Optimal estimates of the field enhancement in presence of a bow-tie structure of perfectly conducting inclusions in two dimensions[∗]

Hyeonbae Kang† KiHyun Yun‡

September 19, 2018

Abstract

This paper deals with the field enhancement, that is, the gradient blow-up, due to presence of a bow-tie structure of perfectly conducting inclusions in two dimensions. The bow-tie structure consists of two disjoint bounded domains which have corners with possibly different aperture angles. The domains are parts of cones near the vertices, and they are nearly touching to each other. We characterize the field enhancement using explicit functions and, as consequences, derive optimal estimates of the gradient in terms of the distance between two inclusions and aperture angles of the corners. The estimates show that the field is enhanced beyond the corner singularities due to the interaction between two inclusions.

Key words. Field enhancement, gradient blow-up, bow-tie structure, corner singularity, perfect conductor

1 Introduction

This paper concerns with the field enhancement, in other words the gradient blow-up, which occurs due to presence of closely located two perfectly conducting inclusions. If we denote those inclusions by Ω_1 and Ω_2 , then the problem to be considered is the following:

$$
\begin{cases}\n\Delta u = 0 & \text{in } \mathbb{R}^2 \setminus \overline{(\Omega_1 \cup \Omega_2)}, \\
u = c_j & \text{on } \partial \Omega_j, \quad j = 1, 2, \\
\int_{\partial \Omega_1} \partial_\nu u ds = 0, \quad j = 1, 2, \\
u(X) - h(X) = O(|X|^{-1}) & \text{as } |X| \to \infty.\n\end{cases}
$$
\n(1.1)

Here, h is a given harmonic function in \mathbb{R}^2 whose gradient represents the background field in absence of inclusions. The values c_1 and c_2 on the boundaries of inclusions are

[‡]Department of Mathematics, Hankuk University of Foreign Studies, Yongin-si, Gyeonggi-do 17035, S. Korea (kihyun.yun@gmail.com).

(unknown) constants depending on h and inclusions, and they are determined by the zero total flux condition on $\partial\Omega_i$ (the third condition of [\(1.1\)](#page-0-0)).

The problem [\(1.1\)](#page-0-0) may be regarded as a conductivity problem in the context of electromagnetism, or an anti-plane elasticity problem in the context of elasticity. The solution u having constant values on $\partial\Omega_j$ indicates that Ω_j is either a perfectly conducting inclusion (the conductivity being ∞) or a hard inclusion (the shear modulus being ∞). The gradient of the solution u to (1.1) is either the electrical field or the stress. It can be arbitrarily large as the distance between two inclusions tends to zero, and the problem is to derive optimal estimates of the blow-up in terms of the distance between inclusions or to characterize its singular behavior using some explicit functions.

Let u be the solution to (1.1) , and let

$$
\epsilon := \text{dist}(\Omega_1, \Omega_2). \tag{1.2}
$$

The problem of estimating $|\nabla u|$ in terms of ϵ was first raised in [\[3\]](#page-25-0) in relation to stress analysis of composites, and there has been significant progress on this problem in the last decade or so. It is proved that the optimal blow-up rate of $|\nabla u|$ is $\epsilon^{-1/2}$ in two dimensions [\[2,](#page-25-1) [17\]](#page-26-0), and $(\epsilon |\ln \epsilon|)^{-1}$ in three dimensions [\[5\]](#page-25-2). The singular behavior of ∇u is characterized asymptotically in [\[1,](#page-25-3) [10,](#page-26-1) [11,](#page-26-2) [12\]](#page-26-3). It is worth mentioning that the gradient estimate was extended to the case of insulating inclusions [\[2,](#page-25-1) [6,](#page-25-4) [18\]](#page-26-4), non-homogeneous case [\[7\]](#page-25-5), p-Laplacian [\[8\]](#page-25-6), and the Lamé system of the linear elasticity [\[4,](#page-25-7) [13\]](#page-26-5).

All the above mentioned work deal with inclusions with smooth boundaries, $C^{2,\alpha}$ boundaries to be precise. However, for some purposes such as imaging, the stronger gradient blow-up is desirable (see, for example, [\[16\]](#page-26-6)), and for that it is natural to consider structures consisting of inclusions with corners instead of those with smooth boundaries. One such a structure is the bow-tie structure as depicted in Figure [1.](#page-1-0) In fact, there are some works dealing with field enhancement on the bow-tie structure, for which we refer to the above mentioned article and references therein. However, a rigorous quantitative analysis of the field enhancement is missing as far as we are aware of, and it is the purpose of this paper to derive optimal estimates for the field enhancement due to presence of the bow-tie structure.

Figure 1: A bow-tie structure

The gradient blow-up due to presence of the bow-tie structure is particularly interesting since two different types of singularities of the gradient are expected: one due to presence of corners and the other due to the interaction between closely located inclusions. Since the fundamental work of Kontratiev [\[14\]](#page-26-7) on the corner singularity (see also [\[9,](#page-25-8) [15\]](#page-26-8)), it is

well known that near the vertex of a corner with the aperture angle α , the gradient of the solution to the Laplace equation has singularity of the form $|X-V|^{-1+\beta}$ where $\beta = \frac{\pi}{2\pi\epsilon}$ $\frac{\pi}{2\pi - \alpha}$. In the bow-tie structure, two vertices are closely located. So one can expect the corner singularity may be amplified due to the interaction of the inclusions. The results of this paper confirm the expectation in a quantitatively precise manner.

Let V_j be the vertex of Ω_j and the aperture angle at V_j be α_j $(j = 1, 2)$. We show, for example, that the gradient of the solution to (1.1) behaves near the vertex V_i as

$$
\frac{\epsilon^{-\beta_j}}{|\log \epsilon|} |X - V_j|^{-1+\beta_j},\tag{1.3}
$$

where

$$
\beta_j := \frac{\pi}{2\pi - \alpha_j}, \quad j = 1, 2,
$$
\n(1.4)

(see Theorem [5.4\)](#page-23-0). So, the corner singularity $|X - V_j|^{-1+\beta_j}$ is amplified by the factor of $\epsilon^{-\beta_j}/|\log \epsilon|$. According to [\(1.3\)](#page-2-0), the magnitude of the gradient is larger than $\epsilon^{-1}/|\log \epsilon|$. provided that $|X - V_i| \leq \epsilon$. This blow-up rate is much larger than the one in the case of inclusions with smooth boundaries, where the blow-up rate is $\epsilon^{-1/2}$ as mentioned before. We also obtain estimates of $|\nabla u(X)|$ when X is relatively away from the vertices (Theorem [5.2\)](#page-21-0), which shows as well that the corner singularity is amplified on the bow-tie structure.

In this paper we assume that the aperture angles α_1 and α_2 satisfies $0 < \alpha_j \leq \pi$ and

$$
C_1 \le \alpha_1 + \alpha_2 \le 2\pi - C_2 \tag{1.5}
$$

for some positive constants C_1 and C_2 . Estimates to be derived in the sequel depend on C_1 and C_2 . So, one of angles is allowed to be π .

This paper is organized as follows. In section [2](#page-2-1) we define the bow-tie structure and investigate the corner singularity in the case of the present paper, where there are two corners. In section [3](#page-7-0) we introduce some auxiliary functions to be used in later sections. In section [4,](#page-11-0) we introduce singular functions which capture singular behavior of ∇u . The main results and their proofs are presented in section [5.](#page-19-0) The last section is to estimate a coefficient, which is crucial in achieving lower bounds.

Throughout this paper, the expression $A \leq B$ implies that there is a constant C independent of ϵ and the background potential h such that $A \leq CB$, and $A \simeq B$ implies that both $A \lesssim B$ and $B \lesssim A$ hold.

2 Corner singularities

Let Γ_1 be the open cone in the left-half space with the vertex at $S_1 := (-1/2, 0)$ and the aperture angle α_1 at S_1 , namely,

$$
\Gamma_1 = \{ X = (x, y) : |y| < -\tan(\alpha_1/2)(x + 1/2) \},\tag{2.1}
$$

and let

$$
\Gamma_2 = \{ X = (x, y) : |y| < \tan(\alpha_2/2)(x - 1/2) \},\tag{2.2}
$$

which is the open cone in the right-half space with the vertex at $S_2 := (1/2, 0)$ and the aperture angle α_2 at S_2 . Then inclusions Ω_1 and Ω_2 , which constitute the bow-tie structure, can be defined locally as translates of Γ_1 and Γ_2 : Let

$$
L_{\epsilon} := \frac{1}{2}(-\epsilon + 1) \quad \text{and} \quad R_{\epsilon} := \frac{1}{2}(\epsilon - 1). \tag{2.3}
$$

Then, Ω_1 and Ω_2 are bounded domains whose boundaries are smooth except at vertices $V_1 := (-\epsilon/2, 0)$ and $V_2 := (\epsilon/2, 0)$, respectively, such that

$$
\Omega_1 \cap B_\delta = (\Gamma_1 + L_\epsilon) \cap B_\delta \quad \text{and} \quad \Omega_2 \cap B_\delta = (\Gamma_2 + R_\epsilon) \cap B_\delta \tag{2.4}
$$

for some $\delta > 0$. Here and throughout this paper $B_{\delta}(P)$ denotes the open disk of radius δ centered at P, and if $P = O$, the origin, then we simply denote it by B_{δ} . We emphasize that if Γ_1 and Γ_2 are scaled by ϵ , then they become Ω_1 and Ω_2 near the origin O, that is,

$$
\epsilon(\Gamma_1 \cup \Gamma_2) \cap B_{\delta} = (\Omega_1 \cup \Omega_2) \cap B_{\delta}.
$$

Figure 2: Polar coordinates with respect to vertices

Choose and fix a point P_j on $\partial \Gamma_j \cap \{(x, y) : y > 0\}$ for $j = 1, 2$, and define $\theta_j(X)$ and $r_j(X)$ for $X \in \mathbb{R}^2 \setminus \overline{\Gamma_j}$ $(j = 1, 2)$ by

$$
\theta_j(X)
$$
 =the angle between $\overrightarrow{S_j P_j}$ and $\overrightarrow{S_j X}$, (2.5)

and

$$
r_j(X) = |X - S_j|.\t\t(2.6)
$$

See Figure [2.](#page-3-0) Let β_j be the number defined by [\(1.4\)](#page-2-2) and define the functions $\mathcal{B}_j(X)$ for $j = 1, 2$ by

$$
\mathcal{B}_j(X) = r_j(X)^{\beta_j} \sin(\beta_j \theta_j(X)), \quad X \in \mathbb{R}^2 \setminus \overline{\Gamma_j} \,. \tag{2.7}
$$

The function B_i is the singular part of the solution to the elliptic problem when the domain has a corner of the angle $2\pi - \alpha_j$ (see [\[9\]](#page-25-8)). Note that $\nabla \mathcal{B}_j$ has a singularity of order $\beta_j - 1$ at the vertex S_i . In fact, one can easily see that

$$
|\nabla \mathcal{B}_j(X)| = \beta_j |X - S_j|^{\beta_j - 1}, \quad j = 1, 2. \tag{2.8}
$$

Since the bow-tie structure has two corners, the function $\mathcal{B}_1 - b\mathcal{B}_2$ plays an important role in the sequel, where b is a positive number determined by angles α_1 and α_2 (see Theorem [5.3\)](#page-22-0). In the following we look into its properties.

Lemma 2.1 *For* $j = 1, 2$ *, let* ν_j *be the normal vector of* $\partial \Gamma_j$ *pointing towards the inside of* Γ_i *. The following holds:*

(i) for $X \in \partial \Gamma_1 \setminus \{S_1\}$

$$
\partial_{\nu_1} \mathcal{B}_1(X) = -|\nabla \mathcal{B}_1(X)| < 0 \quad \text{and} \quad \partial_{\nu_1} \mathcal{B}_2(X) \ge 0,\tag{2.9}
$$

(ii) for $X \in \partial \Gamma_2 \setminus \{S_2\}$

$$
\partial_{\nu_2} \mathcal{B}_2 \left(X \right) = - \left| \nabla \mathcal{B}_2 \left(X \right) \right| < 0 \quad \text{and} \quad \partial_{\nu_2} \mathcal{B}_1 \left(X \right) \ge 0. \tag{2.10}
$$

Proof. Let us prove (i) only. (ii) can be proved similarly.

Since $\mathcal{B}_1 = 0$ on $\partial \Gamma_1$, we have $\partial_{\nu_1} \mathcal{B}_1(X) \nu_1 = \nabla \mathcal{B}_1(X)$ for $X \in \partial \Gamma_1 \setminus \{S_1\}$. Moreover, since $\mathcal{B}_1 > 0$ in $\mathbb{R}^2 \setminus \overline{\Gamma_1}$, $\partial_{\nu_1} \mathcal{B}_1(X) < 0$ by Hopf's lemma. So, the first inequality in [\(2.9\)](#page-4-0) follows.

To prove the second inequality in [\(2.9\)](#page-4-0), we note that $X = (x, y)$ in $\mathbb{R}^2 \setminus \Gamma_2$ can be represented, using the polar coordinates with respect to S_2 as defined in [\(2.5\)](#page-3-1) and [\(2.6\)](#page-3-2), as

$$
x - \frac{1}{2} = r_2 \cos \left(\theta_2 + \frac{\alpha_2}{2}\right), \quad y = r_2 \sin \left(\theta_2 + \frac{\alpha_2}{2}\right).
$$

So we see that

$$
U_{-\theta-\alpha_2/2} \nabla \mathcal{B}_2(X) = (\partial_{r_2} \mathcal{B}_2(X), r_2^{-1} \partial_{\theta_2} \mathcal{B}_2(X))^T
$$
 (T for transpose),

where $U_{-\theta_2-\alpha_2/2}$ is the matrix of rotation by $-\theta_2-\alpha_2/2$ with respect to S_2 . So, one can see that

$$
\nabla \mathcal{B}_2(X) = \beta_2 r_2^{\beta_2 - 1} \left(-\sin \left(\theta_2 + \frac{\alpha_2}{2} - \beta_2 \theta_2 \right), \cos \left(\theta_2 + \frac{\alpha_2}{2} - \beta_2 \theta_2 \right) \right)^T. \tag{2.11}
$$

One can also see that

$$
\nu_1 = -\left(\sin\left(\frac{\alpha_1}{2}\right), \cos\left(\frac{\alpha_1}{2}\right)\right)^T.
$$

It then follows that

$$
\nu_1 \cdot \nabla \mathcal{B}_2(X) = -\cos\left((1 - \beta_2)\theta_2 + \frac{\alpha_1 + \alpha_2}{2}\right). \tag{2.12}
$$

If $X = (x, y) \in \partial \Gamma_1$ with $y \geq 0$, then we have

$$
\pi - \frac{\alpha_1 + \alpha_2}{2} < \theta_2(X) \le \pi - \frac{\alpha_2}{2},
$$

and hence

$$
(1 - \beta_2)\left(\pi - \frac{\alpha_1 + \alpha_2}{2}\right) + \frac{\alpha_1 + \alpha_2}{2} < (1 - \beta_2)\theta_2 + \frac{\alpha_1 + \alpha_2}{2} \le (1 - \beta_2)\left(\pi - \frac{\alpha_2}{2}\right) + \frac{\alpha_1 + \alpha_2}{2}.
$$

Note that the term on the far left-hand side is linear in α_1 . By substituting $\alpha_1 = 0$ and π , we see that it is bounded from below by $\pi/2$. Likewise one can see that the term on the far right-hand side is bounded from above by π . So, we have

$$
\frac{\pi}{2} < (1 - \beta_2)\theta_2 + \frac{\alpha_1 + \alpha_2}{2} < \pi.
$$

Now the second inequality in [\(2.9\)](#page-4-0) follows from [\(2.12\)](#page-4-1), and the proof is complete for $X = (x, y)$ with $y > 0$. The case when $y < 0$ can be treated in the same way. This completes the proof. \Box

The following proposition shows that there is no cancellation between two gradients $\nabla \mathcal{B}_1$ and $-\nabla \mathcal{B}_2$ entering $\nabla \mathcal{B}_1 - b \nabla \mathcal{B}_2$.

Proposition 2.2 *Suppose that* b > 0*. The following holds:*

$$
|\nabla \mathcal{B}_1(X)| + |\nabla \mathcal{B}_2(X)| \lesssim |\nabla \mathcal{B}_1(X) - b\nabla \mathcal{B}_2(X)| \tag{2.13}
$$

for $X \in \mathbb{R}^2 \setminus \overline{\Gamma_1 \cup \Gamma_2}$ *.*

Proof. We begin the proof by showing that [\(2.13\)](#page-5-0) holds on $\partial (B_R \setminus (\Gamma_1 \cup \Gamma_2)) \setminus \{S_1, S_2\}$ for any sufficiently large $R > 0$. To do so, we define l_R^{\pm} $\frac{1}{R}$ by

$$
l_R^{\pm} := \{ X : X = (x, y) \in \partial B_R \setminus (\Gamma_1 \cup \Gamma_2), \pm y > 0 \},\
$$

respectively, so that we have

$$
\partial (B_R \setminus (\Gamma_1 \cup \Gamma_2)) \setminus \{S_1, S_2\} = l_R^+ \cup l_R^- \cup ((\partial \Gamma_1 \cap B_R) \setminus \{S_1\}) \cup ((\partial \Gamma_2 \cap B_R) \setminus \{S_2\}).
$$

First, we prove (2.13) on l_B^+ \overline{R}_{i} . Let (r, θ) be the usual polar coordinates with respect to O, the origin. We write $X = re^{i\theta}$ by identifying points in \mathbb{R}^2 with complex numbers. Note that

$$
\log\left(Re^{i\theta} - \frac{1}{2}\right) = \log r_2 + i\left(\theta_2 + \frac{\alpha_2}{2}\right)
$$
\n(2.14)

on l_R^+ $_R^+$. Since $|Re^{i\theta} - 1/2| = r_2$, we infer that

$$
\frac{r_2}{R} = 1 + O\left(\frac{1}{R}\right) \tag{2.15}
$$

for all sufficiently large R. By differentiating both sides of (2.14) with respect to θ , we obtain

$$
\frac{Rie^{i\theta}}{Re^{i\theta} - \frac{1}{2}} = \frac{1}{r_2} \frac{\partial r_2}{\partial \theta} + i \frac{\partial \theta_2}{\partial \theta},
$$

from which we infer that

$$
\left|\frac{\partial \theta_2}{\partial \theta} - 1\right| + \frac{1}{r_2} \left|\frac{\partial r_2}{\partial \theta}\right| \leq \frac{C}{R} \quad \text{on } l_R^+,
$$

provided that R is sufficiently large. Here and in the following the constant C may differ at each occurrence. It then follows that

$$
\frac{\partial \mathcal{B}_2(X)}{\partial \theta} = \frac{\partial \theta_2}{\partial \theta} \frac{\partial \mathcal{B}_2(X)}{\partial \theta_2} + \frac{\partial r_2}{\partial \theta} \frac{\partial \mathcal{B}_2(X)}{\partial r_2}
$$

= $\left(1 + O\left(\frac{1}{R}\right)\right) \frac{\partial \mathcal{B}_2(X)}{\partial \theta_2} + O\left(\frac{1}{R}\right) r_2 \frac{\partial \mathcal{B}_2(X)}{\partial r_2}$ (2.16)

for all sufficiently large R.

One can see that there is R_0 such that $0 \le \beta_j \theta_2(X) \le \pi/2 - \theta_0$ for some $\theta_0 > 0$ for all $X \in l_R^+$ with $R \ge R_0$. So we have

$$
\sin(\beta_2 \theta_2(X)) \le C \cos(\beta_2 \theta_2(X)),
$$

and hence

$$
0 < r_2 \frac{\partial \mathcal{B}_2(X)}{\partial r_2} \le C \frac{\partial \mathcal{B}_2(X)}{\partial \theta_2}.\tag{2.17}
$$

This together with (2.16) shows that there is R_1 such that

$$
\frac{\partial \mathcal{B}_2(X)}{\partial \theta} \simeq \frac{\partial \mathcal{B}_2(X)}{\partial \theta_2} \tag{2.18}
$$

for all $X \in l_R^+$ with $R \ge R_1$. We also have

$$
|\nabla \mathcal{B}_2(X)| \le C \left(\frac{1}{r_2} \frac{\partial \mathcal{B}_2(X)}{\partial \theta_2} + \frac{\partial \mathcal{B}_2(X)}{\partial r_2} \right) \le C \frac{1}{r_2} \frac{\partial \mathcal{B}_2(X)}{\partial \theta_2}.
$$
 (2.19)

It then follows from (2.15) , (2.18) and (2.19) that

$$
|\nabla \mathcal{B}_2(X)| \le C \frac{1}{R} \frac{\partial \mathcal{B}_2(X)}{\partial \theta}, \quad X \in l_R^+, \tag{2.20}
$$

for all $R \geq R_1$.

In the same way, one can show that there is a positive constant C independent of R such that 1 $\partial \mathcal{B}_1(X)$ $rac{\partial_1(X)}{\partial \theta_1} \leq -C\frac{1}{R}$ $\partial \mathcal{B}_1(X)$

R

and

$$
|\nabla \mathcal{B}_1(X)| \le -C\frac{1}{R}\frac{\partial \mathcal{B}_1(X)}{\partial \theta}, \quad X \in l_R^+, \tag{2.21}
$$

 $\partial \theta$

provided that $R \geq R_1$.

Combining [\(2.20\)](#page-6-3) and [\(2.21\)](#page-6-4), we arrive at

 r_1

$$
|\nabla \mathcal{B}_1(X)| + |\nabla \mathcal{B}_2(X)| \leq -C \left(\frac{1}{R} \frac{\partial \mathcal{B}_1(X)}{\partial \theta} - b \frac{1}{R} \frac{\partial \mathcal{B}_2(X)}{\partial \theta} \right)
$$

$$
\leq C \left| \nabla \mathcal{B}_1(X) - b \nabla \mathcal{B}_2(X) \right| \quad \text{on } l_R^+.
$$

In the same way, we obtain an analogous estimate on $l_R^ R$. In short, we have shown that there are R_2 and $C > 0$ independent of $R \geq R_2$ such that

$$
|\nabla \mathcal{B}_1(X)| + |\nabla \mathcal{B}_2(X)| \le C |\nabla \mathcal{B}_1(X) - b \nabla \mathcal{B}_2(X)| \quad \text{for all } X \in l_R^+ \cup l_R^-.
$$
 (2.22)

Second, we prove [\(2.13\)](#page-5-0) on $((\partial \Gamma_1 \cap B_R) \setminus \{S_1\})$. It follows from [\(2.22\)](#page-6-5) that

$$
|\nabla \mathcal{B}_1(X)| + |\nabla \mathcal{B}_2(X)| \le C |\nabla \mathcal{B}_1(X) - b \nabla \mathcal{B}_2(X)| \quad \text{for all } X \in (\partial \Gamma_1 \cup \partial \Gamma_2) \setminus B_{R_2}.
$$
 (2.23)

By the equality [\(2.8\)](#page-3-3), there exists a constant C depending on aperture angles α_1 and α_2 such that

$$
|\nabla \mathcal{B}_2(X)| \le C|\nabla \mathcal{B}_1(X)| \quad \text{for all } X \in (\partial \Gamma_1 \cap B_{R_2}) \setminus \{S_1\},\tag{2.24}
$$

and

$$
|\nabla \mathcal{B}_1(X)| \le C|\nabla \mathcal{B}_2(X)| \quad \text{for all } X \in (\partial \Gamma_2 \cap B_{R_2}) \setminus \{S_2\}. \tag{2.25}
$$

Suppose $X \in (\partial \Gamma_1 \cap B_{R_2}) \setminus \{S_1\}$. Lemmas [2.1](#page-3-4) (i) and [\(2.24\)](#page-7-1) show that

$$
|\nabla \mathcal{B}_1(X)| + |\nabla \mathcal{B}_2(X)| \leq C|\nabla \mathcal{B}_1(X)| = -C\partial_{\nu_1}\mathcal{B}_1(X).
$$

Since $b > 0$ and $\partial_{\nu_1} \mathcal{B}_2(X) \geq 0$ (the second inequality in [\(2.9\)](#page-4-0)), we have

$$
|\nabla \mathcal{B}_1(X)| + |\nabla \mathcal{B}_2(X)| \leq -C(\partial_{\nu_1} \mathcal{B}_1(X) - b\partial_{\nu_1} \mathcal{B}_2(X)) \leq C|\nabla \mathcal{B}_1(X) - b\nabla \mathcal{B}_2(X)|.
$$

Similarly, one can show that [\(2.13\)](#page-5-0) holds for $X \in (\partial \Gamma_2 \cap B_{R_2}) \setminus \{S_2\}$. These together with [\(2.22\)](#page-6-5) and [\(2.23\)](#page-7-2) complete the proof that [\(2.13\)](#page-5-0) holds on $\partial (B_R \setminus (\Gamma_1 \cup \Gamma_2)) \setminus \{S_1, S_2\}$ for all $R \geq R_2$, as desired.

If we identify points in the plane with complex numbers, then $\nabla \mathcal{B}_1$, $\nabla \mathcal{B}_2$ and $\nabla \mathcal{B}_1$ – $b\nabla\mathcal{B}_2$ are conjugates of analytic functions. Since [\(2.13\)](#page-5-0) holds on $\partial (B_R \setminus (\Gamma_1 \cup \Gamma_2))$ ${S_1, S_2}$, we have

$$
\left| \frac{\nabla \mathcal{B}_1}{\nabla \mathcal{B}_1(X) - b \nabla \mathcal{B}_2(X)} \right| \le C
$$

for any $X \in \partial (B_R \setminus \overline{\Gamma_1 \cup \Gamma_2})$, where C is a constant independent of $R \ge R_2$. It then follows from the maximum modulus theorem that

$$
|\nabla \mathcal{B}_1(X)| \le C |\nabla \mathcal{B}_1(X) - b \nabla \mathcal{B}_2(X)| \quad \text{for all } X \in B_R \setminus \overline{\Gamma_1 \cup \Gamma_2}.
$$

Analogously we can derive the above inequality with \mathcal{B}_1 on the left-hand side is replaced by \mathcal{B}_2 . Since C in the estimates is independent of R, we arrive at [\(2.13\)](#page-5-0), and the proof is complete. \Box

3 Auxiliary functions on cones and their estimates

In this section we construct some auxiliary functions which are used in an essential way for analysing singular behavior of ∇u where u is the solution to [\(1.1\)](#page-0-0). We first construct functions in $\mathbb{R}^2 \setminus \overline{\Gamma_1 \cup \Gamma_2}$, and then scale them by ϵ in the next section.

Let, for ease of notation,

$$
\Pi := \mathbb{R}^2 \setminus \overline{\Gamma_1 \cup \Gamma_2} \quad \text{and} \quad \Pi^+ := \{ (x, y) \in \Pi, \ y > 0 \}. \tag{3.1}
$$

Let P_j be a point on $\partial\Gamma_j \cap \{(x,y): y > 0\}$ for $j = 1,2$ as in the previous section, and let Q be the intersection point of two straight lines containing the line segments $\overline{P_1S_1}$ and $\overline{P_2S_2}$. Specifically, Q is given by

$$
Q = \left(\frac{\cot\frac{\alpha_1}{2}}{\cot\frac{\alpha_1}{2} + \cot\frac{\alpha_2}{2}} - \frac{1}{2}, -\frac{1}{\cot\frac{\alpha_1}{2} + \cot\frac{\alpha_2}{2}}\right). \tag{3.2}
$$

Figure 3: The polar coordinates ρ and ϕ

We emphasize that Q depends on α_1 and α_2 . In fact, $|Q| \to \infty$ as $\alpha_1 + \alpha_2 \to 2\pi$. Under the assumption [\(1.5\)](#page-2-3) of this paper, we have $|Q| \approx 1$.

Using the point Q, we define $\phi(X)$ for $X \in \Pi^+$ to be the angle between $\overrightarrow{QP_1}$ and \overrightarrow{QX} . Let

$$
\gamma := \frac{2\pi}{2\pi - (\alpha_1 + \alpha_2)}.\tag{3.3}
$$

Then one can easily see that

$$
0 < \phi < \pi - \frac{1}{2}(\alpha_1 + \alpha_2) = \frac{\pi}{\gamma}
$$
 in Π^+ .

We also define $\rho = \rho(X)$ to be the distance between X and Q, namely,

$$
\rho(X) := |X - Q|.\tag{3.4}
$$

So, (ρ, ϕ) is the polar coordinate system with respect to Q in Π^+ . See Figure [3.](#page-8-0) Let w be the solution to

$$
\begin{cases}\n\Delta w = 0 & \text{in } \Pi^+, \\
w = 0 & \text{on } \partial \Pi^+ \setminus \left[-\frac{1}{2}, \frac{1}{2} \right] \times \{0\}, \\
\partial_y w = -\partial_y \phi & \text{on } \left[-\frac{1}{2}, \frac{1}{2} \right] \times \{0\}, \\
\int_{\Pi^+} |\nabla w|^2 dx dy < \infty.\n\end{cases} \tag{3.5}
$$

We then extend ϕ and w to Π as symmetric functions with respect to the x-axis, namely,

$$
\phi(x, y) = \phi(x, -y), \quad w(x, y) = w(x, -y).
$$

Lemma 3.1 *The following holds:*

- *(i)* The function $\phi + w$ *is harmonic in* Π , $\phi + w = 0$ *on* $\partial \Gamma_1$, and $\phi + w = \pi/\gamma$ *on* $\partial \Gamma_2$ *.*
- *(ii)* Let $\rho_0 := \max\{|S_1 Q|, |S_2 Q|\}$. There is a constant $C = C(\rho_0)$ *such that*

$$
0 < |\nabla w(X)| \le \frac{C}{|X^* - Q|^{\gamma + 1}} \quad \text{for all } X \in \Pi \setminus \overline{B_2},\tag{3.6}
$$

where $X^* = (x, |y|)$ *for* $X = (x, y)$ *.*

(iii) For each $X \in \Pi$,

$$
0 < (\phi + w)(X) < \frac{\pi}{\gamma}.\tag{3.7}
$$

Proof. Since $\phi + w$ is harmonic in Π^+ and $\partial_y(\phi + w) = 0$ on $\left[-\frac{1}{2}\right]$ $\frac{1}{2}, \frac{1}{2}$ $\frac{1}{2} \times \{0\}, \ \phi + w$ is harmonic in Π. The rest of (i) follows from definitions of ϕ and w.

To prove (ii) we first observe that the set $\{X : \rho > \rho_0, 0 < \phi < \pi/\gamma\}$ is contained in Π^+ . Because of the second condition in [\(3.5\)](#page-8-1), w admits the following Fourier series expansion for $X \in \Pi^+$ satisfying $\rho(X) > \rho_0$:

$$
w(X) = \sum_{n=1}^{\infty} \frac{a_n}{\rho^{n\gamma}} \sin(n\gamma\phi).
$$
 (3.8)

Since

$$
|\nabla w|^2 = |\partial_\rho w|^2 + \rho^{-2} |\partial_\phi w|^2,
$$
\n(3.9)

we have

$$
\sum_{n=1}^{\infty} \frac{|a_n|^2 n\gamma}{\rho_0^{2n\gamma}} \lesssim \int_{\rho_0}^{\infty} \int_0^{\pi/\gamma} |\nabla w|^2 \rho d\phi d\rho \le \int_{\Pi^+} |\nabla w|^2 dx dy < \infty.
$$
 (3.10)

If $X \in \Pi^+ \setminus \overline{B_2}$, then $\rho(X) \ge \rho_0 + 1/2$, and hence

$$
|\nabla w(X)| \le C \sum_{n=1}^{\infty} |a_n| \frac{n\gamma}{\rho^{n\gamma+1}}
$$

$$
\le \frac{C}{\rho} \left(\sum_{n=1}^{\infty} |a_n|^2 \frac{n\gamma}{\rho_0^{2n\gamma}} \right)^{\frac{1}{2}} \left(\sum_{n=1}^{\infty} n\gamma \left(\frac{\rho_0}{\rho} \right)^{2n\gamma} \right)^{\frac{1}{2}} \le \frac{C}{\rho^{\gamma+1}},
$$

that is,

$$
|\nabla w(X)| \leq \frac{C}{|X-Q|^{\gamma+1}}.
$$

Now, (3.6) follows since w is symmetric with respect to the x-axis.

We see from [\(3.9\)](#page-9-0) that

$$
\partial_{\phi}(\phi + w)(X) \ge 1 - |\partial_{\phi}w(X)| \ge 1 - \rho(X)|\nabla w(X)|.
$$

Then (ii) yields

$$
\partial_{\phi} (\phi + w) (X) \ge 1 - \frac{C}{\rho^{\gamma}} > \frac{1}{2},
$$

provided that $\rho > (2C)^{1/\gamma}$. It implies that $\phi + w$ is increasing along the arc $\{X : \rho = \rho_1\}$ where ρ_1 is a constant satisfying $\rho_1 > (2C)^{1/\gamma}$. Since $\phi + w = 0$ on $\partial \Gamma_1$ and $\phi + w = \pi/\gamma$ on $\partial \Gamma_2$, we infer that [\(3.7\)](#page-9-1) holds on the arc $\{X : \rho = \rho_1\}$. Since ρ_1 is an arbitrary constant satisfying $\rho_1 > (2C)^{1/\gamma}$, [\(3.7\)](#page-9-1) holds if $\rho > (2C)^{1/\gamma}$. Since $\phi + w$ is symmetric with respect to the x-axis, (iii) follows from the maximal principle. This completes the proof. \Box

Lemma 3.2 *There are positive constants* a*,* b *and* C *such that*

$$
|\nabla (\phi + w)(X) - a(\nabla \mathcal{B}_1 - b\nabla \mathcal{B}_2)(X)| \le C \quad \text{for all } X \in \Pi. \tag{3.11}
$$

If the aperture angles are the same, namely, $\alpha_1 = \alpha_2$ *, then* $b = 1$ *.*

Proof. We first consider the case when X is near S_1 . Since $\phi + w = 0$ on $\partial \Gamma_1$ and the aperture angle of Γ_1 is $\alpha_1 = 2\pi - \pi/\beta_1$, $\phi + w$ admits the Fourier series expansion

$$
(\phi + w)(X) = ar_1(X)^{\beta_1} \sin(\beta_1 \theta_1(X)) + \sum_{n=2}^{\infty} a_n r_1(X)^{n\beta_1} \sin(n\beta_1 \theta_1(X))
$$

in $B_1(S_1) \setminus \overline{\Gamma_1}$. Since $\sum_{n=2}^{\infty} a_n r_1(X)^{n\beta_1} \sin(n\beta_1 \theta_1(X))$ converges for $r_1 < 1$, its gradient converges uniformly for $r_1 \le r_0 < 1$. We simply take $r_0 = 0.9$. Since $\mathcal{B}_1 = r_1^{\beta_1} \sin(\beta_1 \theta_1)$, we then have

$$
|\nabla(\phi + w)(X) - a\nabla \mathcal{B}_1(X)| \le C \tag{3.12}
$$

for some constant C and for all X in $B_{0.9}(S_1) \setminus \overline{\Gamma_1}$.

Let $\Gamma_{1/2}$ be the arc $\{X : r_1 = 1/2\}$ in $B_1(S_1) \setminus \overline{\Gamma_1}$. Then, the constant a is given by

$$
a = \frac{\beta_1 2^{\beta_1+1}}{\pi} \int_{\Gamma_{1/2}} \sin(\beta_1 \theta_1)(\phi + w) d\theta_1.
$$

We then infer from [\(3.7\)](#page-9-1) that

$$
0 < a < \frac{2^{\beta_1 + 2}}{\gamma}.\tag{3.13}
$$

Applying the same argument to $\phi + w - \pi/\gamma$ in $B_1(S_2) \setminus \overline{\Gamma_2}$, we see that there is a constant \tilde{a} such that

$$
|\nabla (\phi + w)(X) + \tilde{a}\nabla \mathcal{B}_2(X)| \le C \tag{3.14}
$$

for all $X \in B_{0.9}(S_2) \setminus \overline{\Gamma_2}$. Since $0 > \phi + w - \pi/\gamma > -\pi/\gamma$, we obtain in the same way as before

$$
0 < \tilde{a} < \frac{2^{\beta_2 + 2}}{\gamma}.\tag{3.15}
$$

Let $\tilde{a} = ab$. If $\alpha_1 = \alpha_2$, then $\tilde{a} = a$, and hence $b = 1$.

Note that $\nabla \mathcal{B}_2$ is bounded in $B_{0.9}(S_1)$ and $\nabla \mathcal{B}_1$ is bounded in $B_{0.9}(S_2)$. So, it follows from [\(3.12\)](#page-10-0) and [\(3.14\)](#page-10-1) that

$$
|\nabla (\phi + w)(X) - a(\nabla \mathcal{B}_1 - b\nabla \mathcal{B}_2)(X)| \le C \tag{3.16}
$$

for all $X \in B_{0.9}(S_1) \cup B_{0.9}(S_2) \setminus \overline{(\Gamma_1 \cup \Gamma_2)}$.

We now prove (3.11) away from S_1 and S_2 . For doing so, set

$$
\Pi_0 := \Pi \setminus B_{0.9}(S_1) \cup B_{0.9}(S_2).
$$

According to [\(3.7\)](#page-9-1), the harmonic function $\phi + w$ is constant on $\partial \Gamma_1$ and $\partial \Gamma_2$, and its range in Π is bounded by 0 and π/γ . So, for any $X_0 \in \Pi_0$, $\phi + w$ can be extended locally as a harmonic function in $B_{1/2}(X_0)$ so that the extended function is bounded below and above by $-\pi/\gamma$ and $2\pi/\gamma$, respectively. Then, the standard gradient estimate for harmonic functions (with $R = 1/2$) yields

$$
|\nabla (\phi + w) (X_0)| \leq \frac{2}{R} ||\phi + w||_{L^{\infty}(B_R(X_0))} \leq 2\left(\frac{1}{2}\right)^{-1} \frac{2\pi}{\gamma}, \quad X_0 \in \Pi_0.
$$
 (3.17)

Meanwhile, since Π_0 is at distance larger than $1/2$ from S_1 and S_2 , we have

$$
\|\nabla \mathcal{B}_1\|_{L^{\infty}(\Pi_0)} + \|\nabla \mathcal{B}_2\|_{L^{\infty}(\Pi_0)} \leq C.
$$

Therefore, we have for $X \in \Pi_0$

$$
\begin{aligned} \left| \nabla \left(\phi + w \right) (X) - a \left(\nabla \mathcal{B}_1 - b \nabla \mathcal{B}_2 \right) (X) \right| \\ &\leq C \left(\left| \nabla \left(\phi + w \right) (X) \right| + \left| \nabla \mathcal{B}_1 (X) \right| + \left| \nabla \mathcal{B}_2 (X) \right| \right) \leq C. \end{aligned}
$$

This estimate together with (3.16) yield the desired estimate (3.11) .

4 Singular functions and a representation of the solution

In this section we introduce some auxiliary functions on $\mathbb{R}^2 \setminus \overline{(\Omega_1 \cup \Omega_2)}$, which capture the singular behavior of the gradient of the solution to [\(1.1\)](#page-0-0).

Let q be the solution to

$$
\begin{cases}\n\Delta q = 0 & \text{in } \mathbb{R}^2 \setminus \overline{(\Omega_1 \cup \Omega_2)}, \\
q = d_j & \text{on } \partial \Omega_j, \quad j = 1, 2, \\
\int_{\partial \Omega_1} \partial_{\nu} q ds = -\int_{\partial \Omega_2} \partial_{\nu} q ds = -1, \\
q(X) = O(|X|^{-1}) & \text{as } |X| \to \infty.\n\end{cases}
$$
\n(4.1)

Here, d_1 and d_2 are constants determined by the third condition in (4.1) and depend on ϵ . A proof of the existence and uniqueness of the solution to [\(4.1\)](#page-11-1) can be found in [\[1\]](#page-25-3). It is worth mentioning that

$$
q|_{\partial\Omega_1} = d_1 < 0 < d_2 = q|_{\partial\Omega_2},\tag{4.2}
$$

which can be seen using Hopf's lemma.

The singular function of a similar type was first introduced in [\[17\]](#page-26-0) and used to estimate the gradient blow-up when Ω_1 and Ω_2 are planar domains with smooth boundaries. Recently, it has been used in an essential way to characterize the gradient blow-up when the inclusions have smooth boundaries [\[1,](#page-25-3) [10\]](#page-26-1). If domains have smooth boundaries, then we approximate each of them with the osculating disk. Since the singular function is explicit when Ω_i are disks, we can obtain an explicit approximation of q.

However, since the domains under consideration in this paper have corners, such a method do not apply. In this section, we introduce some intermediate auxiliary functions which yield a good approximation of q.

The first intermediate function, η , is defined to be the solution to

$$
\begin{cases}\n\Delta \eta = 0 & \text{in } \mathbb{R}^2 \setminus \overline{(\Omega_1 \cup \Omega_2)}, \\
\eta = 0 & \text{on } \partial \Omega_1, \\
\eta = 1 & \text{on } \partial \Omega_2, \\
\int_{\mathbb{R}^2 \setminus \overline{\Omega_1 \cup \Omega_2}} |\nabla \eta|^2 dx dy < \infty.\n\end{cases} \tag{4.3}
$$

The connection between q and η can be seen in the relations

$$
q = (q|_{\partial \Omega_2} - q|_{\partial \Omega_1})\eta + q|_{\partial \Omega_1}
$$
\n(4.4)

and

$$
\nabla q = (q|_{\partial \Omega_2} - q|_{\partial \Omega_1}) \nabla \eta. \tag{4.5}
$$

We emphasize that (4.4) shows that the solution η to (4.3) uniquely exists. Moreover, it shows that

$$
\eta(X) \to \text{a constant}, \quad \text{as } |X| \to \infty. \tag{4.6}
$$

Since Ω_i are symmetric with respect to the x-axis, so is η , and hence $\partial_\nu \eta = 0$ on the line segment between two vertices V_1 and V_2 . So, in view of (i) and (iii) of Lemma [3.1,](#page-8-3) it is natural to compare η with $\frac{\gamma}{\pi}(\phi+w)(\epsilon^{-1}X)$. For such a comparison we obtain the following lemma. We mention that the dilation $\epsilon^{-1}X$ maps $X \in B_\delta \setminus (\Omega_1 \cup \Omega_2)$ into $\mathbb{R}^2 \setminus (\Gamma_1 \cup \Gamma_2)$. With L_{ϵ} and R_{ϵ} given in [\(2.3\)](#page-3-5), the translation $X - L_{\epsilon}$ maps $B_{\delta} \cap \partial \Omega_1$ into $\partial \Gamma_1$ and $X - R_\epsilon$ maps $B_\delta \cap \partial \Omega_2$ into $\partial \Gamma_2$.

Lemma 4.1 *Define* $v(X)$ *for* $X \in B_\delta \setminus \overline{\Omega_1 \cup \Omega_2}$ *by*

$$
\eta(X) = \frac{\gamma}{\pi} \left(\phi + w \right) \left(\epsilon^{-1} X \right) + v(X). \tag{4.7}
$$

There is $\delta_1 < \delta$ *independent* of ϵ *such that*

$$
|\nabla v(X)| \lesssim |\nabla \mathcal{B}_1(X - L_{\epsilon})| + |\nabla \mathcal{B}_2(X - R_{\epsilon})|, \quad X \in B_{\delta_1} \setminus \overline{\Omega_1 \cup \Omega_2}.
$$
 (4.8)

Proof. We first prove that there are constants $\delta_1 < \delta$, C_1 and C_2 independent of ϵ such that

$$
|\nabla v(X)| \le C_1 \left| \nabla \mathcal{B}_1(X - L_{\epsilon}) - \nabla \mathcal{B}_2(X - R_{\epsilon}) + C_2 \left(x + \frac{1}{2}, y \right) \right| \tag{4.9}
$$

for all $X \in \partial(B_{\delta_1} \setminus (\Omega_1 \cup \Omega_2))$. Furthermore, the right-hand side of the above does not vanish.

To prove [\(4.9\)](#page-12-1) on $\partial\Omega_1$ and $\partial\Omega_2$ near O, let v_{1+} and v_{1-} be the solutions to

$$
\begin{cases}\n\Delta v_{1+} = \Delta v_{1-} = 0 & \text{in } B_\delta \setminus \overline{\Omega_1}, \\
v_{1+} = v_{1-} = 0 & \text{on } \partial \Omega_1 \cap B_\delta, \\
v_{1+} = -v_{1-} = 4 & \text{on } \partial B_\delta \setminus \overline{\Omega_1},\n\end{cases}
$$
\n(4.10)

and v_{2+} and v_{2-} be the solutions to

$$
\begin{cases}\n\Delta v_{2+} = \Delta v_{2-} = 0 & \text{in } B_\delta \setminus \overline{\Omega_2}, \\
v_{2+} = v_{2-} = 0 & \text{on } \partial \Omega_2 \cap B_\delta, \\
v_{2+} = -v_{2-} = 4 & \text{on } \partial B_\delta \setminus \overline{\Omega_2}.\n\end{cases}
$$
\n(4.11)

Note that $v_{1+} - v$ and $v_{1-} - v$ respectively attain the minimum and the maximum on $\partial\Omega_1 \cap B_\delta$. So, by Hopf's lemma, we have

$$
\partial_{\nu}v_{1+} < \partial_{\nu}v < \partial_{\nu}v_{1-} \quad \text{on } \partial\Omega_1 \cap B_{\delta}.\tag{4.12}
$$

In the same way, we also have

$$
\partial_{\nu}v_{2+} < \partial_{\nu}v < \partial_{\nu}v_{2-} \quad \text{on } \partial\Omega_2 \cap B_{\delta}.\tag{4.13}
$$

Let δ_2 be such that $B_{\delta_2}(V_1) \setminus \Omega_1 \subset B_{\delta} \setminus \Omega_1$ and $B_{\delta_2}(V_2) \setminus \Omega_2 \subset B_{\delta} \setminus \Omega_2$. Since $v_{1+} = 0$ on $\partial\Omega_1 \cap B_\delta$, there are positive constants a and C_3 , and a function ψ such that v_{1+} can be expressed as

$$
v_{1+}(X) = a\mathcal{B}_1(X - L_\epsilon) + \psi(X) \tag{4.14}
$$

and

$$
|\nabla \psi(X)| \le C_3 \quad \text{for all } X \in \overline{B_{\delta_2}(V_1)} \setminus \Omega_1. \tag{4.15}
$$

In fact, ψ can be expressed as

$$
\psi(X) = \sum_{n=2}^{\infty} a_n r_1 (X - L_{\epsilon})^{n\beta_1} \sin \left(n\beta_1 \theta_1 (X - L_{\epsilon}) \right)
$$

for some constants a_n , and the Fourier series converges for X satisfying $|X - L_{\epsilon}| < \delta_2 + s$ for some $s > 0$. So we achieve [\(4.15\)](#page-13-0).

Note that there is a constant $C_4 > 0$ such that

$$
|\nabla \mathcal{B}_1(X - L_{\epsilon})| \ge C_4 \quad \text{for all } X \in \overline{B_{\delta_2}(V_1)} \setminus \Omega_1.
$$

So, we infer from [\(4.14\)](#page-13-1) and [\(4.15\)](#page-13-0) that

$$
|\nabla v_{1+}(X)| \le a|\nabla \mathcal{B}_1(X - L_{\epsilon})| + |\nabla \psi(X)|
$$

\n
$$
\le (a + C_3 C_4^{-1})|\nabla \mathcal{B}_1(X - L_{\epsilon})| \lesssim |\nabla \mathcal{B}_1(X - L_{\epsilon})|
$$

for all $X \in B_{\delta_2}(V_1) \setminus \Omega_1$. In the same way we show that

$$
|\nabla v_{1-}(X)| \lesssim |\nabla \mathcal{B}_1(X - L_{\epsilon})|
$$
 for all $X \in \overline{B_{\delta_2}(V_1)} \setminus \Omega_1$.

It then follows from (4.12) that there exists a constant, say C_5 , such that

$$
|\nabla v(X)| \le C_5 |\nabla \mathcal{B}_1 (X - L_{\epsilon})| \tag{4.16}
$$

for all $X \in \partial \Omega_1 \cap B_{\delta_2}(V_1)$.

Since $\mathcal{B}_1(X - L_{\epsilon}) = 0$ for $X \in \partial \Omega_1 \cap B_{\delta_2}(V_1)$, $\nabla \mathcal{B}_1$ in [\(4.16\)](#page-13-2) can be replaced with the normal derivative $\nu_1 \cdot \nabla \mathcal{B}_1$. That is, we have

$$
|\nabla v(X)| \le C_5 |\partial_{\nu_1} \mathcal{B}_1 (X - L_{\epsilon})| \tag{4.17}
$$

Moreover, a small variation of arguments to prove [\(2.9\)](#page-4-0) shows that

$$
\partial_{\nu_1} \mathcal{B}_1(X - L_{\epsilon}) < 0
$$
 and $-\partial_{\nu_1} \mathcal{B}_2(X - R_{\epsilon}) \le 0$ (4.18)

for all $X \in \partial \Omega_1 \cap B_{\delta_2}(V_1)$. Furthermore, one can easily see that

$$
\nu_1 \cdot (x + 1/2, y) < 0 \tag{4.19}
$$

for all $X \in \partial \Omega_1 \cap B_{\delta_2}(V_1)$. So, we infer from [\(4.17\)](#page-13-3) that

$$
|\nabla v(X)| \leq C_5 |\partial_{\nu_1} \mathcal{B}_1(X - L_{\epsilon}) - \partial_{\nu_1} \mathcal{B}_2(X - R_{\epsilon}) + C\nu_1 \cdot (x + 1/2, y)|
$$

\n
$$
\leq C_5 |\nu_1 \cdot (\nabla \mathcal{B}_1(X - L_{\epsilon}) - \nabla \mathcal{B}_2(X - R_{\epsilon}) + C (x + 1/2, y))|
$$

\n
$$
\leq C_5 |\nabla \mathcal{B}_1(X - L_{\epsilon}) - \nabla \mathcal{B}_2(X - R_{\epsilon}) + C (x + 1/2, y)|
$$
\n(4.20)

for all $X \in \partial \Omega_1 \cap B_{\delta_2}(V_1)$. We emphasize that [\(4.20\)](#page-14-0) holds for any positive constant C and its right-hand side is non-vanishing.

Similarly to [\(4.16\)](#page-13-2), we obtain

$$
|\nabla v(X)| \le C_6 |\nabla \mathcal{B}_2 (X - R_\epsilon)| \quad \text{for all } X \in \partial \Omega_2 \cap B_{\delta_2}(V_2). \tag{4.21}
$$

It is worth mentioning that here we use (4.13) , not (4.12) . And, in a similar way, we can show that (4.20) holds with C_5 replaced with some other constant, say C_7 , for all $X \in \partial \Omega_2 \cap B_{\delta_2}(V_2)$ and for any positive constant C.

Choose δ_3 so that $B_{\delta_3} \subset B_{\delta_1}(V_1) \cap B_{\delta_2}(V_2)$. Then, we arrive at

$$
|\nabla v(X)| \le C_8 |\nabla \mathcal{B}_1(X - L_\epsilon) - \nabla \mathcal{B}_2(X - R_\epsilon) + C (x + 1/2, y)| \tag{4.22}
$$

for all $X \in (\partial \Omega_1 \cup \partial \Omega_2) \cap B_{\delta_3}$ and for any positive constant C.

We now prove [\(4.9\)](#page-12-1) on $\partial B_{\delta_1} \setminus (\Omega_1 \cup \Omega_2)$ if $\delta_1 < \delta_3$. By the maximum principle, we have $|\eta| \leq 1$. We also have $\left|\frac{\gamma}{\pi}\right|$ $\frac{\gamma}{\pi}(\phi+w)| \leq 1$ from [\(3.7\)](#page-9-1). So it follows from the definition [\(4.7\)](#page-12-3) of v that

$$
|v(X)| \le 2, \quad X \in B_{\delta_3} \setminus \overline{\Omega_1 \cup \Omega_2}.\tag{4.23}
$$

The function v takes constant values on $B_{\delta_3} \cap \partial \Omega_1$ and $B_{\delta_3} \cap \partial \Omega_2$, and

$$
v|_{B_{\delta_3} \cap \partial \Omega_1} = v|_{B_{\delta_3} \cap \partial \Omega_2}.\tag{4.24}
$$

It is helpful to mention here that v actually takes value 0 on $B_{\delta_3} \cap \partial \Omega_1$ and $B_{\delta_3} \cap \partial \Omega_2$. But we only use the weaker property [\(4.24\)](#page-14-1). We then infer from the standard gradient estimate as used in [\(3.17\)](#page-10-3) that if $\delta_1 < \delta_3$, then there is a constant C_9 (independent of ϵ) such that

$$
|\nabla v(X)| \le C_9 \quad \text{for all } X \in \partial B_{\delta_1} \setminus (\Omega_1 \cup \Omega_2). \tag{4.25}
$$

Since $|\nabla B_1(X-L_\epsilon) - \nabla B_2(X - R_\epsilon)|$ is bounded for all $X \in \partial B_{\delta_1} \setminus (\Omega_1 \cup \Omega_2)$, we may choose the constant C appearing in (4.22) large enough (and denote it by C_2) so that

$$
C_8 |\nabla \mathcal{B}_1(X - L_{\epsilon}) - \nabla \mathcal{B}_2(X - R_{\epsilon}) + C_2 (x + 1/2, y)| \ge C_9
$$

for all $X \in \partial B_{\delta_1} \setminus (\Omega_1 \cup \Omega_2)$, where C_8 and C_9 are constants appearing in [\(4.22\)](#page-14-2) and [\(4.25\)](#page-14-3), respectively. Then, we have

$$
|\nabla v(X)| \leq C_8 |\nabla \mathcal{B}_1(X - L_{\epsilon}) - \nabla \mathcal{B}_2(X - R_{\epsilon}) + C_2 (x + 1/2, y)| \tag{4.26}
$$

for all $X \in \partial B_{\delta_1} \setminus (\Omega_1 \cup \Omega_2)$. Since [\(4.22\)](#page-14-2) holds for any $C > 0$ on $(\partial \Omega_1 \cup \partial \Omega_2) \setminus B_{\delta_1}$, [\(4.9\)](#page-12-1) is proved with $C_1 = C_8$.

If we identify points in the plane with complex numbers, then ∇v and $\nabla \mathcal{B}_1(X - L_{\epsilon})$ – $\nabla B_2(X - R_{\epsilon}) + C_2(x + 1/2, y)$ are conjugates of analytic functions. Furthermore, the

latter function does not vanish in $B_{\delta_1} \setminus (\Omega_1 \cup \Omega_2)$ due to the maximum modulus theorem. So, we see that

$$
\left|\frac{\nabla v(X)}{\nabla \mathcal{B}_1(X - L_{\epsilon}) - \nabla \mathcal{B}_2(X - R_{\epsilon}) + C_2(x + 1/2, y)}\right| \le C, \quad X \in B_{\delta_1} \setminus (\Omega_1 \cup \Omega_2)
$$

for some constant C. It then follows from the triangular inequality that

$$
|\nabla v(X)| \lesssim |\nabla \mathcal{B}_1(X-L_{\epsilon})| + |\nabla \mathcal{B}_2(X-R_{\epsilon})| + |(x+1/2,y)|.
$$

Since $|\nabla B_1(X-L_\epsilon)|+|\nabla B_2(X-R_\epsilon)|\gtrsim 1$ while $|(x+1/2,y)|\lesssim 1$ for all $X\in B_{\delta_1}\setminus(\Omega_1\cup\Omega_2)$, [\(4.8\)](#page-12-4) follows and the proof is complete.

Define the constant $c(u)$ by

$$
c(u) := \frac{u|_{\partial \Omega_2} - u|_{\partial \Omega_1}}{q|_{\partial \Omega_2} - q|_{\partial \Omega_1}},\tag{4.27}
$$

and define the function σ by

$$
u = c(u)q + \sigma. \tag{4.28}
$$

Then σ is harmonic in $\mathbb{R}^2 \setminus \overline{(\Omega_1 \cup \Omega_2)}$ having a constant value on $\partial \Omega_1 \cup \partial \Omega_2$ such that

$$
\sigma|_{\partial\Omega_1} = \sigma|_{\partial\Omega_2}.\tag{4.29}
$$

We prove the following lemma.

Lemma 4.2 *Let* Ω *be a bounded set containing* $\overline{B_6}$ *and* $\overline{\Omega_1 \cup \Omega_2}$ *. There is* δ_1 *independent* $of \epsilon$ *such that*

$$
|\nabla \sigma(X)| \lesssim \|h\|_{L^{\infty}(\Omega)} \left(|\nabla \mathcal{B}_1 \left(X - L_{\epsilon} \right)| + |\nabla \mathcal{B}_2 \left(X - R_{\epsilon} \right)| \right) \tag{4.30}
$$

for all $X \in B_{\delta_1} \setminus \Omega_1 \cup \Omega_2$ *.*

Proof. Thanks to (4.29) , (4.30) can be proved in the same way as the proof of Lemma [4.1,](#page-12-5) once we prove that

$$
\|\sigma\|_{L^{\infty}(B_{\delta}\backslash\overline{\Omega_1\cup\Omega_2})} \lesssim \|h\|_{L^{\infty}(\Omega)}.
$$
\n(4.31)

To prove (4.31) , let

$$
\eta_0 = \lim_{|X| \to \infty} \eta(X),
$$

where the limit exists as seen at [\(4.6\)](#page-12-6). Then we have $0 < \eta_0 < 1$, and

$$
q(X) = (q|_{\partial\Omega_2} - q|_{\partial\Omega_1})\left(\eta(X) - \eta_0\right), \quad X \in \mathbb{R}^2 \setminus \overline{\Omega_1 \cup \Omega_2}.\tag{4.32}
$$

In fact, we denote the right-hand side of the above by f, then f is harmonic in $\mathbb{R}^2 \setminus \overline{\Omega_1 \cup \Omega_2}$, $f(X) \to 0$ as $|X| \to \infty$, f is constant on $\partial \Omega_j$ for $j = 1, 2$, and $f|_{\partial \Omega_2} - f|_{\partial \Omega_1} = q|_{\partial \Omega_2} - q|_{\partial \Omega_1}$. So, [\(4.32\)](#page-15-3) holds. We then have

$$
\sigma(X) = (u|_{\partial \Omega_1} - u|_{\partial \Omega_2}) (\eta(X) - \eta_0) + u(X), \quad X \in \mathbb{R}^2 \setminus \overline{\Omega_1 \cup \Omega_2}.
$$
 (4.33)

It was proven in [\[17\]](#page-26-0) that

$$
u|_{\partial\Omega_2} - u|_{\partial\Omega_1} = \int_{\partial\Omega_1 \cup \partial\Omega_2} h \partial_\nu q ds. \tag{4.34}
$$

Thus, we have

$$
|u|_{\partial\Omega_2} - u|_{\partial\Omega_1}| \leq ||h||_{L^{\infty}(\Omega)} \int_{\partial\Omega_1 \cup \partial\Omega_2} |\partial_{\nu} q| ds.
$$

Since $\partial_{\nu}q$ is either positive or negative on $\partial\Omega_j$ for $j=1,2$, we have

$$
|u|_{\partial\Omega_2} - u|_{\partial\Omega_1}| \le ||h||_{L^{\infty}(\Omega)} \left(\left| \int_{\partial\Omega_1} \partial_{\nu} q ds \right| + \left| \int_{\partial\Omega_2} \partial_{\nu} q ds \right| \right) \le 2||h||_{L^{\infty}(\Omega)}.
$$
 (4.35)

Since $0 < \eta \le 1$ and $0 < \eta_0 < 1$, it follows that

$$
\| (u|_{\partial \Omega_2} - u|_{\partial \Omega_1}) (\eta - \eta_0) \|_{L^\infty(B_\delta \setminus \overline{\Omega_1 \cup \Omega_2})} \le 4 \| h \|_{L^\infty(\Omega)}.
$$
 (4.36)

Since $u(X) - h(X) \to 0$ as $|X| \to \infty$, we have

$$
||u - h||_{L^{\infty}(B_{\delta}\setminus\overline{\Omega_1 \cup \Omega_2})} \le ||u - h||_{L^{\infty}(\partial\Omega_1 \cup \partial\Omega_2)}
$$

\n
$$
\le \max_{\partial\Omega_1 \cup \partial\Omega_2} (u - h) - \min_{\partial\Omega_1 \cup \partial\Omega_2} (u - h)
$$

\n
$$
\le |u|_{\partial\Omega_2} - u|_{\partial\Omega_1}| + 2||h||_{L^{\infty}(\Omega)}.
$$

We then obtain from [\(4.35\)](#page-16-0)

$$
||u||_{L^{\infty}(B_{\delta}\setminus\overline{\Omega_{1}\cup\Omega_{2}})} \leq ||u-h||_{L^{\infty}(B_{\delta}\setminus\overline{\Omega_{1}\cup\Omega_{2}})} + ||h||_{L^{\infty}(B_{\delta}\setminus\overline{\Omega_{1}\cup\Omega_{2}})} \lesssim ||h||_{L^{\infty}(\Omega)}.
$$
 (4.37)

Then (4.31) follows from (4.33) , (4.36) and (4.37) .

Lemma 4.3 *There is* $\epsilon_0 > 0$ *such that*

$$
q|_{\partial\Omega_2} - q|_{\partial\Omega_1} \simeq \frac{1}{|\log\epsilon|} \tag{4.38}
$$

for all $\epsilon \leq \epsilon_0$ *.*

Proof. We first observe from [\(4.5\)](#page-12-7) that

$$
(q|_{\partial\Omega_2} - q|_{\partial\Omega_1}) \int_{\partial\Omega_2} \partial_{\nu} \eta ds = \int_{\partial\Omega_2} \partial_{\nu} q ds = 1.
$$

So, it suffices to prove

$$
\int_{\partial \Omega_2} \partial_{\nu} \eta ds \simeq |\log \epsilon|. \tag{4.39}
$$

To prove [\(4.39\)](#page-16-3), we write

$$
\int_{\partial\Omega_2} \partial_{\nu}\eta ds = \int_{\partial\Omega_2 \backslash B_{\delta_1}} \partial_{\nu}\eta ds + \int_{\partial\Omega_2 \cap B_{\delta_1}} \partial_{\nu}\eta ds =: I + II,
$$
\n(4.40)

where δ_1 is the number appearing in Lemmas [4.1](#page-12-5) and [4.2.](#page-15-5) Since η is constant on $\partial\Omega_2$, $0 \leq \eta \leq 1$, and the set $\partial \Omega_2 \setminus B_{\delta_1}$ is at some distance from the vertex V_2 , there is r_0 independent of ϵ such that η is extended by reflection as a harmonic function in $B_{r_0}(X)$ for each $X \in \partial\Omega_2 \setminus B_{\delta_1}$ by a conformal mapping and the extended function, which is still denoted by η , satisfies $-1 \leq \eta \leq 2$. So, we have

$$
|\nabla \eta(X)| \lesssim \frac{2}{r_0} \|\eta\|_{L^\infty(B_{r_0}(X))} \lesssim \frac{4}{r_0}
$$

for any $X \in \partial \Omega_2 \setminus B_{\delta_1}$. Thus, there exists a constant M_1 independent of ϵ and h such that

$$
I \le M_1. \tag{4.41}
$$

In view of (4.7) , we may write II as

$$
II = \int_{\partial\Omega_2 \cap B_{\delta_1}} \partial_{\nu} v ds + \frac{\gamma}{\pi} \int_{\partial\Omega_2 \cap B_{3\epsilon}} \partial_{\nu} \left((\phi + w)(\epsilon^{-1} X) \right) ds
$$

+
$$
\frac{\gamma}{\pi} \int_{\partial\Omega_2 \cap (B_{\delta_1} \setminus B_{3\epsilon})} \partial_{\nu} \left(w(\epsilon^{-1} X) \right) ds + \frac{\gamma}{\pi} \int_{\partial\Omega_2 \cap (B_{\delta_1} \setminus B_{3\epsilon})} \partial_{\nu} \left(\phi(\epsilon^{-1} X) \right) ds
$$

=:
$$
II_1 + II_2 + II_3 + II_4.
$$

By Lemma [4.1,](#page-12-5) we have

$$
|II_1| \lesssim \int_{\partial\Omega_2 \cap B_{\delta_1}} |\nabla \mathcal{B}_1(X - L_{\epsilon})| + |\nabla \mathcal{B}_2(X - R_{\epsilon})| \, ds \lesssim 1,
$$
\n(4.42)

where the last inequality holds since $\beta_j > 0$. If we make a change of variables $\epsilon^{-1}X \to X$, it follows from Lemma [3.2](#page-9-3) that

$$
|II_2| \leq \frac{\gamma}{\pi} \int_{(\partial \Gamma_2) \cap B_3} |\partial_{\nu}(\phi + w)(X)| ds
$$

\$\lesssim \int_{(\partial \Gamma_2) \cap B_3} (| (\nabla \mathcal{B}_1 - b \nabla \mathcal{B}_2)(X) | + 1) ds \lesssim 1. \tag{4.43}

The same change of variables yields that

$$
|II_3| \lesssim \int_{\partial \Gamma_2 \setminus B_3} |\partial_{\nu} w(X)| ds \le 2 \int_{\partial \Gamma_2^+ \setminus B_{5/2}(S_2)} |\partial_{\nu} w(X)| ds,
$$

where $\partial \Gamma_2^+ = \{ X \in \partial \Gamma_2 : y > 0 \}.$ Let $\rho_0 := \max\{|S_1 - Q|, |S_2 - Q|\}$ as in Lemma [3.1](#page-8-3) (ii). Since $|S_1 - S_2| = 1$, the triangular inequality shows that

$$
\min\{|S_1 - Q|, |S_2 - Q|\} \ge \rho_0 - 1.
$$

So, we have from [\(3.9\)](#page-9-0) that

$$
|II_3| \lesssim \int_{\partial \Gamma_2^+ \backslash B_{3/2+\rho_0}(Q)} |\partial_\nu w(X)| ds
$$

$$
\lesssim \sum_{n=1}^\infty |a_n| n \gamma \int_{3/2+\rho_0}^\infty \frac{1}{\rho^{(n\gamma+1)}} d\rho \lesssim \sum_{n=1}^\infty \frac{|a_n|}{(3/2+\rho_0)^{n\gamma}}.
$$

It then follows from the Cauchy-Schwartz inequality and [\(3.10\)](#page-9-4) that

$$
|II_3| \lesssim \left(\sum_{n=1}^{\infty} \frac{|a_n|^2 n \gamma}{\rho_0^{2n\gamma}}\right)^{1/2} \left(\sum_{n=1}^{\infty} \frac{\rho_0^{2n\gamma}}{(3/2 + \rho_0)^{2n\gamma}}\right)^{1/2} < \infty.
$$
 (4.44)

We apply the same change of variables $\epsilon^{-1}X \to X$ to see that

$$
II_4 \simeq \gamma \int_{\partial \Gamma_2 \cap (B_{1/(2\epsilon)} \setminus B_3)} |\partial_{\nu} \phi(X)| ds.
$$

So, we have

$$
II_4 \simeq \gamma \int_3^{\frac{1}{2\epsilon}} |\partial_\nu \phi(X)| d\rho = \gamma \int_3^{\frac{1}{2\epsilon}} \rho^{-1} |\partial_\phi \phi(X)| d\rho \simeq |\log \epsilon|. \tag{4.45}
$$

Then (4.39) follows from (4.41) - (4.45) . This completes the proof.

Lemma 4.4 *The constant* c(u) *defined by* [\(4.27\)](#page-15-6) *satisfies*

$$
|c(u)| \lesssim \|h\|_{L^{\infty}(\Omega)}.\tag{4.46}
$$

Here, Ω *is the domain appearing in Lemma [4.2.](#page-15-5)*

Proof. From (4.5) , (4.27) , and (4.34) , we have

$$
c(u) = \frac{u|_{\partial\Omega_2} - u|_{\partial\Omega_1}}{q|_{\partial\Omega_2} - q|_{\partial\Omega_1}} = \int_{\partial\Omega_1 \cup \partial\Omega_2} h \partial_\nu \eta ds = \int_{\partial\Omega_1 \cup \partial\Omega_2} (h(X) - h(O)) \partial_\nu \eta ds. \tag{4.47}
$$

We only deal with the integral over $\partial\Omega_2$ to prove that it is bounded independently of ϵ . The integral over $\partial\Omega_1$ can be dealt with in the same way.

Using [\(4.7\)](#page-12-3), we write

$$
\int_{\partial\Omega_2} (h(X) - h(O)) \partial_{\nu} \eta ds
$$
\n
$$
= \int_{\partial\Omega_2 \backslash B_{\delta_1}} (h(X) - h(O)) \partial_{\nu} \eta ds + \int_{\partial\Omega_2 \cap B_{\delta_1}} (h(X) - h(O)) \partial_{\nu} v ds
$$
\n
$$
+ \frac{\gamma}{\pi} \int_{\partial\Omega_2 \cap B_{3\epsilon}} (h(X) - h(O)) \partial_{\nu} \left((\phi + w) \left(\epsilon^{-1} X \right) \right) ds
$$
\n
$$
+ \frac{\gamma}{\pi} \int_{\partial\Omega_2 \cap (B_{\delta_1} \backslash B_{3\epsilon})} (h(X) - h(O)) \partial_{\nu} \left(w(\epsilon^{-1} X) \right) ds
$$
\n
$$
+ \frac{\gamma}{\pi} \int_{(\partial\Omega_2) \cap (B_{\delta_1} \backslash B_{3\epsilon})} (h(X) - h(O)) \partial_{\nu} (\phi(\epsilon^{-1} X)) ds =: \sum_{j=1}^5 I_j.
$$

Using the same arguments for the proof of Lemma [4.3,](#page-16-5) one can show that

$$
|I_j| \lesssim ||h||_{L^{\infty}(\Omega)}, \quad j = 1, \cdots, 4.
$$

To estimate I_5 , let $\partial \Omega_2^{\pm} = \{ X \in \partial \Omega_2 : \pm y \geq 0 \}$. We then have

$$
\left| \int_{\partial \Omega_{2}^{+} \cap (B_{\delta_{1}} \setminus B_{3\epsilon})} (h(X) - h(O)) \partial_{\nu} (\phi(\epsilon^{-1}X)) ds \right|
$$

\n
$$
= \left| \int_{\partial \Gamma_{2}^{+} \cap (B_{\delta_{1}/\epsilon} \setminus B_{3})} (h(\epsilon X) - h(O)) \partial_{\nu} \phi(X) ds \right|
$$

\n
$$
\leq ||\nabla h||_{L^{\infty}(B_{\delta_{1}})} \left| \int_{\partial \Gamma_{2}^{+} \cap (B_{\delta_{1}/\epsilon} \setminus B_{3/2(V_{2}))} } \epsilon |X| \rho^{-1} \partial_{\phi} \phi(X) d\rho \right|
$$

\n
$$
\lesssim ||\nabla h||_{L^{\infty}(B_{\delta_{1}})} \left| \int_{\frac{3}{2}}^{\frac{\delta_{1}}{\epsilon}} \epsilon d\rho \right| \lesssim ||\nabla h||_{L^{\infty}(B_{\delta_{1}})} .
$$

The integral over $\partial\Omega_2^-\cap(B_{\delta_1}\setminus B_{3\epsilon})$ can be dealt with in the exactly same manner. So, we have

$$
|I_5| \lesssim \|\nabla h\|_{L^\infty(B_{\delta_1})} \lesssim \|h\|_{L^\infty(\Omega)}.
$$

This completes the proof. \Box

5 Estimates for the field enhancement

In this section we present main estimates of the gradient ∇u of the solution u to [\(1.1\)](#page-0-0). We derive two different estimates, one for points quite close to the vertices and the other for those relatively away from the vertices.

Let us first consider the case when X is relatively away from the vertices. By (4.5) and (4.28) , we have

$$
\nabla u = c(u)\nabla q + \nabla \sigma = c(u)(q|_{\partial \Omega_2} - q|_{\partial \Omega_1})\nabla \eta + \nabla \sigma.
$$

It then follows from [\(4.7\)](#page-12-3) that

$$
\nabla u(X) = c(u)(q|_{\partial\Omega_2} - q|_{\partial\Omega_1}) \nabla \left(\frac{\gamma}{\pi}(\phi + w)(\epsilon^{-1}X) + v(X)\right) + \nabla\sigma(X)
$$

= $c(u)(q|_{\partial\Omega_2} - q|_{\partial\Omega_1}) \left[\frac{\gamma}{\epsilon\pi}(\nabla\phi + \nabla w)(\epsilon^{-1}X) + \nabla v(X)\right] + \nabla\sigma(X).$ (5.1)

We now show that $(\nabla \phi)(\epsilon^{-1} X)$ is the major term in describing singular behavior of ∇u . To do so, let

$$
a_{\epsilon} := \frac{c(u)(q|_{\partial\Omega_2} - q|_{\partial\Omega_1})\gamma|\log\epsilon|}{\pi} = \frac{(u|_{\partial\Omega_2} - u|_{\partial\Omega_1})\gamma|\log\epsilon|}{\pi}.
$$
(5.2)

Lemmas [4.3](#page-16-5) and [4.4](#page-18-1) show that

$$
|a_{\epsilon}| \lesssim ||h||_{L^{\infty}(\Omega)}.
$$
\n(5.3)

This is a crucial fact in determining a upper bound on $|\nabla u|$ in the sequel. A lower bound on $|a_{\epsilon}|$ also determines a lower bound on $|\nabla u|$. However, a_{ϵ} may or may not be 0 depending on the configuration of inclusions and the background potential h . We show in section [6](#page-23-1) that a_{ϵ} is bounded below if $h(x, y) = x$, given the configuration of the bow-tie structure in the paper.

Let

$$
\mathcal{R}(X) := c(u)(q|_{\partial \Omega_2} - q|_{\partial \Omega_1}) \nabla v(X) + \nabla \sigma(X). \tag{5.4}
$$

Then we obtain the following theorem.

Theorem 5.1 *Let* u *be the solution to [\(1.1\)](#page-0-0). Then* ∇u *admits the following decomposition:*

$$
\nabla u(X) = \frac{a_{\epsilon}}{\epsilon |\log \epsilon|} \left[(\nabla \phi)(\epsilon^{-1} X) + (\nabla w)(\epsilon^{-1} X) \right] + \mathcal{R}(X), \quad X \in B_{\delta_1} \setminus \overline{\Omega_1 \cup \Omega_2}. \tag{5.5}
$$

Moreover, the following estimates hold for all $X \in B_{\delta_1} \setminus \Omega_1 \cup \Omega_2$ *with* $|X| \geq 2\epsilon$ *, where* δ_1 *is the constant appearing in Lemma [4.2:](#page-15-5)*

$$
|(\nabla \phi)(\epsilon^{-1} X)| \simeq \frac{\epsilon}{|X|},\tag{5.6}
$$

$$
|(\nabla w)(\epsilon^{-1}X)| \lesssim \frac{\epsilon^{\gamma+1}}{|X|^{\gamma+1}},\tag{5.7}
$$

$$
|\mathcal{R}(X)| \lesssim \|h\|_{L^{\infty}(\Omega)} (|X|^{\beta_1 - 1} + |X|^{\beta_2 - 1}).
$$
\n(5.8)

Proof. The decomposition [\(5.5\)](#page-20-0) is an immediate consequence of [\(5.1\)](#page-19-1)-[\(5.4\)](#page-20-1).

If $X = (x, y) \in B_{\delta_1} \setminus \Omega_1 \cup \Omega_2$ is such that $|X| \geq 2\epsilon$ and $y > 0$, then

$$
\rho(\epsilon^{-1}X) = |\epsilon^{-1}X - Q| \ge \rho_0
$$

where ρ_0 is the number appearing in Lemma [3.1](#page-8-3) (ii), and

$$
|\epsilon^{-1}X - Q| \simeq \epsilon^{-1}|X|.
$$

So, it follows from [\(3.6\)](#page-8-2) that

$$
| \left(\nabla w \right) (\epsilon^{-1} X) | \lesssim \frac{1}{| \epsilon^{-1} X - Q |^{\gamma + 1}} \lesssim \frac{\epsilon^{\gamma + 1}}{| X |^{\gamma + 1}}.
$$

Since $|\nabla \phi| = \rho^{-1}$, we have

$$
|(\nabla \phi)(\epsilon^{-1}X)| = \rho(\epsilon^{-1}X)^{-1} \simeq \epsilon |X|^{-1}.
$$

So, we have [\(5.6\)](#page-20-2) and [\(5.7\)](#page-20-3) when $y > 0$. Since ϕ and w are symmetric with respect to the x-axis, we obtain [\(5.6\)](#page-20-2) and [\(5.7\)](#page-20-3) for $y < 0$ as well.

According to Lemmas [4.1,](#page-12-5) [4.2,](#page-15-5) [4.3,](#page-16-5) and [4.4,](#page-18-1) we have

$$
|\mathcal{R}(X)| \lesssim \|h\|_{L^{\infty}(\Omega)} \left(|\nabla \mathcal{B}_1(X - L_{\epsilon})| + |\nabla \mathcal{B}_2(X - R_{\epsilon})| \right) \tag{5.9}
$$

.

for any $X \in B_{\delta_1} \setminus \Omega_1 \cup \Omega_2$. Note that $L_{\epsilon} + S_1 = V_1$. So, it follows from [\(2.8\)](#page-3-3) that

$$
|\nabla \mathcal{B}_1(X - L_{\epsilon})| = \beta_1 |X - V_1|^{\beta_1 - 1}.
$$

Likewise, we have

$$
|\nabla \mathcal{B}_2(X - R_{\epsilon})| = \beta_2 |X - V_2|^{\beta_2 - 1}
$$

So, we have

$$
|\mathcal{R}(X)| \lesssim \|h\|_{L^{\infty}(\Omega)} \left(|X - V_1|^{\beta_1 - 1} + |X - V_2|^{\beta_2 - 1} \right) \tag{5.10}
$$

for any $X \in B_{\delta_1} \setminus \Omega_1 \cup \Omega_2$. If $|X| \geq 2\epsilon$, then $|X - V_j| \simeq |X|$. So, [\(5.8\)](#page-20-4) follows from [\(5.10\)](#page-21-1). This completes the proof. \Box

Let us now derive estimates of $|\nabla u|$. We first observe from Theorem [5.1](#page-20-5) that the following holds:

$$
|\nabla u(X)| \lesssim \frac{\|h\|_{L^{\infty}(\Omega)}}{|\log \epsilon|} |X|^{-1}
$$

as long as $X \in B_{\delta_1} \setminus \overline{\Omega_1 \cup \Omega_2}$ and $2\epsilon \le |X| \le |\log \epsilon|^{-1/\beta}$, where $\beta := \min\{\beta_1, \beta_2\}.$

To derive the opposite inequality, we see from $(5.6)-(5.8)$ $(5.6)-(5.8)$ that there are positive constants, say C_{ϕ} , C_{w} and $C_{\mathcal{R}}$, independent of ϵ and X such that

$$
|(\nabla \phi)(\epsilon^{-1}X)| \ge \frac{C_{\phi}\epsilon}{|X|}, \quad |(\nabla w)(\epsilon^{-1}X)| \le \frac{C_w\epsilon^{\gamma+1}}{|X|^{\gamma+1}},
$$

and

$$
|\mathcal{R}(X)| \le C_{\mathcal{R}}(|X|^{\beta_1 - 1} + |X|^{\beta_2 - 1})
$$

as long as $X \in B_{\delta_1} \setminus \Omega_1 \cup \Omega_2$ and $|X| \geq 2\epsilon$. We then have

$$
\left| (\nabla \phi)(\epsilon^{-1} X) - (\nabla w)(\epsilon^{-1} X) \right| \ge |(\nabla \phi)(\epsilon^{-1} X)| - |(\nabla w)(\epsilon^{-1} X)|
$$

$$
\ge \frac{C_{\phi} \epsilon}{|X|} - \frac{C_w \epsilon^{\gamma+1}}{|X|^{\gamma+1}}.
$$

So, if $|X|^{\gamma} \geq 2C_{\phi}^{-1}C_w\epsilon^{\gamma}$, we have

$$
\left| (\nabla \phi)(\epsilon^{-1} X) - (\nabla w)(\epsilon^{-1} X) \right| \ge \frac{C_{\phi} \epsilon}{2|X|}.
$$

It then follows from [\(5.5\)](#page-20-0) that

$$
|\nabla u(X)| \ge \frac{|a_{\epsilon}|}{\epsilon |\log \epsilon|} |(\nabla \phi)(\epsilon^{-1} X) - (\nabla w)(\epsilon^{-1} X)| - |\mathcal{R}(X)|
$$

$$
\ge \frac{|a_{\epsilon}|C_{\phi}}{2|\log \epsilon||X|} - 2C_{\mathcal{R}}|X|^{\beta - 1}.
$$

Here we assumed $|X| \leq 1$. Suppose that $|a_{\epsilon}| \geq a_0$ for some positive constant a_0 . In such a case, if $|X|^{\beta} \leq \frac{1}{8}$ $\frac{1}{8}a_0C_R^{-1}C_\phi|\log\epsilon|^{-1}$, then we have

$$
|\nabla u(X)| \ge \frac{|a_{\epsilon}|C_{\phi}}{4|\log \epsilon||X|}.
$$

In short, we obtain the following theorem.

Theorem 5.2 *Let* $\beta := \min\{\beta_1, \beta_2\}.$

(i) We have

$$
|\nabla u(X)| \lesssim \frac{\|h\|_{L^{\infty}(\Omega)}}{|\log \epsilon|} |X|^{-1}
$$
\n(5.11)

for all $X \in B_{\delta_1} \setminus \overline{\Omega_1 \cup \Omega_2}$ *with* $2\epsilon \leq |X| \leq |\log \epsilon|^{-1/\beta}$.

(ii) Suppose that $|a_{\epsilon}| \ge a_0$ *for some positive constant* a_0 *. There are positive constants* $c_1 \geq 2$ *and* c_2 *independent* of ϵ *and* X *such that*

$$
\frac{1}{|\log \epsilon|} |X|^{-1} \lesssim |\nabla u(X)| \tag{5.12}
$$

for all X *satisfying* $c_1 \epsilon \leq |X| \leq c_2 |\log \epsilon|^{-1/\beta}$.

Theorem [5.2](#page-21-0) reveals that the singularity of $\nabla u(X)$ is stronger than the corner singularity which is of the order $|X|^{-1+\beta_1}$ or $|X|^{-1+\beta_2}$.

We now look into the case when X is close to vertices and obtain the following theorem for asymptotic behavior of $\nabla u(X)$.

Theorem 5.3 Let u be the solution to (1.1) *. Then* ∇u *admits the decomposition*

$$
\nabla u(X) = \frac{a_{\epsilon}a}{\epsilon |\log \epsilon|} (\nabla \mathcal{B}_1 - b \nabla \mathcal{B}_2)(\epsilon^{-1} X) + \mathcal{E}(X), \quad X \in B_{\delta_1} \setminus \overline{\Omega_1 \cup \Omega_2}, \tag{5.13}
$$

where a and b are positive constants independent of $\epsilon > 0$ and h. In particular, if two *aperture angles are the same, namely,* $\alpha_1 = \alpha_2$, then $b = 1$. The error term $\mathcal E$ satisfies

$$
|\mathcal{E}(X)| \lesssim ||h||_{L^{\infty}(\Omega)} \left(\frac{1}{\epsilon |\log \epsilon|} + \sum_{j=1}^{2} |X - V_j|^{\beta_j - 1} \right). \tag{5.14}
$$

Proof. Let

$$
\mathcal{N}(X) := \frac{1}{a} \nabla (\phi + w)(X) - (\nabla \mathcal{B}_1 - b \nabla \mathcal{B}_2)(X). \tag{5.15}
$$

Then, we see from [\(5.5\)](#page-20-0) that [\(5.13\)](#page-22-1) holds with

$$
\mathcal{E}(X) = \frac{a_{\epsilon}a}{\epsilon |\log \epsilon|} \mathcal{N}(\epsilon^{-1}X) + \mathcal{R}(X). \tag{5.16}
$$

We infer from [\(3.11\)](#page-9-2) that

$$
|\mathcal{N}(\epsilon^{-1}X)| \lesssim 1,
$$

which together with (5.10) yields (5.14) . This completes the proof. Since

$$
|(\nabla \mathcal{B}_j)(\epsilon^{-1} X)| = \beta_j |\epsilon^{-1} X - S_j|^{\beta_j - 1} \simeq \epsilon^{-\beta_j + 1} |X - V_j|^{\beta_j - 1}, \quad j = 1, 2,
$$
 (5.17)

we infer from [\(2.13\)](#page-5-0) that

$$
\left| (\nabla \mathcal{B}_1 - b \nabla \mathcal{B}_2)(\epsilon^{-1} X) \right| \simeq \sum_{j=1}^2 |(\nabla \mathcal{B}_j)(\epsilon^{-1} X)| \simeq \sum_{j=1}^2 \epsilon^{-\beta_j + 1} |X - V_j|^{\beta_j - 1}.
$$
 (5.18)

As one can see from [\(5.16\)](#page-22-3), we treat the term $\mathcal{N}(\epsilon^{-1}X)$ as an error term. Since $\mathcal{N}(\epsilon^{-1}X)$ is bounded, the decomposition [\(5.13\)](#page-22-1) is meaningful only if $|(\nabla \mathcal{B}_1 - b\nabla \mathcal{B}_2)(\epsilon^{-1}X)|$ is bounded below, or $|X - V_i| \leq c_0 \epsilon$ for some c_0 . In such a case, we have

$$
\left| (\nabla \mathcal{B}_1 - b \nabla \mathcal{B}_2)(\epsilon^{-1} X) + \mathcal{N}(\epsilon^{-1} X) \right| \ge \left| (\nabla \mathcal{B}_1 - b \nabla \mathcal{B}_2)(\epsilon^{-1} X) \right| - \left| \mathcal{N}(\epsilon^{-1} X) \right|
$$

$$
\ge \sum_{j=1}^2 \epsilon^{-\beta_j + 1} |X - V_j|^{\beta_j - 1}.
$$

Furthermore, if $|X - V_k| \leq c_0 \epsilon$, then

$$
\sum_{j=1}^{2} e^{-\beta_j + 1} |X - V_j|^{\beta_j - 1} \simeq e^{-\beta_k + 1} |X - V_k|^{\beta_k - 1}.
$$

So, we obtain the following theorem.

Theorem 5.4 *(i)* The following holds for $X \in B_{\delta_1} \setminus \Omega_1 \cup \Omega_2$

$$
|\nabla u(X)| \lesssim \frac{\|h\|_{L^{\infty}(\Omega)}}{\epsilon |\log \epsilon|} \left[\sum_{j=1}^{2} \epsilon^{1-\beta_j} |X - V_j|^{\beta_j - 1} + 1 \right]. \tag{5.19}
$$

(ii) Suppose that $|a_{\epsilon}| \ge a_0$ for some positive constant a_0 . There is a constant c_0 inde*pendent of* ϵ *and* X *such that*

$$
|\nabla u(X)| \gtrsim \frac{\epsilon^{-\beta_j}}{|\log \epsilon|} |X - V_j|^{\beta_j - 1} \quad \text{for all } X \in B_{c_0 \epsilon}(V_j), \quad j = 1, 2. \tag{5.20}
$$

Inequalities [\(5.19\)](#page-23-2) and [\(5.20\)](#page-23-3) show that the corner singularity $|X-V_j|^{\beta_j-1}$ is amplified by the factor of $\epsilon^{-\beta_j}/|\log \epsilon|$, which is due to the interaction between two perfectly conducting inclusions. It is worth emphasizing that the blow-up magnitude $\frac{\epsilon^{-\beta_j}}{\log \epsilon}$ $\frac{\epsilon^{-\rho_j}}{|\log \epsilon|} |X-V_j|^{\beta_j-1}$ is much larger than that for the case when inclusions have smooth boundaries, namely, $\epsilon^{-1/2}$, as mentioned in Introduction.

6 A lower estimate of a_{ϵ}

The estimates from below in Theorems [5.2](#page-21-0) and [5.4](#page-23-0) are obtained under the assumption that $|a_{\epsilon}| \ge a_0$ for some positive constant a_0 independent of ϵ . We now show that this assumption can be fulfilled for some background potential h . It is worth emphasizing that there are other cases of h where $a_{\epsilon} = 0$. For example, if inclusions Ω_1 and Ω_2 are symmetric with respect to the y-axis and $h(x, y) = y$, then one can easily see that $u(-x, y)$ is a solution to [\(1.1\)](#page-0-0) if $u(x, y)$ is. It implies that $u|_{\partial \Omega_1} = u|_{\partial \Omega_2}$, and hence $a_{\epsilon} = 0$.

We have the following theorem (without assuming that Ω_1 and Ω_2 are symmetric with respect to the y-axis).

Theorem 6.1 *If* $h(x, y) = x$ *, then*

$$
a_{\epsilon} \simeq 1. \tag{6.1}
$$

Proof. Recall that

$$
a_{\epsilon} = \frac{\gamma |\log \epsilon|}{\pi (q|\partial \Omega_2 - q|\partial \Omega_1)} (q|\partial \Omega_2 - q|\partial \Omega_1) (u|\partial \Omega_2 - u|\partial \Omega_1).
$$

It is already proved in [\(5.3\)](#page-19-2) that a_ϵ is bounded above regardless of ϵ .

By Lemma [4.3,](#page-16-5) there exists a constant C_1 such that

$$
\frac{\gamma|\log\epsilon|}{\pi(q|\partial\Omega_2 - q|\partial\Omega_1)} > C_1 > 0.
$$
\n(6.2)

On the other hand, it follows from [\(4.5\)](#page-12-7) and [\(4.34\)](#page-16-4) that

$$
(q|_{\partial\Omega_2} - q|_{\partial\Omega_1})(u|_{\partial\Omega_2} - u|_{\partial\Omega_1}) = (q|_{\partial\Omega_2} - q|_{\partial\Omega_1}) \int_{\partial\Omega_1 \cup \partial\Omega_2} x \partial_\nu q ds
$$

$$
= \int_{\partial\Omega_1 \cup \partial\Omega_2} x \partial_\nu \eta ds.
$$

Since $(-1)^i \partial_\nu q > 0$ on $\partial \Omega_i$ for $i = 1, 2$, we have

$$
(q|_{\partial\Omega_2} - q|_{\partial\Omega_1})(u|_{\partial\Omega_2} - u|_{\partial\Omega_1}) \ge \int_{\partial\Omega_2} x \partial_\nu \eta ds.
$$

To estimate $\int_{\partial \Omega_2} x \partial_\nu \eta ds$, we choose positive constants r_0 and δ_0 regardless of small $\epsilon > 0$ so that

$$
B_{r_0}(V_1-(\delta_0,0))\subset\Omega_1.
$$

Let $B_0 := B_{r_0}(V_1 - (\delta_0, 0))$ for ease of notation. Let ζ be the solution to

$$
\Delta \zeta = 0 \quad \text{in } \mathbb{R}^2 \setminus \overline{B_0 \cup \Omega_2}
$$

with conditions

$$
\begin{cases} \zeta = 0 & \text{on } \partial B_0, \\ \zeta = 1 & \text{on } \partial \Omega_2, \\ \int_{\mathbb{R}^2 \setminus \overline{B_0 \cup \Omega_2}} |\nabla \zeta|^2 dx dy < \infty. \end{cases}
$$

We emphasize that ζ is independent of ϵ . Since

$$
1 \ge \zeta(X) \ge \eta(X) \ge 0 \quad \text{for } X \in \mathbb{R}^2 \setminus \overline{\Omega_1 \cup \Omega_2}
$$

and

$$
\zeta = \eta = 1 \quad \text{on } \partial\Omega_2,
$$

we infer from Hopf's lemma that

$$
0 < \partial_{\nu} \zeta \le \partial_{\nu} \eta \quad \text{on } \partial \Omega_2.
$$

Hence, there exists a constant $C_2>0$ regardless of ϵ such that

$$
\int_{\partial\Omega_2} x \partial_{\nu} \eta ds \ge \int_{\partial\Omega_2} x \partial_{\nu} \zeta ds \ge C_2.
$$

This together with [\(6.2\)](#page-24-0) shows that a_{ϵ} is bounded below regardless of ϵ , and the proof is \Box complete.

Conclusion

In this paper we deal with the field enhancement due to presence of a bow-tie structure consisting of two perfectly conducting inclusions with corners. We introduce auxiliary functions to capture singular behavior of the field as the distance ϵ between two inclusions tends to 0. As consequences we obtain optimal bounds on the size of the field in the region close to vertices and the region relatively away from (but still close to) vertices. The estimates show that the field is enhanced beyond the corner singularities due to the interaction between inclusions. There may be a gap between two regions of estimates. In the gap the lower bound on $|\nabla u|$ is not obtained, and it is interesting to fill the gap.
