A NOTE ON THE FOLKLORE OF FREE INDEPENDENCE

ARIJIT CHAKRABARTY, SUKRIT CHAKRABORTY, AND RAJAT SUBHRA HAZRA

ABSTRACT. It is shown that a Wishart matrix of standard complex normal random variables is asymptotically freely independent of an independent random matrix, under minimal conditions, in two different sense of asymptotic free independence.

1. INTRODUCTION

Since the seminal discovery of [Voiculescu \(1991\)](#page-10-0), there have been several folklores regarding free independence. For example, one such folklore is that any two independent Wigner matrices are asymptotically freely independent, and another is that any Wishart matrix is asymptotically freely independent of a deterministic matrix. While such folklores are true, more often than not, there are a few problems. The first and foremost problem is that the meaning of the phrase "asymptotically freely independent" varies with context. A widely used definition is in terms of the normalized expected trace (or without the expectation). Unfortunately, in this definition, the claim of asymptotic free independence can easily fail, in the absence of any other assumption. The counter example in [Male \(2017](#page-10-1)) is noteworthy. This articulates the second problem with the folklore, which is that the assumptions are usually missing. Nevertheless, in the literature, there are several rigorous proofs of various versions of Voiculescu's theorem, see for example, the monographs [Nica and Speicher \(2006\)](#page-10-2), [Anderson](#page-10-3) et al. [\(2010](#page-10-3)) and [Mingo and Speicher \(2017](#page-10-4)). The reader will notice that the versions in the above references are not monotonic in strength, that is, one version does not necessarily imply another. In other words, there is no general theorem regarding asymptotic free independence from which most results of interest follow.

This note is a modest attempt at settling some of the issues mentioned above in a specific example. Theorems [2.1](#page-2-0) and [2.2](#page-3-0) claim asymptotic free independence of a Wishart matrix W_N of standard complex normal random variables and an independent matrix Y_N , in two different definitions of asymptotic free independence. The former is the usual definition, in terms of normalized expected trace, while the latter is in terms of the limiting

¹⁹⁹¹ Mathematics Subject Classification. Primary 60B20; Secondary 46L54.

Key words and phrases. Voiculescu's theorem, random matrix theory, asymptotic free independence, Wishart.

spectral distribution of random matrices, which is weaker than the former. In both the above theorems, the limiting spectral distribution of Y_N is assumed to be compactly supported, at the least. This assumption is relaxed in Theorem [2.3,](#page-3-1) a consequence of which is that the claim is also significantly weakened. The proofs of Theorems [2.2](#page-3-0) and [2.3](#page-3-1) is based on a truncation argument.

The authors chose to work with the complex normal distribution because they yield the strongest results in that the assumptions on Y_N become minimal. Theorem 22.35 of [Nica and Speicher \(2006](#page-10-2)) astutely notes this, for example. It's worth noting that the results in [Hiai and Petz \(2000\)](#page-10-5) are similar in spirit. Although the results are stated for a Wishart matrix, they hold for a Wigner matrix too.

2. The results

Let $(Z_{i,j} : i, j \in \mathbb{N})$ be a family of i.i.d. standard complex Normal random variables. That is, $(\Re(Z_{i,j}) : i, j \geq 1)$ and $(\Im(Z_{i,j}) : i, j \geq 1)$ are independent families of i.i.d. real random variables from $N(0, 1/2)$. Suppose that $(M_N:$ $N \geq 1$) is a sequence of positive integers such that

(2.1)
$$
\lim_{N \to \infty} \frac{N}{M_N} = \lambda \in (0, \infty).
$$

For each $N \geq 1$, let X_N be the $M_N \times N$ random matrix defined by

$$
X_N(i,j) := Z_{i,j}, \ 1 \le i \le M_N, \ 1 \le j \le N.
$$

For $N \geq 1$, define an $N \times N$ random Hermitian matrix by

$$
W_N := \frac{1}{M_N} X_N^* X_N.
$$

Notice that for $1 \leq i, j \leq N$,

$$
W_N(i,j) = \frac{1}{M_N} \sum_{k=1}^{M_N} \overline{Z_{k,i}} Z_{k,j}.
$$

Hence, W_N is a Wishart matrix.

For a random Hermitian $N \times N$ matrix Z, its "empirical spectral distribution" and "expected empirical spectral distribution", denoted by $\text{ESD}(Z)$ and $\text{EESD}(Z)$, respectively, are probability measures on \mathbb{R} , defined as

$$
\text{ESD}(Z) = \frac{1}{N} \sum_{i=1}^{N} \mathbf{1}(\lambda_i \in \cdot),
$$

$$
\text{EESD}(Z) = \frac{1}{N} \sum_{i=1}^{N} P(\lambda_i \in \cdot),
$$

where $\lambda_1, \ldots, \lambda_N$ are the eigenvalues of Z, counted with multiplicity.

It is well known that as $N \to \infty$,

$$
\mathrm{ESD}(W_N)\to \nu_\lambda\,,
$$

weakly in probability, where ν_{λ} , with λ as in [\(2.1\)](#page-1-0), is the Marc̆enko-Pastur distribution, defined by

$$
\nu_{\lambda}(dx) = \begin{cases} \left(1 - \frac{1}{\lambda}\right) \mathbf{1}(0 \in dx) + \frac{1}{2\pi} \frac{\sqrt{(\lambda - x)(x - \lambda -)} }{\lambda x} \mathbf{1}_{[\lambda - ,\lambda +]}(x) dx, & \lambda > 1, \\ \frac{1}{2\pi} \frac{\sqrt{(\lambda - x)(x - \lambda -)} }{\lambda x} \mathbf{1}_{[\lambda - ,\lambda +]}(x) dx, & \lambda \leq 1, \end{cases}
$$

with $\lambda_{\pm} = (1 \pm \sqrt{\lambda})^2$.

For each $N \geq 1$, Y_N is an $N \times N$ random complex Hermitian matrix, **independent** of $(Z_{i,j} : i, j \in \mathbb{N})$. The exact assumption on the spectrum of Y_N will vary from result to result, and hence will be mentioned in the statements of the respective results. However, at the very least, there exists a (non-random) probability measure μ on $\mathbb R$ such that

(2.2) ESD(Y^N) → µ ,

weakly in probability, as $N \to \infty$.

The statements of the following results are based on the theory of C^* probability spaces. A reader unacquainted with this may look at [Nica and Speicher](#page-10-2) [\(2006\)](#page-10-2). It is known that given probability measures μ_1 and μ_2 which are supported on a compact subset of $\mathbb R$, there exists a C^* -probability space (\mathcal{A}, φ) and two freely independent self-adjoint elements $a_1, a_2 \in \mathcal{A}$ such that

$$
\varphi(a_i^n) = \int_{-\infty}^{\infty} x^n \mu_i(dx), \ n \in \mathbb{N}, \ i = 1, 2.
$$

The probability measures μ_1 and μ_2 are called the distributions of a_1 and a_2 , and denoted by $\mathcal{L}(a_1)$ and $\mathcal{L}(a_2)$, respectively.

The first result shows asymptotic free independence between W_N and Y_N in the sense of normalized expected trace.

Theorem 2.1. Assume that μ is compactly supported, and that for each $n \in \mathbb{N}$,

(2.3)
$$
\lim_{N \to \infty} \mathbf{E} \left[\frac{1}{N} \operatorname{Tr}(Y_N^n) \right] = \int_{-\infty}^{\infty} x^n \mu(dx),
$$

(2.4) and
$$
\lim_{N \to \infty} \text{Var}\left[\frac{1}{N} \text{Tr}(Y_N^n)\right] = 0.
$$

Then, there exists a C^* -probability space (\mathcal{A}, φ) , in which there are two freely independent self-adjoint elements w and y, having distribution ν_{λ} and μ , respectively, and satisfying the following. For every polynomial p in two variables having complex coefficients,

(2.5)
$$
\lim_{N \to \infty} \frac{1}{N} \mathbb{E} \operatorname{Tr} \left[p \left(W_N, Y_N \right) \right] = \varphi \big(p(w, y) \big) .
$$

Consequently, if $p(W_N, Y_N)$ has real eigenvalues, a.s., for all N, then as $N \to \infty$,

(2.6)
$$
\text{EESD}(p(W_N, Y_N)) \xrightarrow{w} \mathcal{L}(p(w, y)) .
$$

Remark [2.1](#page-2-0). When Y_N is deterministic, the assumptions of Theorem 2.1 just mean that

$$
\lim_{n \to \infty} \frac{1}{N} \mathbf{E} \left(\text{Tr}(Y_N^n) \right) = \int_{-\infty}^{\infty} x^n \mu(dx) \,,
$$

which is stronger than (2.2) .

Remark 2.2. The claim (2.6) is an immediate consequence of (2.5) , whenever p is such that the eigenvalues of $p(W_N, Y_N)$ are a.s. real. For example, W_N is non-negative definite implies that the above holds for

$$
p(x,y)=xy.
$$

In the next result, both – the hypotheses and the claim are weakened to [\(2.2\)](#page-2-1) and [\(2.6\)](#page-2-2), respectively. In other words, this results proves asymptotic free independence in the sense of [\(2.6\)](#page-2-2) as opposed to [\(2.5\)](#page-2-3).

Theorem 2.2. If μ , as in [\(2.2\)](#page-2-1) is compactly supported, then, for every polynomial p in two variables having complex coefficients, such that $p(W_N, Y_N)$ has real eigenvalues, a.s., for all N, then (2.6) holds.

The last result deals with the case when the support of μ is possibly unbounded. For measures with possibly unbounded support, '⊞' and '⊠' denote their free additive and multiplicative convolutions, respectively. For the latter, at least of one of the two measures has to be supported on the non-negative half line. See [Bercovici and Voiculescu \(1993](#page-10-6)) for the details.

Theorem 2.3. If (2.2) holds for a probability measure μ which is not necessarily compactly supported, then

$$
\begin{array}{ccc}\n\text{EESD}(Y_N + W_N) & \xrightarrow{w} & \mu \boxplus \nu_\lambda\,,\\ \nand, & \text{EESD}(Y_N W_N) & \xrightarrow{w} & \mu \boxtimes \nu_\lambda\,,\n\end{array}
$$

as $N \to \infty$.

Remark [2.3](#page-3-1). Theorems [2.1](#page-2-0) – 2.3 hold true, if Wishart matrix is replaced by a Wigner matrix with standard complex normal entries, and Marc \check{c} enko-Pastur distribution is replaced by the semicircle law.

3. Some facts

For the proofs of the results mentioned in Section [2,](#page-1-1) a few facts will be needed, which are stated here. The proofs are omitted because the results are either elementary or can be found in a cited reference.

The first one is a comparison between ranks of deterministic matrices.

Fact 3.1. Let p be a polynomial in two variables, with complex coefficients. Then, there exists a finite constant C , depending only on the polynomial p, such that

Rank $(p(A, B) - p(A', B)) \leq C$ Rank $(A - A')$,

for square matrices A, A', B of the same order.

The next result, which is also based on rank, follows from Theorem A.43, page 503 of [Bai and Silverstein \(2010](#page-10-7)).

Fact 3.2. For probability measures μ_1 and μ_2 on \mathbb{R} , let $d(\mu_1, \mu_2)$ denote their sup distance, defined by

$$
d(\mu_1, \mu_2) := \sup_{x \in \mathbb{R}} |\mu_1((-\infty, x]) - \mu_2((-\infty, x])|.
$$

For $N \times N$ random Hermitian matrices A and B, it holds that

$$
d
$$
(EESD(A), EESD(B)) $\leq \frac{1}{N}$ E [Rank(A – B)].

The next two facts are elementary.

Fact 3.3. For each $N \geq 1$, suppose that Y_N is an $N \times N$ random Hermitian matrix satisfying [\(2.3\)](#page-2-4) and [\(2.4\)](#page-2-4). Then, it holds that for any $n \geq 1$ and $k_1, \ldots, k_n \geq 0,$

$$
\lim_{N \to \infty} N^{-n} \mathcal{E}\left(\prod_{i=1}^n \text{Tr}\left(Y_N^{k_i}\right)\right) = \prod_{i=1}^n \alpha_{k_i},
$$

where α_n denotes the right hand side of [\(2.3\)](#page-2-4), for $n \geq 1$.

Fact 3.4. Let Z_1, \ldots, Z_N follow i.i.d. standard complex Normal, that is, for each $i = 1, ..., N$, real and imaginary parts of Z_i are independent $N(0, 1/\sqrt{2})$. If Z denotes the column vector whose *i*-th component is Z_i , and U is an $N \times N$ deterministic unitary matrix, then the components of UZ are also i.i.d. from standard complex Normal.

The next fact has essentially been proved in page 386 of [Nica and Speicher](#page-10-2) [\(2006\)](#page-10-2). As mentioned therein, an $N \times N$ Haar unitary matrix is a random matrix distributed according to the Haar measure on the group of $N \times$ N unitary matrices. Before stating the fact, we need to introduce a few notations. Let S_n denote the group of permutations on $\{1,\ldots,n\}$, for $n\geq 1$. A permutation is identified with the partition of $\{1, \ldots, n\}$, induced by the cyclic decomposition. For $\alpha \in S_n$, $\#\alpha$ denotes the number of blocks in α , that is, the number of cycles. For any block $\theta \in \alpha$, $\#\theta$ denotes the length of the cycle θ . For example, for

$$
\alpha \in S_4
$$

defined by

$$
\alpha(1) = 2, \alpha(2) = 4, \alpha(3) = 3, \alpha(4) = 1,
$$

we write

$$
\alpha = \{(1, 2, 4), (3)\},\
$$

and hence $\#\alpha = 2$. If the elements of α , as listed above, are labelled as θ_1 and θ_2 , respectively, then

$$
\#\theta_1 = 3, \, \#\theta_2 = 1 \, .
$$

Fact 3.5. For a fixed N, let A and B be deterministic $N \times N$ Hermitian matrices. If U is an $N \times N$ Haar unitary matrix, then for any $1 \leq n \leq N$ and $k_1, \ldots, k_n \geq 0$,

$$
\begin{split} &= \operatorname{Tr}\left[\prod_{i=1}^{n} \left(UA^{k_i}U^*B\right)\right] \\ &= \sum_{\alpha,\beta \in S_n} Wg(N,\alpha^{-1}\beta) \left(\prod_{\theta \in \alpha} \operatorname{Tr}\left(A^{\sum_{i \in \theta} k_i}\right)\right) \left(\prod_{\theta \in \beta^{-1}\gamma} \operatorname{Tr}\left(B^{\#\theta}\right)\right), \end{split}
$$

where Wg is the Weingarten function defined by

$$
Wg(N,\alpha) = \mathbf{E}\left[U(1,1)\dots U(n,n)\overline{U(1,\alpha(1))}\dots\overline{U(n,\alpha(n))}\right],
$$

for $\alpha \in S_n$, $N \geq n$ and

$$
\gamma = \{(1,\ldots,n)\} \in S_n \, .
$$

The following has essentially been proved in the course of the proof of Theorem 23.14 of [Nica and Speicher \(2006\)](#page-10-2).

Fact 3.6. For a fixed $n \geq 1$ and $\alpha \in S_n$,

$$
\lim_{N \to \infty} N^{2n - \# \alpha} W g(N, \alpha) = \phi(\alpha) \in \mathbb{R}.
$$

Furthermore, if (A, φ) , w and y are as in the statement of Theorem [2.1,](#page-2-0) then for $n \geq 1$ and $k_1, \ldots, k_n \geq 0$,

$$
\varphi\left(w^{k_1}y \dots w^{k_n}y\right) = \sum_{\alpha,\beta \in S_n: \#(\alpha^{-1}\beta) + \# \alpha + \#(\beta^{-1}\gamma) = 2n+1} \left[\varphi(\alpha^{-1}\beta)\left(\prod_{\theta \in \alpha} \varphi\left(w^{\sum_{i \in \theta} k_i}\right)\right)\right]
$$

$$
\left(\prod_{\theta \in \beta^{-1}\gamma} \varphi\left(y^{\#\theta}\right)\right)\right].
$$

The following result is Corollary 2 of [Azoff \(1974](#page-10-8)).

Fact 3.7. For a fixed $N \in \mathbb{N}$, there exists a measurable map

$$
\psi: \mathbb{C}^{N \times N} \to \mathbb{C}^{N \times N},
$$

where $\mathbb{C}^{N\times N}$ is the space of all $N\times N$ matrices with complex entries, such that $\psi(M)$ is an unitary matrix for every $M \in \mathbb{C}^{N \times N}$, and

$$
\psi(M)^*M\psi(M)
$$

is upper triangular for every M.

4. Proofs

Proof of Theorem [2.1.](#page-2-0) Let (A, φ) , w and y be as in the statement. In order to prove the claim, all that needs to be shown is that

(4.1)
$$
\lim_{N \to \infty} N^{-1} \mathbf{E} \left[\text{Tr} \left(W_N^{k_1} Y_N \dots W_N^{k_n} Y_N \right) \right] = \varphi \left(w^{k_1} y \dots w^{k_n} y \right),
$$

for fixed $n \geq 1$ and $k_1, \ldots, k_n \geq 0$.

The foremost task is to show that the expectation on the left hand side of (4.1) exists. To that end, it suffices to show that there exists N_0 such that

(4.2)
$$
E[|Y_N(i,j)|^n] < \infty \text{ for all } N \ge N_0, 1 \le i, j \le N.
$$

Since

$$
\sum_{i,j=1}^N \mathbf{E}\left[|Y_N(i,j)|^{2n}\right] \leq \mathbf{E}\left[\text{Tr}(Y_N^{2n})\right],
$$

and (2.3) implies that right hand side is finite for N large, an N_0 satisfying (4.2) exists.

Proceeding towards [\(4.1\)](#page-6-0), fix $N \geq N_0$ and let

$$
\mathcal{F} := \sigma\left(X_N, Y_N\right) ,
$$

that is F is the smallest σ -field with respect to which the entries of X_N and Y_N are measurable. Let U_N be a Haar unitary matrix, independent of F. Fact [3.4](#page-4-0) implies that conditioned on U_N , the entries of $U_N X_N$ are i.i.d. standard complex Normal. That is, the conditional joint distribution of the entries of $U_N X_N$, given U_N , is same as that of X_N . Therefore,

$$
(U_N W_N U_N^*, Y_N) \stackrel{d}{=} (W_N, Y_N) .
$$

As a result,

$$
C_N := \mathbf{E} \left[\text{Tr} \left(W_N^{k_1} Y_N \dots W_N^{k_n} Y_N \right) \right]
$$

\n
$$
= \mathbf{E} \left[\text{Tr} \left((U_N W_N U_N^*)^{k_1} Y_N \dots (U_N W_N U_N^*)^{k_n} Y_N \right) \right]
$$

\n
$$
= \mathbf{E} \left[\text{Tr} \left(U_N W_N^{k_1} U_N^* Y_N \dots U_N W_N^{k_n} U_N^* Y_N \right) \right]
$$

\n
$$
= \mathbf{E} \mathbf{E}_{\mathcal{F}} \left[\text{Tr} \left(U_N W_N^{k_1} U_N^* Y_N \dots U_N W_N^{k_n} U_N^* Y_N \right) \right],
$$

where $E_{\mathcal{F}}$ is the conditional expectation given \mathcal{F} . By an appeal to Fact [3.5,](#page-5-0)

$$
\begin{split} & \mathbf{E}_{\mathcal{F}} \left[\text{Tr} \left(U_N W_N^{k_1} U_N^* Y_N \dots U_N W_N^{k_n} U_N^* Y_N \right) \right] \\ & = \sum_{\alpha, \beta \in S_n} Wg(N, \alpha^{-1} \beta) \left(\prod_{\theta \in \alpha} \text{Tr} \left(W_N^{\sum_{i \in \theta} k_i} \right) \right) \left(\prod_{\theta \in \beta^{-1} \gamma} \text{Tr} \left(Y_N^{\# \theta} \right) \right) \,. \end{split}
$$

Taking the unconditional expectation of both sides, and using the independence of W_N and Y_N , we get that (4.3)

$$
C_N = \sum_{\alpha,\beta \in S_n} Wg(N, \alpha^{-1}\beta) \mathbb{E}\left(\prod_{\theta \in \alpha} \text{Tr}\left(W_N^{\sum_{i \in \theta} k_i}\right)\right) \mathbb{E}\left(\prod_{\theta \in \beta^{-1}\gamma} \text{Tr}\left(Y_N^{\#\theta}\right)\right).
$$

It is well known that for all $k \in \mathbb{N}$,

$$
\lim_{N \to \infty} \mathcal{E}\left(N^{-1} \operatorname{Tr}(W_N^k)\right) = \varphi(w^k),
$$

$$
\lim_{N \to \infty} \operatorname{Var}\left(N^{-1} \operatorname{Tr}(W_N^k)\right) = 0.
$$

Combining the above with Fact [3.3](#page-4-1) yields that

(4.4)
$$
\lim_{N \to \infty} \mathbb{E} \left(\prod_{\theta \in \alpha} N^{-1} \operatorname{Tr} \left(W_N^{\sum_{i \in \theta} k_i} \right) \right) = \prod_{\theta \in \alpha} \varphi \left(w^{\sum_{i \in \theta} k_i} \right).
$$

Similarly, [\(2.3\)](#page-2-4), [\(2.4\)](#page-2-4) and Fact [3.3](#page-4-1) together imply that

(4.5)
$$
\lim_{N \to \infty} \mathcal{E} \left(\prod_{\theta \in \beta^{-1} \gamma} N^{-1} \operatorname{Tr} \left(Y_N^{\# \theta} \right) \right) = \prod_{\theta \in \beta^{-1} \gamma} \varphi \left(y^{\# \theta} \right)
$$

Rewrite [\(4.3\)](#page-7-0) as

$$
= \sum_{\alpha,\beta \in S_n}^{N^{-1}C_N} N^{\#\alpha + \#(\beta^{-1}\gamma) - 1} W g(N, \alpha^{-1}\beta)
$$

$$
E \left(\prod_{\theta \in \alpha} N^{-1} \operatorname{Tr} \left(W_N^{\sum_{i \in \theta} k_i} \right) \right) E \left(\prod_{\theta \in \beta^{-1}\gamma} N^{-1} \operatorname{Tr} \left(Y_N^{\#\theta} \right) \right).
$$

.

The first claim of Fact [3.6](#page-5-1) implies that for fixed $\alpha, \beta \in S_n$,

$$
N^{\#\alpha + \#(\beta^{-1}\gamma) - 1} W g(N, \alpha^{-1}\beta) = O\left(N^{\#(\alpha^{-1}\beta) + \# \alpha + \#(\beta^{-1}\gamma) - 2n - 1}\right)
$$

= O(1),

because

$$
\#\alpha + \#(\alpha^{-1}\beta) + \#(\beta^{-1}\gamma) \le 2n + 1,
$$

as shown in (23.4) and the following display on page 387 in [Nica and Speicher](#page-10-2) [\(2006\)](#page-10-2). Therefore, letting $N \to \infty$ in [\(4.6\)](#page-8-0) and using the first claim of Fact [3.6](#page-5-1) along with [\(4.4\)](#page-7-1) and [\(4.5\)](#page-7-2), we get that

$$
\lim_{N \to \infty} N^{-1} C_N
$$
\n
$$
= \sum_{\alpha, \beta \in S_n: \#(\alpha^{-1}\beta) + \# \alpha + \#(\beta^{-1}\gamma) = 2n+1} \left[\phi(\alpha^{-1}\beta) \left(\prod_{\theta \in \alpha} \varphi(w^{\sum_{i \in \theta} k_i}) \right) \right]
$$
\n
$$
\left(\prod_{\theta \in \beta^{-1}\gamma} \varphi(y^{\# \theta}) \right) .
$$

The second claim of Fact [3.6](#page-5-1) shows that the right hand side of the above equation is same as that of [\(4.1\)](#page-6-0). Thus, the latter follows, which completes the proof. \Box

Proof of Theorem [2.2.](#page-3-0) Since μ is compactly supported, let $M > 1$ be such that

$$
\mu\left([-(M-1),M-1]\right) = 1.
$$

Letting ψ be as in Fact [3.7,](#page-5-2) define

$$
P_N = \psi(Y_N)\,,
$$

and

$$
T_N := P_N^* Y_N P_N,
$$

which is an upper triangular matrix. Define an $N \times N$ matrix T_N' by

$$
T'_{N}(i,j) := \begin{cases} T_{N}(i,j), & i \neq j, \\ T_{N}(i,i) \mathbf{1}(|T_{N}(i,i)| \leq M), & i = j, \end{cases}
$$

and let

(4.6)
$$
Y_N' := P_N T_N' P_N^*.
$$

In order to complete the proof, it suffices to show that for a fixed polynomial p satisfying the hypothesis,

(4.7)
$$
\text{EESD}(p(W_N, Y_N')) \xrightarrow{w} \mathcal{L}(p(w, y)),
$$

and

(4.8)
$$
\lim_{N \to \infty} d\left(\text{EESD}(p(W_N, Y_N)), \text{EESD}(p(W_N, Y_N'))\right) = 0.
$$

We start with showing [\(4.8\)](#page-8-1). To that end, note that

$$
N^{-1} \text{Rank}(Y_N - Y'_N) = N^{-1} \text{Rank}(T_N - T'_N)
$$

\n
$$
\leq N^{-1} \# \{1 \leq i \leq N : |T_N(i, i)| > M\}
$$

\n
$$
= (\text{ESD}(Y_N)) ([-M, M]^c),
$$

the inequality in the second line being based on the fact that $T_N - T'_N$ is a diagonal matrix, and hence

(4.9)
$$
N^{-1} \operatorname{Rank}(Y_N - Y_N') \stackrel{P}{\longrightarrow} 0,
$$

as $N \to \infty$. Fact [3.1](#page-3-2) and the bounded convergence theorem show that

$$
\lim_{N \to \infty} \mathcal{E}\left[\frac{1}{N} \operatorname{Rank}(p(W_N, Y_N) - p(W_N, Y'_N))\right] = 0.
$$

An appeal to Fact [3.2](#page-4-2) establishes [\(4.8\)](#page-8-1).

Proceeding towards [\(4.7\)](#page-8-2), in view of Theorem [2.1](#page-2-0) and Remark [2.2,](#page-3-3) it suffices to show that [\(2.3\)](#page-2-4) and [\(2.4\)](#page-2-4) hold with Y_N replaced by Y'_N . Equation [\(4.9\)](#page-8-3) and the hypotheses imply that

$$
\mathrm{ESD}(Y_N') \to \mu \,,
$$

weakly in probability, as $N \to \infty$. Since

$$
\left(\text{ESD}(Y_N')\right)([-M, M]^c) = \left(\text{ESD}(T_N')\right)([-M, M]^c) = 0, N \ge 1,
$$

and

$$
\mu\left([-M+1,M-1]^{c}\right) =0\,,
$$

it follows that for a fixed $n \geq 1$, as $N \to \infty$,

$$
\int_{-\infty}^{\infty} x^n \left(\text{ESD}(Y_N') \right) (dx) \stackrel{P}{\longrightarrow} \int_{-\infty}^{\infty} x^n \mu(dx).
$$

The observations that

$$
\frac{1}{N}\operatorname{Tr}\left[(Y'_{N})^{n}\right]=\int_{-\infty}^{\infty}x^{n}\left(\mathrm{ESD}(Y'_{N})\right)(dx),
$$

and that the modulus of the above quantity is bounded by M , show that (2.3) and (2.4) hold, with Y_N replaced by Y'_N . Theorem [2.1](#page-2-0) shows (4.7) , which in turn completes the proof. \Box

Proof of Theorem [2.3.](#page-3-1) As in the preceding proof, let

$$
P_N = \psi(Y_N), N \ge 1.
$$

Fix $M > 0$ and let Y_N' be as in [\(4.6\)](#page-8-0), M being suppressed in the notation. Theorem [2.2](#page-3-0) implies that

$$
EESD(Y'_N + W_N) \xrightarrow{w} \mu_M \boxplus \nu_\lambda,
$$

and

$$
EESD(Y'_{N}W_{N}) \xrightarrow{w} \mu_{M} \boxtimes \nu_{\lambda},
$$

as $N \to \infty$, where

$$
\mu_M(B) = \mu(B \cap [-M, M]) + \mu([-M, M]^c) \mathbf{1}(0 \in B),
$$

for every Borel set $B \subset \mathbb{R}$. Proposition 4.13 and Corollary 6.7 of [Bercovici and Voiculescu](#page-10-6) [\(1993\)](#page-10-6) imply, respectively, that as $M \to \infty$,

$$
\mu_M \boxplus \nu_\lambda \xrightarrow{w} \mu \boxplus \nu_\lambda,
$$

and $\mu_M \boxtimes \nu_\lambda \xrightarrow{w} \mu \boxtimes \nu_\lambda.$

In order to complete the proof, in view of Fact [3.1,](#page-3-2) it suffices to show that

$$
\lim_{M \to \infty} \limsup_{N \to \infty} \frac{1}{N} \mathbb{E} \left[\text{Rank}(Y_N - Y_N') \right] = 0 \,.
$$

However, arguments as in the proof of Theorem [2.2](#page-3-0) show that for M such that

$$
\mu(\{-M,M\})=0\,,
$$

it holds that

$$
\limsup_{N \to \infty} \frac{1}{N} \mathbf{E} [\text{Rank}(Y_N - Y_N')] \le \mu ([-M, M]^c) .
$$

Hence, the proof follows.
