) p. 16] and Proposition [2.1,](#page-2-3) $G_v \cong \mathbb{Z}_5$, D_5 , F_{20} , A_5 or S_5 , and $|T_v| = |G_v||T|/|G| = 2^8 \cdot 3^2 \cdot 5$, $2^9 \cdot 3^2 \cdot 5$, $2^{10} \cdot 3^2 \cdot 5$, $2^{10} \cdot 3^3 \cdot 5$ or $2^{11} \cdot 3^3 \cdot 5$, respectively. By Proposition [2.1,](#page-2-3) $(G_v, T_v) \cong (D_5, \mathbb{Z}_2^6 \rtimes \Gamma\mathbb{L}(2, 4))$, and by MAGMA, G contains two conjugacy classes of subgroups isomorphic to D_5 . By taking a given T_v in each conjugacy class, computation shows that for each G_v there are 40 feasible g, and for every such g, the corresponding coset graph Γ is a connected pentavalent G-symmetric graph with $A = \text{PSL}(2, 25) \times \mathbb{Z}_2$. Thus, $G \leq A$, a contradiction.

Suppose $(G, T) = (PSL(2, 16), PSp(4, 4))$. Then $|T_v|/|G_v| = |T|/|G| = 2^4 \cdot 3 \cdot 5 \cdot |T_v|$. Since $|T| = 2^8 \cdot 3^2 \cdot 5^2 \cdot 17$, Proposition [2.1](#page-2-3) implies $T_v \cong A_4 \times A_5$, $(A_4 \times A_5) \rtimes \mathbb{Z}_2$, $S_4 \times S_5$, ASL $(2,4)$, AGL $(2,4)$, A Σ L $(2,4)$, A Γ L $(2,4)$. However, by MAGMA, PSp $(4,4)$ has no subgroup isomorphic to $(A_4 \times A_5) \rtimes \mathbb{Z}_2$, $S_4 \times S_5$, $\text{ASL}(2,4)$, $\text{AGL}(2,4)$, $\text{AZL}(2,4)$ or AFL(2, 4). For $T_v \cong A_4 \times A_5$, T_v has two conjugacy classes in T. By taking a given T_v in each conjugacy class, computation shows that there is no feasible t , a contradiction.

Suppose $(G, T) = (PSL(2, 7), PSL(3, 4))$. Then $|T| = 2^6 \cdot 3^2 \cdot 5 \cdot 7$ and $|T_v|/|G_v|$ $|T|/|G| = 2^3 \cdot 3 \cdot 5 |T_v|$. Note that there is no pentavalent graph of odd order. By Proposition [2.1,](#page-2-3) $T_v \cong S_5$, $A_4 \times A_5$ or $(A_4 \times A_5) \rtimes \mathbb{Z}_2$. By the Atlas [\[2,](#page-14-5) p. 23], T has no subgroup isomorphic to S_5 , $A_4 \times A_5$ or $(A_4 \times A_5) \rtimes \mathbb{Z}_2$, a contradiction.

Suppose $(G, T) = (\text{PSL}(2, 7), A_7)$. Then $|T_v|/|G_v| = |T|/|G| = 3 \cdot 5 |T_v|$. By the Atlas [\[2,](#page-14-5) p. 10] and Proposition [2.1,](#page-2-3) $T_v \cong A_5$. By MAGMA, $T_v \cong A_5$ has two conjugacy classes in T and by taking a given T_v in each conjugacy class, computation shows that there is no feasible t , a contradiction.

Suppose $(G, T) = (PSL(3, 2), A_8)$. Then $|T_v|/|G_v| = |T|/|G| = 2^3 \cdot 3 \cdot 5 |T_v|$. By the Atlas [\[2,](#page-14-5) p. 22] and Proposition [2.1,](#page-2-3) $T_v \cong S_5$. By MAGMA, $T_v \cong S_5$ has two conjugacy classes and by taking a given T_v in each conjugate class, computation shows that there is no feasible t , a contradiction.

Suppose $(G, T) = (PSL(2, 8), PSp(6, 2))$. Then $|T_v|/|G_v| = |T|/|G| = 2^6 \cdot 3^2 \cdot 5 |T_v|$. Since $|T| = 2^9 \cdot 3^4 \cdot 5 \cdot 7$, Proposition [2.1](#page-2-3) implies $T_v \cong S_4 \times S_5$, AGL(2, 4) or AFL(2, 4). However, by the Atlas [\[2,](#page-14-5) p. 46], $PSp(6, 2)$ has no subgroup isomorphic to $S_4 \times S_5$, $AGL(2, 4)$ or $A\Gamma L(2, 4)$, a contradiction.

Suppose $(G, T) = (A_8, A_{10})$ or (A_7, A_{10}) . Then $3^2 \mid |T|/|G| = |T_v|/|G_v|$, and by the Atlas [\[2,](#page-14-5) p. 48] and Proposition [2.1,](#page-2-3) $T_v \cong A_4 \times A_5$ or $(A_4 \times A_5) \rtimes \mathbb{Z}_2$. For each case, by MAGMA, T_v has two conjugacy classes. By taking a given T_v in each conjugacy class, computation shows that there is no feasible t , a contradiction.

Suppose $(G, T) = (A_9, P\Omega^+(8, 2))$ or $(PSp(6, 2), P\Omega^+(8, 2))$. Then $|T_v|/|G_v| = |T|/|G|$ $2^6 \cdot 3 \cdot 5$ or $2^3 \cdot 3 \cdot 5$. By Proposition [2.1,](#page-2-3) $T_v \cong S_5$, $A_4 \times A_5$, $(A_4 \times A_5) \rtimes \mathbb{Z}_2$, $S_4 \times S_5$, ASL(2, 4), AGL(2, 4), ACL(2, 4), A $\Gamma L(2, 4)$ or $\mathbb{Z}_2^6 \rtimes \Gamma L(2, 4)$. By MAGMA, $P\Omega^+(8, 2)$ has no subgroup isomorphic to $S_4 \times S_5$, $ASL(2,4)$, $AGL(2,4)$, $A\Sigma L(2,4)$, $A\Gamma L(2,4)$ or $\mathbb{Z}_2^6 \rtimes \Gamma L(2,4)$. Thus, $T_v \cong S_5$, $A_4 \times A_5$ or $(A_4 \times A_5) \rtimes \mathbb{Z}_2$, and the computation shows that T_v has 15, 3, 3 conjugacy classes, respectively. By taking a given T_v in each conjugacy class, there is no feasible t respectively, a contradiction. \Box

Lemma 3.7 *Let* Γ *be a connected pentavalent symmetric* G*-vertex-transitive graph and let* Aut(Γ) *have a non-trivial radical* R *with at least three orbits. Assume* $G \ntrianglelefteq$ Aut(Γ) *and* $RG = R \times G$. Then Aut(Γ) *contains a non-abelian simple normal subgroup* T *such that* $G < T$ and $(G, T) = (\Omega_8^-(2), \text{PSp}(8, 2)), (A_{14}, A_{16}), (\text{PSL}(2, 8), A_9)$ or (A_{n-1}, A_n) with $n \geq 8$ and $n \mid 2^9 \cdot 3^2 \cdot 5$.

Proof: Set $A = \text{Aut}(\Gamma)$ and $B = RG = R \times G$. Since $R \neq 1$ has at least three orbits, by Proposition [2.2,](#page-2-4) the quotient graph Γ_R is a connected pentavalent A/R -symmetric graph with $A/R \leq \text{Aut}(\Gamma_R)$. Furthermore, Γ_R is B/R -vertex-transitive and G is characteristic in B. It follows that $B \nsubseteq A$ because $G \nsubseteq A$, and hence $G \cong B/R \nsubseteq A/R$. Since R is the largest solvable normal subgroup of A, A/R has trivial radical. By Lemma [3.6,](#page-7-0) A/R has a non-abelian simple normal subgroup I/R such that $B/R \leq I/R \approx T$ and $(B/R, I/R) \cong (G, T) = (\Omega_8^-(2), \text{PSp}(8, 2)), (A_{14}, A_{16}), (\text{PSL}(2, 8), A_9) \text{ or } (A_{n-1}, A_n)$ with $n \geq 6$ and $n \mid 2^9 \cdot 3^2 \cdot 5$. If $(G, T) \neq (A_5, A_6)$ then $A = S_6$, contrary to the fact that A has a non-trivial radical. Thus, $n \geq 8$

Let $C = C_I(R)$. Then $G \leq C$ as $B = R \times G \leq I$. Clearly, $C \leq I$ and $C \cap R \leq Z(C)$. Since $G \cong R \times G/R \leq CR/R$ and $C/C \cap R \cong CR/R \leq I/R \cong T$, we have $C \cap R = Z(C)$, $C/Z(C) \cong T$ and $I = CR$. Thus, $C'/C' \cap Z(C) \cong C'Z(C)/Z(C) = (C/Z(C))' = C$ $C/Z(C) \cong T$, and so $Z(C') = C' \cap Z(C)$, $C = C'Z(C)$ and $C'/Z(C') \cong T$. Furthermore, $C' = (C'Z(C))' = C''$, implying that C' is a covering group of T. It follows $G \leq C'$ because C/C' is abelian.

By [\[18,](#page-15-11) Theorem 5.1.4] and the Atlas [\[2,](#page-14-5) p. 123], $Mult(A_n) = \mathbb{Z}_2$ for $n \geq 8$ and Mult(PSp(8, 2)) = 1. Since C' is a covering group of T, we have $Z(C') = 1$ or \mathbb{Z}_2 .

Suppose $Z(C') = \mathbb{Z}_2$. Then $(G, T) = (A_{14}, A_{16}), (PSL(2, 8), A_9)$, or (A_{n-1}, A_n) with $n \geq 8$ and $n \mid 2^9 \cdot 3^2 \cdot 5$. Furthermore, C' is the unique double cover of A_n with $n \geq 8$, that is, $C' = 2.A_n$. Since $Z(C') \leq I$ and $I/R \cong T$ is simple, we have $Z(C') \leq R$, and hence $G \times Z(C') \leq C'$ as $B = G \times R$.

Let $(G, T) = (A_{14}, A_{16})$. Then $C' = 2.A_{16}$. Clearly, A_{14} has no proper subgroup of index less than 13, and by MAGMA, it also has no subgroup of index 15 or 16. This implies that each subgroup of A_{16} isomorphic to A_{14} fixes exactly two vertices in $\{1, 2, \dots, 16\}$, and so lies in a subgroup of index 16 of A_{16} . It follows that $G \times Z(C')$ lies in a subgroup of index 16 of C', that is, $G \times Z(C') \leq L$ and $|C' : L| = 16$ for some $L \leq C'$. By Proposition [2.6,](#page-4-2) $L \cong 2.A_{15}$ and $G \times Z(C') \cong \mathbb{Z}_2 \times A_{14}$, which is impossible because $G \times Z(C') \cong A_{14} \times \mathbb{Z}_2.$

Let $(G, T) = (PSL(2, 8), A_9)$. Then $C' = 2.A_9 = G \cdot C_9'$ \int_v^{\prime} , and so 3^2 | $|C'_i$ $|C'| =$ $2^7 \cdot 3^4 \cdot 5 \cdot 7$. By Proposition [2.1,](#page-2-3) C'_i $\mathcal{U}_v \cong A_4 \times A_5$, $(A_4 \times A_5) \rtimes \mathbb{Z}_2$, $S_4 \times S_5$, $\text{ASL}(2, 4)$ or $\text{AGL}(2, 4)$. Note that C' has a subgroup H isomorphic to 2. A_6 with $Z(C') \leq H$. Since $H \cong SL(2, 9)$, $Z(C')$ is the unique subgroup of order 2 in H. Since $Z(C') \leq C'$, we have $Z(C') \nleq C'$ $_v'$ Suppose that $|H_w|$ is odd for any $w \in V(\Gamma)$. Then $|w^H| = |H|/|H_w| = 2^4 \cdot (3^2 \cdot 5/|H_w|)$, implying that the orbit of H containing w has length a multiple of 2^4 , and so $|V(\Gamma)|$ is a multiple of 2^4 , contrary to the fact $|V(\Gamma)|$ | $|\text{PSL}(2,8)| = 2^3 \cdot 3^2 \cdot 7$. Thus, we may assume that H_v is even. Since $H_v = H \cap C'_v$ \mathcal{Z}'_v and $Z(C')$ is the unique subgroup of order 2 in H, we have $Z(C') \leq H_v$ and hence $Z(C') \leq C_v'$ v' , a contradiction.

Let $(G,T) = (A_{n-1}, A_n)$ with $n \geq 8$. Then $G \times Z(C')$ is a subgroup of index n of C' isomorphic to $A_{n-1} \times \mathbb{Z}_2$, which is impossible by Proposition [2.6.](#page-4-2)

The above contradictions give rise to $Z(C') = 1$. Then $C' \cong T$ and $G < C' \leq I$. Since $|I| = |I/R||R| = |T||R| = |\tilde{C}'||R|$ and $C' \cap R = 1$, we have $I = C' \times R$. Then C' is characteristic in I, and so $C' \subseteq A$ because $I \subseteq A$. It follows that A has a non-abelian simple normal subgroup C' such that $G < C'$ and $(G, C') \cong (G, T) = (\Omega_8^-(2), \text{PSp}(8, 2)),$ $(A_{14}, A_{16}), (PSL(2,8), A_9) \text{ or } (A_{n-1}, A_n) \text{ with } n \geq 8 \text{ and } n \mid 2^9 \cdot 3^2 \cdot 5.$ \Box

Now, we are ready to prove Theorem [1.1.](#page-2-2)

The proof of Theorem [1.1:](#page-2-2) Let G be a non-abelian simple group and Γ a connected pentavalent symmetric G-vertex-transitive graph with $v \in V(\Gamma)$. Let $A = Aut(\Gamma)$ and R the radical of A. To prove the theorem, we may assume $G \nleq A$. If $R = 1$, the theorem is true by Lemma [3.6.](#page-7-0) In what follows we assume $R \neq 1$. If $G = A_5$, by Lemma [3.1,](#page-4-1) $\Gamma = K_6$ and $A = S_6$, which is impossible because A has trivial radical. Thus, $G \neq A_5$.

Set $B = RG$. Then $G \cap R = 1$ and $|B| = |R||G|$. By Lemma [3.2,](#page-5-0) $|R| = |B_v|/|G_v|$ $2^9 \cdot 3^2 \cdot 5$.

Suppose that R has one or two orbits on $V(\Gamma)$. Since $|G| = |V(\Gamma)||G_v|$, we have $|R| = |v^R||R_v| = |G||R_v|/|G_v|$ or $|G||R_v|/(2 \cdot |G_v|)$, and since R and G_v are $\{2, 3, 5\}$ -groups, G is a non-abelian $\{2, 3, 5\}$ -simple group. By Proposition [2.4,](#page-3-2) $G = A_6$ or PSU(4, 2) as $G \neq A_5$, and since $|R| = |B_v|/|G_v|$, we have $|B_v| = |G||R_v|$ or $|G||R_v|/2$. Note that $5 \mid |G|$, and so $5 \mid |B_v|$, that is, Γ is B-symmetric. If $R_v = 1$, then $|B_v| = |G|$ or $|G|/2$, that is, $|B_v| = 2^3 \cdot 3^2 \cdot 5$, $2^2 \cdot 3^2 \cdot 5$, $2^6 \cdot 3^4 \cdot 5$ or $2^5 \cdot 3^4 \cdot 5$, of which all are impossible by Proposition [2.1.](#page-2-3) If $R_v \neq 1$ then $5 \mid |R_v|$ as $R \leq A$, and in this case, $5^2 \mid |B_v| = |G||R_v|$, a contradiction.

Now we have shown that R has at least three orbits. By Lemma [3.7,](#page-10-0) if $B = R \times G$ then the theorem is true. To finish the proof, we only need to show $B = R \times G$.

By Proposition [2.2,](#page-2-4) R is semiregular on $V(\Gamma)$ and the quotient graph Γ_R is a connected pentavalent A/R-symmetric graph with $A/R \leq \text{Aut}(\Gamma_R)$. Moreover, Γ_R is B/R -vertextransitive. Since R is the largest solvable normal subgroup of A, A/R has trivial radical, by Lemma [3.6,](#page-7-0) $B/R \leq A/R$ or A/R has a non-abelian simple normal subgroup I/R such that $B/R \leq I/R$ and $(B/R, I/R) \cong (G, T)$ with $(G, T) = (\Omega_8^-(2), \text{PSp}(8, 2)), (A_{14}, A_{16}),$ $(PSL(2,8), A_9)$ or (A_{n-1}, A_n) with $n \ge 6$ and $n \mid 2^9 \cdot 3^2 \cdot 5$.

Suppose $B/R \trianglelefteq A/R$. Then $B \trianglelefteq A$ and $5 |B_v|$. Note that $1 \neq |R| = |B_v|/|G_v|$. Then $5 \mid |R|$ or $5 \mid |G_v|$. By Lemmas [3.3](#page-5-2) and [3.5,](#page-6-0) $B = R \times G$, that is, G is characteristic in B, and hence $G \leq A$, contrary to the assumption $G \ntriangleleft A$. Thus, $B/R \leq I/R \leq A/R$. It follows $(I/R)_{\alpha} \neq 1$ for $\alpha \in V(\Gamma_R)$ and hence $5 \mid |(I/R)_{\alpha}|$. Thus, Γ_R is I/R -symmetric. Since $|V(\Gamma_R)| = |V(\Gamma)|/|R| = |G|/(|R||G_v|)$ and $|T| = |I/R| = |V(\Gamma_R)||(I/R)_{\alpha}| =$ $|G|/(|R||G_v|) \cdot |(I/R)_{\alpha}|$, we have $|(I/R)_{\alpha}| = |R||T||G_v|/|G|$, and by Proposition [2.1,](#page-2-3) $|R||T||G_v|/|G|$ is a divisor of $2^9 \cdot 3^2 \cdot 5$.

Since $|R| \ 2^9 \cdot 3^2 \cdot 5$, we may write $|R| = 2^m \cdot 3^n \cdot 5^k$, where $0 \le m \le 9$, $0 \le n \le 2$ and $0 \leq k \leq 1$. Since R is solvable, there exists a series of subgroups of B:

$$
B > R = R_s > \cdots > R_1 > R_0 = 1
$$

such that $R_i \leq B$ and R_{i+1}/R_i is an elementary abelian r-group with $0 \leq i \leq s-1$, where $r = 2, 3$ or 5. Clearly, $G \leq B$ has a natural action on R_{i+1}/R_i by conjugation.

Suppose to the contrary $B \neq R \times G$. Then there exists some $0 \leq j \leq s - 1$ such that $GR_i = G \times R_i$ for any $0 \leq i \leq j$, but $GR_{j+1} \neq G \times R_{j+1}$. If G acts trivially on R_{j+1}/R_j by conjugation, then $[GR_j/R_j, R_{j+1}/R_j] = 1$. Since $GR_j/R_j \cong G$ is simple, we have $(GR_j/R_j) \cap (R_{j+1}/R_j) = 1$. Note that $|GR_{j+1}/R_j| = |GR_{j+1}/R_{j+1}||R_{j+1}/R_j| =$ $|G||R_{j+1}/R_j| = |GR_j/R_j||R_{j+1}/R_j|$. Then $GR_{j+1}/R_j = GR_j/R_j \times R_{j+1}/R_j$. In particular, $GR_j \trianglelefteq GR_{j+1}$ and so $G \trianglelefteq GR_{j+1}$ because $GR_j = G \times R_j$ implies that G is characteristic in GR_j . It follows that $GR_{j+1} = G \times R_{j+1}$, a contradiction. Thus, G acts non-trivially on R_{j+1}/R_j , and the simplicity of G implies that G acts faithfully on R_{j+1}/R_j .

Set $|R_{j+1}/R_j| = r^{\ell}$. Since $|R| = 2^m \cdot 3^n \cdot 5^k$, we have $\ell \leq m \leq 9$ for $r = 2, \ell \leq 2$ for $r = 3$ and $\ell \leq 1$ for $r = 5$. Recall that G acts faithfully on R_{j+1}/R_j and R_{j+1}/R_j is elementary abelian. Then $G \le GL(\ell,r)$. If $r = 3$ or 5 then $G \le GL(2,3)$ or $GL(1,5)$, yielding that G is solvable, a contradiction. Thus, $G \le GL(m, 2) = PSL(m, 2)$ with $m \le 9$. Recall that $(G, T) = (\Omega_8^-(2), \text{PSp}(8, 2)), (A_{14}, A_{16}), (\text{PSL}(2, 8), A_9)$ or (A_{n-1}, A_n) with $n \geq 6$ and $n \mid 2^9 \cdot 3^2 \cdot 5.$

Let $G = A_{14}$ or A_{n-1} with $n \mid 2^9 \cdot 3^2 \cdot 5$ and $n \ge 12$. Since $11 \mid |A_{n-1}|$ and $11 \nmid |PSL(9, 2)|$, we have $G \nleq \text{PSL}(9, 2)$, a contradiction.

Let $G = \text{PSL}(2,8)$ or A_7 , since $|G| = |V(\Gamma)||G_v|$ and R is semiregular on $V(\Gamma)$, we have $|R| \, |G|/|G_v|$, and so $m \leq 2$ because Γ_R cannot be of odd order. It follows that $A_7 \leq \text{PSL}(2, 2)$ or $\text{PSL}(2, 8) \leq \text{PSL}(2, 2)$, a contradiction. Similarly, for $G = A_9$, we have $m \leq 5$ and $A_9 \leq \text{PSL}(5, 2)$, which is also impossible because $3^4 \mid A_9 \mid$ and $3^4 \nmid \text{PSL}(5, 2) \mid$.

Since $G \neq A_5$, the left pairs are $(G, T) = (A_8, A_9)$ or $(\Omega_8^-(2), \text{PSp}(8, 2))$. For $(G, T) =$ (A_8, A_9) , since $|(I/R)_{\alpha}| = |R||T||G_v|/|G|$ and $5 ||(I/R)_{\alpha}|$, $|R|$ or $|G_v|$ is divisible by 5, by Lemmas [3.3](#page-5-2) and [3.5,](#page-6-0) $B = R \times G$, a contradiction. Thus, $(G, T) = (\Omega_8^-(2), \text{PSp}(8, 2)).$

Since $|T|/|G| = 2^4 \cdot 3 \cdot 5$ and $|R||T||G_v|/|G|$ is a divisor of $2^9 \cdot 3^2 \cdot 5$, $|R|$ is a divisor of $2^5 \cdot 3$. Then $m \leq 5$ and $G \leq \text{PSL}(5, 2)$, which is impossible because $17 \mid |\Omega_8|$ $\frac{1}{8}(2)$ and $17 \nmid$ $|PSL(5,2)|$.

The above contradictions imply $B = R \times G$, as required. This completes the proof of Theorem [1.1.](#page-2-2)

The proof of Corollary [1.2:](#page-2-5) Let G be a non-abelian simple group and Γ a connected pentavalent G-symmetric graph with $v \in V(\Gamma)$. Let $A = Aut(\Gamma)$ and let R the radical of A. To prove the corollary, we may assume $G \ntrianglelefteq A$. By Theorem [1.1,](#page-2-2) A has a non-abelian simple normal subgroup T such that $G < T$ and (G, T) is as given in Theorem [1.1.](#page-2-2) Since G is symmetric and $G < T \leq A$, $|G_v|$ and $|T_v|$ are divisible by 5, and since $|T|/|G| = |T_v|/|G_v|$, by Proposition [2.1](#page-2-3) $(G, T) = (A_{n-1}, A_n)$ with $n \ge 6$, $n \mid 2^9 \cdot 3^2$ and $n \ne 2^9, 2^8, 2^7, 2^6, 2^9 \cdot 3^8$. $3, 2^8 \cdot 3.$

Let $(G, T) = (A_{2^3-1}, A_{2^3})$ or (A_{3^2-1}, A_{3^2}) . By Lemma [3.4,](#page-5-1) $G \leq A$, a contradiction.

Let $(G, T) = (A_{2\cdot 3^{2}-1}, A_{2\cdot 3^{2}})$. By Proposition [2.1,](#page-2-3) $(G_{v}, T_{v}) \cong (F_{20} \times \mathbb{Z}_{2}, A_{4} \times A_{5})$ or $(F_{20} \times \mathbb{Z}_4, (A_4 \times A_5) \rtimes \mathbb{Z}_2)$. However, by MAGMA, $A_4 \times A_5$ or $(A_4 \times A_5) \rtimes \mathbb{Z}_2$ has no subgroup isomorphic to $F_{20} \times \mathbb{Z}_2$ or $F_{20} \times \mathbb{Z}_4$, respectively, a contradiction.

Let $T = A_6$. Then $G = A_5$ and by Lemma [3.4,](#page-5-1) $\Gamma = K_6$ and $A = S_6$. To finish the proof, we only need to show that for $n = 2^5, 2^7 \cdot 3, 2^7 \cdot 3^2, 2^8 \cdot 3^2$ and $2^9 \cdot 3^2$, we have $A = T$. To do this, it suffices to show $A_v = T_v$ because $A = TA_v$.

Let $n = 2^9 \cdot 3^2$ or $2^8 \cdot 3^2$. By Proposition [2.1,](#page-2-3) $(G_v, T_v) \cong (\mathbb{Z}_5, \mathbb{Z}_2^6 \rtimes \Gamma\mathbb{L}(2, 4))$ or $(D_5, \mathbb{Z}_2^6 \rtimes \Gamma\mathcal{L}(2, 4)),$ respectively. This forces $A_v = T_v$ because $T_v \leq A_v$, as required.

Let $n = 2^7 \cdot 3^2$. By Proposition [2.1,](#page-2-3) $(G_v, T_v) \cong (\mathbb{Z}_5, \text{ATL}(2, 4)), (F_{20}, \mathbb{Z}_2^6 \rtimes \text{TL}(2, 4))$ or $(D_{10}, \mathbb{Z}_2^6 \rtimes \text{FL}(2, 4)).$ Clearly, if $(G_v, T_v) \cong (F_{20}, \mathbb{Z}_2^6 \rtimes \text{FL}(2, 4))$ or $(D_{10}, \mathbb{Z}_2^6 \rtimes \text{FL}(2, 4)),$ then $T_v = A_v$. Assume $(G_v, T_v) \cong (\mathbb{Z}_5, \text{ATL}(2, 4))$. If $T_v \neq A_v$, then by Proposition [2.1](#page-2-3) we have $A_v = \mathbb{Z}_2^6 \rtimes \text{FL}(2, 4)$, and since $T \leq A$, we have $T_v \leq A_v$. This implies that $\mathbb{Z}_2^6 \rtimes \text{FL}(2, 4)$ has a normal subgroup isomorphic to $\text{ATL}(2, 4)$, which is impossible by [\[30,](#page-16-9) Theorem 1.1] and MAGMA. Thus, $T_v = A_v$, as required.

Let $n = 2^7 \cdot 3$. By Proposition [2.1,](#page-2-3) $(G_v, T_v) \cong (\mathbb{Z}_5, A\Sigma L(2, 4))$ or $(A_5, \mathbb{Z}_2^6 \rtimes \Gamma L(2, 4))$. For the latter, $A_v = T_v$. Assume $(G_v, T_v) \cong (\mathbb{Z}_5, \mathrm{AZL}(2, 4))$. If $A_v \neq T_v$ then by Proposition [2.1](#page-2-3) we have $A_v = \mathbb{Z}_2^6 \rtimes \Gamma\mathbb{L}(2,4)$ or $\text{ATL}(2,4)$, which are impossible because $\mathbb{Z}_2^6 \rtimes \text{FL}(2,4)$ and $\text{ATL}(2,4)$ have no normal subgroup isomorphic to $\text{A}\Sigma\text{L}(2,4)$ by [\[30,](#page-16-9) Theorem 1.1] and MAGMA. Thus, $T_v = A_v$, as required.

Let $n = 2^5$. By Proposition [2.1,](#page-2-3) $(G_v, T_v) \cong (A_5, A\Sigma L(2, 4))$ or $(A_4 \times A_5, \mathbb{Z}_2^6 \rtimes \Gamma L(2, 4)).$ A similar argument to the above paragraph implies $T_v = A_v$, as required. This completes the proof of Corollary [1.2.](#page-2-5) \Box

The proof of Corollary [1.3:](#page-2-1) Let G be a non-abelian simple group and Γ a connected pentavalent G-regular graph with $v \in V(\Gamma)$. Let $A = \text{Aut}(\Gamma)$ and R the radical of A. To prove the corollary, we may assume $G \ntrianglelefteq A$. By Theorem [1.1,](#page-2-2) A contains non-abelian simple normal subgroup T containing G such that (G, T) is given in Theorem [1.1.](#page-2-2) Since G is regular and $G < T \leq A$, $G_v = 1$ and T is symmetric. Since $|T|/|G| = |T_v|/|G_v| = |T_v|$, by Proposition [2.1,](#page-2-3) $(G, T) = (A_{n-1}, A_n)$ with $n = 2 \cdot 5$, $2^2 \cdot 5$, $2^3 \cdot 5$, $2 \cdot 3 \cdot 5$, $2^4 \cdot 5$, $2^3 \cdot 3 \cdot 5$,

 \Box

 $2^4 \cdot 3^2 \cdot 5$, $2^6 \cdot 3 \cdot 5$, $2^5 \cdot 3^2 \cdot 5$, $2^7 \cdot 3 \cdot 5$, $2^6 \cdot 3^2 \cdot 5$, $2^7 \cdot 3^2 \cdot 5$ or $2^9 \cdot 3^2 \cdot 5$.

To end the paper, we give an example to show that the pair $(G, T) = (A_{39}, A_{40})$ in Corollary [1.3](#page-2-1) can happen.

Example 3.8 *Let* $G = A_{39}$ *and* $T = A_{40}$ *. Define* $x, y, z, g \in T$ *as following:*

 $x = (1\ 2\ 7\ 18\ 5)(3\ 11\ 8\ 17\ 14)(4\ 9\ 22\ 33\ 15)(6\ 20\ 19\ 10\ 21)(12\ 28\ 26\ 31\ 23)$ (13 27 24 32 30)(16 35 34 25 36)(29 39 38 40 37)*,* $y = (1\ 3\ 12\ 6)(2\ 8\ 23\ 10)(4\ 13\ 29\ 16)(5\ 17\ 28\ 19)(7\ 14\ 31\ 20)(9\ 24\ 37\ 25)$ (11 26 21 18)(15 32 39 34) (22 30 40 35)(27 38 36 33)*,* $z = (1\ 4)(2\ 9)(3\ 13)(5\ 15)(6\ 16)(7\ 22)(8\ 24)(10\ 25)(11\ 27)(12\ 29)(14\ 30)\ (17\ 32)$ (18 33)(19 34)(20 35)(21 36)(23 37)(26 38)(28 39)(31 40)*,* $g = (1\ 7)(2\ 24)(3\ 14)(4\ 40)(5\ 11)(6\ 20)(8\ 37)(9\ 10)(12\ 31)(13\ 35)(15\ 36)(16\ 30)$ (17 26)(18 19)(21 28)(22 29)(23 25)(27 39)(32 33)(34 38)*.*

By MAGMA[\[1\]](#page-14-3), $H = \langle x, y, z \rangle \cong F_{20} \times \mathbb{Z}_2$, $T = \langle H, g \rangle$, $|H : H \cap H^g| = 5$ and H is regular on $\{1, 2, \dots, 40\}$. Thus, $T = GH$ with $G \cap H = 1$ and the coset graph $\Gamma = \text{Cos}(T, H, HgH)$ is a connected pentavalent T-symmetric G-regular graph, where G and T are viewed as groups of automorphisms of Γ by right multiplication.

By Corollary [1.3,](#page-2-1) $T \leq \text{Aut}(\Gamma)$. Again by MAGMA [\[1\]](#page-14-3), $\text{Aut}(T, H, HgH) \cong H$, where H is the automorphism group of T induced by conjugation of elements in H . Thus, $Aut(\Gamma) = T$ by [\[29,](#page-16-5) Lemma 2.10].
