Abstract

We consider a stochastic matching model with a general compatibility graph, as introduced in [11]. We show that the natural necessary condition of stability of the system is also sufficient for the natural matching policy 'First Come, First Matched' (FCFM). For doing so, we derive the stationary distribution under a remarkable product form, by using an original dynamic reversibility property related to that of [2] for the bipartite matching model.

1   Introduction

Consider a general stochastic matching model (GM), as introduced in [11]: items of various classes enter a system one by one, to be matched by couples and to leave the system immediately upon matching. Two items are compatible if and only if their classes are adjacent in a compatibility graph G that is fixed beforehand. The classes of the entering items are drawn following a prescribed probability measure μ on $\mathcal{V}$, the set of nodes of G. This model is a variant of the Bipartite Matching model (BM) introduced in [8], see also [1]. In the BM, the compatibility graph is bipartite (say $\mathcal{V} = \mathcal{V}_1 \cup \mathcal{V}_2$). Along the various natural applications of this model, the nodes of $\mathcal{V}_1$ and $\mathcal{V}_2$ represent respectively classes of customers and servers, kidneys and patients, blood givers and blood receivers, houses and applicants, and so on. The items are matched by couples of $\mathcal{V}_1 \times \mathcal{V}_2$, and also arrive by couples of $\mathcal{V}_1 \times \mathcal{V}_2$. The classes of the elements of the entering couples are random, and it is assumed in the aforementioned references that the class of the entering element of $\mathcal{V}_1$ is always independent of that of the entering element of $\mathcal{V}_2$. Several declinations of the BM can be found in a recent literature, along various applications: the Max-weight policy is shown asymptotically optimal for models with relaxations in [6]. A model for taxi platforms is investigated in [4, 5], in which the bipartite graph is bipartite-complete, but the nominal matchings between items are themselves random. A fluid model for an overloaded system representing an housing allocation platform is analyzed in [16], and [3] addresses an organ transplant system under real-time constraint. An extension of GM models to the case where the matching structure is an hypergraph (i.e. a set of nodes with edges possibly gathering more than two nodes) was recently proposed in [15], addressing the form of the stability region in function of the geometry of the considered hypergraph.

An important generalization of the BM is the so-called Extended Bipartite Matching model (EBM) introduced in [7], where this independent assumption is relaxed. Possible entering couples are element of a bipartite arrival graph on the bipartition $\mathcal{V}_1 \cup \mathcal{V}_2$. The construction of perfect infinite matchings for EBM models, i.e. of random graphs gathering the entered nodes and whose edges represent the executed matches, was recently presented in [12]. Importantly, notice that the GM can in fact be seen as a particular case of EBM, taking the bipartite double cover of G as compatibility graph, and duplicating arrivals with a copy of an item of the same class.

The main question raised in [11] is the shape of the stability region of the model, that is, the set of probability measures on $\mathcal{V}$ rendering the natural Markov chain of corresponding system positive

recurrent. Partly relying on the aforementioned connection between GM and EBM, and the results of [7], [11] show that the stability region is always included in the set of measures satisfying the natural condition (3) below. The form of the stability region is then heavily dependent on the structural properties of the compatibility graph, and on the matching policy, i.e. the rule of choice of a match for an entering item whenever several matches are possible. A matching policy is then said to have a maximal stability region for G if the system is stable for any measure satisfying (3). It is shown in [11] that a GM on a bipartite G is never stable, that a designated class of graphs (the complete k-partite graphs for $k \geq 3$, see below) makes the stability region maximal for all matching policies, and that the policy 'Match the Longest' always has a maximal stability region for a non-bipartite G. Applying fluid unstability arguments to a continuous-time version of the GM, [13] shows that, aside for a very particular class of graphs, whenever G is not complete k-partite there always exists a policy of the strict priority type that does not have a maximal stability region, and that the 'Uniform' random policy (natural in the case where no information is available to the entering items on the state of the system) never has a maximal stability region, thereby providing a partial converse of the result in [11]. Related models are studied in [9] and [14], proposing optimization schemes for models of various matching structures (general graphs and hypergraphs), and the executions of matchings (which are possibly retarded, i.e. compatible items may not to be matched right away in order to wait for a more profitable future match) are associated to a cost or a reward.

In this paper we are concerned with the stability region of the GM under the 'First Come, First Matched' (FCFM) policy, consisting in always performing the match of the entering item with the oldest compatible item in the system. Compared to the aforementioned stability studies, this matching policy raises technical problems, mainly due to the intricate form of the state space of its natural Markov representation. In the history of study of the BM, the corresponding First Come, First Served' (FCFS) policy was the first one considered in the seminal papers [8, 1], which show the existence of a stationary matching whenever the measure μ satisfies a natural resource pooling condition analog to the one in (3) below. Further, [2] recently showed that the stationary distribution of the Markov chain of the system can be obtained in a remarkable product form, which is obtained using an original dynamic reversibility argument. However, these results cannot be directly applied to the present context, for the GM is *not* a particular case of a BM, but of an EBM, for which the latter reversibility argument is unlikely to hold in general. (Observe that the maximality of FCFS for the EBM is conjectured, but left as on open problem in [7].) We show hereafter that we can in fact construct a reversibility scheme that is related to the one proposed in [2] for the BM, to show that the stability region of FCFM is indeed maximal for the GM, and that the stationary state of the Markov representation also satisfies a product form.

The paper is organized as follows. In Section 2 we introduce and formalize our model. In Section 3 we develop our reversibility scheme for the FCFM system, leading to our main result, Theorem 1, which establishes the existence of a stationary probability under a product form for the natural Markov representation of the system, under the natural condition that μ is an element of the set defined by (3). Under the same condition, the construction of perfect infinite FCFM-matchings is presented in Section 4.

2   The model

2.1   General notation

Denote by $\mathbb{R}$ the set of real numbers, by $\mathbb{N}$ the set of non-negative integers and by $\mathbb{N}_+$, the subset of positive integers. For any two integers m and n, denote by $[\![m, n]\!] = [m, n] \cap \mathbb{N}$. For any $n \in \mathbb{N}_+$, let $\mathfrak{S}_n$ be the group of permutations of $[\![1, n]\!]$. Let A^* (respectively, $A^{\mathbb{N}}$) be the set of finite (resp., infinite) words over the alphabet A. Denote by $\emptyset$, the empty word of A^*. For any word $w \in A^*$ and any subset B of A, we let $|w|_B$ be the number of occurrences of elements of B in w. For any letter $a \in A$, we denote $|w|_a := |w|_{\{a\}}$, and for any finite word w we let $|w| = \sum_{a \in A} |w|_a$ be the *length* of w.

For a word $w \in A^*$ of length $|w| = q$, we write $w = w_1 w_2 ... w_q$, i.e. w_i is the i-th letter of the word w. In the proofs below, we understand the word $w_1 ... w_k$ as $\emptyset$ whenever $k = 0$. Also, for any $w \in A^*$ and any $i \in [\![1, |w|]\!]$, we denote by $w_{[i]}$, the word of length $|w| - 1$ obtained from w by deleting its i-th letter.

Consider a simple undirected graph $G = (\mathcal{V}, \mathcal{E})$, where $\mathcal{V}$ denotes the set of nodes, and $\mathcal{E} \subset \mathcal{V}^2 \setminus \Delta$ is the set of edges, where $\Delta = \{(i, i) : i \in \mathcal{V}\}$, i.e. we do not allow self-loops. We use the notation $u{-}v$ for $(u, v) \in \mathcal{E}$ and $u{\neq}v$ for $(u, v) \notin \mathcal{E}$. For $U \subset \mathcal{V}$, we define $U^c = \mathcal{V} \setminus U$ and

$$\mathcal{E}(U) = \{v \in \mathcal{V} : \exists u \in U, \ u - v\} .$$

An *independent set* of G is a non-empty subset $\mathcal{I} \subset \mathcal{V}$ which does not include any pair of neighbors, *i.e.* $\left(\forall i, j \in \mathcal{V}, \ i{-}j \Rightarrow i \notin \mathcal{I} \text{ or } j \notin \mathcal{I} \right)$. Let $\mathbb{I}(G)$ be the set of independent sets of G. An independent set $\mathcal{I}$ is said to be *maximal* if $\mathcal{I} \cup \{j\} \notin \mathbb{I}(G)$ for any $j \notin \mathcal{I}$.

Recall that a connected graph $G = (\mathcal{V}, \mathcal{E})$ is said *complete p-partite*, $p \geq 2$, if there exists a partition of $\mathcal{V}$ into maximal independent sets $\mathcal{I}_1, \ldots, \mathcal{I}_p$, such that

$$\forall i \neq j, \forall u \in \mathcal{I}_i, \forall v \in \mathcal{I}_j, \ u{-}v .$$

Notice that such graphs are referred to as *separable* in the references [11] and [13].

For $w = w_1 w_2 ... w_q \in \mathcal{V}^*$, we denote by $\tilde{w}$ the reversed version of w, i.e. $\tilde{w} = w_q w_{q-1} ... w_2 w_1$. Let $\overline{\mathcal{V}}$ be an independent copy of the set $\mathcal{V}$, i.e. a set of cardinality $|\mathcal{V}|$, disjoint of $\mathcal{V}$ and containing copies of the elements of $\mathcal{V}$. We denote by $\overline{a}$, the copy of any element a of $\mathcal{V}$, and also say that $\overline{a}$ is the *counterpart* of a, and vice-versa. For any $\overline{a} \in \overline{\mathcal{V}}$, let us denote $\overline{\overline{a}} = a$. Let $\mathbf{V} := \mathcal{V} \cup \overline{\mathcal{V}}$. For any word $\mathbf{w} \in \mathbf{V}^*$, denote by $\mathcal{V}(\mathbf{w})$ (respectively, $\overline{\mathcal{V}}(\mathbf{w})$) the set of letters of $\mathcal{V}$ (resp., $\overline{\mathcal{V}}$) that are present in $\mathbf{w}$:

$$\mathcal{V}(\mathbf{w}) = \left\{ a \in \mathcal{V} : |\mathbf{w}|_a > 0 \right\}; \qquad \overline{\mathcal{V}}(\mathbf{w}) = \left\{ \overline{a} \in \overline{\mathcal{V}} : |\mathbf{w}|_{\overline{a}} > 0 \right\}.$$

For any $\mathbf{w} \in \mathbf{V}^*$, the *restriction* of $\mathbf{w}$ to $\mathcal{V}$ (respectively, to $\overline{\mathcal{V}}$) is the word $\mathbf{w}|_{\mathcal{V}} \in \mathcal{V}^*$ (resp., $\mathbf{w}|_{\overline{\mathcal{V}}} \in \overline{\mathcal{V}}^*$) of size $|\mathbf{w}|_{\mathcal{V}}$ (resp. of size $|\mathbf{w}|_{\overline{\mathcal{V}}}$), obtained by keeping only the letters belonging to $\mathcal{V}$ (resp. to $\overline{\mathcal{V}}$) in $\mathbf{w}$, in the same order. The *dual* $\overline{\mathbf{w}}$ of the word $\mathbf{w} = \mathbf{w}_1 ... \mathbf{w}_q \in \mathbf{V}^*$ is the word obtained by exchanging the letters of $\mathbf{w}$ with their counterpart, i.e. $\overline{\mathbf{w}} = \overline{\mathbf{w}_1} ... \overline{\mathbf{w}_q}$.

Example 1. Take for instance $\mathbf{w} = a\, b\, \overline{a}\, c\, \overline{b}\, \overline{c}\, \overline{b}\, d\, a$. Then we obtain $\mathcal{V}(\mathbf{w}) = \{a, b, c, d\}$, $\overline{\mathcal{V}}(\mathbf{w}) = \{\overline{a}, \overline{b}, \overline{c}\}$, $\mathbf{w}|_{\mathcal{V}} = a\, b\, c\, d\, a$, $\mathbf{w}|_{\overline{\mathcal{V}}} = \overline{a}\, \overline{b}\, \overline{c}\, \overline{b}$, $\overline{\mathbf{w}} = \overline{a}\, \overline{b}\, a\, \overline{c}\, b\, c\, b\, \overline{d}\, \overline{a}$, $\tilde{\mathbf{w}} = a\, d\, \overline{b}\, \overline{c}\, \overline{b}\, c\, \overline{a}\, b\, a$.

2.2   Formal definition of the model

We consider a *general stochastic matching model*, as was defined in [11]: items enter one by one a system, and each of them belongs to a determinate class. The set of classes is denoted by $\mathcal{V}$, and identified with $[\![1, |\mathcal{V}|]\!]$. We fix a connected simple graph $G = (\mathcal{V}, \mathcal{E})$ having set of nodes $\mathcal{V}$, termed *compatibility graph*. Upon arrival, any incoming item of class, say, $i \in \mathcal{V}$ is either matched with an item present in the buffer, of a class j such that $i{-}j$, if any, or if no such item is available, it is stored in the buffer to wait for its match. Whenever several matches are possible for an incoming item i, it is the role of the matching policy to decide the match of the latter item without ambiguity. Throughout, we assume that the matching policy is 'First Come, First Matched' (FCFM), that is, the match of i is the oldest among all stored items of neighboring classes of i. Each matched pair departs the system right away.

We assume that the successive classes of entering items are random. We fix an underlying probability space $(\Omega, \mathcal{F}, \mathbb{P})$, on which all random variables (r.v.'s, for short) are defined. For any $n \in \mathbb{N}$, let $V_n \in \mathcal{V}$ denote the class of the n-th incoming item. Throughout this work, we assume that the sequence $(V_n)_{n \in \mathbb{N}}$ is iid, from the distribution μ on $\mathcal{V}$. Without loss of generality, we assume that μ has full support $\mathcal{V}$ (we write $\mu \in \mathcal{M}(\mathcal{V})$). Altogether, according to the terminology in [11], we thus consider the general matching (GM) model associated to (G, μ, FCFM).

2.3 Markov representation

Fix the compatibility graph $G = (\mathcal{V}, \mathcal{E})$ until the end of this section. Fix an integer $n_0 \geq 1$, and a realization $v_1, ..., v_{n_0}$ of $V_1, ..., V_{n_0}$. Define the word $\mathbf{v} \in \mathcal{V}^*$ by $\mathbf{v} := v_1...v_{n_0}$. Then, there exists a unique FCFM *matching* of the word $\mathbf{v}$, that is, a graph having set of nodes $\{v_1, ..., v_{n_0}\}$ and whose edges represent the matches performed in the system until time n_0, if the successive arrivals are given by $\mathbf{v}$ and the matching policy is FCFM. This matching is denoted by $M^{\mathrm{FCFM}}(\mathbf{v})$. The state of the system is defined as the word $W^{\mathrm{FCFM}}(\mathbf{v}) \in \mathcal{V}^*$, whose letters are the classes of the unmatched items at time n_0, i.e. the isolated vertices in the matching $M^{\mathrm{FCFM}}(\mathbf{v})$, in their order of arrivals. The word $W^{\mathrm{FCFM}}(\mathbf{v}) \in \mathcal{V}^*$ is called *queue detail* at time n_0. Then any admissible queue detail belongs to the set

$$\mathbb{W} = \Big\{ w \in \mathcal{V}^* \ : \ \forall (i,j) \in \mathcal{E}, \ |w|_i |w|_j = 0 \Big\}. \tag{1}$$

Fix a (possibly random) word $Y \in \mathbb{W}$. Denote for all $n \geq 0$ by $W_n^{\{Y\}}$ the buffer content at time n (i.e. just before the arrival of item n) if the buffer content at time 0 was set to w, in other words

$$W_n^{\{Y\}} = W^\phi \left(Y V_0 ... V_{n-1} \right).$$

Then the buffer-content sequence is stochastic recursive, since we clearly have that

$$\begin{cases} W_0^{\{Y\}} & = Y; \\ W_{n+1}^{\{Y\}} & = W_n^{\{Y\}} \odot_{\mathrm{FCFM}} (V_n), \ n \in \mathbb{N}, \end{cases}$$

where for all $w \in \mathbb{W}$ and $v \in \mathcal{V}$,

$$w \odot_{\mathrm{FCFM}} (v) = \begin{cases} wv & \text{if } |w|_{\mathcal{E}(v)} = 0; \\ w_{[\Phi(w,v)]} & \text{else, where } \Phi(w,v) = \min\{k \in [\![1, |w|]\!], \ : \ w_k \in \mathcal{E}(v)\}. \end{cases}$$

Consequently, if we assume that the sequence $(V_n)_{n \in \mathbb{N}}$ is independent of Y, the queue detail $\left(W_n^{\{Y\}} \right)_{n \in \mathbb{N}}$ is a $\mathbb{W}$-valued $\mathcal{F}_n$-Markov chain, where $\mathcal{F}_0 = \sigma(Y)$ and $\mathcal{F}_n = \sigma(Y, V_0, ..., V_{n-1})$ for all $n \geq 1$. The sequence $(W_n)_{n \in \mathbb{N}}$ is termed *natural chain* of the system.

2.4 Stability of the matching model

Fix a connected graph G. The chain $(W_n)_{n \in \mathbb{N}}$ is clearly irreducible, as all states of $\mathbb{W}$ lead to $\emptyset$. In line with [11] we define the *stability region* of the GM model (G, μ, FCFM) by

$$\mathrm{STAB}(G, \mathrm{FCFM}) := \Big\{ \mu \in \mathcal{M}(\mathcal{V}) \ : \ (W_n)_{n \in \mathbb{N}} \text{ is positive recurrent} \Big\}, \tag{2}$$

which is clearly independent of the initial state Y in view of the above observation. Let us also define the set of measures

$$\mathrm{NCOND}(G) : \{\mu \in \mathcal{M}(\mathcal{V}) \ : \ \text{for any } \mathcal{I} \in \mathbb{I}(G), \mu(\mathcal{I}) < \mu(\mathcal{E}(\mathcal{I}))\} \tag{3}$$

which, from Theorem 1 in [11], is non-empty if and only if G is non-bipartite. We know from Proposition 2 in [*ibid.*] that for any policy Φ in the set of so-called *admissible* matching policies (that includes FCFM), the stability region of the GM model associated to (G, μ, Φ), defined similarly to (2), is included in $\mathrm{NCOND}(G)$. An admissible policy Φ is said to be *maximal* if these two sets coincide. Theorem 2 in [*ibid.*] establishes the maximality of the matching policy 'Match the Longest' for any non-bipartite graph, however priority policies and the uniform policy are in general not maximal (respectively, Theorem 3 and Proposition 7 in [13]). Last, it is stated in Theorem 2 in [11] that any GM model on a graph G that is p-partite complete for $p \geq 3$ has a stability region that coincides with $\mathrm{NCOND}(G)$ whatever the admissible matching policy; in other word *any* admissible policy is maximal in this case.

We show in this paper that the policy FCFM is maximal, and characterize the steady state of the system under the condition that $\mu \in \mathrm{NCOND}(G)$.

3   Product form

In this section we establish our main result, Theorem 1, which establishes the maximality of the policy First Come, First Matched, by constructing explicitly the stationary distribution of the natural chain on $\mathbb{W}$. Interestingly enough, this probability distribution has a remarkable product form, detailed in (4).

Theorem 1. *Let $G = (\mathcal{V}, \mathcal{E})$ be a non-bipartite graph. Then the sets* $\textsc{stab}(G, \textsc{fcfm})$ *and* $\textsc{Ncond}(G)$, *defined respectively by (2) and (3), coincide. In other words the GM model $(G, \mu, \textsc{fcfm})$ is stable if and only if μ belongs to the set* $\textsc{Ncond}(G)$*. In that case, the following is the only stationary probability of the natural chain* $(W_n)_{n \in \mathbb{N}}$*:*

$$\Pi_W(w) = \alpha \prod_{\ell=1}^{q} \frac{\mu(w_\ell)}{\mu\Big(\mathcal{E}\left(\{w_1, ..., w_\ell\}\right)\Big)}, \quad \text{for any } w = w_1...w_q \in \mathbb{W}, \tag{4}$$

where

$$\alpha = \left\{ 1 + \sum_{\mathcal{I} \in \mathbb{I}(G)} \sum_{\sigma \in \mathfrak{S}_{|\mathcal{I}|}} \prod_{j=1}^{|\mathcal{I}|} \frac{\mu(i_{\sigma(j)})}{\mu\left(\mathcal{E}\left(\{i_{\sigma(1)}, ..., i_{\sigma(j)}\}\right)\right) - \mu\left(\{i_{\sigma(1)}, ..., i_{\sigma(j)}\}\right)} \right\}^{-1}. \tag{5}$$

The remainder of this Section is devoted to the proof of Theorem 1, which, as will be demonstrated below, is based on a subtle reversibility scheme that is related to the proof of reversibility for the BM model in [2]. Let us recall however that the GM model is not a particular case of BM model, so the proof below presents many specificities with respect to [2].

3.1   Auxiliary Markov representations

We now introduce two auxiliary Markov representations of the system: the $\mathbf{V}^*$-valued Backwards and Forwards detailed chains, similar in construction to the backwards and forwards 'pair by pair detailed FCFS matching processes', introduced in subsection 5.1 of [2].

Backwards detailed chain   We define the $\mathbf{V}^*$-valued backwards detailed process $(B_n)_{n \in \mathbb{N}}$ as follows: $B_0 = \emptyset$ and for any $n \geq 1$,

- if $W_n = \emptyset$ (i.e. all the items arrived up to time n are matched at time n), then we set $B_n = \emptyset$;

- if not, we let $i(n) \leq n$ be the index of the oldest item in line. Then, the word B_n is of length $n - i(n) + 1$, and for any $\ell \in [\![1, n - i(n) + 1]\!]$, we set

$$B_n(\ell) = \begin{cases} V_{i(n)+\ell-1} & \text{if } V_{i(n)+\ell-1} \text{ has not been matched up to time } n; \\ \overline{V_k} & \text{if } V_{i(n)+\ell-1} \text{ is matched at or before time } n, \text{ with item } V_k \\ & \text{(where } k \leq n). \end{cases}$$

In other words, assuming that the initial system is empty, the word B_n gathers the class indexes of all unmatched items entered up to n, and the copies of the class indexes of the items matched after the arrival of the oldest unmatched item at n, at the place of the class index of the item they have been matched to. Observe that we necessarily have that $B_n(1) = V_{i(n)} \in \mathcal{V}$. Moreover, the word B_n necessarily contains all the letters of W_n. More precisely, we have

$$W_n^{\{\emptyset\}} = B_n|_{\mathcal{V}}, \quad n \geq 0. \tag{6}$$

It is easily seen that $(B_n)_{n \in \mathbb{N}}$ also is a $\mathcal{F}_n$-Markov chain: for any $n \geq 0$, the value of B_{n+1} can be deduced from that of B_n and the class V_{n+1} of the item entered at time $n + 1$.

Forward detailed chain   The $\mathbf{V}^*$-valued forward detailed process $(F_n)_{n\in\mathbb{N}}$ is defined as follows: $F_0 = \emptyset$ and for any $n \geq 1$,

- if $W_n = \emptyset$, then we also set $F_n = \emptyset$;

- if not, we let $\mathscr{U}_n$ be the set of items entered up to n and not yet matched at n (which is non empty since $W_n \neq \emptyset$), and set

$$j(n) = \sup\{m > n \ : \ V_m \text{ is matched with an element of } \mathscr{U}_n\}.$$

Notice that $j(n)$ is possibly infinite. Then, F_n is the word of $\mathbf{V}^*$ of size $j(n) - n$ (respectively of $\mathbf{V}^{\mathbb{N}}$ if $j(n) = +\infty$), such that for any $\ell \in [\![1, j(n) - n]\!]$ (resp., $\ell \in \mathbb{N}_+$),

$$F_n(\ell) = \begin{cases} V_{n+\ell} & \text{if } V_{n+\ell} \text{ is not matched with an item arrived up to } n; \\ \overline{V_k} & \text{if } V_{n+\ell} \text{ is matched with item } V_k, \text{ where } k \leq n. \end{cases}$$

In other words, assuming that the initial system is empty, the word F_n contains the copies of all the class indexes of the items entered up to time n and matched after n, together with the class indexes of all unmatched items entered before the last item matched with an item entered up to n, if any. Observe that if $F_n \in \mathbf{V}^*$ is finite, then $F_n(j(n) - n) \in \overline{\mathcal{V}}$ since by definition, the item $V_{j(n)}$ is matched with some V_k for $k \leq n$, and therefore $F_n(j(n) - n) = \overline{V}_k$. It is also clear that $(F_n)_{n\in\mathbb{N}}$ is a $\mathcal{F}_n$-Markov chain, as for any $n \geq 0$, the value of F_{n+1} depends solely on F_n and the class index $V_{j(n)+1}$ of the item entered at time $n + j(n) + 1$.

Example 2. Consider the compatibility graph of Figure 1, addressed in Section 5 of [11] (this is the smallest graph that is neither bipartite nor complete p-partite). An arrival scenario together with successive values of the natural chain, the backwards and the forwards chain are represented in Figure 2.

Figure 1: Compatibility graph of Example 2.

3.2   Reversibility

For both chains $(B_n)_{n\in\mathbb{N}}$ and $(F_n)_{n\in\mathbb{N}}$, a state $\mathbf{w} \in \mathbf{V}^*$ is said admissible if it can be reached by the chain under consideration under FCFM. We denote

$$\mathbb{B} := \left\{\mathbf{w} \in \mathbf{V}^* \ : \ \mathbf{w} \text{ is admissible for } (B_n)_{n\in\mathbb{N}}\right\}; \tag{7}$$

$$\mathbb{F} := \left\{\mathbf{w} \in \mathbf{V}^* \ : \ \mathbf{w} \text{ is admissible for } (F_n)_{n\in\mathbb{N}}\right\}.$$

Define the following measure on $\mathbf{V}^*$,

$$\begin{cases} \nu_B(\emptyset) & = 1; \\ \nu_B(\mathbf{w}) & = \prod\limits_{i=1}^{p} \mu(i)^{|\mathbf{w}|_i + |\overline{\mathbf{w}}|_i}, \ \mathbf{w} \in \mathbf{V}^* \setminus \{\emptyset\}. \end{cases} \tag{8}$$

Observe that by the very definition (8), the measure of a word $\mathbf{w}$ does not change whenever any of its letters a is exchanged with $\bar{a}$. In particular, we have $\nu_B(\overset{\leftarrow}{\overline{\mathbf{w}}}) = \nu_B(\mathbf{w})$ for any $\mathbf{w}$ in $\mathbf{V}^*$. We have the following result,
Figure 2: An arrival scenario on the graph of Figure 1, and the trajectories of the three Markov chains.

Proposition 1. *Suppose that μ belongs to $\textsc{Ncond}(G)$ defined by (3). Then the measure ν_B defined by (8) is finite on $\mathbb{B}$. Moreover, the Backwards detailed Markov chain $(B_n)_{n \in \mathbb{N}}$ is positive recurrent, and admits $\beta \nu_B$ as a stationary measure for any $\beta > 0$.*

Before showing Proposition 1 we need to introduce a few technical results.

Lemma 1. *Let $\mathbf{w} = \mathbf{w}_1...\mathbf{w}_q \in \mathbf{V}^*$. Then $\mathbf{w} \in \mathbb{B}$ if, and only if the following three conditions hold,*

$$\mathbf{w}_1 \in \mathcal{V}; \tag{9}$$

$$\mathbf{w}_k \not\sim \mathbf{w}_\ell \text{ for any } k, \ell \in [\![1, q]\!] \text{ such that } \mathbf{w}_k \in \mathcal{V} \text{ and } \mathbf{w}_\ell \in \mathcal{V}; \tag{10}$$

$$\mathbf{w}_k \not\sim \overline{\mathbf{w}_j} \text{ for any } k, j, \ 1 \le k < j \le q, \text{ such that } \mathbf{w}_k \in \mathcal{V} \text{ and } \overline{\mathbf{w}_j} \in \overline{\mathcal{V}}. \tag{11}$$

Proof of Lemma 1. By the very definition of $(B_n)_{n \in \mathbb{N}}$, (9) holds true for any (non-empty) admissible word of the chain. Moreover the necessity of (10) is obvious: would an element $\mathbf{w}$ of $\mathbb{B}$ contain two compatible letters in $\mathcal{V}$, the two corresponding items would have been matched. Let us prove the necessity of (11). Fix two such indexes k and j in $[\![1, q]\!]$. This means that $V_{i(n)+j-1}$ is matched with an item V_ℓ of class $\overline{\mathbf{w}_j}$. Then, it can be easily checked that $\mathbf{w}_k - \overline{\mathbf{w}_j}$ implies that V_ℓ is matched with $V_{i(n)+k-1}$, an absurdity since $V_{i(n)+k-1}$ of class $\mathbf{w}_k$ is still unmatched at n. This completes the proof of necessity.

Regarding sufficiency, fix a non-empty state $\mathbf{w}$ satisfying (9), (10) and (11):

$$\mathbf{w} = b_1 \, \overline{a_{11}} \, \overline{a_{12}} ... \overline{a_{1k_1}} \, b_2 \, \overline{a_{21}}...\overline{a_{2k_2}} \, b_3....b_q \, \overline{a_{q1}}...\overline{a_{qk_q}},$$

where $q \ge 1$, $k_q \in \mathbb{N}$ for all q, $b_\ell \in \mathcal{V}$ for all ℓ and $a_{\ell j} \in \mathcal{V}$ for all ℓ, j. In particular, from (10) we have that $b_i \not\sim b_j$ for any $i \neq j$ whereas from (11), $a_{\ell j} \not\sim b_i$ for any j and any $i \le \ell$. Let us show that the

7

chain $(B_n)_{n\in\mathbb{N}}$ can reach the state $\mathbf{w}$. For this we construct inductively an arrival vector A leading to $\mathbf{w}$ from the state $\emptyset$. At first, set

$$A := (V_{n-q+1}, V_{n-q+2}, ..., V_n) = (b_1, ..., b_q).$$

Then, we investigate all elements $\overline{a_{\ell j}}$ from left to right, as follows. We start from a_{11}:

(1) If there is no element $\overline{a_{\ell' j'}}$ to the right of $\overline{a_{11}}$ such that $a_{11}-a_{\ell' j'}$, then set $V_{n-q-1} = a_{11}$, $V_{n-q} = b_1$, $V_{n-q+1} = c \in \mathcal{E}\,(a_{11})$, in a way that the a_{11}-item is matched with that of class b, and we retrieve the letter $\overline{a_{11}}$ to the right of b_1 because the c-item is matched with a_{11};

(2) If there exists an element $\overline{a_{\ell' j'}}$ to the right of $\overline{a_{11}}$ such that $a_{11}-a_{\ell' j'}$, we investigate all terms $\overline{a_{\ell'' j''}}$ to the left of $\overline{a_{\ell' j'}}$. If one of them, $\overline{a_{\ell'' j''}}$ is such that $a_{\ell'' j''}-a_{\ell' j'}$, then $a_{\ell' j'}$ can be matched in FCFM with another item than a_{11}. Then we do as in case (1): $V_{n-q-1} = a_{11}$, $V_{n-q} = b_1$, $V_{n-q+1} = c \in \mathcal{E}\,(a_{11})$;

(3) If an element $\overline{a_{\ell' j'}}$ to the right of $\overline{a_{11}}$ is such that $a_{11}-a_{\ell' j'}$, and no term $\overline{a_{\ell'' j''}}$ to the left of $\overline{a_{\ell',j'}}$ is such that $a_{\ell'' j''}-a_{\ell' j'}$, we interpose a term $a_{\ell' j'}$ in A between b_1 and b_2 (or at the extreme right of A if $q = 1$), and a term a_{11} between $b_{\ell'}$ and $b_{\ell'+1}$ (or at the extreme right of A if $q = \ell'$), in a way that the two corresponding items are matched.

Then, by induction we can investigate in the same way all the terms $\overline{a_{\ell j}}$ not yet considered,

(1) If there is no element $\overline{a_{\ell' j'}}$ to the right of $\overline{a_{\ell j}}$ such that $a_{\ell j}-a_{\ell' j'}$, then in A we interpose a letter $a_{\ell j}$ just to the left of b_1, and a letter $c \in \mathcal{E}\,(a_{\ell j})$ to the left of $b_{\ell+1}$ if $\ell < q$ (or at the extreme right of A if $\ell = q$); the items of classes c and $a_{\ell,j}$ are matched and a term $\overline{a_{\ell j}}$ appears at the right place in the detailed state of the system;

(2) We do as in case (1) if there exists an element $\overline{a_{\ell' j'}}$ to the right of $\overline{a_{\ell j}}$ such that $a_{\ell j}-a_{\ell' j'}$, but one of the non yet investigated terms $\overline{a_{\ell' j'}}$ to the left of $\overline{a_{\ell' j'}}$ is such that $a_{\ell'' j''}-a_{\ell' j'}$.

(3) If there exists an element $\overline{a_{\ell' j'}}$ to the right of $\overline{a_{\ell j}}$ such that $a_{\ell j}-a_{\ell' j'}$, and no term $\overline{a_{\ell'' j''}}$ to the left of $\overline{a_{\ell' j'}}$ is such that $a_{\ell'' j''}-a_{\ell' j'}$, then in A we interpose a term $a_{\ell' j'}$ just to the left of $b_{\ell+1}$ (or at the extreme right of A if $\ell = q$), and a term $a_{\ell j}$ to the immediate left of $b_{\ell'+1}$ (or at the extreme right of A if $\ell' = q$), in a way that the two corresponding items are matched.

We continue this construction, until all the letters $\overline{a_{\ell j}} \in \mathbf{w}|_{\overline{\mathcal{V}}}$ are investigated and the corresponding items are matched. The resulting vector A that we obtain is of size $q' \in [\![q + \sum_{\ell=1}^{q} k_\ell, q + 2\sum_{\ell=1}^{q} k_\ell]\!]$. Indeed, the number of items added to A is at least equal to the number of letters of $\mathbf{w}|_{\overline{\mathcal{V}}}$, and at most equal to twice the latter number (which is the case if all the corresponding items entered the system before the item of class b_1 and are matched after the arrival time of the latter). Finally, for any $n \geq q + 2\sum_{\ell=1}^{q} k_\ell$, if $B_{n-q'} = \emptyset$, an arrival scenario A for the q' following time epochs yields to a state $B_n = \mathbf{w}$. This concludes the proof. ∎

As a consequence,

Lemma 2. *The mapping $\mathbf{w} \mapsto \overleftarrow{\overline{\mathbf{w}}}$ is one-to-one from $\mathbb{B}$ into $\mathbb{F}$.*

Proof. From Lemma 1, it is sufficient to prove that a state $\mathbf{w}$ belongs to $\mathbb{F}$ if and only if $\overleftarrow{\overline{\mathbf{w}}}$ satisfies (9), (10) and (11). The proof of this statement is similar to that of Lemma 1. ∎

We can now state the following connection between the dynamics of $(B_n)_{n\in\mathbb{N}}$ and $(F_n)_{n\in\mathbb{N}}$,

Lemma 3. *Let ν_B be the measure on $\mathcal{V}^*$ defined by (8). Then, for any $\mathbf{w}, \mathbf{w}' \in \mathbb{B}$ such that $\mathbb{P}\,[B_{n+1} = \mathbf{w}'|B_n = \mathbf{w}] > 0$ we have that*

$$\nu_B(\mathbf{w})\mathbb{P}\,[B_{n+1} = \mathbf{w}'|B_n = \mathbf{w}] = \nu_B\left(\overleftarrow{\overline{\mathbf{w}'}}\right) \mathbb{P}\left[F_{n+1} = \overleftarrow{\overline{\mathbf{w}}}|F_n = \overleftarrow{\overline{\mathbf{w}'}}\right]. \tag{12}$$

Proof. Fix $\mathbf{w} \in \mathbb{B}$ (so that $\overset{\leftarrow}{\overline{\mathbf{w}}} \in \mathbb{F}$ from Lemma 2). Whenever $\mathbf{w} \neq \emptyset$ we set $\mathbf{w} = \mathbf{w}_1...\mathbf{w}_q \in \mathbf{V}^*$, and recall that $\mathbf{w}_1 \in \mathcal{V}$ in that case. There are five possible cases for the transition of $(B_n)_{n\in\mathbb{N}}$, which we address one by one,

(1) Suppose that $\mathbf{w} \neq \emptyset$ and $\mathbf{w}' = \mathbf{w}a$ for some $a \in \mathcal{V}$. Plainly, such a state is admissible if and only if $a \in \mathcal{E}\left(\mathcal{V}(\mathbf{w})\right)^c$. The backwards chain moves from $\mathbf{w}$ to $\mathbf{w}a$ at $n+1$ whenever $V_{n+1} = a$, so we have that $\mathbb{P}\left[B_{n+1} = \mathbf{w}a | B_n = \mathbf{w}\right] = \mu(a)$. On the other hand, $F_n = \overset{\leftarrow}{\overline{\mathbf{w}a}}$ entails that the item entering at $n+1$ is matched with an item of class a entered up to time n. Therefore we necessarily have that $F_{n+1} = \overset{\leftarrow}{\overline{\mathbf{w}}}$, in other words

$$\nu_B\left(\overset{\leftarrow}{\overline{\mathbf{w}a}}\right) \mathbb{P}\left[F_{n+1} = \overset{\leftarrow}{\overline{\mathbf{w}}} | F_n = \overset{\leftarrow}{\overline{\mathbf{w}a}}\right] = \nu_B\left(\overset{\leftarrow}{\overline{\mathbf{w}a}}\right)$$
$$= \nu_B(\mathbf{w})\mu(a) = \nu_B(\mathbf{w})\mathbb{P}\left[B_{n+1} = \mathbf{w}a | B_n = \mathbf{w}\right].$$

(2) Suppose now that $\mathbf{w} \neq \emptyset$ and $\mathbf{w}' = \mathbf{w}_1...\mathbf{w}_{k-1}\,\overline{a}\,\mathbf{w}_{k+1}...\mathbf{w}_q\overline{\mathbf{w}_k}$. This means that $\mathbf{w}_k \in \mathcal{V}$ and that the item V_{n+1} is of class a, where $a \in \mathcal{E}\left(\mathbf{w}_k\right) \cap \mathcal{E}\left(\mathcal{V}\left(\mathbf{w}_1....\mathbf{w}_{k-1}\right)\right)^c$, so that in FCFM, V_{n+1} is matched with the item $V_{i(n)+k-1}$ of class $\mathbf{w}_k$. Suppose that

$$F_n = \overset{\leftarrow}{\overline{\mathbf{w}'}} = \mathbf{w}_k\overline{\mathbf{w}_q}\,\overline{\mathbf{w}_{q-1}}...\overline{\mathbf{w}_{k+1}}\,a\,\overline{\mathbf{w}_{k-1}}...\overline{\mathbf{w}_1}.$$

Then from Lemma 1, $\mathbf{w}_k$ is not adjacent to any of the elements of $\mathcal{V}\left(\overline{\mathbf{w}_q}\,\overline{\mathbf{w}_{q-1}}...\overline{\mathbf{w}_{k+1}}\right)$. But $\mathbf{w}_k - a$, so the item V_{n+1} of class $\mathbf{w}_k$ is matched with the item $V_{n+q-k+2}$ of class a, and we have with probability 1,

$$F_{n+1} = \overline{\mathbf{w}_q}\,\overline{\mathbf{w}_{q-1}}...\overline{\mathbf{w}_{k+1}}\,\overline{\mathbf{w}_k}\,\overline{\mathbf{w}_{k-1}}...\overline{\mathbf{w}_1} = \overset{\leftarrow}{\overline{\mathbf{w}}}.$$

Therefore, in this case,

$$\nu_B\left(\overset{\leftarrow}{\overline{\mathbf{w}'}}\right) \mathbb{P}\left[F_{n+1} = \overset{\leftarrow}{\overline{\mathbf{w}}} | F_n = \overset{\leftarrow}{\overline{\mathbf{w}'}}\right] = \nu_B\left(\overset{\leftarrow}{\overline{\mathbf{w}'}}\right)$$
$$= \nu_B\left(\overset{\leftarrow}{\overline{\mathbf{w}}}\right)\mu(a)$$
$$= \nu_B(\mathbf{w})\mu(a) = \nu_B(\mathbf{w})\mathbb{P}\left[B_{n+1} = \mathbf{w}' | B_n = \mathbf{w}\right].$$

(3) Now, suppose that $\mathbf{w} \neq \emptyset$ and $\mathbf{w}' = \mathbf{w}_k\mathbf{w}_{k+1}...\mathbf{w}_q\overline{\mathbf{w}_1}$ for some $k \in [\![2,q]\!]$. This means that the class of item V_{n+1} belongs to $\mathcal{E}\left(\mathbf{w}_1\right)$, so V_{n+1} is matched with the oldest item in line $V_{i(n)}$. Then $\mathbf{w}_2, \mathbf{w}_3, ..., \mathbf{w}_{k-1}$ all belong to $\overline{\mathcal{V}}$, and so $\mathbf{w}_k \in \mathcal{V}$ and is the class of the oldest item in line after $V_{i(n)}$, now becoming the new oldest one. Suppose that

$$F_n = \overset{\leftarrow}{\overline{\mathbf{w}'}} = \mathbf{w}_1\overline{\mathbf{w}_q}\,\overline{\mathbf{w}_{q-1}}...\overline{\mathbf{w}_{k+1}}\,\overline{\mathbf{w}_k}.$$

Applying again Lemma 1, we obtain that $\mathbf{w}_1$ is not adjacent to any of the elements of the set $\mathcal{V}\left(\overline{\mathbf{w}_q}\,\overline{\mathbf{w}_{q-1}}...\overline{\mathbf{w}_k}\right)$, so the state $\overset{\leftarrow}{\overline{\mathbf{w}'}}$ clearly belongs to $\mathbb{F}$. All the same, again in view of Lemma 1, $\mathbf{w}_1$ is not adjacent to any of the elements $\overline{\mathbf{w}_2}, \overline{\mathbf{w}_3}, ..., \overline{\mathbf{w}_{k-1}}$, which all are elements of $\mathcal{V}$. So we obtain

$$F_{n+1} = \overline{\mathbf{w}_q}\,\overline{\mathbf{w}_{q-1}}...\overline{\mathbf{w}_{k+1}}\,\overline{\mathbf{w}_k}\,\overline{\mathbf{w}_{k-1}}...\overline{\mathbf{w}_2}\,\overline{\mathbf{w}_1} = \overset{\leftarrow}{\overline{\mathbf{w}}}$$

if the incoming items $V_{n+q-k+3},...,V_{n+q}$ are of respective classes $\overline{\mathbf{w}_{k-1}},...,\overline{\mathbf{w}_2}$ and V_{n+q+1} is of a class belonging to $\mathcal{E}\left(\mathbf{w}_1\right)$. This occurs with probability

$$\mu\left(\overline{\mathbf{w}_{k-1}}\right)...\mu\left(\overline{\mathbf{w}_2}\right)\mu\left(\mathcal{E}\left(\mathbf{w}_1\right)\right).$$

Gathering all the above we obtain that

$$\nu_B\left(\overset{\leftarrow}{\overline{\mathbf{w}'}}\right) \mathbb{P}\left[F_{n+1} = \overset{\leftarrow}{\overline{\mathbf{w}}} | F_n = \overset{\leftarrow}{\overline{\mathbf{w}'}}\right] = \nu_B\left(\overset{\leftarrow}{\overline{\mathbf{w}'}}\right)\mu\left(\overline{\mathbf{w}_{k-1}}\right)...\mu\left(\overline{\mathbf{w}_2}\right)\mu\left(\mathcal{E}\left(\mathbf{w}_1\right)\right)$$
$$= \nu_B\left(\overset{\leftarrow}{\overline{\mathbf{w}}}\right)\mu\left(\mathcal{E}\left(\mathbf{w}_1\right)\right)$$
$$= \nu_B(\mathbf{w})\mu\left(\mathcal{E}\left(\mathbf{w}_1\right)\right) = \nu_B(\mathbf{w})\mathbb{P}\left[B_{n+1} = \mathbf{w}' | B_n = \mathbf{w}\right].$$

9

(4) Suppose now that $\mathbf{w} \neq \emptyset$ and $\mathbf{w}' = \emptyset$, which is possible only if $\mathbf{w}_1 \in \mathcal{V}$, the incoming item V_{n+1} belongs to $\mathcal{E}(\mathbf{w}_1)$, and if $q \geq 2$, $\mathbf{w}_2, ..., \mathbf{w}_q \in \overline{\mathcal{V}}$, which implies again from Lemma 1 that $\mathbf{w}_1 \neq \overline{\mathbf{w}_j}$ for any $j \in [\![2, q]\!]$. Thus, $F_n = \emptyset$ leads to the state $F_{n+1} = \overleftarrow{\overline{\mathbf{w}}} = \overline{\mathbf{w}_q}\,\overline{\mathbf{w}_{q-1}}....\overline{\mathbf{w}_2}\,\overline{\mathbf{w}_1}$ if and only if V_{n+1} is of class $\mathbf{w}_1$, and then V_{n+2} is of class $\overline{\mathbf{w}_q}$, V_{n+3} is of class $\overline{\mathbf{w}_{q-1}}$, and so on ..., V_{n+q} is of class $\overline{\mathbf{w}_2}$ and V_{n+q+1} is of a class belonging to $\mathcal{E}(\mathbf{w}_1)$. This event occurs with probability $\mu(\mathbf{w}_1)\mu(\overline{\mathbf{w}_q})....\mu(\overline{\mathbf{w}_2})\mu(\mathcal{E}(\mathbf{w}_1))$. So we obtain

$$\nu_B(\emptyset)\,\mathbb{P}\left[F_{n+1} = \overleftarrow{\overline{\mathbf{w}}}|F_n = \emptyset\right] = \mu(\mathbf{w}_1)\,\mu(\overline{\mathbf{w}_2})\mu(\overline{\mathbf{w}_3})...\mu(\overline{\mathbf{w}_q})\mu(\mathcal{E}(\mathbf{w}_1))$$

$$= \nu_B(\mathbf{w})\mu(\mathcal{E}(\mathbf{w}_1)) = \nu_B(\mathbf{w})\mathbb{P}[B_{n+1} = \mathbf{w}'|B_n = \mathbf{w}].$$

(5) The only case that remains to be treated is when $\mathbf{w} = \emptyset$. Then for any $a \in \mathcal{V}$, we obtain $B_{n+1} = a$ provided that V_{n+1} is of class a, which occurs with probability $\mu(a)$. Then, $F_n = \overline{a}$ means that V_{n+1} is matched with an item of class a that was entered before n. Then we necessarily have that $F_{n+1} = \emptyset$, and thus

$$\nu_B(\overline{a})\,\mathbb{P}[F_{n+1} = \emptyset|F_n = \overline{a}] = \nu_B(a) = \mu(a) = \nu_B(\emptyset)\mathbb{P}[B_{n+1} = a|B_n = \emptyset].$$

This completes the proof.   ∎

We can now turn to the proof of Proposition 1.

Proof of Proposition 1. Suppose that μ belongs to the set $\text{NCOND}(G)$ defined by (3). From Lemma 1, we know that for any word $\mathbf{w}$ in $\mathbb{B}$, $\mathcal{V}(\mathbf{w})$ is an element of $\mathbb{I}(G)$, that is, the letters of $\mathcal{V}$ present in $\mathbf{w}$ form an independent set of $\mathcal{V}$. Also, the intermediate letters of $\mathbf{w}$ in $\overline{\mathcal{V}}$ have counterparts in $\mathcal{V}$ that are not adjacent to any prior letter of $\mathbf{w}$ in $\mathcal{V}$. Therefore, we can partition the set $\mathbb{B}$ as follows: Denote for any independent set $\mathcal{I} := \{i_1, ..., i_{|\mathcal{I}|}\} \in \mathbb{I}(G)$, and for any permutation σ in $\mathfrak{S}_{|\mathcal{I}|}$, by $\mathbb{B}_{\mathcal{I},\sigma}$, the set of non-empty words $\mathbf{w} \in \mathbb{B}$ whose letters in $\mathcal{V}$ are exactly the elements of $\mathcal{I}$ (i.e., $\mathcal{V}(\mathbf{w}) = \mathcal{I}$), and $i_{\sigma(1)}$, $i_{\sigma(2)}$, ... $i_{\sigma(|\mathcal{I}|)}$ denote the letters of $\mathcal{V}(\mathbf{w})$ ranked in their order of first occurence in the word $\mathbf{w}$. In other words, in $\mathbf{w}$ read from left to right, the letter $i_{\sigma(1)}$ appears first (possibly several times), the first letter in $\mathcal{V}(\mathbf{w}) \setminus \{i_{\sigma(1)}\}$ is $i_{\sigma(2)}$, the first letter in $\mathcal{V}(\mathbf{w}) \setminus \{i_{\sigma(1)}, i_{\sigma(2)}\}$ is $i_{\sigma(3)}$, and so on. Then, we clearly have the following disjoint union,

$$\mathbb{B} = \{\emptyset\} \cup \bigcup_{\mathcal{I} \in \mathbb{I}(G)} \bigcup_{\sigma \in \mathfrak{S}_{|\mathcal{I}|}} \mathbb{B}_{\mathcal{I},\sigma}. \tag{13}$$

Now, fix $\mathcal{I} \in \mathbb{I}(G)$ and $\sigma \in \mathfrak{S}_{|\mathcal{I}|}$. Then, for any word $\mathbf{w}$ in $\mathbb{B}_{\mathcal{I},\sigma}$, and any $j \in [\![1, |\mathcal{I}|]\!]$, between the first occurrence of the letter $i_{\sigma(j)}$ (excluded) and the first occurrence of the letter $i_{\sigma(j+1)}$ (or to the right of $i_{\sigma(|\mathcal{I}|)}$ if $j \equiv |\mathcal{I}|$), there are, say, $\varphi(j)$ letters in $\mathbf{w}$ (where $\varphi(j) \in \mathbb{N}$) that belong to the set $\{i_{\sigma(1)}, ..., i_{\sigma(j)}\}$. Denote these letters (again, read from left to right) by $k_1, ..., k_{\varphi(j)}$, and set $k_0 := i_{\sigma(j)}$. In between these letters, say between k_l and k_{l+1} for $\varphi(j) > 0$ and $l \in [\![0, \varphi(j) - 1]\!]$ (or to the right of $k_{\varphi(j)}$ for $l \equiv \varphi(j)$), there can be in $\mathbf{w}$, any number $\psi(l) \in \mathbb{N}$ of letters in $\overline{\mathcal{V}}$ whose counterpart in $\mathcal{V}$ are element of $\mathcal{E}(\{i_{\sigma(1)}, ..., i_{\sigma(j)}\})^c$. Denote by $\{h_1, ..., h_{r(j)}\}$, the elements of $\mathcal{E}(\{i_{\sigma(1)}, ..., i_{\sigma(j)}\})^c$, whenever the latter is non empty. Denoting also for all $m = 1, ..., r(j)$, by p_m, the number of occurences

of the letter $\overline{h_m}$ in between k_l and k_{l+1} in the word $\mathbf{w}$, we obtain the following,

$$
\nu_B\left(\mathbb{B}_{\mathcal{I},\sigma}\right) = \prod_{j=1}^{|\mathcal{I}|} \sum_{\varphi(j)\in\mathbb{N}} \sum_{\substack{(k_1,\ldots,k_{\varphi(j)}) \\ \in\{i_{\sigma(1)},\ldots,i_{\sigma(j)}\}^{\varphi(j)}}} \prod_{l=0}^{\varphi(j)} \mu(k_l) \sum_{\psi(l)\in\mathbb{N}} \sum_{\substack{p_1,\ldots,p_{r(j)}\in\mathbb{N}: \\ p_1+\ldots+p_{r(j)}=\psi(l)}} \binom{\psi(l)}{p_1,\ldots,p_{r(j)}} \prod_{m=1}^{r(j)} \mu\left(h_m\right)^{p_m}
$$

$$
= \prod_{j=1}^{|\mathcal{I}|} \sum_{\varphi(j)\in\mathbb{N}} \sum_{\substack{(k_1,\ldots,k_{\varphi(j)}) \\ \in\{i_{\sigma(1)},\ldots,i_{\sigma(j)}\}^{\varphi(j)}}} \prod_{l=0}^{\varphi(j)} \mu(k_l) \sum_{\psi(l)\in\mathbb{N}} \left(\sum_{m=1}^{r(j)} \mu(h_m)\right)^{\psi(l)}
$$

$$
= \prod_{j=1}^{|\mathcal{I}|} \sum_{\varphi(j)\in\mathbb{N}} \sum_{\substack{(k_1,\ldots,k_{\varphi(j)}) \\ \in\{i_{\sigma(1)},\ldots,i_{\sigma(j)}\}^{\varphi(j)}}} \prod_{l=0}^{\varphi(j)} \frac{\mu(k_l)}{\mu\left(\mathcal{E}\left(\{i_{\sigma(1)},\ldots,i_{\sigma(j)}\}\right)\right)},
$$

where products and sums over empty sets are respectively understood as 1 and 0. Now, if $\varphi(j) > 0$, denoting for all $n = 1,\ldots,j$, by q_n, the number of occurences of the letter $i_{\sigma(n)}$ in the word $k_1\ldots k_{\varphi(j)}$, the above becomes

$$
\nu_B\left(\mathbb{B}_{\mathcal{I},\sigma}\right) = \prod_{j=1}^{|\mathcal{I}|} \frac{\mu\left(i_{\sigma(j)}\right)}{\mu\left(\mathcal{E}\left(\{i_{\sigma(1)},\ldots,i_{\sigma(j)}\}\right)\right)} \sum_{\varphi(j)\in\mathbb{N}} \frac{\displaystyle\sum_{\substack{q_1,\ldots,q_j\in\mathbb{N}: \\ q_1+\ldots+q_j=\varphi(j)}} \binom{\varphi(j)}{q_1,\ldots,q_j} \prod_{n=1}^{j} \mu\left(i_{\sigma(n)}\right)^{q_n}}{\mu\left(\mathcal{E}\left(\{i_{\sigma(1)},\ldots,i_{\sigma(j)}\}\right)\right)^{\varphi(j)}}
$$

$$
= \prod_{j=1}^{|\mathcal{I}|} \frac{\mu\left(i_{\sigma(j)}\right)}{\mu\left(\mathcal{E}\left(\{i_{\sigma(1)},\ldots,i_{\sigma(j)}\}\right)\right)} \sum_{\varphi(j)\in\mathbb{N}} \left(\frac{\mu\left(\{i_{\sigma(1)},\ldots,i_{\sigma(j)}\}\right)}{\mu\left(\mathcal{E}\left(\{i_{\sigma(1)},\ldots,i_{\sigma(j)}\}\right)\right)}\right)^{\varphi(j)}
$$

$$
= \prod_{j=1}^{|\mathcal{I}|} \frac{\mu\left(i_{\sigma(j)}\right)}{\mu\left(\mathcal{E}\left(\{i_{\sigma(1)},\ldots,i_{\sigma(j)}\}\right)\right)} \frac{\mu\left(\mathcal{E}\left(\{i_{\sigma(1)},\ldots,i_{\sigma(j)}\}\right)\right)}{\mu\left(\mathcal{E}\left(\{i_{\sigma(1)},\ldots,i_{\sigma(j)}\}\right)\right) - \mu\left(\{i_{\sigma(1)},\ldots,i_{\sigma(j)}\}\right)}
$$

$$
= \prod_{j=1}^{|\mathcal{I}|} \frac{\mu\left(i_{\sigma(j)}\right)}{\mu\left(\mathcal{E}\left(\{i_{\sigma(1)},\ldots,i_{\sigma(j)}\}\right)\right) - \mu\left(\{i_{\sigma(1)},\ldots,i_{\sigma(j)}\}\right)},
$$

where the assumption that $\mu \in \text{NCOND}(G)$ is used in the third equality, as $\{i_{\sigma(1)},\ldots,i_{\sigma(j)}\}$ is an independent set of G for any j as above. As a conclusion, from (13) we obtain that

$$
\nu_B(\mathbb{B}) = 1 + \sum_{\mathcal{I}\in\mathbb{I}(G)} \sum_{\sigma\in\mathfrak{S}_{|\mathcal{I}|}} \prod_{j=1}^{|\mathcal{I}|} \frac{\mu\left(i_{\sigma(j)}\right)}{\mu\left(\mathcal{E}\left(\{i_{\sigma(1)},\ldots,i_{\sigma(j)}\}\right)\right) - \mu\left(\{i_{\sigma(1)},\ldots,i_{\sigma(j)}\}\right)}, \tag{14}
$$

and so ν_B is a finite measure on $\mathbb{B}$.

Then, it suffices to apply Kelly's Lemma ([10], Section 1.7): define for any $\mathbf{w}, \mathbf{w}' \in \mathbb{B}$,

$$
P_{\mathbf{w}',\mathbf{w}} = \frac{\mathbb{P}\left[B_{n+1} = \mathbf{w}' \mid B_n = \mathbf{w}\right] \nu_B(\mathbf{w})}{\nu_B(\mathbf{w}')}. \tag{15}
$$

Then, ν_B is a stationary distribution of $(B_n)_{n\in\mathbb{N}}$ if P defines a transition operator on $\mathbb{B}$. But this is a simple consequence of Lemmas 2 and 3: for any $\mathbf{w}' \in \mathbb{B}$ we have that

$$
\sum_{\mathbf{w}\in\mathbb{B}} P_{\mathbf{w}',\mathbf{w}} = \sum_{\mathbf{w}\in\mathbb{B}} \frac{\nu_B\left(\overleftarrow{\mathbf{w}'}\right) \mathbb{P}\left[F_{n+1} = \overleftarrow{\overline{\mathbf{w}}} \mid F_n = \overleftarrow{\mathbf{w}'}\right]}{\nu_B(\mathbf{w}')}
$$

$$
= \sum_{\mathbf{w}\in\mathbb{B}} \mathbb{P}\left[F_{n+1} = \overleftarrow{\overline{\mathbf{w}}} \mid F_n = \overleftarrow{\mathbf{w}'}\right] = 1,
$$

which concludes the proof   ∎

Remark 1. As is easily seen, we can exchange the roles of B_n, B_{n+1} and F_n, F_{n+1} in (15), implying that $(F_n)_{n \in \mathbb{N}}$ is the reversed Markov chain of $(B_n)_{n \in \mathbb{N}}$, on a sample space where arrivals are reversed in time and exchanged with their match. In particular, the forward chain $(F_n)_{n \in \mathbb{N}}$ also admits ν_B as a stationary measure on $\mathbb{F}$.

We are now in position to prove our main result.

3.3 Proof of Theorem 1

We know from Proposition 2 of [11] that if μ is not an element of $\mathrm{NCOND}(G)$, then the chain $(W_n)_{n \in \mathbb{N}}$ is transient or null recurrent. If we now assume that $\mu \in \mathrm{NCOND}(G)$, then, first, observe that in view of (14), the measure defined for all $\mathbf{w} \in \mathbb{B}$ by $\alpha \nu_B(\mathbf{w})$, for α in (5) and ν_B defined by (8), defines a probability measure on $\mathbb{B}$. Second, from Proposition 1, the auxiliary chain $(B_n)_{n \in \mathbb{N}}$ is positive recurrent, and admits ν_B as a stationary measure. So from (6), $(W_n)_{n \in \mathbb{N}}$ is also positive recurrent. As it is also irreducible on $\mathbb{W}$, it has a unique stationary probability. To check that the latter is given by Π_W defined by (4), it thus suffices to check that

$$\Pi_W(w) = \alpha \sum_{\mathbf{w} \in \mathbb{B} : \, \mathbf{w}|_{\mathcal{V}} = w} \nu_B(\mathbf{w}) \quad \text{for any } w \in \mathbb{W}.$$

Let $w = w_1 ... w_q \in \mathbb{W}$. From Lemma 1, any $\mathbf{w} \in \mathbb{B}$ such that $\mathbf{w}|_{\mathcal{V}} = w$ is of the form

$$\mathbf{w} = w_1 \overline{a_{11}}\, \overline{a_{12}} ... \overline{a_{1k_1}}\, w_2\, \overline{a_{21}} ... \overline{a_{2k_2}}\, w_3 ... w_q \overline{a_{q1}} ... \overline{a_{qk_q}},$$

where any of the elements $a_{\ell j}$ is such that $a_{\ell j} \neq w_i$ for any $i \leq \ell$. We then obtain that

$$
\begin{aligned}
\alpha \sum_{\mathbf{w} \in \mathbb{B} : \, \mathbf{w}|_{\mathcal{V}} = w} \nu_B(\mathbf{w}) &= \alpha \prod_{\ell=1}^{q} \left(\mu(w_\ell) \left(1 + \sum_{k \in \mathbb{N}_+} \sum_{(a_{\ell 1}, ..., a_{\ell k}) \in (\mathcal{E}(\{w_1, ..., w_\ell\})^c)^k} \prod_{j=1}^{k} \mu(a_{\ell j}) \right) \right) \\
&= \alpha \prod_{\ell=1}^{q} \left(\mu(w_\ell) \sum_{k \in \mathbb{N}} \left(\mu \Big(\mathcal{E}\big(\{w_1, ..., w_\ell\} \big)^c \Big) \right)^k \right) \\
&= \alpha \prod_{\ell=1}^{q} \frac{\mu(w_\ell)}{1 - \mu \Big(\mathcal{E}\big(\{w_1, ..., w_\ell\} \big)^c \Big)} \\
&= \alpha \prod_{\ell=1}^{q} \frac{\mu(w_\ell)}{\mu \Big(\mathcal{E}\big(\{w_1, ..., w_\ell\} \big) \Big)} = \Pi_W(w).
\end{aligned}
$$

3.4 Characteristics at equilibrium

We can easily deduce from Theorem 1, closed form formulas for performance measures of the system in steady state. Denote by W_∞, the stationary queue detail of the system, that is, a random variable distributed following the stationary probability Π_W.

First, for any class $i \in \mathcal{V}$, the average number of items of class i in storage at equilibrium is given by

$$\mathbf{E}\left[|W_\infty|_i \right] = \sum_{k \in \mathbb{N}} k \Pi_W \left(\{ w \in \mathbb{W} : |w|_i = k \} \right),$$

for Π_W in (4). The average total number of items in storage at equilibrium then reads

$$\mathbf{E}\left[|W_\infty|\right] = \sum_{i \in \mathcal{V}} \mathbf{E}\left[|W_\infty|_i\right] = \sum_{k \in \mathbb{N}} k \Pi_W \left(\{w \in \mathbb{W} \,:\, |w| = k\}\right).$$

According to Little's law, for any $i \in \mathcal{V}$, the waiting time before getting matched, for an item of class i entering the system in steady state, is given by

$$\frac{\mathbf{E}\left[|W_\infty|\right]}{\mu(i)} = \frac{1}{\mu(i)} \sum_{k \in \mathbb{N}} k \Pi_W \left(\{w \in \mathbb{W} \,:\, |w|_i = k\}\right).$$

In particular, the probability that a class i-item does have to wait before getting matched in a stationary system reads

$$\mathbb{P}\left[|W_\infty|_{\mathcal{E}(i)} = 0\right] = \Pi_W \left(\{w \in \mathbb{W} \,:\, |w|_{\mathcal{E}(i)} = 0\}\right),$$

for Π_W in (4).

4 Perfect FCFM-matchings

4.1 Perfect Infinite FCFM-matchings

As is easily seen, the model (G, μ, FCFM) generates a family of random graphs, as follows. For any $n \in \mathbb{N}$, we consider the (initially empty) FCFM-matching

$$\mathbf{M}_n^0 := M^{\text{FCFM}}\left(V_0 \dots V_{n-1}\right),$$

that is, the random graph in which the nodes are the items from 0 to $n-1$, and there is an edge between two nodes if and only if the corresponding items are matched in FCFM. The nodes of this random graph are labelled according to their classes, and (implicitly) to their arrival dates. However, for notational simplicity, we only keep the first labelling (i.e., the classes), and remove the second one, which is implicitly given by the order of nodes (from left to right) in Figures 3 and 4 below.

The definition of a FCFM-matching can then be extended to any time points $m < n$ in $\mathbb{N}$ such that $W_m = \emptyset$, by setting

$$\mathbf{M}_n^m := M^{\text{FCFM}}\left(V_m \dots V_{n-1}\right).$$

In $\mathbf{M}_n^m$, all nodes are of degree 0 or 1. The finite matching $\mathbf{M}_n^m$ is then said to be *perfect* if all of its nodes are of degree 1. It is then immediate that for any m such that $W_m = \emptyset$ and any $n > m$, $\mathbf{M}_n^m$ is an induced subgraph of $\mathbf{M}_{n+1}^m$. See in Figure 3, an example concerning once again the graph G of Figure 1.

In particular, we can easily construct from the increasing sequence $\left(\mathbf{M}_n^0\right)_{n \in \mathbb{N}}$, the limiting object $\mathbf{M}_\infty^0$ as the infinite labelled random graph obtained when letting n go to infinity in the above. We then say that $\mathbf{M}_\infty^0$ is perfect if all its nodes are of degree 1. We have the following result,

Proposition 2. *If the graph G is non-bipartite and condition (3) is satisfied, then the infinite labelled random graph $\mathbf{M}_\infty^0$ is a.s. perfect.*

Proof. From Theorem 1, the chain $\left(W_n^{\{\emptyset\}}\right)_{n \in \mathbb{N}}$ is positive recurrent, so the family of integers

$$\mathscr{C} := \left\{n \in \mathbb{N} \,:\, W_n^{\{\emptyset\}} = \emptyset\right\}$$

is a.s. infinite. The elements of the latter set, denoted $0 := C_0 < C_1 < C_2 < \dots$, are called *construction points* of the model. Then, we readily get

$$\mathbf{M}_\infty^0 = \lim_{k \to \infty} \mathbf{M}_{C_k}^0 = \lim_{k \to \infty} \bigcup_{j=1}^{k} \mathbf{M}_{C_j}^{C_{j-1}} = \bigcup_{j=1}^{\infty} \mathbf{M}_{C_j}^{C_{j-1}},$$

13

Figure 3: Construction of the increasing sequence $\left(\mathbf{M}_n^0\right)_{n\in\mathbb{N}}$ and the constructions points, for the compatibility graph G of Figure 1 and the sample 134231.

which is a union of finite perfect FCFM-matchings. It follows that all the nodes are of degree 1. ∎

4.2 Perfect FCFM-matchings in reverse time

Perfect FCFM-matchings have an interesting time-reversibility property. First, observe that we can complete the "exchange" mechanism introduced in Section 3.1, using construction points as follows: Consider two construction points $C_m < C_n \in \mathscr{C}$. Then, in the perfect finite FCFM-matching $\mathbf{M}_{C_n}^{C_m}$, replace the indexes of all nodes (i.e. the classes of the corresponding items) by the copies of the classes of their matches. Last, keep all edges of $\mathbf{M}_{C_n}^{C_m}$ unchanged. This procedure is illustrated in Figure 4.

Figure 4: Top: A perfect FCFM-matching on two construction points, say $\mathbf{M}_{C_n}^{C_{n-2}}$.

Middle: The matching $\mathbf{M}_{C_n}^{C_{n-2}}$ after completing the exchanges on the two perfectly matched blocks.

Bottom: The resulting matching $\overline{\mathbf{M}_{C_{n-2}}^{\overleftarrow{C_n}}}$ after time reversal is a FCFM-matching.

It is then immediate to observe that the resultant indexed random graph, which we denote $\overline{\mathbf{M}_{C_m}^{\overleftarrow{C_n}}}$, is a perfect matching in the sense that all its nodes are a.s. of degree 1. We call it the *reversed* perfect matching between C_n and C_m. We have the following result,

Proposition 3. *For all $n > 0$, the reversed perfect matching $\overline{\mathbf{M}_0^{\overleftarrow{C_n}}} = \overline{\mathbf{M}_{C_0}^{\overleftarrow{C_n}}}$ obtained in the above procedure is a perfect FCFM-matching.*

14

Proof. Let the four nodes i, j, k and ℓ be such that in G, $i-k$, $j-k$ and $i-\ell$, and suppose that, for $m \leq n$, after the exchange procedure over the matching $\mathbf{M}_{C_m}^{C_{m-1}}$, four copies $\bar{i}$, $\bar{j}$, $\bar{k}$ and $\bar{\ell}$ are read in that order, in reverse time, i.e. from right to left. Let us also assume that the FCFM rule in reverse time is violated on this quadruple: then the $\bar{k}$ item is matched with the $\bar{j}$ item while the $\bar{i}$ item is still unmatched, and then the latter item is matched with the $\bar{\ell}$ item. This occurs if and only if, in direct time, the four items of classes i, j, k and ℓ arrive in that order, and the k item choses the j item over the i item for its match, and then the unmatched i item is matched with the ℓ item. This violates in turn the FCFM policy, according to which the k item should have been matched with the i item instead of the j item. Thus, the reversed perfect matching $\overline{\overleftarrow{\mathbf{M}_{C_{m-1}}^{C_m}}}$ is a perfect FCFM-matching. We finally observe that, by the very definition of the construction points,

$$\overline{\overleftarrow{\mathbf{M}_0^{C_n}}} = \bigcup_{m=1}^{n} \overline{\overleftarrow{\mathbf{M}_{C_{m-1}}^{C_m}}}.$$

It completes the proof.   ∎
