DIMENSION FREE PROPERTIES OF STRONG MUCKENHOUPT AND REVERSE HÖLDER WEIGHTS FOR RADON MEASURES

O. BEZNOSOVA AND A. REZNIKOV

ABSTRACT. In this paper we prove self-improvement properties of strong Muckenhoupt and Reverse Hölder weights with respect to a general Radon measure on \mathbb{R}^n . We derive our result via a Bellman function argument. An important feature of our proof is that it uses only the Bellman function for the one-dimensional problem for Lebesgue measure; with this function in hand, we derive dimension free results for general measures and dimensions.

Keywords: Bellman function, Dimension free estimates, Muckenhoupt weights, Reverse Hölder weights.

Mathematics Subject Classification: Primary: 42B35; Secondary: 43A85

1. INTRODUCTION

It is well known that Muckenhoupt weights on a real line with respect to the Lebesgue measure satisfy self-improvement properties in the following sense: for $p > q$ we always have $A_q \subset A_p$; but also for any function $w \in A_p$, there is an $\varepsilon > 0$ such that $w \in A_{p-\varepsilon}$ (we refer to Definition [1](#page-1-0) for precise definitions). Besides that, there always exists a *q* such that $w \in RH_q$. These self-improvement properties allow one to prove many important results in harmonic analysis, see, e.g., [\[4\]](#page-4-0) or a more recent paper [\[5\]](#page-4-1). In [\[7\]](#page-4-2), the authors considered *strong Muckenhoupt classes*; in particular, it was proven that for a Radon measure μ on \mathbb{R}^n which is absolutely continuous with respect to the Lebesgue measure dx, any weight $w \in A_p^*$ satisfies a Reverse Hölder property with an exponent that does not depend on the dimension *n*.

For $p > 1$, we say that *w* belongs to the *strong Muckenhoupt class with respect to* μ , $w \in A_p^*$, if there exists a number $Q > 1$ such that for any rectangular box $R \subset \mathbb{R}^n$ with edges parallel to axis, we have

$$
\langle w \rangle_R \langle w^{-1/(p-1)} \rangle_R^{p-1} \leqslant Q,
$$

where $\langle \phi \rangle_R$ denotes the average of the function ϕ over *R*:

$$
\langle \varphi \rangle_R := \frac{1}{\mu(R)} \int_R \varphi(x) d\mu(x).
$$

For $p > 1$, we say that *w* belongs to the *strong Reverse Hölder class with respect to* μ , $w \in RH_P^*$, if there exists a constant $Q > 1$ such that for any rectangular box *R* with edges parallel to axis, we have

$$
\langle w^p \rangle_R^{1/p} \leqslant Q \langle w \rangle_R.
$$

We proceed with the following definition.

Date: August 25, 2021.

Definition 1. Let μ be a Radon measure on \mathbb{R}^n and w be a function which is positive μ -a.e. For $p > 1$, we denote the A_p^* -*characteristic of w* by

$$
[w]_p := \sup_R \langle w \rangle_R \langle w^{-1/(p-1)} \rangle_R^{p-1}
$$

and the *Reverse Hölder characteristic of w* by

$$
[w]_{RH_p} := \sup_R \langle w^p \rangle_R^{1/p} \langle w \rangle_R^{-1},
$$

where both suprema are taken over rectangular boxes *R* with edges parallel to axis. If $[w]_p < \infty$, we have $w \in A_p^*$ and if $[w]_{RH_p} < \infty$, we have $w \in RH_p^*$.

In [\[7\]](#page-4-2) it was proved that if μ is an absolutely continuous Radon measure on \mathbb{R}^n and $[w]_p < \infty$, then for some $q > 1$ we have $[w]_{RH_q} < C < \infty$ with an explicit dimension free estimates on *q* and *C*. It is of a particular importance that we can take

$$
q = 1 + \frac{1}{2^{p+2}[w]_p}.
$$

To prove this result, the authors used a clever version of the Calderón–Zygmund decomposition from [\[6\]](#page-4-3). The aim of this paper is to derive a sharp result from the one-dimensional case for Lebesgue measure (i.e., for the classical A_p and RH_p classes on \mathbb{R}). In this case the result from [\[7\]](#page-4-2) can be obtained, for example, by means of a so-called Bellman function; i.e., a function of two variables that satisfies certain boundary and concavity conditions in its domain. In the one-dimensional case this function is known explicitly, see [\[10\]](#page-4-4). It has been understood for some time that, for classes of functions like *Ap*, *RH^p* or *BMO_p*, when we work with their strong multi-dimensional analogs (e.g., A_p^* and RH_p^*), the one-dimensional Bellman function should prove the higher-dimensional results with dimension free constants. For the Lebesgue measure and the inclusion $RH_p^* \subset A_q^*$, this was done in [\[1\]](#page-4-5). The trick of using the Bellman function for one-dimensional problems was also used in [\[3\]](#page-4-6), [\[2\]](#page-4-7) and [\[9\]](#page-4-8) (in a slightly different setting, the same trick was also used in [\[8\]](#page-4-9)). In this paper, we present a simple version of this trick for general measures; we prove the result from [\[7\]](#page-4-2) as well as all other results of self-improving type for strong Muckenhoupt and Reverse Hölder weights.

Acknowledgements: we are very grateful to Vasiliy Vasyunin for helpful discussions and suggestions on the presentation of this paper.

2. STATEMENT OF THE MAIN RESULT

2.1. **Properties of Muckenhoupt weights** A_p^* . For $p_1 := -1/(p-1)$ and every $t \in [0,1]$ define $u_{p_1}^{\pm}(t)$ to be solutions of the equation

$$
(1-u)(1-p_1u)^{-1/p_1}=t.
$$

The function $u_{p_1}^+$ is decreasing and maps [0, 1] onto [0, 1]; the function $u_{p_1}^-$ is increasing and maps [0, 1] onto $[1/p_1, 0]$. For a fixed $Q > 1$, define

(1)
$$
s_{p_1}^{\pm} = s_{p_1}^{\pm}(Q) := u_{p_1}^{\pm}(1/Q).
$$

Our first main result is the following.

Theorem 2.1. Let μ be a Radon measure on \mathbb{R}^n with $\mu(H) = 0$ for every hyperplane H *orthogonal to one of the coordinate axis. Fix numbers* $p > 1$ *and* $Q > 1$ *and set* $p_1 :=$ $-1/(p-1)$ *. Then for every weight w with* $[w]_p = Q$ *we have*

$$
w\in A_q^*,\quad 1-s_{p_1}^-(Q)
$$

and

$$
w\in RH_q^*,\quad 1\leqslant q<1/s_{p_1}^+(Q),
$$

where $s_{p_1}^{\pm}(Q)$ are defined in [\(1\)](#page-1-1). These ranges for q are sharp for $n = 1$ and $\mu = dx$.

2.2. **Properties of Reverse Hölder weights.** For $p > 1$ and every $t \in [0,1]$ we define $v_p^{\pm}(t)$ to be solutions of the equation

$$
(1 - pv)^{1/p}(1 - v)^{-1} = t.
$$

In this case, v_p^+ is a decreasing function that maps [0, 1] onto [0, 1/*p*] and v_p^- is an increasing function that maps [0,1] onto [−∞,0]. As before for a fixed *Q* > 1, we define

(2)
$$
s_p^{\pm} = s_p^{\pm}(Q) := v_p^{\pm}(1/Q).
$$

Our second main result concerning Reverse Hölder weights is the following.

Theorem 2.2. Let μ be a Radon measure on \mathbb{R}^n with $\mu(H) = 0$ for every hyperplane H *orthogonal to one of the coordinate axis. Fix numbers* $p > 1$ *and* $Q > 1$ *. Then for every weight w with* $[w]_{RH_p} = Q$ *we have*

$$
w \in A_q^*, \quad 1 - s_p^-(Q) < q < \infty,
$$

and

$$
w \in RH_q^*, \quad 1 \leqslant q < 1/s_p^+(Q),
$$

where $s_p^{\pm}(Q)$ are defined in [\(2\)](#page-2-0). These ranges for q are sharp for $n = 1$ and $\mu = dx$.

3. PROOF OF THE MAIN RESULTS

We begin with the following Theorem from [\[10\]](#page-4-4). This theorem ensures the existence of a certain Bellman function for a one-dimensional problem. In what follows, by letters without sub-indices (e.g., x , x^{\pm}) we denote points in \mathbb{R}^2 and by letters with sub-indices we denote the corresponding coordinates (e.g., x_1^+ $_1^+$ denotes the first coordinate of x^+).

Theorem 3.1 (Theorem 1 in [\[10\]](#page-4-4)). *Fix p* > 1 *and set p*₁ := $-1/(p-1)$ *. Also fix an r* ∈ $(1/s_{p_1}^-, p_1] \cup [1, 1/s_{p_1}^+)$ *for* $s_{p_1}^{\pm}(Q)$ *defined in* [\(1\)](#page-1-1)*. For every Q* > 1 *there exists a non* a_2 *negative function* $B_Q(x)$ *defined in the domain* $\Omega_Q:=\{x=(x_1,x_2)\in\mathbb{R}^2\colon 1\leqslant x_1x_2^{-1/p_1}\leqslant x_2^{-1/p_2}\}$ Q [}] with the following property: $B_Q(x)$ is continuous in x and Q, and for any line segment $[x^-, x^+]$ ⊂ Ω_Q *and* $x = \lambda x^- + (1 - \lambda)x^+$, $\lambda \in [0,1]$ *, we have*

$$
B_Q(x) \geq \lambda B_Q(x^-) + (1 - \lambda)B_Q(x^+).
$$

Moreover, $B(x_1, x_1^{p_1})$ $\binom{p_1}{1}$ = x_1^r and $B_Q(x) \leqslant c(r, Q)x_1^r$ for some positive constant $c(r, Q)$ and *every* $x \in \Omega_Q$ *.*

To use the concavity property of the function B_O for our proof, we need the following lemma. Its proof is given in [\[10,](#page-4-4) Lemma4] with an interval instead of the rectangle; however, the proof remains the same in our case.

Lemma 3.2. Let the measure μ be as before. Fix two numbers $Q_1 > Q > 1$ and a rect*angular box* $R ⊂ \mathbb{R}^n$ *with edges parallel to the axis. For every coordinate vector* **e***, there exists a hyperplane H normal to* e *that splits R into two rectangular boxes R*¹ *and R*² *with the following properties:*

(i) For i = 1,2 *we have* $\mu(R^i)/\mu(R)$ ∈ $(c, 1 - c)$ *for some constant* $c \in (0, 1)$ *;*

(ii) For every weight w with $[w]_p \leq Q$, we have $[x^1, x^2] \subset \Omega_{Q_1}$ and, therefore,

$$
B_{Q_1}(x_1,x_2) \geq \frac{\mu(R^1)}{\mu(R)} B_{Q_1}(x_1^1,x_2^1) + \frac{\mu(R^2)}{\mu(R)} B_{Q_1}(x_2^i,x_2^2),
$$

where

$$
x_1 = \langle w \rangle_R, \qquad x_2 = \langle w^{p_1} \rangle_R
$$

$$
x_1^i = \langle w \rangle_{R^i}, \qquad x_2^i = \langle w^{p_1} \rangle_{R^i}.
$$

We are ready to prove our main result.

Proof of Theorem [2.1.](#page-2-1) Fix a rectangular box *R* with edges parallel to the axis, and take any $Q_1 > Q$. We first explain how we split *R* into two rectangular boxes. Take one of the (*n*−1)-dimensional faces of *R*, call it *Rn*−1, that has the largest (*n*−1)-area. Among all $(n-2)$ -dimensional faces of R_{n-1} , take one of those (call it R_{n-2}) that have the largest $(n-2)$ -area. We proceed like this to get R_{n-1} , ..., R_1 . Now take a vector **e** that is orthogonal to every R_i , $i = 1, ..., n-1$.^{*} We now split *R* according to Lemma [3.2.](#page-3-1) Notice that all the corresponding *i*-dimensional faces of $R¹$ and $R²$ have smaller *i*-areas than the corresponding *i*-dimensional faces of *R*. We now take the boxes $R¹$ and $R²$ and repeat the same procedure. If we repeat this *M* times, we get a family of rectangular boxes $\mathscr{R} = \{R^{i,\bar{M}}\}_{i=1...2^{\bar{M}}}$. Denote

$$
x_1 = \langle w \rangle_R, \qquad x_2 = \langle w^{p_1} \rangle_R
$$

$$
x_1^{i,M} = \langle w \rangle_{R^{i,M}}, \qquad x_2^{i,M} = \langle w^{p_1} \rangle_{R^{i,M}}
$$

.

Abusing the notation, we also define step-functions

$$
x_1^M(t) := \sum_{i=1}^{2^M} x_1^{i,M} 1\!\!1_{R^{i,M}}(t), \qquad x_2^M(t) := \sum_{i=1}^{2^M} x_2^{i,M} 1\!\!1_{R^{i,M}}(t).
$$

From the construction of rectangular boxes, we notice that $x_1^M(t) \to w(t)$ and $x_2^M(t) \to$ $w^{p_1}(t)$ as $M \to \infty$ for μ -a.e. $t \in R$. Indeed, our splitting procedure (and the fact that we have $\mu(R^i)/\mu(R) \in (1-c,c)$ at every step) guarantees that

$$
\max_{i=1,\ldots,2^M} \text{diam}(R^{i,M}) \to 0, M \to \infty,
$$

and we obtain the convergence of $x_1^M(t)$ and $x_2^M(t)$ from the Lebegue differentiation theorem for Radon measures. Therefore,

$$
B_{Q_1}(x_1,x_2) \geqslant \sum_{i=1}^{2^M} \frac{\mu(R^{i,M})}{\mu(R)} B_{Q_1}(x_1^{i,M},x_2^{i,M}) = \frac{1}{\mu(R)} \int_R B_{Q_1}(x_1^M(t),x_2^M(t))d\mu(t).
$$

 $\overline{P_{\text{th}}}$ the case $n = 2$, we just take **e** orthogonal to the longest side of *R*.

By the Fatou lemma,

(3)
$$
B_{Q_1}(x_1, x_2) \ge \frac{1}{\mu(R)} \int_R \lim_{M \to \infty} B_{Q_1}(x_1^M(t), x_2^M(t)) d\mu(t) =
$$

$$
\frac{1}{\mu(R)} \int_R B_{Q_1}(w(t), w^{p_1}(t)) d\mu(t) = \frac{1}{\mu(R)} \int_R w^r(t) dt = \langle w^r \rangle_R.
$$

Since $B_{Q_1}(x_1, x_2)$ is continuous in Q_1 and the above estimate holds for any $Q_1 > Q$, we get

$$
c(r,Q)\langle w \rangle_R^r = c(r,Q)x_1^r \leq \langle w^r \rangle_R.
$$

If we use this estimate for $q = r \in [1, 1/s_{p_1}^+]$, we obtain $w \in RH_q^*$. If we use this estimate for $-1/(q-1) = r \in (1/s_{p_1}^-, p_1]$, we obtain $w \in A_q^*$ for $1 - s_{p_1}^-(Q) < q < \infty$.

To prove Theorem [2.2](#page-2-2) we need to use a different Bellman function B_Q . Namely, the following result holds.

Theorem 3.3 (Theorem 1 in [\[10\]](#page-4-4)). *Fix p* > 1 *and r* ∈ ($1/s_p^-$, 1]∪[*p*, $1/s_p^+$) *for* s_p^{\pm} *defined in* [\(2\)](#page-2-0). For every $Q > 1$ there exists a non-negative function $B_O(x)$ defined in the domain $\Omega_Q:=\{x=(x_1,x_2)\in\mathbb{R}^2\colon 1\leqslant x_1x_2^{-1/p}\leqslant Q\}$ with the following property: $B_Q(x)$ is con*tinuous in x and Q, and for any line segment* $[x^-,x^+] \subset \Omega_Q$ *and* $x = \lambda x^- + (1-\lambda)x^+$ *,* $\lambda \in [0,1]$ *, we have*

$$
B_Q(x) \geq \lambda B_Q(x^-) + (1 - \lambda)B_Q(x^+).
$$

Moreover, $B(x_1, x_1^p)$ $\binom{p}{1} = x_1^r$ and $B_Q(x) \leqslant c(r, Q)x_1^r$ for some positive constant $c(r, Q)$ and *every* $x \in \Omega$ *Q.*

We also notice that the analog of Lemma [3.2](#page-3-1) reads the same, and with this in hand, the proof of Theorem [2.1](#page-2-1) is analogous to the proof of Theorem [2.2;](#page-2-2) we leave the details to the reader.
