

# Max-min Fair Beamforming for SWIPT Systems with Non-linear EH Model

(Invited Paper)

Elena Boshkovska, Xiaoming Chen, Linglong Dai, Derrick Wing Kwan Ng, and Robert Schober

**Abstract**—We study the beamforming design for multiuser systems with simultaneous wireless information and power transfer (SWIPT). Employing a practical non-linear energy harvesting (EH) model, the design is formulated as a non-convex optimization problem for the maximization of the minimum harvested power across several energy harvesting receivers. The proposed problem formulation takes into account imperfect channel state information (CSI) and a minimum required signal-to-interference-plus-noise ratio (SINR). The globally optimal solution of the design problem is obtained via the semidefinite programming (SDP) relaxation approach. Interestingly, we can show that at most one dedicated energy beam is needed to achieve optimality. Numerical results demonstrate that with the proposed design a significant performance gain and improved fairness can be provided to the users compared to two baseline schemes.

## I. INTRODUCTION

In the past decades, the increasing interest in data hungry applications and heterogenous services has triggered the consumption of tremendous amounts of energy in wireless communication systems. In practice, mobile devices are usually powered by batteries with limited energy storage capacity which becomes a bottleneck in perpetuating the lifetime of networks. To address this issue, energy harvesting (EH)-based communication technology has been proposed. In particular, this technology enables self-sustainability of power-constrained communication devices. Communication systems may be equipped with energy harvesters [1]–[3] to scavenge energy from renewable natural energy sources such as solar and wind. Yet, these conventional energy sources are only available at specific locations which limits the mobility of portable devices. Besides, the intermittent and uncontrollable nature of these natural energy sources is a concern for wireless communications, where uninterrupted and stable quality of service (QoS) are of paramount importance.

Recently, radio frequency (RF)-based wireless power transfer (WPT) has received considerable interest from both industry and academia [4]–[7]. For example, industrial companies such as Samsung Electronics and Huawei Technology, have begun to launch research and study groups to facilitate the development and standardization of WPT [4]. In fact,

the introduction of WPT avoids the high potential costs of planning, installing, displacing, and maintaining power cables in buildings and infrastructure. Specifically, for RF-based communication networks, energy from ambient propagating electromagnetic (EM) waves in radio frequency (RF) can be harvested by energy-limited communication transceivers for prolonging their lifetimes and supporting the energy consumption required for future information transmission. This technology eliminates the need for power cords and manual recharging. Moreover, the broadcast nature of wireless channels facilitates one-to-many wireless charging and the possibility of simultaneous wireless information and power transfer (SWIPT) [5]–[7]. Compared to conventional EH, RF-based EH technology can provide on-demand energy replenishment which makes it suitable for smart wireless communication devices having strict QoS and energy requirements.

In practice, wireless power has to be transferred via a signal with high carrier frequency such that antennas with small size can be used for harvesting the power. However, the associated path loss severely attenuates the signal leading to a small harvested power at the receiver. Hence, multiple antenna beamforming has been proposed to facilitate efficient WPT [8]–[12]. In [8], the concept of energy beamforming was first proposed to maximize the efficiency of WPT. In [9]–[11], energy beamforming was advocated to provide secure SWIPT in multiple-antenna systems. The authors of [12] investigated the impact of a massive number of antennas on the energy efficiency of SWIPT systems. However, most of the beamforming designs for SWIPT systems were based on an over-simplified linear EH model. In fact, this model was recently shown to be incapable of capturing the non-linear characteristics of practical RF EH circuits [13]. Besides, the results obtained in [8]–[12] were based on the assumption of perfect knowledge of the channel state information (CSI) of information receivers which is not realistic in practice. Furthermore, resource allocation fairness was not considered in [8]–[12] which may lead to an unsatisfactory performance for some users.

In this paper, we address these problems. In particular, we formulate the beamforming design as an optimization problem to provide max-min fairness in WPT to energy harvesting receivers equipped with practical non-linear energy harvesting circuits. The optimization problem is solved by a semidefinite programming (SDP) based resource allocation algorithm. Simulation results illustrate an interesting trade-off between user fairness in energy harvesting and individual user data rate.

**Notation:** We use boldface capital and lower case letters to denote matrices and vectors, respectively.  $\mathbf{A}^H$ ,  $\text{Tr}(\mathbf{A})$ , and

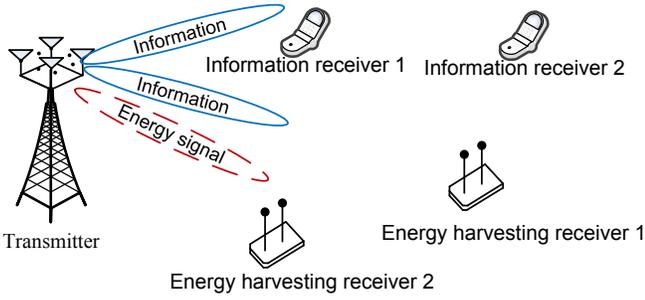

Fig. 1. A system model of a SWIPT system with  $K = 2$  IRs and  $J = 2$  ERs.

$\text{Rank}(\mathbf{A})$  represent the Hermitian transpose, trace, and rank of matrix  $\mathbf{A}$ , respectively;  $\mathbf{A} \succ \mathbf{0}$  and  $\mathbf{A} \succeq \mathbf{0}$  indicate that  $\mathbf{A}$  is a positive definite and a positive semidefinite matrix, respectively;  $\mathbf{I}_N$  is the  $N \times N$  identity matrix;  $[\mathbf{B}]_{a:b,c:d}$  returns the  $a$ -th to the  $b$ -th rows and the  $c$ -th to the  $d$ -th column block submatrix of  $\mathbf{B}$ ;  $\mathbb{C}^{N \times M}$  denotes the set of all  $N \times M$  matrices with complex entries;  $\mathbb{H}^N$  denotes the set of all  $N \times N$  Hermitian matrices. The circularly symmetric complex Gaussian (CSCG) distribution is denoted by  $\mathcal{CN}(\mathbf{m}, \mathbf{\Sigma})$  with mean vector  $\mathbf{m}$  and covariance matrix  $\mathbf{\Sigma}$ ;  $\sim$  means “distributed as”;  $\mathcal{E}\{\cdot\}$  denotes statistical expectation;  $|\cdot|$  represents the absolute value of a complex scalar.  $[x]^+$  stands for  $\max\{0, x\}$ , and  $[\cdot]^T$  represents the transpose operation.

## II. SYSTEM MODEL

In this section, we present the channel model for downlink SWIPT systems.

### A. Channel Model

We consider a frequency flat and slowly time varying downlink communication channel. In the SWIPT system, there are one transmitter,  $K$  information receivers (IRs), and  $J$  EH receivers (ER), cf. Figure 1. The transmitter is equipped with  $N_T \geq 1$  antennas and serves both the IRs and the ERs simultaneously in the same frequency band. We assume that each IR is a single-antenna device and each ER is equipped with  $N_R \geq 1$  receive antennas. The received signals at IR  $k \in \{1, \dots, K\}$  and ER  $j \in \{1, \dots, J\}$  are given by

$$y_k = \mathbf{h}_k^H \left( \sum_{k=1}^K \mathbf{w}_k s_k + \mathbf{w}_E \right) + n, \text{ and} \quad (1)$$

$$\mathbf{y}_{\text{ER}_j} = \mathbf{G}_j^H \left( \sum_{k=1}^K \mathbf{w}_k s_k + \mathbf{w}_E \right) + \mathbf{n}_{\text{ER}_j}, \forall j \in \{1, \dots, J\}, (2)$$

respectively, where  $\mathbf{w}_k \in \mathbb{C}^{N_T \times 1}$  and  $s_k \in \mathbb{C}$  are the information beamforming vector and the associated information symbol for IR  $k$ , respectively. Without loss of generality, we assume that  $\mathcal{E}\{|s_k|^2\} = 1, \forall k$ . The vector channel of the transmitter-to-IR  $k$  link is denoted by  $\mathbf{h}_k \in \mathbb{C}^{N_T \times 1}$  and the channel matrix of the transmitter-to-ER  $j$  link is denoted by  $\mathbf{G}_j \in \mathbb{C}^{N_T \times N_R}$ . Variables  $n \sim \mathcal{CN}(0, \sigma_s^2)$  and  $\mathbf{n}_{\text{ER}_j} \sim \mathcal{CN}(\mathbf{0}, \sigma_s^2 \mathbf{I}_{N_R})$  denote the additive white Gaussian noises (AWGN) at IR  $k$  and ER  $j$ , respectively, where  $\sigma_s^2$

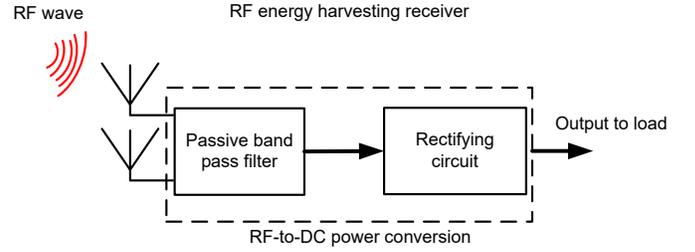

Fig. 2. Block diagram of an ER.

denotes the noise power at the receiver.  $\mathbf{w}_E \in \mathbb{C}^{N_T \times 1}$  is a Gaussian pseudo-random sequence generated by the transmitter to facilitate efficient WPT. In particular,  $\mathbf{w}_E$  is modeled as a complex Gaussian random vector with

$$\mathbf{w}_E \sim \mathcal{CN}(\mathbf{0}, \mathbf{W}_E), \quad (3)$$

where  $\mathbf{W}_E \in \mathbb{H}^{N_T}$ ,  $\mathbf{W}_E \succeq \mathbf{0}$ , is the covariance matrix of the pseudo-random energy signal.

### B. Achievable Rate

Since the energy signal  $\mathbf{w}_E$  is a Gaussian pseudo-random sequence which is known to all transceivers, IR  $k$  can remove it via successive interference cancellation (SIC). Then, the achievable rate (bit/s/Hz) between the transmitter and IR  $k$  is given by

$$R_k = \log_2 \left( 1 + \frac{\mathbf{w}_k^H \mathbf{H}_k \mathbf{w}_k}{\sum_{i \neq k} \mathbf{w}_i^H \mathbf{H}_k \mathbf{w}_i + \sigma_s^2} \right), \quad (4)$$

where the interference caused by the energy signal, i.e.,  $\text{Tr}(\mathbf{h}_k^H \mathbf{W}_E \mathbf{h}_k)$  has been removed via SIC.

### C. Non-linear EH Model

Figure 2 shows a general block diagram of an ER consisting of a passive filter and a rectifying circuit. In practice, the implementation of an ER depends on the adopted circuit components which vary for different designs. To isolate the EH model from a specific circuit design, two general tractable models, i.e., the linear model and the non-linear model, have been proposed in the literature for characterizing the RF EH process. Mathematically, the total received RF power<sup>1</sup> at ER  $j$  is given by

$$P_{\text{ER}_j} = \text{Tr} \left( \left( \sum_{k=1}^K \mathbf{w}_k \mathbf{w}_k^H + \mathbf{W}_E \right) \mathbf{G}_j \mathbf{G}_j^H \right). \quad (5)$$

For the linear EH model which as adopted e.g. in [8]–[12], the total harvested power at ER  $j$ ,  $\Phi_{\text{ER}_j}^{\text{Linear}}$ , is typically modelled by the following linear equation:

$$\Phi_{\text{ER}_j}^{\text{Linear}} = \eta_j P_{\text{ER}_j}, \quad (6)$$

where  $0 \leq \eta_j \leq 1$  is the constant power conversion efficiency of ER  $j$ .

<sup>1</sup>In this paper, the unit of Joule-per-second is used for measuring energy. Thus, the terms “power” and “energy” are interchangeable.

Yet, practical RF-based EH circuits are inherently non-linear and the conventional linear model fails to capture this important characteristic, as shown experimentally in [14]–[16]. Motivated by this, a parametric non-linear EH model was proposed in [13], [17] which has been shown to be in excellent agreement closely with practical measurement results. In this paper, we adopt the more realistic non-linear EH model and the total harvested power at ER  $j$ ,  $\Phi_{\text{ER}_j}$ , is modelled as:

$$\Phi_{\text{ER}_j} = \frac{[\Psi_{\text{ER}_j} - M_j \Omega_j]}{1 - \Omega_j}, \quad \Omega_j = \frac{1}{1 + \exp(a_j b_j)}, \quad (7)$$

$$\text{where } \Psi_{\text{ER}_j} = \frac{M_j}{1 + \exp(-a_j(P_{\text{ER}_j} - b_j))} \quad (8)$$

is a sigmoidal function which has the received RF power,  $P_{\text{ER}_j}$ , as the input. Three parameters, namely,  $M_j$ ,  $a_j$ , and  $b_j$ , are introduced to describe the shape of the logistic function which depends on the physical properties of the RF EH circuit. Specifically,  $M_j$ ,  $a_j$ , and  $b_j$  are constants which determine the maximum harvestable power, the charging rate with respect to the input power, and the minimum required voltage to turn on the EH circuit<sup>2</sup>, respectively.

#### D. Channel State Information

We take into account the imperfection of the channel state information (CSI) for beamforming design. To this end, we adopt a deterministic model [11], [18]. In particular, we model the CSI of the links as:

$$\mathbf{h}_k = \hat{\mathbf{h}}_k + \Delta \mathbf{h}_k, \quad (9)$$

$$\Upsilon_k \triangleq \left\{ \Delta \mathbf{h}_k \in \mathbb{C}^{N_{\text{T}} \times 1} : \|\Delta \mathbf{h}_k\|_2^2 \leq \rho_k^2 \right\}, \quad (10)$$

$$\mathbf{G}_j = \hat{\mathbf{G}}_j + \Delta \mathbf{G}_j, \quad \forall j \in \{1, \dots, J\}, \quad \text{and} \quad (11)$$

$$\Xi_j \triangleq \left\{ \Delta \mathbf{G}_j \in \mathbb{C}^{N_{\text{T}} \times N_{\text{R}}} : \|\Delta \mathbf{G}_j\|_{\text{F}}^2 \leq v_j^2 \right\}, \quad \forall j, \quad (12)$$

respectively, where  $\hat{\mathbf{h}}_k$  and  $\hat{\mathbf{G}}_j$  are the estimates of channel vector  $\mathbf{h}_k$  and channel matrix  $\mathbf{G}_j$ , respectively. The channel estimation errors of  $\mathbf{h}_k$  and  $\mathbf{G}_j$  are denoted by  $\Delta \mathbf{h}_k$  and  $\Delta \mathbf{G}_j$ , respectively. Sets  $\Upsilon_k$  and  $\Xi_j$  collect all possible channel estimation errors. Constants  $\rho_k$  and  $v_j$  denote the maximum values of the norms of the CSI estimation error vector  $\Delta \mathbf{h}_k$  and the CSI estimation error matrix  $\Delta \mathbf{G}_j$ , respectively.

### III. PROBLEM FORMULATION AND SOLUTION

The system objective is to maximize the minimum harvested power among all the ERs, i.e., to provide max-min fairness [19], while guaranteeing the QoS of information communication. To this end, we formulate the resource allocation

algorithm design as the following non-convex optimization problem:

$$\begin{aligned} & \underset{\mathbf{W}_{\text{E}} \in \mathbb{H}^{N_{\text{T}}}, \mathbf{w}_k}{\text{maximize}} && \min_{\substack{\Delta \mathbf{G}_j \in \Xi_j \\ j \in \{1, \dots, J\}}} \Psi_{\text{ER}_j} && (13) \\ & \text{s.t.} && \text{C1: } \sum_{k=1}^K \|\mathbf{w}_k\|_2^2 + \text{Tr}(\mathbf{W}_{\text{E}}) \leq P_{\text{max}}, \\ & && \text{C2: } \min_{\Delta \mathbf{h}_k \in \Upsilon_k} \frac{\mathbf{w}_k^H \mathbf{H}_k \mathbf{w}_k}{\sum_{i \neq k} \mathbf{w}_i^H \mathbf{H}_k \mathbf{w}_i + \sigma_s^2} \geq \Gamma_{\text{req}_k}, \\ & && \text{C3: } \mathbf{W}_{\text{E}} \succeq \mathbf{0}. \end{aligned}$$

The objective function in (13) takes into account the CSI uncertainty set  $\Xi_j$  to provide robustness against CSI imperfection. Constants  $P_{\text{max}}$  and  $\Gamma_{\text{req}_k}$  in constraints C1 and C2 denote the maximum transmit power allowance and the QoS requirement on the minimum received signal-to-interference-plus-noise ratio (SINR) at IR  $k$ , respectively. Constraint C3 and  $\mathbf{W}_{\text{E}} \in \mathbb{H}^{N_{\text{T}}}$  constrain matrix  $\mathbf{W}_{\text{E}}$  to be a positive semidefinite Hermitian matrix.

It can be observed that constraint C2 is non-convex. Besides, there are infinitely many possibilities in both the objective function and constraint C2, due to the CSI uncertainties. In order to design a computationally efficient resource allocation algorithm, we first define  $\mathbf{W}_k = \mathbf{w}_k \mathbf{w}_k^H$  and transform the considered problem into the following equivalent rank-constrained semidefinite program (SDP):

$$\begin{aligned} & \underset{\substack{\mathbf{W}_{\text{E}}, \mathbf{W}_k \in \mathbb{H}^{N_{\text{T}}}, \\ \beta, \tau}}{\text{maximize}} && \tau \\ & \text{s.t.} && \text{C1: } \sum_{k=1}^K \text{Tr}(\mathbf{W}_k) + \text{Tr}(\mathbf{W}_{\text{E}}) \leq P_{\text{max}}, \\ & && \text{C2: } \min_{\Delta \mathbf{h}_k \in \Upsilon_k} \frac{\text{Tr}(\mathbf{W}_k \mathbf{H}_k)}{\Gamma_{\text{req}_k}} \geq \sum_{i \neq k} \text{Tr}(\mathbf{W}_i \mathbf{H}_k) + \sigma_s^2, \\ & && \text{C3: } \mathbf{W}_{\text{E}} \succeq \mathbf{0}, \\ & && \text{C4: } \frac{M_j}{\left(1 + \exp(-a_j(\beta_j - b_j))\right)} \geq \tau(1 - \Omega_j) + M_j \Omega_j, \quad \forall j, \\ & && \text{C5: } \min_{\Delta \mathbf{G}_j \in \Xi_j} \text{Tr} \left( \left( \sum_{k=1}^K \mathbf{W}_k + \mathbf{W}_{\text{E}} \right) \mathbf{G}_j \mathbf{G}_j^H \right) \geq \beta_j, \quad \forall j, \\ & && \text{C6: } \text{Rank}(\mathbf{W}_k) \leq 1, \\ & && \text{C7: } \mathbf{W}_k \succeq \mathbf{0}, && (14) \end{aligned}$$

where  $\mathbf{H}_k = \mathbf{h}_k \mathbf{h}_k^H$ . Vector  $\beta = \{\beta_1, \dots, \beta_j, \dots, \beta_J\}$  and  $\tau$  are auxiliary optimization variables. We note that C7 and  $\text{Rank}(\mathbf{W}_k) \leq 1$  in (14) are imposed such that  $\mathbf{W}_k = \mathbf{w}_k \mathbf{w}_k^H$ . Now, the transformed problem in (14) involves infinitely many constraints only in C2 and C5. Besides, the rank constraint in C6 is combinatorial. We first handle constraints C2 and C5 by transforming them into linear matrix inequalities (LMIs) using the following lemma:

*Lemma 1 (S-Procedure [20]):* Let a function  $f_m(\mathbf{x})$ ,  $m \in \{1, 2\}$ ,  $\mathbf{x} \in \mathbb{C}^{N \times 1}$ , be defined as

$$f_m(\mathbf{x}) = \mathbf{x}^H \mathbf{A}_m \mathbf{x} + 2\text{Re}\{\mathbf{b}_m^H \mathbf{x}\} + c_m, \quad (15)$$

<sup>2</sup>We note that these parameters can be determined for any given EH circuit.

where  $\mathbf{A}_m \in \mathbb{H}^N$ ,  $\mathbf{b}_m \in \mathbb{C}^{N \times 1}$ , and  $c_m \in \mathbb{R}$ . Then, the implication  $f_1(\mathbf{x}) \leq 0 \Rightarrow f_2(\mathbf{x}) \leq 0$  holds if and only if there exists a  $\delta \geq 0$  such that

$$\delta \begin{bmatrix} \mathbf{A}_1 & \mathbf{b}_1 \\ \mathbf{b}_1^H & c_1 \end{bmatrix} - \begin{bmatrix} \mathbf{A}_2 & \mathbf{b}_2 \\ \mathbf{b}_2^H & c_2 \end{bmatrix} \succeq \mathbf{0}, \quad (16)$$

provided that there exists a point  $\hat{\mathbf{x}}$  such that  $f_m(\hat{\mathbf{x}}) < 0$ .

Applying Lemma 1, the original constraint C2 holds if and only if there exists a  $\delta_k \geq 0$ , such that the following LMI constraint holds:

$$\begin{aligned} \text{C2: } \mathbf{S}_{C_{2k}}(\mathbf{W}_k, \delta_k) &= \begin{bmatrix} \delta_k \mathbf{I}_{N_T} & \mathbf{0} \\ \mathbf{0} & -\delta_k \rho_k^2 - \sigma_s^2 \end{bmatrix} \\ &+ \mathbf{U}_{\hat{\mathbf{h}}_k}^H \left( \frac{\mathbf{W}_k}{\Gamma_{\text{req}_k}} - \sum_{i \neq k} \mathbf{W}_i \right) \mathbf{U}_{\hat{\mathbf{h}}_k} \succeq \mathbf{0}, \end{aligned} \quad (17)$$

where  $\mathbf{U}_{\hat{\mathbf{h}}_k} = [\mathbf{I}_{N_T} \quad \hat{\mathbf{h}}_k]$ . Similarly, constraint C5 can be equivalently written as

$$\begin{aligned} \text{C5: } \mathbf{S}_{C_{5j}}(\mathbf{W}_k, \mathbf{W}_E, \boldsymbol{\nu}, \beta) & \\ = & \begin{bmatrix} \nu_j \mathbf{I}_{N_T N_R} & \mathbf{0} \\ \mathbf{0} & -\beta_j - \nu_j \nu_j^2 \end{bmatrix} \\ + & \mathbf{U}_{\tilde{\mathbf{g}}_j}^H \left\{ \sum_{k=1}^K (\mathbf{W}_k + \mathbf{W}_E) \right\} \mathbf{U}_{\tilde{\mathbf{g}}_j} \succeq \mathbf{0}, \forall j, \end{aligned} \quad (18)$$

where  $\boldsymbol{\nu} = \{\nu_1, \dots, \nu_j, \dots, \nu_J\}$ ,  $\nu_j \geq 0$ ,  $\mathbf{W}_k = \mathbf{I}_{N_R} \otimes \mathbf{W}_k$ ,  $\mathbf{W}_E = \mathbf{I}_{N_R} \otimes \mathbf{W}_E$ ,  $\mathbf{U}_{\tilde{\mathbf{g}}_j} = [\mathbf{I}_{N_T N_R} \quad \tilde{\mathbf{g}}_j]$ , and  $\tilde{\mathbf{g}}_j = \text{vec}(\hat{\mathbf{G}}_j)$ . Then, the considered optimization problem can be rewritten as

$$\begin{aligned} & \underset{\substack{\mathbf{W}_E, \mathbf{W}_k \in \mathbb{H}^{N_T}, \\ \boldsymbol{\nu}, \tau}}{\text{maximize}} & \tau & (19) \\ & \text{s.t.} & \text{C1, C3, C4, C7,} \\ & & \text{C2: } \mathbf{S}_{C_{2k}}(\mathbf{W}_k, \delta_k) \succeq \mathbf{0}, \forall k, \\ & & \text{C5: } \mathbf{S}_{C_{5j}}(\mathbf{W}_k, \mathbf{W}_E, \boldsymbol{\nu}, \beta) \succeq \mathbf{0}, \forall j, \\ & & \text{C6: } \text{Rank}(\mathbf{W}_k) \leq 1, \end{aligned}$$

where  $\delta_k \geq 0$  and  $\boldsymbol{\nu} \geq 0$  are the auxiliary optimization variables introduced in Lemma 1 for handling constraints C2 and C5, respectively. We note that C2 and C5 are now LMIs with finite numbers of constraints which are relatively easier to handle compared to the infinite numbers of constraints in the original problem formulation. However, the rank constraint in C6 is still an obstacle to solving the considered optimization problem due to its combinatorial nature. As a result, we adopt SDP relaxation by removing constraint C6 from the problem formulation which yields:

$$\begin{aligned} & \underset{\substack{\mathbf{W}_E, \mathbf{W}_k \in \mathbb{H}^{N_T}, \\ \boldsymbol{\nu}, \tau}}{\text{maximize}} & \tau & (20) \\ & \text{s.t.} & \text{C1, C3, C4, C7,} \\ & & \text{C2: } \mathbf{S}_{C_{2k}}(\mathbf{W}_k, \delta_k) \succeq \mathbf{0}, \forall k, \\ & & \text{C5: } \mathbf{S}_{C_{5j}}(\mathbf{W}_k, \mathbf{W}_E, \boldsymbol{\nu}, \beta) \succeq \mathbf{0}, \forall j, \\ & & \text{C6: } \text{Rank}(\mathbf{W}_k) \leq 1. \end{aligned}$$

TABLE I  
SIMULATION PARAMETERS.

Carrier center frequency	915 MHz
Bandwidth	200 kHz
Transceiver antenna gain	10 dBi
Number of receive antennas $N_R$	2
Noise power $\sigma^2$	-95 dBm
Maximum transmit power $P_{\text{max}}$	36 dBm
Transmitter-to-ER fading distribution	Rician with Rician factor 3 dB
Transmitter-to-IR fading distribution	Rayleigh

The problem in (20) is a standard convex optimization problem and can be solved numerically with computationally efficient off-the-shelf convex programs solvers such as CVX [21]. However, it is unclear if the obtained solution satisfies  $\text{Rank}(\mathbf{W}_k) \leq 1, \forall k$ . Therefore, we introduce the following theorem to reveal the structure of the solution of (20).

*Theorem 1:* Let the optimal beamforming matrix and energy covariance matrix of (20) be  $\mathbf{W}_k^*$  and  $\mathbf{W}_E^*$ , respectively. Assuming the considered problem is feasible for  $P_{\text{max}} > 0$  and  $\Gamma_{\text{req}_k} > 0, \forall k$ , then  $\text{Rank}(\mathbf{W}_k^*) = 1, \forall k$ , and  $\text{Rank}(\mathbf{W}_E^*) \leq 1$ .

*Proof:* Please refer to the Appendix.

Thus, the globally optimal solution of (20) can be obtained. In particular, employing information beamforming for each IR and at most one energy beam is optimal for the considered problem, despite the imperfection of the CSI and the non-linearity of the RF EH circuits.

#### IV. SIMULATION

In this section, the performance of the proposed optimal beamforming design is evaluated via simulations. The important simulation parameters are summarized in Table I. Unless specified otherwise, we assume that there are  $K = 2$  IRs and  $J = 4$  ERs which are located 100 meters and 5 meters from the transmitter, respectively. Furthermore, we choose the normalized maximum channel estimation errors of ER  $j$  and IR  $k$  as  $\sigma_{\text{est}_{G_j}}^2 = 1\% \geq \frac{\nu_j^2}{\|\mathbf{G}_j\|_F^2}, \forall j$ , and  $\sigma_{\text{est}_{h_k}}^2 = 1\% \geq \frac{\rho^2}{\|\mathbf{h}_k\|_2^2}$ , respectively. Besides, we assume that all IRs require the same minimum data rate, i.e.,  $\Gamma_{\text{req}_k} = \Gamma_{\text{req}}$ . For the non-linear EH circuits, we set the maximum harvested power per wireless powered device to  $M_j = 24$  mW. Besides, we adopt  $a_j = 150$  and  $b_j = 0.014$ . We solve the optimization problem in (13) and obtain the average system performance by averaging over different channel realizations.

In Figure 3, we show the average minimum harvested power per ER in the considered SWIPT systems for the optimal robust beamforming design. As can be observed, there is a non-trivial trade-off between the minimum harvested power per ER and the minimum required data rate per IR. In particular, the achievable data rate per user and the minimum harvested power per ER cannot be maximized simultaneously. Besides, for the optimal resource allocation, the trade-off region of the minimum achievable rate and the harvested energy is enlarged significantly for larger  $N_T$  and  $N_R$ . This is due to the fact that the extra degrees of freedom offered by multiple transmit antennas can be used to focus both the information and energy beams which improves the beamforming efficiency. On the

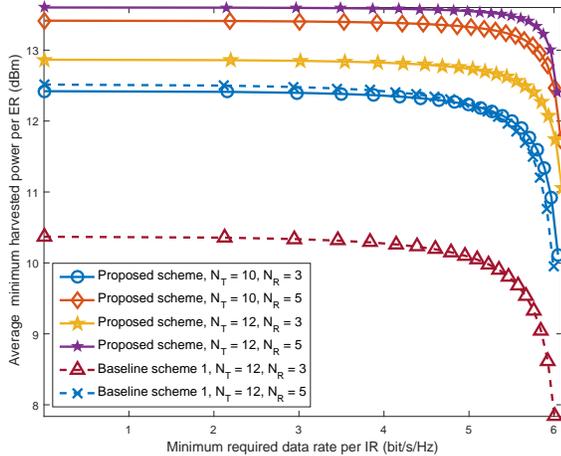

Fig. 3. Average minimum harvested power per ER (dBm) versus the minimum required data rate per ER (bit/s/Hz) for different numbers of antennas.

other hand, increasing the number of receive antennas  $N_R$  at the ER can significantly improve the minimum harvested energy per ER. In fact, the additional receive antennas act as additional energy collectors which enable a more efficient energy transfer. Furthermore, we verified by simulation that  $\text{Rank}(\mathbf{W}_k) = 1$  can be obtained for all considered channel realizations which confirms the correctness of Theorem 1. On the other hand, we also show the performance of a baseline scheme for comparison in Figure 3. For baseline scheme 1, an existing linear EH model with  $\eta_j = 1$ , cf. (6), is adopted for resource allocation algorithm design. Specifically, we optimize  $\mathbf{w}_k$  and  $\mathbf{W}_E$  to maximize the minimum harvested power per ER subject to the constraints in (13). Then, the resource allocation designed by baseline scheme 1 is applied in the considered system with non-linear ERs. We observe from Figure 4 that a substantial gain in harvested power is achieved by the proposed optimal resource allocation algorithm compared to baseline scheme 1. This is because baseline scheme 1 does not take into account the non-linearity of practical EH circuits leading to mismatches in resource allocation.

In Figure 4, we study the average minimum harvested power per ER versus the number of ERs for different maximum normalized channel estimation error variances and beamforming schemes. The minimum required SINR is set to  $\Gamma_{\text{req}_k} = 10$  dB and there are  $N_R = 3$  and  $N_T = 10$  antennas equipped at each ER and the transmitter, respectively. Besides, the maximum normalized channel estimation error variance of the transmitter-to-IR links and the transmitter-to-ER links are set to be identical, i.e.,  $\sigma_{\text{est}_{G_j}}^2 = \sigma_{\text{est}_{h_k}}^2 = \sigma_{\text{est}}^2$ . As can be observed, the average minimum harvested power per ER in the system decreases with an increasing number of ERs. In fact, the more ERs are in the system, the more difficult it is for the transmitter to provide fair resource allocation for all ERs. In particular, for a large number of ERs in the system, it is more likely that there are some ERs with poor channel qualities. Thus, the transmitter is forced to steer the information and

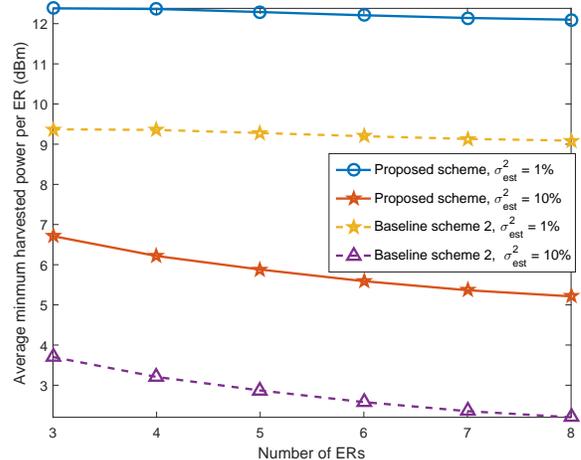

Fig. 4. Average minimum harvested power per ER (dBm) versus the number of ERs for  $N_T = 10$  and  $N_R = 3$ .

energy signals toward ERs with weak channel conditions which reduces the minimum harvested power per ER. On the other hand, the average minimum harvested power per ER decreases with increasing  $\sigma_{\text{est}}^2$ , since the CSI quality degrades with increasing  $\sigma_{\text{est}}^2$ . In particular, for a larger value of  $\sigma_{\text{est}}^2$ , it becomes more difficult for the transmitter to accurately focus the transmitter energy as would be necessary for achieving a high efficiency in SWIPT. For comparison, we also show the performance of baseline scheme 2 which adopts an isotropic radiation pattern for  $\mathbf{W}_E$ . Then, we maximize the minimum harvested power per ER by optimizing  $\mathbf{W}_k$  and the power of  $\mathbf{W}_E$  subject to the same constraints as in (14) via SDP relaxation. It can be seen that the performance of the baseline scheme is unsatisfactory compared to the proposed scheme. In fact, baseline scheme 2 cannot fully exploit the available degrees of freedom for efficient WPT as the beamforming direction of  $\mathbf{W}_E$  is fixed.

## V. CONCLUSIONS

We studied the beamforming design for multiuser SWIPT systems with the objective of ensuring max-min fairness in WPT. The design was formulated as a non-convex optimization problem which took into account the non-linearity of practical EH circuits and the imperfection of the CSI. The optimization problem was solved by applying SDP relaxation. Simulation results demonstrated that the proposed optimal beamforming design offers significant performance gains compared to two baseline schemes.

## APPENDIX-PROOF OF THEOREM 1

We follow a similar approach as in [22] to prove Theorem 1. We note that the relaxed problem in (20) is jointly convex with respect to the optimization variables. Besides, it can be verified that the problem satisfies the Slater's constraint qualification and thus has a zero duality gap. Therefore, to reveal the

structure of  $\mathbf{W}_k$  and  $\mathbf{W}_E$ , we consider the Lagrangian of problem (20) which is given by:

$$L = \tau - \lambda \left( \sum_{k=1}^K \text{Tr}(\mathbf{W}_k) + \text{Tr}(\mathbf{W}_E) - P_{\max} \right) \quad (21)$$

$$+ \sum_{k=1}^K \text{Tr}(\mathbf{S}_{C_{2k}}(\mathbf{W}_k, \delta_k) \mathbf{D}_{C_{2k}}) + \sum_{k=1}^K \text{Tr}(\mathbf{W}_k \mathbf{Y}_k)$$

$$+ \sum_{j=1}^J \text{Tr}(\mathbf{S}_{C_{5j}}(\mathbf{W}_k, \mathbf{W}_E, \nu, \beta) \mathbf{D}_{C_{5j}}) + \text{Tr}(\mathbf{W}_E \mathbf{Z}) + \Delta,$$

where  $\lambda \geq 0$ ,  $\mathbf{D}_{C_{2k}} \succeq \mathbf{0}$ ,  $\mathbf{Z} \succeq \mathbf{0}$ ,  $\mathbf{D}_{C_{5j}} \succeq \mathbf{0}$ ,  $\forall j \in \{1, \dots, J\}$ , and  $\mathbf{Y}_k \succeq \mathbf{0}$  are the dual variables for constraints C1, C2, C3, C5, and C7, respectively. Besides, we denote  $\Delta$  as a collection of variables and constants that are not relevant to the proof. For notational convenience, we denote the optimal primal and dual variables of the SDP relaxed version of (20) by the corresponding variables with an asterisk superscript in the following. Now, we focus on those Karush-Kuhn-Tucker (KKT) conditions which are needed for the proof.

$$\mathbf{Y}_k^*, \mathbf{Z}^*, \mathbf{D}_{C_{3k}}^*, \mathbf{D}_{C_{5j}}^* \succeq \mathbf{0}, \quad \lambda^* \geq 0, \quad (22a)$$

$$\mathbf{Y}_k^* \mathbf{W}_k^* = \mathbf{0}, \quad \mathbf{Z}^* \mathbf{W}_E^* = \mathbf{0}, \quad (22b)$$

$$\mathbf{Y}_k^* = \lambda^* \mathbf{I}_{N_T} - \Xi_k, \quad (22c)$$

$$\Xi_k = \mathbf{U}_{\hat{\mathbf{h}}_k} \frac{\mathbf{D}_{C_{2k}}^*}{\Gamma_{\text{req}_k}} \mathbf{U}_{\hat{\mathbf{h}}_k}^H - \sum_{i \neq k} \mathbf{U}_{\hat{\mathbf{h}}_i} \mathbf{D}_{C_{2i}}^* \mathbf{U}_{\hat{\mathbf{h}}_i}^H$$

$$+ \sum_{j=1}^J \sum_{l=1}^{N_R} \left[ \mathbf{U}_{\hat{\mathbf{g}}_j} \mathbf{D}_{C_{5j}}^* \mathbf{U}_{\hat{\mathbf{g}}_j}^H \right]_{a:b,c:d}, \quad (22d)$$

$$\mathbf{Z}^* = \lambda^* \mathbf{I}_{N_T} - \sum_{j=1}^J \sum_{l=1}^{N_R} \left[ \mathbf{U}_{\hat{\mathbf{g}}_j} \mathbf{D}_{C_{5j}}^* \mathbf{U}_{\hat{\mathbf{g}}_j}^H \right]_{a:b,c:d}, \quad (22e)$$

where  $a = (l-1)N_T + 1$ ,  $b = lN_T$ ,  $c = (l-1)N_T + 1$ , and  $d = lN_T$ .

From (22b), we know that the columns of  $\mathbf{W}_k^*$  lie in the null space of  $\mathbf{Y}_k^*$ . In order to reveal the rank of  $\mathbf{W}_k^*$ , we investigate the structure of  $\mathbf{Y}_k^*$ . First, it can be shown that  $\lambda^* > 0$  since constraint C1 is active at the optimal solution. Then, we show that  $\Xi_k$  in (22c) is a positive semidefinite matrix by contradiction. Suppose  $\Xi_k$  is a negative definite matrix, then from (22c),  $\mathbf{Y}_k^*$  becomes a full-rank and positive definite matrix. By (22b),  $\mathbf{W}_k^*$  is forced to be the zero matrix which is not an optimal solution for  $P_{\max} > 0$  and  $\Gamma_{\text{req}_k} > 0$ . Thus, in the following, we focus on the case  $\Xi_k \succeq \mathbf{0}$ . Since matrix  $\mathbf{Y}_k^* = \lambda^* \mathbf{I}_{N_T} - \Xi_k$  is positive semidefinite, the following inequality holds:

$$\lambda^* \geq \lambda_{\Xi_k}^{\max} \geq 0, \quad (23)$$

where  $\lambda_{\Xi_k}^{\max}$  is the maximum eigenvalue of matrix  $\Xi_k$ . From (22c), if  $\lambda^* > \lambda_{\Xi_k}^{\max}$ , matrix  $\mathbf{Y}_k^*$  will become a positive definite matrix with full rank. However, this will again yield the solution  $\mathbf{W}_k^* = \mathbf{0}$  which is not optimal since  $\Gamma_{\text{req}_k} > 0$ . Thus, at the optimal solution,  $\lambda^* = \lambda_{\Xi_k}^{\max}$  must hold. Besides, in order to have a bounded optimal dual solution, it follows that

the null space of  $\mathbf{Y}_k^*$  is spanned by vector  $\mathbf{u}_{\Xi_k, \max} \in \mathbb{C}^{N_T \times 1}$ , which is the unit-norm eigenvector of  $\Xi_k$  associated with eigenvalue  $\lambda_{\Xi_k}^{\max}$ . As a result, the optimal beamforming matrix  $\mathbf{W}_k^*$  has to be a rank-one matrix and is given by

$$\mathbf{W}_k^* = \psi \mathbf{u}_{\Xi_k, \max} \mathbf{u}_{\Xi_k, \max}^H, \quad (24)$$

where  $\psi$  is a parameter such that the power consumption satisfies constraint C2.

On the other hand, for revealing the structure of  $\mathbf{Z}^*$ , we focus on (22e). Define an auxiliary variable matrix  $\mathbf{B} = \sum_{j=1}^J \sum_{l=1}^{N_R} \left[ \mathbf{U}_{\hat{\mathbf{g}}_j} \mathbf{D}_{C_{5j}}^* \mathbf{U}_{\hat{\mathbf{g}}_j}^H \right]_{a:b,c:d} \succeq \mathbf{0}$  and the corresponding maximum eigenvalue  $\lambda_{\mathbf{B}}^{\max}$ . Since  $\mathbf{Z}^* \succeq \mathbf{0}$ , we have  $\lambda^* \geq \lambda_{\mathbf{B}}^{\max} \geq 0$ . If  $\lambda^* = \lambda_{\mathbf{B}}^{\max}$ , then  $\text{Rank}(\mathbf{Z}^*) = N_T - 1$  and  $\text{Rank}(\mathbf{W}_E^*) = 1$ . If  $\lambda^* > \lambda_{\mathbf{B}}^{\max}$ , then  $\text{Rank}(\mathbf{Z}^*) = N_T$  and  $\text{Rank}(\mathbf{W}_E^*) = 0$ . Therefore,  $\text{Rank}(\mathbf{W}_E^*) \leq 1$  and at most one energy beam is required to achieve optimality. ■
