(Dated: July 10, 2022)

A renormalizable non-Abelian theory of strong interactions of pions, mediated by rho-mesons, is formulated at tree- and at one-loop level in perturbation theory. Hadron masses are generated through spontaneous symmetry breaking using the Higgs mechanism. Quantization and gauge fixing is achieved using the generalized class of R_ξ gauges. As an application of this theory, pion-pion scattering lengths are obtained at tree-level in good agreement with data.

I. INTRODUCTION

A viable Abelian renormalizable quantum field theory of pionic strong interactions mediated by a neutral, massive rho-meson was proposed long ago by Kroll, Lee and Zumino (KLZ) [1, 2]. The Lagrangian has the form

$$\mathcal{L} = \partial_\mu \phi \partial^\mu \phi^* - m^2 \phi \phi^* - \frac{1}{4} F_{\mu\nu} F^{\mu\nu} + \frac{1}{2} M^2 A_\mu A^\mu + i g_{\rho\pi\pi} A_\mu J_\pi^\mu + g_{\rho\pi\pi}^2 A_\mu A^\mu \phi \phi^*. \quad (1.1)$$

with m and M the pion and rho-meson masses, respectively, A_μ a vector field of the ρ_0 meson ($\partial_\mu A^\mu = 0$), ϕ a complex pseudo-scalar field describing the π^\pm mesons, $F_{\mu\nu}$ the field strength tensor, $F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu$, and J_π^μ the π^\pm current, $J_\pi^\mu = \phi^* \overleftrightarrow{\partial}^\mu \phi$, with $\partial_\mu J_\pi^\mu = 0$. Renormalizability is ensured by the massive gauge boson being coupled to a conserved current [3, 4]. This theory provides the necessary platform supporting the purely phenomenological Vector Meson Dominance Model (VMD) [5, 6]. Examples of successful applications of the KLZ theory are the electromagnetic form factor of the pion in the time-like region [7], as well as in the space-like region [8], and the pion scalar radius [9] and scalar form factor in the space-like region [10].

The Abelian nature of this theory limits the range of applications, and precludes its candidacy for becoming a viable theory covering the intermediate energy region between threshold, dominated by chiral perturbation theory (CHPT), and the onset of perturbative QCD. A clear way forward is to formulate a non-Abelian, renormalizable quantum field theory of pionic interactions, invoking spontaneous symmetry breaking to generate the mass of the gauge bosons. This approach is described in some detail here, at the tree-level in perturbation theory. As an application of this theory, the pion-pion scattering lengths are obtained, at tree-level, in good agreement with data. A one-loop determination would involve considerable work, well beyond the scope of this paper

II. SU(2) EXTENSION

A generalization of the Abelian KLZ theory must accommodate the full triplet of pseudoscalar pions $\{\pi^-, \pi^0, \pi^+\}$, and vector rho-mesons $\{\rho^-, \rho^0, \rho^+\}$. To accomplish this generalization some approximations to simplify the process are required. For instance, one can ignore the small mass differences between the charged and uncharged particles. These are $m_{\pi^\pm} - m_{\pi^0} = 4.5936 \pm 0.0005$ MeV, and $m_{\rho^\pm} - m_{\rho^0} = 0.7 \pm 0.8$ MeV, i.e. negligible on a hadronic scale. This degeneracy in masses allows for the use of the larger Isospin gauge group SU(2). The gauge principle guides in the construction of a Lagrangian which is invariant under SU(2) gauge transformations, and is renormalizable. This naturally leads to a Yang-Mills type Lagrangian. The pion field is labelled as $\Phi(x) \equiv \phi^a \in \{\phi^1, \phi^2, \phi^3\}$ and the rho-meson field as $A_\mu(x) \equiv A_\mu^a T^a$, with $A_\mu^a \in \{A_\mu^1, A_\mu^2, A_\mu^3\}$. The gauge transformation is

$$U = e^{i\alpha^a(x)T^a} \in \text{SU}(2), \quad (2.1)$$

$$\Phi \rightarrow \Phi' = U\Phi, \quad (2.2)$$

$$A_\mu \rightarrow A'_\mu = U A_\mu U^\dagger + \frac{1}{ie} U \partial_\mu U^\dagger, \quad (2.3)$$

with the covariant derivative being

$$D_\mu = \partial_\mu + ie T^a A_\mu^a, \quad (2.4)$$

and $a \in \{1, 2, 3\}$. Here $e \equiv g_{\rho\pi\pi}$ is the dimensionless gauge coupling, and T^a belongs to the SU(2) Lie algebra. We define

$$F_{\mu\nu}^a \equiv \partial_\mu A_\nu^a - \partial_\nu A_\mu^a, \quad (2.5)$$

so that the non-Abelian field strength tensor is

$$G_{\mu\nu}^a = F_{\mu\nu}^a - e \varepsilon_{abc} A_\mu^b A_\nu^c. \quad (2.6)$$

The locally SU(2) gauge invariant Lagrangian becomes

$$\mathcal{L} = \frac{1}{2} (D_\mu \Phi)^\dagger D^\mu \Phi - \frac{1}{4} G_{\mu\nu}^a G^{a\mu\nu}. \quad (2.7)$$

The gauge principle also allows for the inclusion of a polynomial with an infinite number of terms of the form

$$P(\Phi) = \sum_{n=1}^{\infty} c_n (\Phi^\dagger \Phi)^n \\ = -\frac{1}{2} b^2 \Phi^\dagger \Phi + \frac{\lambda_4}{8} (\Phi^\dagger \Phi)^2 + \sum_{n=3}^{\infty} c_n (\Phi^\dagger \Phi)^n. \quad (2.8)$$

This pionic quartic coupling term was left out in the U(1) KLZ model [1]. There is no legitimate reason at this stage to exclude this term, so it will be kept in the Lagrangian. For terms with $n > 3$, the c_n have dimension of inverse mass, $\text{Dim}[c_n] = M^{-n}$. This poses a problem for the requirements of a renormalizable theory [11]. Hence, terms with $n \geq 3$ will not be considered. The Lagrangian then takes the form

$$\mathcal{L}_{\phi A} = \frac{1}{2} (\partial_\mu \phi_a \partial^\mu \phi_a + b^2 \phi_a^2) - \frac{1}{2} e^2 \varepsilon_{aij} \varepsilon_{bjk} \phi_i \phi_k A_\mu^a A^{b\mu} \\ + \frac{1}{2} e \varepsilon_{aij} A_\mu^a (\phi_j \partial^\mu \phi_i - \phi_i \partial^\mu \phi_j) - \frac{\lambda_4}{8} (\phi_a^2 \phi_b^2) \\ - \frac{1}{4} F_{\mu\nu}^a F^{a\mu\nu} + \frac{1}{2} e \varepsilon_{abc} A^{b\mu} A^{c\nu} F_{\mu\nu}^a \\ - \frac{1}{4} e^2 \varepsilon_{abc} \varepsilon_{ade} A_\mu^b A_\nu^c A^{d\mu} A^{e\nu}. \quad (2.9)$$

III. SPONTANEOUS SYMMETRY BREAKING

The rho-meson mass will be generated dynamically through spontaneous symmetry breaking, invoking the Higgs mechanism. The Lagrangian, Eq.(2.9) would accomplish this but it would break Isospin symmetry. Thus, we introduce a complex doublet of fields X , which satisfies the gauge transformation

$$X \rightarrow X' = UX, \quad (3.1)$$

and construct an SU(2) gauge invariant Higgs Lagrangian,

$$\mathcal{L} = (D_\mu X)^\dagger (D^\mu X) - V(X, X^\dagger) - \kappa (X^\dagger X) (\Phi^\dagger \Phi), \quad (3.2)$$

where the potential $V(X, X^\dagger)$ is

$$V(X, X^\dagger) = \frac{\lambda}{8} (X^\dagger X)^2 - \frac{\mu^2}{2} (X^\dagger X), \quad (3.3)$$

which has been tuned for symmetry breaking with $\lambda > 0$, and $\mu^2 > 0$. The term $\kappa (X^\dagger X) (\Phi^\dagger \Phi)$ is present as it is gauge invariant, with κ a dimensionless coupling. The doublet is parametrized as

$$X = \frac{1}{\sqrt{2}} \begin{pmatrix} x_2 + ix_1 \\ x_0 - ix_3 \end{pmatrix}. \quad (3.4)$$

Defining $\nu^2 \equiv \frac{\mu^2}{\lambda}$, the X field acquires its vacuum expectation value with the above choice of a minimum. The

vacuum configuration is

$$X_M = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ 2\nu \end{pmatrix}. \quad (3.5)$$

Considering fluctuations around the minimum X_M we define

$$\chi \equiv X - X_M, \quad (3.6)$$

where χ is the new field perturbed around the vacuum, and parametrized as

$$\chi = \frac{1}{\sqrt{2}} \begin{pmatrix} \chi_2 + i\chi_1 \\ \chi_0 - i\chi_3 \end{pmatrix}, \quad (3.7)$$

Expressing the Lagrangian, Eq.(3.2), in terms of this new translated field and relabelling χ_0 as $\chi_0 \equiv H$, which we refer to as the Higgs field, leads to

$$\mathcal{L}_H = \frac{1}{2} (\partial_\mu H \partial^\mu H - \mu^2 H^2) + \frac{1}{2} \partial_\mu \chi_a \partial^\mu \chi_a \\ + i e \partial^\mu A_\mu^a \left[X_M^\dagger T^a \chi - \chi^\dagger T^a X_M \right] - \frac{1}{4} e \varepsilon_{abc} \left(\chi_a \overleftrightarrow{\partial}^\mu \chi_b \right) A_\mu^c \\ - \frac{1}{2} e \left(\chi_a \overleftrightarrow{\partial}^\mu H \right) A_\mu^a + \frac{1}{2} e^2 \nu^2 A_\mu^a A^{a\mu} + \frac{1}{2} e^2 \nu H A_\mu^a A^{a\mu} \\ + \frac{1}{8} e^2 H^2 A_\mu^a A^{a\mu} + \frac{1}{8} e^2 \chi_b^2 A_\mu^a A^{a\mu} - \frac{\lambda}{32} H^4 - \frac{\lambda}{16} H^2 \chi_a^2 \\ - \frac{\lambda}{32} \chi_a^2 \chi_b^2 - \frac{\nu\lambda}{4} H^3 - \frac{\nu\lambda}{4} H \chi_a^2 - \frac{1}{2} (4\kappa\nu^2) \phi_a^2 \\ - 2\kappa\nu H \phi_a^2 - \frac{1}{2} \kappa H^2 \phi_a^2 - \frac{1}{2} \kappa \chi_a^2 \phi_a^2 + \frac{1}{2} \mu^2 \nu^2. \quad (3.8)$$

Considering small perturbations around the vacuum field configuration generates the mass terms for the vector field, $\frac{1}{2} e^2 \nu^2 A_\mu^a A^{a\mu}$. A contribution to the potential of the pion was generated during the symmetry breaking process, $\frac{1}{2} (4\kappa\nu^2) \phi_a^2$. A mass term for the Higgs field was also generated in this process, $\frac{1}{2} \mu^2 H^2$. The χ_a are the three massless Goldstone fields. The classical Lagrangian is then given as the sum of the pion-rho Lagrangian and the Higgs Lagrangian

$$\mathcal{L}_{cl} \equiv \mathcal{L}_{\phi A} + \mathcal{L}_H \quad (3.9)$$

IV. FADDEEV-POPOV GHOSTS AND GAUGE FIXING

The classical Lagrangian, Eq.(3.9) is now ready for quantization. The gauge transformation partitions the configuration space of fields. Thus it sets up an equivalence class for sets of physically equivalent fields. Since there are infinitely many field configurations related to each other via a gauge transformation, this leads to a divergence when summing over all field contributions. Hence one needs to count only one member from each partition. This is done through a gauge fixing function designed to span the configuration space, and intersect the

set of all physically equivalent fields only once. This is implemented using the identity

$$\Delta[A] \int \mathcal{D}\mu[U] \delta[G^a(A[U]) - w^a] = 1, \quad (4.1)$$

where $\Delta[A]$ is a determinant, and $\mathcal{D}\mu[U]$ is the invariant Haar measure [11]. Inserting Eq.(4.1) into the path integral, and exploiting its invariance under gauge transformations, allows for the extraction of the multiplicative divergence. Dividing out the Haar volume, one can define a path integral not affected by over-counting as

$$\mathcal{Z} = \int \mathcal{D}A e^{iS[A]} \exp \left[-\frac{i}{2\xi} \int d^4x G_a^2(A) \right] \Delta[A], \quad (4.2)$$

where $\Delta[A]$ is the Faddeev-Popov determinant [12]

$$\Delta[A] = \det \left[\frac{\delta G^b[\alpha A; x]}{\delta \alpha^c(y)} \right] = \det M^{bc}(x, y). \quad (4.3)$$

One can choose a class of gauge fixing functions of the form [13, 14]

$$G^b[\alpha A; x] = \partial^\mu A_\mu^b + \xi i e \left(X_M^\dagger T^b \chi - \chi^\dagger T^b X_M \right). \quad (4.4)$$

Computing the variational derivative of the gauge fixing function with respect to the group parameters gives

$$\begin{aligned} M^{bc} &= \left[-\partial_x^\mu D_\mu^{bc} - \xi e^2 \nu^2 \delta^{bc} - \frac{1}{2} \xi e^2 \nu \chi_0 \delta^{bc} \right. \\ &\quad \left. + \frac{1}{2} \xi e^2 \nu \chi_a \varepsilon_{abc} \right] \frac{1}{e} \delta(x - y). \end{aligned} \quad (4.5)$$

The Faddeev-Popov determinant can be expressed as a Berezin-type functional integral [15] over Grassmann fields

$$\begin{aligned} \Delta[A] &= \det[M^{bc}] \\ &= \int \mathcal{D}\bar{u} \mathcal{D}u \exp \left[-i e \int d^4x d^4y \bar{u}^b(x) M^{bc}(x, y) u^c(y) \right], \end{aligned} \quad (4.6)$$

where \bar{u}^a, u^a are the anti-commuting Grassmann fields (Faddeev-Popov ghosts). Substituting the determinant into the path integral leads to

$$\mathcal{Z} = \int \mathcal{D}\bar{u} \mathcal{D}u \mathcal{D}A \exp \left(i \int d^4x \mathcal{L}_{\text{eff}} \right), \quad (4.7)$$

where

$$\begin{aligned} \mathcal{L}_{\text{eff}} &= \mathcal{L}_{\text{cl}} - \frac{1}{2\xi} G_a^2(A) + \bar{u}^a (\partial^\mu \partial_\mu + \xi e^2 \nu^2) u^a \\ &\quad + e \varepsilon_{abc} A_\mu^a (\partial^\mu \bar{u}^b) u^c + \frac{1}{2} \xi e^2 \nu \chi_0 \bar{u}^a u^a \\ &\quad - \frac{1}{2} \xi e^2 \nu \varepsilon_{abc} \chi_a \bar{u}^b u^c. \end{aligned} \quad (4.8)$$

V. SCATTERING LENGTHS

We consider the elastic scattering process

$$\phi^a(p_1) + \phi^b(p_2) \rightarrow \phi^c(p_3) + \phi^d(p_4), \quad (5.1)$$

where particles are external asymptotic states, i.e. $p_i^2 = m^2$. We label the incoming and outgoing three momentum in the centre of mass frame as \mathbf{q} and \mathbf{q}' , respectively, with the constraints

$$\mathbf{q} \neq \mathbf{q}' \quad \text{and} \quad |\mathbf{q}| = |\mathbf{q}'|. \quad (5.2)$$

Next, the cosine of the scattering angle and the ratio R are

$$z = \cos \theta, \quad R = \frac{|\mathbf{q}|^2}{m^2}. \quad (5.3)$$

The Mandelstam invariants in terms of z and R are

$$s = 4m^2(1 + R), \quad (5.4)$$

$$t = -2m^2(1 - z)R, \quad (5.5)$$

$$u = -2m^2(1 + z)R. \quad (5.6)$$

A. Tree-Level Scattering Lengths

We are now in a position to calculate the pion-pion scattering lengths. The required tree-level diagrams generated from the Feynman rules are shown in figure 1. The s channel scattering process mediated by the rho meson leads to the amplitude

$$M_s^A = S_A (\delta_{ad} \delta_{bc} - \delta_{ac} \delta_{bd}), \quad (5.7)$$

$$S_A = -4i e^2 m^2 \frac{z R}{4m^2(1 + R) - M^2}. \quad (5.8)$$

In the t channel it becomes

$$M_t^A = T_A (\delta_{ab} \delta_{cd} - \delta_{bc} \delta_{ad}), \quad (5.9)$$

$$T_A = 2i e^2 m^2 \frac{2 + (3 + z) R}{2m^2(1 - z) R + M^2}, \quad (5.10)$$

and in the u channel

$$M_u^A = U_A (\delta_{ab} \delta_{cd} - \delta_{ac} \delta_{bd}), \quad (5.11)$$

$$U_A = 2i e^2 m^2 \frac{2 + (3 - z) R}{2m^2(1 + z) R + M^2}. \quad (5.12)$$

The total amplitude is then

$$\begin{aligned} T_A^{ab,cd} &= (T_A + U_A) \delta_{ab} \delta_{cd} - (S_A + U_A) \delta_{ac} \delta_{bd} \\ &\quad + (S_A - T_A) \delta_{ad} \delta_{bc}. \end{aligned} \quad (5.13)$$

For the s, t and u channel scattering processes mediated by the Higgs-boson the results are

$$M_s^H = S_H \delta_{ab} \delta_{cd}, \quad S_H = -i \frac{16\kappa^2 \nu^2}{s - m_H^2}, \quad (5.14)$$

$$M_t^H = T_H \delta_{ac} \delta_{bd}, \quad T_H = -i \frac{16\kappa^2 \nu^2}{t - m_H^2}, \quad (5.15)$$

$$M_u^H = U_H \delta_{ad} \delta_{bc}, \quad U_H = -i \frac{16\kappa^2 \nu^2}{u - m_H^2}. \quad (5.16)$$

The total amplitude due to the Higgs-boson is

$$T_H^{ab,cd} = S_H \delta_{ab} \delta_{cd} + T_H \delta_{ac} \delta_{bd} + U_H \delta_{ad} \delta_{bc}. \quad (5.17)$$

Finally, the amplitude due to four-pion scattering is

$$T_\lambda^{ab,cd} = S_\lambda (\delta_{ab} \delta_{cd} + \delta_{ad} \delta_{bc} + \delta_{ac} \delta_{bd}), \quad S_\lambda = -i\lambda_4. \quad (5.18)$$

FIG. 1: Tree-level $\pi - \pi$ scattering processes.

B. Isospin Amplitudes

The most general form of the scattering amplitude is

$$M^{ab,cd} = F(s, t, u) \delta_{ab} \delta_{cd} + G(s, t, u) \delta_{ac} \delta_{bd} + H(s, t, u) \delta_{ad} \delta_{bc}. \quad (5.19)$$

This amplitude can be decomposed in an Isospin invariant basis as

$$M^{ab,cd} = \sum_{m=0}^2 T^m P_m^{abcd}, \quad (5.20)$$

where T^m are the Isospin amplitudes and the basis vectors [19] are

$$P_0^{abcd} = \frac{1}{3} \delta_{ab} \delta_{cd}, \quad (5.21)$$

$$P_1^{abcd} = \frac{1}{2} (\delta_{ac} \delta_{bd} - \delta_{ad} \delta_{bc}), \quad (5.22)$$

$$P_2^{abcd} = \frac{1}{2} (\delta_{ac} \delta_{bd} + \delta_{ad} \delta_{bc}) - \frac{1}{3} \delta_{ab} \delta_{cd}. \quad (5.23)$$

Expanding the amplitude, Eq.(5.20), and identifying coefficients of the Kronecker delta between Eq.(5.19) and Eq.(5.20), leads to a system of linear equations with the solution

$$T^0 = 3F(s, t, u) + G(s, t, u) + H(s, t, u), \quad (5.24)$$

$$T_1 = G(s, t, u) - H(s, t, u), \quad (5.25)$$

$$T_2 = G(s, t, u) + H(s, t, u). \quad (5.26)$$

The Isospin amplitudes with rho-meson exchange are given by

$$T_A^0 = 4ie^2 m^2 \left[\frac{2 + (3+z)R}{2m^2(1-z)R + M^2} + \frac{2 + (3-z)R}{2m^2(1+z)R + M^2} \right], \quad (5.27)$$

$$T_A^2 = -\frac{1}{2} T_A^0 \quad (5.28)$$

$$T_A^1 = 2ie^2 m^2 \left[\frac{4zR}{4m^2(1+R) - M^2} + \frac{2 + (3+z)R}{2m^2(1-z)R + M^2} - \frac{2 + (3-z)R}{2m^2(1+z)R + M^2} \right], \quad (5.29)$$

The Isospin amplitudes with Higgs-exchange become

$$T_H^0 = 16i\kappa^2 \nu^2 \left[\frac{1}{2m^2(1-z)R + m_H^2} - \frac{3}{4m^2(1+R) - m_H^2} + \frac{1}{2m^2(1+z)R + m_H^2} \right], \quad (5.30)$$

$$T_H^1 = 16i\kappa^2\nu^2 \left[\frac{1}{2m^2(1-z)R + m_H^2} + \frac{1}{2m^2(1+z)R + m_H^2} \right], \quad (5.31)$$

$$T_H^2 = 16i\kappa^2\nu^2 \left[\frac{1}{2m^2(1-z)R + m_H^2} + \frac{1}{2m^2(1+z)R + m_H^2} \right]. \quad (5.32)$$

The Isospin amplitudes corresponding to the four-pion vertex are given by

$$T_\lambda^0 = -5i\lambda_4 \quad T_\lambda^1 = 0 \quad T_\lambda^2 = -2i\lambda_4. \quad (5.33)$$

The scattering lengths are computed from the coefficients of the partial wave scattering amplitude obtained from the projection of the Isospin amplitudes over the Legendre polynomials. The Isospin amplitude $T^I(q^2, z)$ expressed as a sum over partial wave scattering amplitudes $T_m^I(q^2)$ is

$$T^I(q^2, z) = 32\pi \sum_{m=0}^{\infty} (2m+1) P_m(z) T_m^I(q^2), \quad (5.34)$$

where $P_m(z)$ are the Legendre polynomials, with $z = \cos\theta$. From the orthogonality of the Legendre polynomials, the partial-wave scattering amplitudes can be extracted by projecting $T^I(q^2, z)$ onto the Legendre polynomials

$$T_n^I(q^2) = \frac{1}{64\pi} \int_{-1}^1 P_n(z) T^I(q^2, z) dz. \quad (5.35)$$

These amplitudes can be expanded in a power series in terms of q^2 [20] as

$$T_n^I = iR^n [a_n^I + b_n^I R + \dots], \quad (5.36)$$

where $R = \frac{q^2}{m^2}$ is defined in Eq.(5.3), and a_n^I and b_n^I are the scattering lengths given by

$$a_0^0 = \frac{e^2}{2\pi} \frac{m^2}{M^2} + \frac{\kappa^2\nu^2}{\pi} \left[\frac{1}{m_H^2} - \frac{3}{2(4m^2 - m_H^2)} \right] + \frac{5\lambda_4}{32\pi} \quad (5.37)$$

$$b_0^0 = \frac{e^2}{4\pi} \frac{m^2}{M^2} \left(3 - 4 \frac{m^2}{M^2} \right) + \frac{2m^2\kappa^2\nu^2}{\pi m_H^4} \left[\frac{3m_H^4}{(4m^2 - m_H^2)^2} - 1 \right] \quad (5.38)$$

$$a_1^0 = 0 \quad b_1^0 = 0 \quad (5.39)$$

$$a_2^0 = \frac{2e^2}{15\pi} \frac{m^4}{M^4} \left(1 + 4 \frac{m^2}{M^2} \right) + \frac{16}{15\pi} \frac{m^4\kappa^2\nu^2}{m_H^6} \quad (5.40)$$

$$b_2^0 = \frac{4e^2}{5\pi} \frac{m^6}{M^6} \left(1 - 12 \frac{m^2}{M^2} \right) - \frac{96}{5\pi} \frac{m^8\kappa^2\nu^2}{m_H^8} \quad (5.41)$$

$$a_0^1 = 0 \quad b_0^1 = 0 \quad (5.42)$$

$$a_1^1 = \frac{e^2}{24\pi} \frac{16m^6 - 3m^2M^4}{4m^2M^4 - M^6} + \frac{2}{3\pi} \frac{m^2\kappa^2\nu^2}{m_H^4} \quad (5.43)$$

$$b_1^1 = \frac{e^2}{6\pi} \frac{m^4 \left(1 - \frac{64}{3} \frac{m^6}{M^6} + 16 \frac{m^4}{M^4} - 4 \frac{m^2}{M^2} \right)}{M^4 \left(1 - 4 \frac{m^2}{M^2} \right)^2} + \frac{8}{3\pi} \frac{m^4\kappa^2\nu^2}{m_H^6} \quad (5.44)$$

$$a_2^1 = 0 \quad b_2^1 = 0 \quad (5.45)$$

$$a_0^2 = -\frac{e^2}{8\pi} \frac{m^2}{M^2} + \frac{\kappa^2\nu^2}{2\pi m_H^2} - \frac{\lambda_4}{32\pi} \quad (5.46)$$

$$b_0^2 = -\frac{e^2}{48\pi} \frac{m^2}{M^2} \left(3 - 4 \frac{m^2}{M^2} \right) - \frac{1}{3\pi} \frac{m^2\kappa^2\nu^2}{m_H^4} \quad (5.47)$$

$$a_1^2 = 0 \quad b_1^2 = 0 \quad (5.48)$$

$$a_2^2 = -\frac{e^2}{30\pi} \frac{m^4}{M^4} \left(1 + 4 \frac{m^2}{M^2} \right) + \frac{8}{15\pi} \frac{m^4\kappa^2\nu^2}{m_H^6} \quad (5.49)$$

$$b_2^2 = -\frac{e^2}{15\pi} \frac{m^6}{M^6} \left(1 - 12 \frac{m^2}{M^2} \right) - \frac{16}{5\pi} \frac{m^6\kappa^2\nu^2}{m_H^8}. \quad (5.50)$$

The experimental input [21] for the average masses of the charged and neutral pions and rho-mesons is $m = 0.1372734 \pm 0.0000007$ GeV, and $M = 0.77649 \pm 0.00034$ GeV. The $\rho\pi\pi$ coupling, $e \equiv g_{\rho\pi\pi}$ in standard VMD [5] equals the rho-meson leptonic decay constant [21], $f_\rho = 4.97 \pm 0.07$, as determined from its leptonic decay rate. However, data on the electromagnetic form factor of the pion [23], as well as theory (Large N_c - QCD) [22] shows a substantial deviation $e = (1.21 \pm 0.02)f_\rho$. Taking this into account gives $e = 6.0 \pm 0.1$. The value of the vacuum expectation value ν can be inferred from the definition of the mass of the rho-meson, becoming

$$\nu = 0.130 \pm 0.004 \text{ GeV}. \quad (5.51)$$

The pion decay constant is [21] $F_\pi = 92.1 \pm 1.2$ MeV. The four-pion coupling is [24]

$$\lambda_4 = \left(\frac{m}{F} \right)^2 = 2.45074 \pm 0.1568. \quad (5.52)$$

The mass of the symmetry breaking field m_H is taken to be the mass of the $f_0(500)$ -meson [25]

$$m_H = m_{f_0} = 0.450 \pm 0.016 \text{ GeV}. \quad (5.53)$$

This choice is motivated by the fact that the energy range of validity of this non-Abelian theory is of order $\mathcal{O}(1 \text{ GeV})$, rather than the mass scale of the actual Higgs boson. Using the above values of the parameters and those for a_0^0 and b_0^0 , one extracts an averaged value for κ

$$\kappa = 1.31 \pm 0.03. \quad (5.54)$$

The results for the scattering lengths are shown in Table I, together with some predictions from Chiral Perturba-

tion Theory (CHPT), and available experimental values.

| Scattering Lengths | Weinberg [28] | CHPT (LO) [26] | CHPT (NLO) [26] | This work | CHPT [20],[27] | Experiment [26],[29] |
|---------------------|---------------|----------------|-----------------|-----------|----------------|----------------------|
| a_0^0 | 0.20 | 0.16 | 0.20 | 0.21 | 0.220 | 0.220 ± 0.005 |

TABLE I: Summary of predicted values of the scattering lengths at tree-level in this theory, together with other determinations from CHPT, and available experimental data [26], [29].

VI. DISCUSSION AND CONCLUSION

The Abelian KLZ theory of pionic interactions [1], at leading order in perturbation theory, was successfully applied to determine the electromagnetic pion form factor in the time-like region (from the rho-meson self energy) [7]. This form factor agreed well with experimental data, as it coincided with the Gounaris-Sakurai expression [30] in the vicinity of the rho-peak. Further applications of this theory are the pion electromagnetic form factor in the space-like region [8], from the one-loop triangle diagram, the scalar radius of the pion [9], and the scalar form factor of the pion in the space-like region [10].

On the basis of this success, and given the need for a strong interaction theory of pionic interactions covering the energy region between CHPT (around threshold), and below the onset of QCD, we proposed here a non-Abelian extension of the KLZ theory. This new theory has the added advantage of being renormalizable. Mass generation was achieved by invoking the Higgs

mechanism, with a Higgs boson mass comparable to the mass of the $f_0(500)$ -meson, i.e. in the region of applicability of the theory. To test its reliability, pion-pion scattering lengths were determined at tree-level, in reasonable agreement with data, and various CHPT predictions. This provides encouraging support for this strong interaction theory of pionic interactions. Further applications would involve the next order in perturbation theory which, however, is beyond the scope of this work.

VII. ACKNOWLEDGEMENTS

This work was supported in part by the National Research Foundation (South Africa), the National Institute for Theoretical Physics (South Africa), the University of Cape Town (South Africa), the Alexander von Humboldt Foundation (Germany), and the Deutsche Forschungsgemeinschaft (Germany). Discussions with Hubert Spiesberger are greatly appreciated.
