AN INFINITE SURFACE WITH THE LATTICE PROPERTY II: DYNAMICS OF PSEUDO-ANOSOVS

W. PATRICK HOOPER

ABSTRACT. We study the behavior of hyperbolic affine automorphisms of a translation surface which is infinite in area and genus that is obtained as a limit of surfaces built from regular polygons studied by Veech. We find that hyperbolic affine automorphisms are not recurrent and yet their action restricted to cylinders satisfies a mixing-type formula with polynomial decay. Then we consider the extent to which the action of these hyperbolic affine automorphisms satisfy Thurston's definition of a pseudo-Anosov homeomorphism. In particular we study the action of these automorphisms on simple closed curves and on homology classes. These objects are exponentially attracted by the expanding and contracting foliations but exhibit polynomial decay. We are able to work out exact asymptotics of these limiting quantities because of special integral formula for algebraic intersection number which is attuned to the geometry of the surface and its deformations.

Introduction

Translation surfaces built from two copies of a regular polygon as depicted below were studied by Veech and proven to have beautiful properties [Vee89]. Perhaps most surprisingly, these surfaces admit affine symmetries distinct from the obvious Euclidean symmetries. An understanding of these symmetries allowed Veech to prove his famed dichotomy theorem: In all but countably many directions every trajectory equidistributes, and the countably many exceptional directions are completely periodic. Veech also used this symmetry group to answer natural counting problems on these surfaces.

Let X_n denote the double regular n-gon surface. In [Hoo14], we showed that by choosing affine maps A_n of the plane which send three consecutive vertices of the regular n-gon to the points

FIGURE 1. Veech's double 10-gon surface. Edge labels indicate glued edges.

Figure 2. From left to right, the surfaces $P_{\cos\frac{2\pi}{a}}$, P_1 and $P_{\frac{5}{4}}$ are shown.

(-1,1), (0,0) and (1,1), the sequence of surfaces $\mathbf{P}_{\cos\frac{\pi}{n}}=A_n(\mathbf{X}_n)$ converges to the infinite area surface \mathbf{P}_1 built from two polygonal parabolas, the convex hulls of the sets $\{(n,n^2):n\in\mathbb{Z}\}$ and $\{(n,-n^2):n\in\mathbb{Z}\}$. The limiting surface \mathbf{P}_1 is depicted in the center of Figure 2.

An affine automorphism of a translation surface S is a homeomorphism $\phi: S \to S$ which is a real affine map in local coordinates. Using the natural identification between tangent spaces to non-singular points of S with the plane, we see that the derivative $D\phi$ of such a map must be constant and so we interpret $D\phi$ as an element of $GL(2,\mathbb{R})$. The subgroup of $GL(2,\mathbb{R})$ consisting of derivatives of affine homeomorphisms of S is called the surface's *Veech group*. (We allow orientation reversing elements in the Veech group, which differs from conventions in some other articles.) For the surfaces we will consider, the Veech groups are contained in $SL^{\pm}(2,\mathbb{R})$, the group of 2×2 matrices with real entries and determinant ± 1 .

In [Hoo14], it was shown that the symmetries of $\mathbf{P}_{\cos\frac{\pi}{n}}$ persist to the limiting surface \mathbf{P}_1 and beyond: There are surfaces \mathbf{P}_c defined for $c\geq 1$ and all these surfaces have topologically conjugate affine automorphism group actions [Hoo14, Theorem 7]. The Veech groups of \mathbf{P}_c vary continuously in c and lie in the image of the representation $\rho_c:\mathcal{G}\to SL^\pm(2,\mathbb{R})$ where $\mathcal{G}=(C_2*C_2*C_2)\times C_2$ with C_2 denoting the cyclic group of order two and

$$\rho_c(\mathcal{G}) = \left\langle \begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix}, \begin{bmatrix} -1 & 2 \\ 0 & 1 \end{bmatrix}, \begin{bmatrix} -c & c-1 \\ -c-1 & c \end{bmatrix}, \begin{bmatrix} -1 & 0 \\ 0 & -1 \end{bmatrix} \right\rangle$$

describes the images of the generators.

We call a matrix in $SL^{\pm}(2,\mathbb{R})$ *hyperbolic* if it has two eigenvalues with distinct absolute values and call an affine automorphism *hyperbolic* if its derivative is hyperbolic. A hyperbolic matrix in

 $SL^{\pm}(2,\mathbb{R})$ has two real eigenvalues λ^u and λ^s with $|\lambda^u| > 1$, $|\lambda^s| < 1$ and $\lambda^u \lambda^s = \pm 1$. The Veech group $\rho_1(\mathcal{G})$ of \mathbf{P}_1 has numerous hyperbolic elements.

A significant goal of this paper is to address the extent to which hyperbolic affine automorphisms of infinite surfaces satisfy the defining properties of pseudo-Anosov homeomorphisms of closed surfaces. The example we study is very special which enables us to say more about these questions than we'd expect to be able to for a general surface, so in particular we expect this paper sets some limits on what we could hope to be true in general.

For closed surfaces, the dynamics of hyperbolic affine automorphisms are well known to be mixing since they admit Markov partitions [FLP12, §10.5]. On the surface \mathbf{P}_1 we observe that cylinders satisfy a mixing-type formula but with polynomial decay. A *cylinder* on a translation surface is a subset isometric to $\mathbb{R}/c\mathbb{Z} \times [0,h]$ for some circumference c>0 and height h>0. We say two sequences a_n and b_n are asymptotic and write $a_n \sim b_n$ if $\lim_{n\to\infty} \frac{a_n}{b_n} = 1$.

Theorem 1. Let A and B be cylinders in P_1 and $\phi : P_1 \to P_1$ be a hyperbolic affine automorphism with derivative $D\phi = \rho_1(g)$. Then

$$Area(\phi^n(\mathcal{A}) \cap \mathcal{B}) \sim \frac{1}{4\sqrt{2\pi}} \left(\frac{1}{\beta n}\right)^{\frac{3}{2}} Area(\mathcal{A}) Area(\mathcal{B}) \quad \textit{where} \quad \beta = \frac{1}{\lambda_1^u} \left[\frac{d}{dc} \lambda_c^u\right]_{c=1}$$

is a positive constant which can be computed using the formula above where we use λ_c^u to denotes the eigenvalue of $\rho_c(g)$ with greatest absolute value.

Note that λ_c^u is real and varies analytically in a neighborhood of c=1 because the entries of the matrix $\rho_c(g)$ are real polynomials in c and $\rho_1(g)$ is hyperbolic (and hyperbolicity is stable under perturbation of the matrix). This ensures that the quantity $[\frac{d}{dc}\lambda_c^u]_{c=1}$ is a well-defined real number. It will follow from later work (Lemma 5) that the quantity β is positive.

As a consequence of this theorem, we note that no hyperbolic ϕ is recurrent because of the $n^{\frac{-3}{2}}$ decay rate seen above:

Corollary 2. If $\phi: \mathbf{P}_1 \to \mathbf{P}_1$ is hyperbolic then its action on \mathbf{P}_1 is totally dissipative: there is a countable collection \mathcal{W} of Lebesgue-measurable subsets of \mathbf{P}_1 so that

- (1) the Lebesgue measure of the complement $\mathbf{P}_1 \setminus \bigcup_{W \in \mathcal{W}} W$ is zero, and
- (2) each $W \in \mathcal{W}$ is wandering in the sense that the collection $\{\phi^{-n}(W): n \geq 0\}$ is pairwise disjoint.

Because of non-recurrence, we tend to think points as the wrong objects to act to study hyperbolic affine automorphisms of \mathbf{P}_1 . Fortunately, some famous observations of Thurston suggest that acting on simple closed curves might be more natural.

We briefly recall Thurston's definition of a pseudo-Anosov homeomorphism of a closed surface M following [Thu86]. Let $\mathcal{S} = \mathcal{S}(M)$ be the collection of homotopically non-trivial simple closed curves up to isotopy on M. Letting $i: \mathcal{S} \times \mathcal{S} \to \mathbb{R}$ denote geometric intersection number (i.e., the minimum number of transverse intersections among curves from the isotopy classes), we have an induced map

$$i_*: \mathcal{S} \to \mathbb{R}^{\mathcal{S}}$$
 defined by $i_*(\alpha)(\beta) = i(\alpha, \beta)$

so that the image is contained in the non-negative cone of $\mathbb{R}^{\mathcal{S}}$. We let $\mathbb{PR}^{\mathcal{S}}$ denote the projectivization $\mathbb{R}^{\mathcal{S}}/(\mathbb{R} \setminus \{\mathbf{0}\})$ and $P: \mathbb{R}^{\mathcal{S}} \to \mathbb{PR}^{\mathcal{S}}$ denote the projectivization map. We endow $\mathbb{R}^{\mathcal{S}}$ with the product topology and $\mathbb{PR}^{\mathcal{S}}$ with the quotient topology. Thurston observed that for a compact surface M the projectivized image $P \circ i_*(\mathcal{S}(M))$ has compact closure which we will denote by $\mathcal{PS}(M)$. As long as the surface M has negative Euler characteristic, the closure $\mathcal{PS}(M)$

Figure 3. The horizontal cylinders A_i of P_1 .

is a sphere of dimension one less than the dimension of the Teichmüller space $\mathcal{T}(M)$ (and forms its *Thurston boundary*). The space $\mathcal{PS}(M)$ was identified with the space of projective measured foliations on M which Thurston also introduced and gives a geometric meaning to \mathcal{PS} . Homeomorphisms of M naturally act on $\mathcal{PS}(M)$ and isotopic homeomorphisms act in the same way. A *pseudo-Anosov* homeomorphism of M is a homeomorphism $\phi: M \to M$ for which there are non-zero μ^u and μ^s in \mathbb{R}^S such that their projections lie in $\mathcal{PS}(M)$ and so that there is a $\lambda > 0$ so that $\mu^u \circ \phi^{-1} = \lambda \mu^u$ and $\mu^s \circ \phi = \lambda^{-1} \mu^s$. The action of a pseudo-Anosov homeomorphism ϕ on $\mathcal{PS}(M)$ is analogous the action of a hyperbolic isometry on the boundary of hyperbolic space: For any $\alpha \in \mathcal{S}(M)$,

(1)
$$\lim_{n \to +\infty} P \circ i_* (\phi^n(\alpha)) = P(\mu^u) \quad \text{and} \quad \lim_{n \to +\infty} P \circ i_* (\phi^{-n}(\alpha)) = P(\mu^s),$$

see [FLP12, Corollary 12.3]. Thurston showed that more generally for any $P(\nu) \in \mathcal{PS}(M) \setminus \{P(\mu^u), P(\mu^s)\},$

(2)
$$\lim_{n \to \infty} P(\nu \circ \phi^{-n}) = P(\mu^u) \quad \text{and} \quad \lim_{n \to \infty} P(\nu \circ \phi^n) = P(\mu^s).$$

This paper investigates the extent to which the above results hold for the surface P_1 . We begin with trying to emulate the above definitions for P_1 .

Perhaps we have been slightly abusing terminology to call \mathbf{P}_1 a "surface". It has two infinite cone singularities coming from the vertices of the polygonal parabola. These singularities do not have neighborhoods locally homeomorphic to an open subset of the plane, so we define \mathbf{P}_1° to be \mathbf{P}_1 with these singularities removed. The space \mathbf{P}_1° is an infinite genus topological surface. We define $\mathcal{S} = \mathcal{S}(\mathbf{P}_1^\circ)$ to be the collection of simple closed curves in \mathbf{P}_1° up to isotopy and define $i_*: \mathcal{S} \to \mathbb{R}^{\mathcal{S}}$, $\mathbb{PR}^{\mathcal{S}}$ and $P: \mathbb{R}^{\mathcal{S}} \to \mathbb{PR}^{\mathcal{S}}$ as above. We define

$$\mathcal{PS}(\mathbf{P}_1^{\circ}) = \overline{P \circ i_*(\mathcal{S}(\mathbf{P}_1^{\circ}))}$$

only this time we note that \mathcal{PS} is not compact. (If α_n is a sequence of simple closed curves exiting every compact subset of \mathbf{P}_1° then $\lim i_*(\alpha_n) = \mathbf{0} \in \mathbb{R}^{\mathcal{S}}$ and no subsequence of $P \circ i_*(\alpha_n)$ converges in $\mathbb{PR}^{\mathcal{S}}$.) We show:

Theorem 3. Fix a hyperbolic affine automorphism $\phi: \mathbf{P}_1 \to \mathbf{P}_1$ and let $\lambda_1^u \in \mathbb{R}$ denote the expanding eigenvalue of $D\phi$. Let μ^u and μ^s be the elements of $\mathbb{R}^{\mathcal{S}(\mathbf{P}_1^\circ)}$ corresponding to the transverse measures on \mathbf{P}_1 to foliations parallel to the expanding and contracting eigenspaces of $D\phi$ respectively. Then:

- (1) We have $\mu^u \circ \phi^{-1} = |\lambda_1^u| \mu^u$ and $\mu^s \circ \phi^{-1} = |\lambda_1^u|^{-1} \mu^s$.
- (2) For any $\alpha \in \mathcal{S}(\mathbf{P}_1^{\circ})$, equation (1) holds. In fact, in the space $\mathbb{R}^{\mathcal{S}(\mathbf{P}_1^{\circ})}$ we have

$$\lim_{n\to\infty} \frac{n^{\frac{3}{2}}}{|\lambda_1^u|^n} i_* \left(\phi^n(\alpha)\right) = \frac{\mu^s(\alpha)}{4\beta^{\frac{3}{2}}\sqrt{2\pi} \left|\mathbf{u}^u\wedge\mathbf{u}^s\right|} \mu^u \quad \textit{and} \quad \lim_{n\to\infty} \frac{n^{\frac{3}{2}}}{|\lambda_1^u|^n} i_* \left(\phi^{-n}(\alpha)\right) = \frac{\mu^u(\alpha)}{4\beta^{\frac{3}{2}}\sqrt{2\pi} \left|\mathbf{u}^u\wedge\mathbf{u}^s\right|} \mu^s$$

where β is given as in Theorem 1 and \mathbf{u}^u and \mathbf{u}^s denote expanding and contracting unit eigenvectors of $D\phi$. In particular, we have $P \circ i_*(\phi^n(\alpha)) \to P(\mu^u)$ and $P \circ i_*(\phi^{-n}(\alpha)) \to P(\mu^s)$ so that $P(\mu^u), P(\mu^s) \in \mathcal{PS}(\mathbf{P}_1^\circ)$.

On the other hand, it is not true (2) holds for every $P(\nu) \in \mathcal{PS}(\mathbf{P}_1^\circ) \setminus \{P(\mu^u), P(\mu^s)\}$. For every direction θ of irrational slope and every c>1, there is a direction θ' and a homeomorphism $h: \mathbf{P}_1 \to \mathbf{P}_c$ (in the isotopy class of a standard identification between these surfaces) which carries the foliation on \mathbf{P}_1 in direction θ to the foliation in direction θ' on \mathbf{P}_c . Furthermore, if θ was stabilized by a hyperbolic affine automorphism $\phi: \mathbf{P}_1 \to \mathbf{P}_1$ then θ' is stabilized by an affine automorphism $\phi': \mathbf{P}_c \to \mathbf{P}_c$ which is the same up to the canonical identification and isotopy. We can pull back the transverse measure on \mathbf{P}_c in direction θ' to obtain another measured on the foliation of \mathbf{P}_1 in direction θ which is stabilized by ϕ . This was proved in a more general context in [Hoo15, Theorem 4.4]. This new measure corresponds to a distinct ϕ -invariant element of $\mathbb{R}^{\mathcal{S}(\mathbf{P}_1^\circ)}$. In fact we can see this element lives in $\mathcal{PS}(\mathbf{P}_1^\circ)$ in many cases because the straight-line flow in many eigendirections of pseudo-Anosov homeomorphisms is ergodic [Hoo15, Theorem 4.5], so that we can obtain projective approximations by simple closed curves by flowing point forward until it returns close and closing it up. As we increase the flow time, convergence to $P(\mu^u)$ is guaranteed for almost every starting point by the ratio ergodic theorem.

We have shown that elements in $P(\mathcal{S}(\mathbf{P}_1^{\circ}))$ are attracted under ϕ and ϕ^{-1} -orbits respectively by $P(\mu^u)$ and $P(\mu^s)$, but noted that this does not hold on the closure $\mathcal{PS}(P_1^{\circ})$, so it is natural to wonder how attractive $P(\mu^u)$ and $P(\mu^s)$ are in other contexts.

Since \mathbf{P}_1 is a translation surface, it is natural to orient our foliations in each direction and to consider our transverse measures to be signed measures. Informally, let $H_1(\mathbf{P}_1^\circ; \mathbb{R})$ be real weighted finite sums of homology classes of closed curves in \mathbf{P}_1° , and let $H_1(\mathbf{P}_1, \Sigma; \mathbb{R})$ be real weighted finite sums of homology classes of closed curves and curves joining the singularities of \mathbf{P}_1 . Algebraic intersection number gives a weakly non-degenerate bilinear map

$$\cap: H_1(\mathbf{P}_1^{\circ}; \mathbb{R}) \times H_1(\mathbf{P}_1, \Sigma; \mathbb{R}) \to \mathbb{R}.$$

Let $\mathcal{H} = \operatorname{Hom}(H_1(\mathbf{P}_1, \Sigma; \mathbb{R}), \mathbb{R})$ be the collection of linear maps from $H_1(\mathbf{P}_1, \Sigma; \mathbb{R})$ to \mathbb{R} and let $\mathcal{PH} = \mathcal{H}/(\mathbb{R} \setminus \{0\})$ be the projectivization of this space. In a parallel construction to geometric intersection number, we get a map induced by algebraic intersection and a projectivization map:

$$\cap_*: H_1(\mathbf{P}_1^\circ; \mathbb{R}) \to \mathcal{H}, \qquad P: \mathcal{H} \to \mathcal{PH}.$$

Given an oriented arc on P_1 we can lift it to the universal cover and project it to the plane under the developing map. The *holonomy vector* of the arc is the difference of the developed end

point and the starting point. Holonomy gives rise to linear maps

$$hol_1: H_1(\mathbf{P}_1^\circ; \mathbb{R}) \to \mathbb{R}^2$$
 and $hol_1: H_1(\mathbf{P}_1, \Sigma; \mathbb{R}) \to \mathbb{R}^2$,

where we write hol_1 to indicate we are computing holonomy on P_1 . Given a direction described by a unit vector $\mathbf{u} \in \mathbb{R}^2$ we get an element of \mathcal{H} using the linear map

(3)
$$H_1(\mathbf{P}_1, \Sigma; \mathbb{R}) \to \mathbb{R}; \quad \sigma \mapsto \mathbf{u} \wedge hol_1(\sigma)$$

where $\wedge: \mathbb{R}^2 \times \mathbb{R}^2 \to \mathbb{R}$ is the usual wedge product: $(a,b) \wedge (c,d) = ad - bc$.

If $\phi: \mathbf{P}_1 \to \mathbf{P}_1$ is an affine homeomorphism with hyperbolic derivative, then the choice of unit unstable and stable eigenvectors of $D\phi$ give rise via (3) to respective elements μ^u and μ^s of \mathcal{H} satisfying

$$\mu^u \circ \phi^{-1} = \lambda_1^u \mu^u$$
 and $\mu^s \circ \phi^{-1} = \lambda_1^s \mu^s$

where λ_1^u and λ_1^s are the expanding and contracting eigenvalues of $D\phi$. We show that the projectivized classes $P(\mu^u)$ and $P(\mu^s)$ respectively attract and repel every element of $P \circ \cap_* (H_1(\mathbf{P}_1^\circ; \mathbb{R}))$, but unlike in prior results the rate of polynomial decay depends on the chosen homology class.

Theorem 4. If $\gamma \in H_1(\mathbf{P}_1^{\circ}; \mathbb{R})$ is non-zero then

$$\lim_{n\to +\infty}P\circ \cap_* \left(\phi^n(\gamma)\right)=P(\mu^u)\quad \text{and}\quad \lim_{n\to +\infty}P\circ \cap_* \left(\phi^{-n}(\gamma)\right)=P(\mu^s).$$

Moreover, there is a descending sequence of subspaces indexed by \mathbb{N}

$$H_1(\mathbf{P}_1^{\circ}; \mathbb{R}) = S_0 \supset S_1 \supset S_2 \dots$$
 so that:

- (1) Each S_{j+1} is codimension one in S_j (i.e., S_{j+1} is the kernel of a surjective linear map $S_j \to \mathbb{R}$). (2) The intersection $\bigcap_{j\geq 0} S_j$ is the zero subspace $\{\mathbf{0}\}$.
- (3) For any $\gamma \in S_j \setminus S_{j+1}$ the sequence $\frac{n^{j+\frac{3}{2}}}{(\lambda_i^n)^n} \cap_* (\phi^n(\gamma))$ converges in \mathcal{H} to a non-zero scalar multiple of μ^u .

We remark that statement (3) also holds in the opposite direction, i.e., $\frac{n^{j+\frac{3}{2}}}{(\lambda_1^s)^{-n}} \cap_* (\phi^{-n}(\gamma))$ converges to a multiple of μ^s , but the rate given by j is determined by a different sequence of nested subspaces. This theorem is a consequence of our Theorem 19 which is stronger in that it gives a formula for the constant appearing in the limit in statement (3). The proof of Theorem 4 contains a concrete description of the subspaces S_j and gives a slightly different formula for the limiting constant; see (34).

Again we could consider trying to extend this type of convergence to a larger space, and \mathcal{PH} itself would be a natural candidate but this space also contains fixed points corresponding to measured foliations on P_c . It is not clear to the author if there is a natural intermediate space between $P \circ \cap_* (H_1(\mathbf{P}_1^\circ; \mathbb{R}))$ and \mathcal{PH} in which we see $P(\mu^u)$ and $P(\mu^s)$ as the global attractor and repeller.

We will now briefly discuss the method we use to prove these results. The main idea is to completely understand algebraic intersection numbers, and we provide a formula for computing the algebraic intersection numbers between curves on P_1 . It first needs to be observed that the surfaces P_c for $c \ge 1$ are canonically homeomorphic, with the homeomorphisms coming from viewing P_c for $c \geq 1$ as a parameterized deformation of translation surfaces. Fixing a curve $\gamma \in \mathbf{P}_1$ representing a homology class we can use these canonical homeomorphisms to obtain corresponding curves in P_c . We observe that the holonomies of these curves measured on P_c denoted $hol_c\gamma\in\mathbb{R}^2$ depend polynomially in c. Thus this quantity makes sense for all $c\in\mathbb{R}$. In Lemma 12, we show that for any two curves γ and σ representing homology classes on \mathbf{P}_1 , their algebraic intersection number is given by

(4)
$$\gamma \cap \sigma = \frac{1}{2\pi} \int_0^{\pi} ((hol_{\cos t} \gamma) \wedge (hol_{\cos t} \sigma)) (1 - \cos t) dt.$$

This result gives a mechanism to reduce the Theorems above to questions involving the asymptotics of certain trigonometric integrals.

Organization of article.

- In §1 we provide a condensed description of main ideas we use from the theory of translation surfaces. We give more formal descriptions of the homological spaces mentioned above.
- In §2 we investigate the continuous family of representations that arises out of considering the Veech groups of the surfaces \mathbf{P}_c . This family of representations is studied in the abstract and we prove results about eigenvalues that are crucial for our later arguments.
- Section 3 addresses the geometry and dynamics of P_1 .
 - In §3.1 we review the construction of the surfaces P_c .
 - In §3.2 we compute generating sets for the homological spaces we work with.
 - In §3.3 we explain how holonomies of homology classes deform as we vary c and formalize our intersection number formula described in (4).
 - In §3.4 we describe the affine automorphism groups of the surfaces \mathbf{P}_c for $c \geq 1$.
 - In §3.5 we prove Theorem 19, which is the most important result in the paper: it gives an asymptotic formula for algebraic intersections of the form $\phi^n(\gamma) \cap \sigma$. We use it to prove Theorem 4.
 - In §3.6 we prove our asymptotic formula for intersections of cylinder described by Theorem 1. The key is the observation that the area of intersection of two cylinders is largely governed by algebraic intersection numbers between the core curves.
 - In §3.7 we consider geometric intersection numbers and prove Theorem 3.

1. Background and notation

A translation surface is a topological surface with an atlas of charts to the plane so that the transition functions are translations. Equivalently, an translation surface S is a surface whose universal cover is equipped with a local homeomorphism called the *developing map dev* from the universal cover \tilde{S} to \mathbb{R}^2 so that for any deck transformation $\Delta: \tilde{S} \to \tilde{S}$, there is a translation $T: \mathbb{R}^2 \to \mathbb{R}^2$ so that $dev \circ \Delta = T \circ dev$. Such a surface should be considered equivalent to the surface obtained by post-composing the developing map with a translation. Note that this definition does not allow for cone singularities on the surface but they may be treated as punctures.

In this paper we will be considering surfaces of infinite genus, but our surfaces will be decomposable into countably many triangles. Each translation surface we consider S will be a countable disjoint union of triangles with edges glued together pairwise by translations in such a way so that each point on the interior of an edge has a neighborhood isometric to an open subset of the plane. (Figure 6 depicts such a decomposition for P_1 .) We will use Σ to denote the *singularities* which are the equivalence classes of the vertices of the triangles in S. The surface $S \setminus \Sigma$ is a translation surface, while S itself is not a surface if countably many triangles meet at a singularity.

Let R be a ring containing \mathbb{Z} such as \mathbb{Z} or \mathbb{R} . For us, first relative homology over R is $H_1(\mathbf{S}, \Sigma; R)$ may be viewed as the R-module generated by oriented edges of the triangulation of \mathbf{S} and subject

to the conditions that the sum of two copies of the same edge with opposite orientations is zero as is the sum of edges oriented as the boundary of a triangle. Less formally, $H_1(\mathbf{S}, \Sigma; R)$ may be viewed as homology classes consisting of finite weighted sums of curves joining points in Σ and closed curves subject to the condition that they pass through only finitely many triangles. Any such curve is homotopic to a union of edges and the resulting class in $H_1(\mathbf{S}, \Sigma; R)$ is independent of the choice of such a homotopy.

Let S° denote $S \setminus \Sigma$. We define $H_1(S^{\circ}; \mathbb{Z})$ to be the abelianization of $\pi_1(S^{\circ})$. Note that by compactness a closed curve in S° only intersects finitely many triangles defining S. We define $H_1(S^{\circ}; R)$ to be $H_1(S^{\circ}; \mathbb{Z}) \otimes_{\mathbb{Z}} R$. Again, we may consider $H_1(S^{\circ}; R)$ to represent all finite sums of closed curves in S° weighted by elements of R.

We use \cap to denote the algebraic intersection number

$$\cap: H_1(\mathbf{S}^\circ; \mathbb{Z}) \times H_1(\mathbf{S}, \Sigma; \mathbb{Z}) \to \mathbb{Z}$$

which is bilinear. We follow the convention that $\alpha \cap \beta$ is positive if α is moving rightward and β is moving upward. With R as above, algebraic intersection extends to a bilinear map

$$\cap: H_1(\mathbf{S}^\circ; R) \times H_1(\mathbf{S}, \Sigma; R) \to R.$$

Let $\gamma:[0,1]\to \mathbf{S}$ be a curve and let $\tilde{\gamma}:[0,1]\to \tilde{\mathbf{S}}$ be a lift to the universal cover. The holonomy vector of γ is

$$hol \ \gamma = dev \circ \tilde{\gamma}(1) - dev \circ \tilde{\gamma}(0).$$

Observe that this quantity is independent of the choice of lift. Holonomy yields linear maps

$$hol: H_1(\mathbf{S}, \Sigma; \mathbb{R}) \to \mathbb{R}^2 \quad \text{and} \quad hol: H_1(\mathbf{S}^\circ; \mathbb{R}) \to \mathbb{R}^2$$

which send a weighted sum of curves to the corresponding weighted sum of holonomy vectors. We use hol for both maps because the following map diagram commutes

$$H_1(\mathbf{S}^\circ; \mathbb{R}) \xrightarrow{hol} H_1(\mathbf{S}, \Sigma; \mathbb{R})$$

where $H_1(\mathbf{S}^\circ; \mathbb{R}) \to H_1(\mathbf{S}, \Sigma; \mathbb{R})$ is induced by the inclusion \mathbf{S}° of into \mathbf{S} .

Let S be a translation surface built as above by gluing together triangles in a countable set \mathcal{T} . Let $f: S \to S$ be a homeomorphism preserving the singular set Σ and satisfying the condition that for any $T \in \mathcal{T}$, the image $f(T \setminus \Sigma)$ intersects only finitely many triangles in \mathcal{T} . Then f acts naturally on the homological spaces defined above. We denote this action by f_* . Let $\tilde{f}: \tilde{S} \to \tilde{S}$ be a lift to the universal cover. We say that f is an affine automorphism of S if there is an affine map $A: \mathbb{R}^2 \to \mathbb{R}^2$ so that

$$dev \circ \tilde{f} = A \circ dev.$$

This notion does not depend on the lift \tilde{f} . The derivative of an affine automorphism $f: \mathbf{S} \to \mathbf{S}$ is the element $Df \in GL(2,\mathbb{R})$ which is given by A post-composed by a translation (so that the origin is fixed). We say f is *hyperbolic* if Df is a hyperbolic matrix, i.e., Df has distinct eigenvalues and their absolute values differ. Observe that if f is an affine automorphism then for any homology class σ we have

$$hol\ f_*(\sigma) = Df \cdot hol(\sigma).$$

Figure 4. The fixed point sets of A_c , B_c and C_c in the upper half plane model depicted from left to right for the cases of $c = \cos \frac{\pi}{4}$, c = 1, and $c = \frac{5}{4}$ from left to right.

The collection of all affine automorphisms of **S** forms a group which we denote by $Aff(\mathbf{S})$. In this paper, the *Veech group* of **S** is $DAff(\mathbf{S}) \subset GL(2,\mathbb{R})$. (Some papers consider the Veech group to be $DAff(\mathbf{S}) \cap SL(2,\mathbb{R})$.)

2. A SUBGROUP DEFORMATION

For each real $c \in \mathbb{R}$ let Γ_c denote the subgroup of $SL^{\pm}(2,\mathbb{R})$ generated by -I together with the involutions

(5)
$$A_c = \begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix}, \quad B_c = \begin{bmatrix} -1 & 2 \\ 0 & 1 \end{bmatrix}, \quad \text{and} \quad C_c = \begin{bmatrix} -c & c - 1 \\ -c - 1 & c \end{bmatrix}.$$

We will later see that Γ_c realizes the Veech group $DAff(\mathbf{P}_c)$ for $c \geq 1$, but in this section we will be interested in proving some results about how the deformation Γ_c effects hyperbolic elements of Γ_1 .

The group $PGL(2,\mathbb{R})$ is naturally identified with the isometry group of the hyperbolic plane, and each of these three matrices act by reflections in a line in the hyperbolic plane (called the axis of the reflection). Figure 4 depicts the axes of reflections corresponding to the matrices above. Observe that the relationship between the lines A and C changes as c varies. We will be concerned with the groups Γ_c when $c \geq -1$. Observe that $C_{-1} = -B_{-1}$. When -1 < c < 1, the axes of reflections A_c and C_c intersect at an angle of θ where $\cos \theta = c$. When $\theta = \frac{2\pi}{n}$, the group Γ_c is discrete with the triangle formed by the reflection axes forming a fundamental domain for the group action. When c = 1, these reflection axes become tangent at infinity, and Γ_c becomes the congruence two subgroup of $SL^\pm(2,\mathbb{Z})$ whose fundamental domain is the ideal triangle enclosed by the three reflection axes. When $c \geq 1$, the group stays discrete but is no longer a lattice since the fundamental domain which consists of the enclosed ultra-ideal triangle has infinite area.

We will think of these groups as a continuous family of representations of the abstract group

(6)
$$\mathcal{G} = (C_2 * C_2 * C_2) \times C_2,$$

where $C_2 = \mathbb{Z}/2\mathbb{Z}$ is the cyclic group of order two. We define the representation

(7) $\rho: \mathcal{G} \to SL^{\pm}(2, \mathbb{Z}[c])$ sending the generators of \mathcal{G} to A_c, B_c, C_c and -I respectively.

For any $z \in \mathbb{C}$, we define

(8)
$$\rho_z: \mathcal{G} \to SL^{\pm}(2, \mathbb{C}); \quad g \mapsto \rho(g)(z),$$

i.e., we evaluate $\rho(g)$ with c=z. Below and throughout this paper, we abuse notation by identifying the free variable c temporarily with a constant, so we will simply write ρ_c rather than ρ_z .

The following is the main result we will need about this family of representations.

Lemma 5. Let $g \in \mathcal{G}$ be such that $\rho_1(g)$ has a real eigenvalue λ_1^u with $|\lambda_1^u| > 1$. For each $c \in \mathbb{R}$, let λ_c^u denote the choice of an eigenvalue realizing the maximum value of the absolute value of an eigenvalue of $\rho_c(g)$. Then:

- (1) We have $|\lambda_c^u| < |\lambda_1^u|$ whenever $-1 \le c < 1$.
- (2) The function $c \mapsto \lambda_c^u$ is differentiable at c=1 and the constant $\beta = \frac{1}{\lambda_1^u} \left[\frac{d}{dc} \lambda_c^u \right]_{c=1}$ is positive.

We remark that the constant β appeared in Theorems 1 and 3.

The remainder of the section is devoted to a proof of the Lemma and the following consequence which involves the operator norm $\|\cdot\|$ on real 2×2 matrices defined using the Euclidean metric on \mathbb{R}^2 .

Proposition 6. Let $g \in \mathcal{G}$ be as in Lemma 5. Let $c_0 \in \mathbb{R}$ be a number so that $-1 \leq c_0 < 1$. Then there is a constant $\xi \in \mathbb{R}$ with $1 < \xi < \lambda_1^u$ so that $\|\xi^{-n}\rho_c(g)^n\|$ converges to zero uniformly for $c \in [-1, c_0]$.

The group $PGL(2,\mathbb{R})$ is the isometry group of the hyperbolic plane. For a hyperbolic $G \in PGL(2,\mathbb{R})$ the eigenvalue λ^u of largest absolute value has the geometric significance:

(9)
$$\inf_{x \in \mathbb{H}^2} dist(x, Gx) = 2 \log |\lambda^u|.$$

Moreover, this infimum is achieved. The collection of points where this infimum is achieved is a geodesic in \mathbb{H}^2 called the *axis* of the hyperbolic isometry G. The axis has a canonical orientation determined by the direction G translates the geodesic. If G belongs to a discrete group Γ , then this axis projects to a curve of length $2\log|\lambda^u|$ in the quotient \mathbb{H}^2/Γ .

We will need to extend these ideas to triangular billiard tables which are not quotients of \mathbb{H}^2 by a discrete group. Let Δ be any triangle in \mathbb{H}^2 (with the case of interest being the triangles shown in Figure 4). We label the edges by the $\{A, B, C\}$ and we will use ℓ_a , ℓ_b , and ℓ_c to denote the bi-infinite geodesics in \mathbb{H}^2 that contain the marked edges. Let $\mathcal{G}' \cong C_2 * C_2 * C_2 * C_2$ represent \mathcal{G} modulo the central C_2 in \mathcal{G} . Given Δ we get a representation $\rho_\Delta : \mathcal{G}' \to PGL(2, \mathbb{R})$ where we send the generators $g_A, g_B, g_C \in \mathcal{G}'$ to the reflections in ℓ_a, ℓ_b , and ℓ_c respectively.

Each conjugacy class [g] in \mathcal{G}' has a representative of the form

(10)
$$g = g_{L_0} g_{L_1} \dots g_{L_{n-1}}$$
 with each $L_i \in \{A, B, C\}$

where $L_i \neq L_{i+1}$ for any $i \in \{0, \ldots, n-1\}$ and addition taken modulo n. Moreover this representative is unique up to cyclic permutations. We define the *orbit-class* $\Omega([g])$ to be the collection of all closed rectifiable curves in \mathbb{H}^2 that visit the lines $\ell_{L_0}, \ell_{L_1}, \ldots, \ell_{L_{n-1}}$ in that order. We define the *orbit-length* of [g] to be $\mathcal{L}([g]) = \inf_{\gamma \in \Omega([g])} length(\gamma)$.

We have the following lemma.

Lemma 7. Fix Δ and notation as above. Let $g \in \mathcal{G}'$ and let [g] be its conjugacy class. Let λ^u denote the eigenvalue of $\rho_{\Delta}(g)$ with largest absolute value. Then $2 \log |\lambda^u| \leq \mathcal{L}([g])$.

The proof is essentially the "unfolding" construction from polygonal billiards:

Proof. The statement is certainly true unless $|\lambda^u| > 1$. Since eigenvalues are a conjugacy invariant, we may assume that g is given as in (10). If the conclusion is false, there is a $\gamma \in \Omega(G)$ with length less than $2 \log |\lambda^u|$. We will draw a contradiction by construct a new path γ' in \mathbb{H}^2 with length equal to that of γ such that $\rho_{\Delta}(g)$ translates the starting point of γ' to the ending point of γ' violating (9).

We may assume γ begins on the geodesic ℓ_{L_0} and then travels to ℓ_{L_1} and so on. For $i \in \{0,\ldots,n-1\}$, let γ_i be the portion of γ which travels from $\ell_{L_{i-1}}$ to ℓ_{L_i} with subscripts taken modulo n so that $\gamma = \gamma_1 \cup \ldots \cup \gamma_{n-1} \cup \gamma_0$. Define $h_0,\ldots,h_n \in \mathcal{G}'$ inductively so that h_0 is the identity element of \mathcal{G}' and $h_{i+1} = h(i)g_{L_i}$. This makes $h_n = g$ as given in (10). For $i \in \{0,\ldots,n-1\}$ set $\gamma_i' = \rho_\Delta(h_i)(\gamma_i)$ and set $\gamma_n' = \rho_\Delta(h_n)(\gamma_0)$. We observe

- (1) The collection $\gamma_0' \cup \ldots \cup \gamma_n'$ is a continuous curve.
- (2) We have $\gamma'_n = \rho_{\Delta}(h_n)(\gamma'_0)$.

Statement (2) holds by construction since $\gamma_0 = \gamma_0'$ (as h_0 is the identity). To see statement (1) observe that γ_i terminates at ℓ_{L_i} at the same point at which γ_{i+1} starts. Thus, $\gamma_i \cup \rho_{\Delta}(g_{L_i})(\gamma_{i+1})$ passes continuously through ℓ_{L_i} . It follows that the arcs $\gamma_i' = \rho_{\Delta}(h_i)(\gamma_i)$ and $\gamma_{i+1}' = \rho_{\Delta}(h_ig_{L_i})(\gamma_{i+1})$ are joined at some point on $\rho_{\Delta}(h_i)(\ell_{L_i})$. This proves (1).

From (1) we see that a point on γ'_0 is joined to the corresponding point on γ'_n by a path of length equal to the length of γ , and from (2) we see that these points differ by an application of the hyperbolic isometry $\rho_{\Delta}(h_n)$. Recalling that $h_n = g$, we see this violates (9).

We will need to introduce one more idea. The *Klein model* for the hyperbolic plane consists of $\mathbb{KH}^2 = \{(x^2,y^2) \in \mathbb{R}^2 \mid x^2+y^2 < 1\}$. The boundary $\partial \mathbb{KH}^2 = \{(x^2,y^2) \in \mathbb{R}^2 \mid x^2+y^2 = 1\}$. Geodesics in the Klein model are Euclidean line segments. Distance between points in the Klein model may be computed in two ways. Let P_1 and P_2 be two points in \mathbb{KH}^2 , and let $\overline{P_1P_2}$ be the Euclidean line through them. Let Q_1 and Q_2 be the two points of $\partial \mathbb{KH}^2 \cap \overline{P_1P_2}$, chosen so that P_1 is closest in the Euclidean metric to Q_1 . Then the distance between P_1 and P_2 is given by the logarithm of the cross ratio,

(11)
$$dist_{\mathbb{KH}^2}(P_1, P_2) = \log \left(\frac{dist_{\mathbb{R}^2}(P_1, P_2) dist_{\mathbb{R}^2}(Q_1, Q_2)}{dist_{\mathbb{R}^2}(P_1, Q_1) dist_{\mathbb{R}^2}(P_2, Q_2)} \right).$$

Alternately, we can compute distance by using the metric tensor ds.

(12)
$$ds = \sqrt{\frac{dx^2 + dy^2}{1 - x^2 - y^2} + \frac{(xdx + ydy)^2}{(1 - x^2 - y^2)^2}}.$$

The distance between two points can be computed by integrating the metric tensor over the geodesic path between them. See [CFKP97] or any hyperbolic geometry text for more details.

As discussed above the projectivization of $\rho_c(\mathcal{G})$ to a subgroup of $PGL(2,\mathbb{R})$ is generated by the reflections in the sides of a triangle Δ_c in \mathbb{H}^2 . See Figure 4. When $c = \cos \theta \leq 1$, the triangle has two ideal vertices and one vertex with angle θ . For our purposes, we will think of $\Delta_c \subset \mathbb{KH}^2$. We define

(13)
$$\Delta_c = \operatorname{Convex} \operatorname{Hull}(\{P_1, P_2, P_3\}) \subset \mathbb{KH}^2$$

where $P_1=(-1,0)$, $P_2=(1,0)$, and $P_3=(0,\frac{\sqrt{1+c}}{\sqrt{2}})$. It is an elementary check that this triangle is isometric to the triangle used to define the reflection group $\rho_c(\mathcal{G})$. The reflection lines of the elements A_c , B_c , and C_c are given by $\ell_A=\overline{P_3P_1}$, $\ell_B=\overline{P_1P_2}$, and $\ell_C=\overline{P_2P_3}$ respectively.

FIGURE 5. A segment and its image under M_c .

Fixing c observe that $\rho_c: \mathcal{G} \to SL^{\pm}(2,\mathbb{R})$ projectivizes to a representation $\rho'_c: \mathcal{G}' \to PGL(2,\mathbb{R})$. The generators $g_A, g_B, g_C \in \mathcal{G}'$ are mapped under ρ'_c respectively to A_c, B_c and C_c of (5) viewed as elements of $PGL(2,\mathbb{R})$. Then ℓ_A, ℓ_B , and ℓ_C are the fixed point sets of these hyperbolic reflections.

Proof of Lemma 5, statement (1). Choose $g \in \mathcal{G}$ so that $\rho_1(g)$ has a real eigenvalue λ_1^u with $|\lambda_1^u| > 1$. Let $G_1 = \rho_1(g)$ which we think of as a hyperbolic transformation of \mathbb{H}^2 . In the case of c = 1, the group $\rho_1'(\mathcal{G}')$ is discrete and Δ_1 is a fundamental domain for the action. Thus, the projection of the axis of G_1 to $\mathbb{H}^2/\rho_1(\mathcal{G})$ minimizes length in the *orbit-class* $\Omega(g)$. In particular, this billiard path γ_1 realizes the infimum discussed in Lemma 7.

Let $|\lambda_c^u|$ denote the greatest absolute value of an eigenvalue of $G_c = \rho_c(g)$. We will use Lemma 7 to show that $|\lambda_c^u| < |\lambda_1^u|$ for all $-1 \le c < 1$. In coordinates on the closure of \mathbb{KH}^2 consider the linear map

(14)
$$M_c: \overline{\mathbb{KH}^2} \to \overline{\mathbb{KH}^2}: (x,y) \mapsto \left(x, \frac{y\sqrt{1+c}}{\sqrt{2}}\right).$$

Observe from our formula for the vertices that $M_c(\Delta_1) = \Delta_c$. We claim that M_c shortens every line segment in Δ_1 except line segments contained in the side $\overline{P_1P_2}$. Consider a segment \overline{XY} with finite length in Δ_1 . Let \overline{PQ} be the geodesic containing \overline{XY} , so that $P,Q \in \partial \mathbb{KH}^2$ with P the closest to X as in the left side of Figure 5. Then by (11),

$$\begin{array}{lcl} \operatorname{dist}_{\mathbb{KH}^{2}}(X,Y) & = & \log \Big(\frac{\operatorname{dist}_{\mathbb{R}^{2}}(X,Y)\operatorname{dist}_{\mathbb{R}^{2}}(P,Q)}{\operatorname{dist}_{\mathbb{R}^{2}}(X,P)\operatorname{dist}_{\mathbb{R}^{2}}(Y,Q)} \Big) \\ & = & \log \Big(\frac{\operatorname{dist}_{\mathbb{R}^{2}}(M_{c}(X),M_{c}(Y))\operatorname{dist}_{\mathbb{R}^{2}}(M_{c}(P),M_{c}(Q))}{\operatorname{dist}_{\mathbb{R}^{2}}(M_{c}(X),M_{c}(P))\operatorname{dist}_{\mathbb{R}^{2}}(M_{c}(Y),M_{c}(Q))} \Big). \end{array}$$

And, let $P',Q'\in\partial\mathbb{KH}^2$ be the points where the geodesic $\overline{M_c(P)M_c(Q)}$ intersects the boundary. Then,

$$\mathit{dist}_{\mathbb{KH}^2}(M_c(X), M_c(Y)) = \log \Big(\frac{\mathit{dist}_{\mathbb{R}^2}(M_c(X), M_c(Y)) \mathit{dist}_{\mathbb{R}^2}(P', Q')}{\mathit{dist}_{\mathbb{R}^2}(M_c(X), P') \mathit{dist}_{\mathbb{R}^2}(M_c(Y), Q')} \Big).$$

It is a standard computation that $dist_{\mathbb{KH}^2}(X,Y) > dist_{\mathbb{KH}^2}(M_c(X), M_c(Y))$ so long as the line segment $\overline{P'Q'}$ strictly contains the line segment $\overline{M_c(P)M_c(Q)}$, i.e., as long as $M_c(P) \neq P'$ or $M_c(Q) \neq Q'$. In particular, the only time this inequality could be false is when $PQ \subset \{(x,y)|y=0\}$. Our claim is proved.

To finish the proof, we apply the claim to the billiard path γ_1 constructed in the first paragraph. No finite length billiard path can have a segment contained in the line y=0, therefore

$$length(M_c(\gamma_1)) < length(\gamma_1).$$

whenever $-1 \le c < 1$. Then by Lemma 7, for all such c,

$$2\log|\lambda_c^u| \leq length(M_c(\gamma_1)) < length(\gamma_1) = 2\log|\lambda_1^u|.$$

Thus
$$|\lambda_c^u| < |\lambda_1^u|$$
.

Proof of Lemma 5, statement (2). Let $g \in \mathcal{G}$ be chosen so that $\rho_1(g)$ has an eigenvalue λ_1^u so that $|\lambda_1^u| > 1$. By possibly replacing $\rho_1(g)$ with $-I\rho_1(g)$ we may assume $\lambda_1^u > 1$. Let λ_c^u be the largest eigenvalue of $G_c = \rho_c(g)$, which by continuity of $c \mapsto G_c$ satisfies $\lambda_c^u > 1$ in a neighborhood of 1. We must show

$$\left. \frac{d}{dc} \lambda_c^u \right|_{c=1} > 0.$$

The quantity $\frac{d}{dc}\lambda_c^u$ exists at c=1, since entries of G_c vary polynomially in c. Thus we can afford to just look for a one-sided derivative and we will restrict attention to the case of c<1 so that we can make use of the map $M_c:\Delta_1\to\Delta_c$ of (14).

Let $m=\frac{\sqrt{1+c}}{\sqrt{2}}$. We have $\frac{d}{dc}m=\frac{1}{2\sqrt{2+2c}}$, and $\frac{d}{dc}m|_{c=1}=\frac{1}{4}$. By (12), the \mathbb{KH}^2 length of the tangent vector $\mathbf{i}=(1,0)$ at the point $(x,y)\in\mathbb{KH}$ is given by

$$I_1 = \frac{\sqrt{1 - y^2}}{1 - x^2 - y^2}.$$

The length of the tangent vector $M_c(\mathbf{i}) = (1,0)$ at the point $M_c(x,y) = (x,my)$ is given by

$$I_2 = \frac{\sqrt{1 - m^2 y^2}}{1 - x^2 - m^2 y^2}.$$

We compute

$$\frac{d}{dc}\frac{I_2}{I_1}\Big|_{c=1} = \frac{y^2(1+x^2-y^2)}{4(1-y^2)(1-x^2-y^2)}$$

which is positive on all of \mathbb{KH}^2 other than those points where y=0. Note, we are perturbing c in the negative direction. This says that off the line y=0, M_c is compressing every horizontal vector enough to be detected by the first derivative. Let J_1 be the \mathbb{KH}^2 length of the tangent vector $\mathbf{j} = (0,1)$ at the point $(x,y) \in \mathbb{KH}$ and J_2 be the \mathbb{KH}^2 length of the vector $M_c(\mathbf{j}) = (0,m)$ at the point $M_c(x,y) = (x,my)$. We have

$$J_1 = \frac{\sqrt{1-x^2}}{1-x^2-y^2}$$
 and $J_2 = \frac{m\sqrt{1-x^2}}{1-x^2-m^2y^2}$.

We compute

$$\frac{d}{dc}\frac{J_2}{J_1}\Big|_{c=1} = \frac{1 - x^2 + y^2}{4(1 - x^2 - y^2)} > 0.$$

In this case, M_c is compressing every vertical vector enough to be detected by the first derivative. The argument concludes in the same manner as the previous proof. Let γ_1 be the billiard path on Δ_1 corresponding to G_1 . The argument above tells us that $\frac{d}{dc}length(M_c(\gamma_1)) = k > 0$. But for c < 1,

$$2\log\lambda_c^u \leq \operatorname{length}(M_c(\gamma_1)) = \operatorname{length}(\gamma_1) - k(1-c) + \operatorname{higher order terms}.$$

By taking a straight forward derivative, we get

$$2\log \lambda_c^u = 2\log \lambda_1^u - (1-c)\frac{2\frac{d}{dc}\lambda_c^u|_{c=1}}{\lambda_1^u} + \textit{higher order terms}.$$

This pair of equations imply

$$\frac{d}{dc}\lambda_c^u|_{c=1} \ge \frac{k\lambda_1^u}{2} > 0.$$

Proof of Proposition 6. Fix a $c_0 < 1$. The function $c \mapsto |\lambda_c^u|$ is continuous so attains its maximum in $[-1, c_0]$. By (1) of Lemma 5 we know this maximum is less than λ_1^u , so we can select ξ so that $|\lambda_c^u| < \xi < \lambda_1^u$ for all $c \in [-1, c_0]$. We will show that $\xi^{-n} \rho_c(g)^n$ tends to the zero matrix uniformly in the operator norm.

First observe that it suffices to find an $N' \in \mathbb{N}$ so that $n \geq N'$ implies $\|\rho_c(g)^n\| < \xi^n$ for $c \in [-1, c_0]$. Suppose this statement is true and fix an $\epsilon > 0$. We will find an N so that n > N implies that the operator norm $\|\xi^{-n}\rho_c(g)^n\| < \epsilon$. By continuity of $c \mapsto \|\rho_c(g)^{N'}\|$ we can set

$$\begin{array}{rcl} \xi' & = & \sup \big\{ \| \rho_c(g)^{N'} \|^{\frac{1}{N'}} : \ c \in [-1,c_0] \big\} < \xi \\ M & = & \sup \big\{ \xi^{-n} \| \rho_c(g)^n \| : \ 0 \le n < N' \ \text{and} \ c \in [-1,c_0] \big\}. \end{array}$$

Then choose K sufficiently large so that

$$k > K$$
 implies $M\left(\frac{\xi'}{\xi}\right)^{-kN'} < \epsilon$.

Any n > (K+1)N' can be written in the form n = kN' + n' for some k > K and some n' satisfying $0 \le n' < N'$ so that by submultiplicativity of the operator norm we have

$$|\xi^{-n}||\rho_c(g)^n|| \le |\xi^{-n'}||\rho_c(g)^{n'}|| \cdot (|\xi^{-N'}||\rho_c(g)^{N'}||)^k \le M \left(\frac{\xi'}{\xi}\right)^{-kN'} < \epsilon.$$

The main idea is to continuously diagonalize the matrix action of $\rho_c(g)^n$. However there is a minor difficulty that for some values of c the matrix might not be diagonalizable. The matrices $\rho_c(g)$ have constant determinant ± 1 and so the eigenvalues are distinct except in the case that the determinant is one and the trace is ± 2 . There are only finitely many c at which the trace of $\rho_c(g)$ is ± 2 since the trace is polynomial in c and is not constant (by statement (2) of Lemma 5).

Let c_1, \ldots, c_k denote the finitely many values of c in $[-1, c_0]$ for which $\rho_c(g)$ has trace ± 2 . Observe that if $P \in SL(2,\mathbb{R})$ is a any matrix with determinant one and trace ± 2 , then the operator norm $\|P^n\|$ grows asymptotically linearly. We conclude that for each $i \in \{1, \ldots, k\}$ there is a N_i so that $n > N_i$ implies that $\|\rho_{c_i}(g)^n\| < \xi^n$. Then by continuity and submultiplicativity of the operator norm (similar to the argument above), we can find an $r_i > 0$ and a $N_i' > N_i$ so that

(15)
$$\|\rho_c(g)^n\| < \xi^n \quad \text{when } n > N_i' \text{ and } |c - c_i| \le r_i.$$

It remains to consider the complement $[-1,c_0] \setminus \bigcup_{i=1}^k (c_i-r_i,c_i+r_i)$. Let J be the closure of this complement which is a finite union of closed intervals. On each J the matrix $\rho_c(g)$ is continuously diagonalizable. That is, we have a continuous functions $\mathbf{v}^u,\mathbf{v}^s:J\to\mathbb{C}^2$ and continuous $\lambda^u,\lambda^s:J\to\mathbb{C}$ with $\lambda^u_c\neq\lambda^s_c$ for all $c\in J$ so that

$$\rho_c(g)(\mathbf{v}_c^u) = \lambda_c^u \mathbf{v}_c^u \quad \text{and} \quad \rho_c(g)(\mathbf{v}_c^s) = \lambda_c^s \mathbf{v}_c^s \quad \text{for } c \in J.$$

(Note that at this point u and s are just being used to distinguish eigenvectors and do not necessarily correspond to expanding and contracting directions.) Let P_c^u be the projection matrix

so that \mathbf{v}^u is an eigenvector with eigenvalue 1 and so that \mathbf{v}^s is an eigenvector with eigenvalue zero. Let P_c^s be the matrix with the \mathbf{v}^u and \mathbf{v}^s playing opposite roles. Then P_c^s and P_c^u vary continuously for $c \in J$ and we have

(16)
$$\rho_c(g)^n = (\lambda_c^u)^n P_c^u + (\lambda_c^s)^n P_c^s \quad \text{for all } n \in \mathbb{N} \text{ and } c \in J.$$

Letting M denote the supremum of the operator norms of all matrices of the form P_c^u and P_c^s with $c \in [-1, c_0]$ we see that

$$\|\rho_c(g)^n\| \le M(|\lambda_c^u|^n + |\lambda_c^s|^n) \le 2M(\xi')^n$$

where ξ' is the supremum of $|\lambda_c^u|$ and $|\lambda_c^s|$ over $c \in J$. Then by definition of ξ we have $\xi' < \xi$ and thus $2M(\frac{\xi'}{\xi})^n$ tends exponentially to zero. In particular, there is a N_J so that n>N implies that $\|\rho_c(g)^n\| < \xi^n \text{ for all } c \in J.$

Setting $N' = \max\{N'_1, \dots, N'_k, N_J\}$ we see that for any n > N' we have $\|\rho_c(g)^n\| < \xi^n$. From our first observation this proves the proposition.

3. The parabola surface

3.1. Construction. We follow the construction of the parabola surface as an affine limit of Veech's surfaces built from 2 regular n-gons as described in [Hoo14]. Consider the regular ngon in \mathbb{R}^2 to be the convex hull of the orbit of (1,0) under the rotation matrix

(17)
$$R_t = \begin{pmatrix} \cos t & -\sin t \\ \sin t & \cos t \end{pmatrix} \quad \text{where } t = \frac{2\pi}{n}.$$

Three points on this orbit are given by

$$R_t^{-1}(1,0) = (\cos t, -\sin t), \quad (1,0) \quad \text{and} \quad R_t^{-1}(1,0) = (\cos t, \sin t).$$

There is an affine transformation $C_t: \mathbb{R}^2 \to \mathbb{R}^2$ of the plane which carries these three points to (-1,1), (0,0) and (1,1), respectively and a calculation shows

(18)
$$C_t(x,y) = \left(\frac{y}{\sin t}, \frac{x-1}{\cos t - 1}\right).$$

The image of the regular polygon under C_t is the polygon Q_c^+ whose vertices lie in the orbit of (0,0) under $T_c = C_t \circ R_t \circ C_t^{-1}$ which we compute to be the affine map

(19)
$$T_c: \mathbb{R}^2 \to \mathbb{R}^2; \quad \begin{pmatrix} x \\ y \end{pmatrix} \mapsto \begin{pmatrix} c & c-1 \\ c+1 & c \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} + \begin{pmatrix} 1 \\ 1 \end{pmatrix} \quad \text{where } c = \cos t.$$

Observe that because T_c is an affine transformation defined with coefficients in $\mathbb{Z}[c]$, for any

 $k \in \mathbb{Z}$, the k-th vertex $T_c^k(0,0)$ of Q_c^+ has coordinates which are polynomial in c.

From the above it can be observed that when $c = \cos\frac{2\pi}{n}$ that Q_c^+ is an n-gon. When c = 1, the T_c -orbit is given by $T_c^n(0,0)=(n,n^2)$, and we interpret Q_c^+ as a polygonal parabola. Similarly, when c > 1, Q_c^+ should be interpreted as a polygonal hyperbola.

We let Q_c^- be the image of Q_c^+ under rotation by π about the origin. To form a surface \mathbf{P}_c for some $c = \cos \frac{2\pi}{n}$ or $c \geq 1$, we identify each edge e of Q_c^+ by translation with the image of the edge of Q_c^- obtained by applying this rotation. These surfaces are depicted in Figure 2.

FIGURE 6. Left: the surface P_1 with saddle connections σ_i labeled. Right: the closed geodesic γ_{-3} .

3.2. **Homological generators.** We use Σ to denote the collection of two singularities of \mathbf{P}_1 .

Proposition 8. The saddle connections in the common boundaries of the parabolas Q_1^+ and Q_1^- generate $H_1(\mathbf{P}_1, \Sigma; \mathbb{Z})$.

We denote these saddle connections by σ_i for $i \in \mathbb{Z}$. See Figure 6.

Proof. The surface \mathbf{P}_1 is triangulated by the saddle connections in the set $\{\sigma_i\}$ together with horizontal and slope one saddle connections. See Figure 6. Observe that by using the relation that the sum of edges around a triangle is zero, we can inductively write each horizontal and slope one saddle connection as a sum of the σ_i .

For each integer $j \neq 0$ we define γ_j to be the closed geodesic which travels within Q_1^+ from the midpoint of σ_0 to the midpoint of σ_j and then travel back within Q_1^- . See the right side of Figure 6. Let $\mathbf{P}_1^{\circ} = \mathbf{P}_1 \setminus \Sigma$.

Proposition 9. The curves γ_j generate $H_1(\mathbf{P}_1^{\circ}; \mathbb{Z})$.

Proof. Consider the polygonal region R in \mathbb{R}^2 formed by gluing together Q_1^+ and Q_1^- (not including vertices) along the interior of the edge σ_0 . The region R is simply connected. To form \mathbf{P}_1° we glue along the interiors of edges σ_j for $j \neq 0$. Thus the fundamental group of \mathbf{P}_1° is generated by curves within R which cross over exactly one of these edges. These are our γ_j curves, and this means that they also generate the abelianization of the fundamental group $H_1(\mathbf{P}_1^\circ; \mathbb{Z})$.

3.3. **Deformation and holonomy.** The surfaces \mathbf{P}_c for $c \geq 1$ are all homeomorphic by homeomorphisms $\mathbf{P}_c \to \mathbf{P}_{c'}$ respecting the decompositions $\mathbf{P}_c = Q_c^+ \cup Q_c^-$ and $\mathbf{P}_{c'} = Q_{c'}^+ \cup Q_{c'}^-$ and sending the orbit $n \mapsto T_c^n(0,0)$ of vertices of Q_c^+ to the orbit $n \mapsto T_{c'}^n(0,0)$ of vertices of $Q_{c'}^+$. This uniquely characterizes the homeomorphism up to isotopy.

The paper [Hoo14] noted that the surfaces \mathbf{P}_c for $c \geq 1$ are all naturally homeomorphic, and proved that the surfaces have the same geodesics in a coding sense and have affine automorphism groups which act in the same way (up to the natural homeomorphism on the surfaces).

For each $c \geq 1$ we have notion of holonomy on \mathbf{P}_c . Using the canonical homeomorphism $\mathbf{P}_1 \to \mathbf{P}_c$ we can evaluate this holonomy on classes in \mathbf{P}_1 giving us a family of holonomy maps

$$hol_c: H_1(\mathbf{P}_1, \Sigma, \mathbb{Z}) \to \mathbb{R}^2$$
 defined for $c \ge 1$.

Observe that T_c has determinant one and entries which are polynomial in c. Thus all vertices of Q_c^+ have coordinates which are integer polynomials in c. It follows that for any $\sigma \in H_1(\mathbf{P}_1, \Sigma; \mathbb{Z})$ the map $c \mapsto hol_c \sigma$ lies in $\mathbb{Z}[c]^2$. We define the *deformation holonomy map* of the family of surfaces \mathbf{P}_c to be the map

$$\widetilde{hol}: H_1(\mathbf{P}_1, \Sigma; \mathbb{Z}) \to \mathbb{Z}[c]^2$$

so that for $c \geq 1$ we have $\widetilde{hol}(\sigma)(c) = hol_c(\sigma)$.

By tensoring with \mathbb{R} we extend hol to

(20)
$$\widetilde{hol}: H_1(\mathbf{P}_1, \Sigma; \mathbb{R}) \to \mathbb{R}[c]^2.$$

We have the following:

Proposition 10. The map hol of (20) is an isomorphism of \mathbb{R} -modules.

Proof. For $d \ge 0$ let P_d denote the collection of polynomials of degree at most d with coefficients in \mathbb{R} . Because we have normalized three vertices joined by σ_{-1} and σ_0 in our construction of Q_c^+ we can see that

(21)
$$\widetilde{hol} \, \sigma_0 = (1,1) \quad \text{and} \quad \widetilde{hol} \, \sigma_{-1} = (1,-1).$$

Both these vectors lie in P_0^2 . Recall that T_c carries each vertex of Q_c^+ to the subsequent vertex. From the definition of T_c in (19) we see that for all $j \in \mathbb{Z}$,

$$\widetilde{hol}\,\sigma_{j+1} = \left(\begin{array}{cc} c & c-1 \\ c+1 & c \end{array}\right) \widetilde{hol}\,\sigma_{j} \quad \text{and} \quad \widetilde{hol}\,\sigma_{j-1} = \left(\begin{array}{cc} c & -c+1 \\ -c-1 & c \end{array}\right) \widetilde{hol}\,\sigma_{j}.$$

Just considering the cs appearing in these matrices we can prove inductively that for k > 0,

(22)
$$\widetilde{hol} \, \sigma_k \in ((2c)^k, (2c)^k) + P_{k-1}^2 \quad \text{and} \quad \widetilde{hol} \, \sigma_{-k-1} \in ((2c)^k, -(2c)^k) + P_{k-1}^2.$$

To prove the proposition, it suffices to show that for every $n \geq 0$, the restriction of \widetilde{hol} to $span_{\mathbb{R}} \{ \sigma_{-n-1}, \sigma_{-n}, \dots, \sigma_{n-1}, \sigma_n \}$ is an isomorphism to P_n^2 . Noting that there are 2n+2 vectors in the list which matches the dimension of the space P_n^2 , we see it suffices to prove that

$$\widetilde{hol}ig(\operatorname{span}_{\mathbb{R}}\big\{\sigma_{-n-1},\sigma_{-n},\ldots,\sigma_{n-1},\sigma_{n}\big\}ig)\supset P_{n}^{2}$$

We prove this by induction. From 21 we see that the statement is true when n=0. Now assuming the statement holds for n=k-1, i.e., $\widetilde{hol}\left(\operatorname{span}_{\mathbb{R}}\left\{\sigma_{-k-2},\ldots,\sigma_{k-1}\right\}\right)\supset P_{k-1}^2$, we see from (22) that by adding σ_k and σ_{-k-1} to the list, the image of the new span contains P_k^2 .

Now consider the related map

(23)
$$\widetilde{hol}: H_1(\mathbf{P}_1^\circ; \mathbb{R}) \to \mathbb{R}[c]^2.$$

To understand it, consider the exact sequence of groups

$$0 \to H_1(\mathbf{P}_1^{\circ}; \mathbb{R}) \xrightarrow{\iota_*} H_1(\mathbf{P}_1, \Sigma; \mathbb{R}) \xrightarrow{\partial_*} H_0(\Sigma; \mathbb{R}) \to H_0(\mathbf{P}_1^{\circ}; \mathbb{R}) \to H_0(\mathbf{P}_1, \Sigma; \mathbb{R}) \to 0.$$

This is the standard relative homology long exact sequence in our setting, where we have used the observation that $H_*(\mathbf{P}_1; \mathbb{R}) \cong H_*(\mathbf{P}_1^\circ; \mathbb{R})$ since the two singularities are isolated and of infinite cone type guaranteeing that \mathbf{P}_1 is homotopy equivalent to \mathbf{P}_1° . The holonomy map factors

through the inclusion ι_* , i.e., $\widetilde{hol} \circ \iota_* = \widetilde{hol}$ and the above exact sequence says that ι_* is an inclusion so we see that the holonomy map (23) is an isomorphism to a subspace of $\mathbb{R}[c]^2$. To figure out what that subspace is observe that $\iota_*(H_1(\mathbf{P}_1^\circ; \mathbb{R})) = \ker \partial_*$. We can enumerate the two singularities as s_0 representing the identified vertices $\{(n,n^2)\}$ of the polygonal parabola with even coordinates and s_1 representing the identified vertices with odd coordinates. The image of δ_* is the collection elements of $H_0(\Sigma; \mathbb{R})$ of the form $x[s_1] - x[s_0]$ for some $x \in \mathbb{R}$. We can recover this value of x as the image of $H_1(\mathbf{P}_1, \Sigma; \mathbb{R})$ using the map

$$\epsilon: H_1(\mathbf{P}_1, \Sigma; \mathbb{R}) \to \mathbb{R}; \quad \sigma \mapsto \frac{1}{2} (\partial \sigma(s_1) - \partial \sigma(s_0))$$

which allows us to define the short exact sequence

$$0 \to H_1(\mathbf{P}_1^{\circ}; \mathbb{R}) \xrightarrow{\iota_*} H_1(\mathbf{P}_1, \Sigma; \mathbb{R}) \xrightarrow{\epsilon} \mathbb{R} \to 0.$$

Proposition 11. For $\sigma \in hol(\mathbf{P}_1, \Sigma; \mathbb{R})$ and $(x, y) = \widetilde{hol}(\sigma)$ the quantity y(-1) gives the value of $\epsilon(\sigma)$. Thus we have the isomorphism

$$\widetilde{hol}: H_1(\mathbf{P}_1^\circ; \mathbb{R}) \to \{(x, y) \in \mathbb{R}[c]^2: y(-1) = 0\}.$$

Proof. Since the map sending σ to y(-1) is linear, it suffices to check that $\epsilon(\sigma)$ agrees with y(-1) on our basis σ_j for $hol(\mathbf{P}_1, \Sigma; \mathbb{R})$. Observe that $\epsilon(\sigma_j) = (-1)^j$. Using formulas from the proof of Proposition 10 we can compute that

$$hol_{-1}(\sigma_j) = (-1)^j (2j+1,1),$$

and note that the *y*-coordinate matches $\epsilon(\sigma_i)$.

We will now prove the integral formula mentioned in the introduction.

Lemma 12 (Intersection as integration). The algebraic intersection number of any $\gamma \in H_1(\mathbf{P}_1^\circ; \mathbb{R})$ and any $\sigma \in H_1(\mathbf{P}_1, \Sigma; \mathbb{R})$ is given by

$$\frac{1}{2\pi} \int_0^{\pi} \left((\widetilde{hol} \ \gamma) \wedge (\widetilde{hol} \ \sigma) \right) (1 - \cos t) \ dt,$$

where the wedge product in the integral yields an element of $\mathbb{Z}[c]$ interpreted as a function of t by setting $c = \cos t$.

Proof. Observe that the integral expression is bilinear in γ and σ . Algebraic intersection number is bilinear as well, so it suffices to check the formula on our generating sets for $H_1(\mathbf{P}_1^\circ; \mathbb{Z})$ and $H_1(\mathbf{P}_1, \Sigma; \mathbb{Z})$. Observe that γ_j (oriented to move from σ_1 to σ_j in Q_1^+) intersects σ_j with positive sign and σ_0 with negative sign. Thus $\gamma_j \cap \sigma_k = \delta_{j,k} - \delta_{0,k}$ where $\delta_{a,b}$ equals 1 if a = b is zero otherwise. We will show that the integral evaluates to the same expression.

First we need to compute $hol \ \gamma_j$ and $hol \ \sigma_k$. Let $v_n = T_c^n(0,0) \in \mathbb{Z}[c]^2$ be the n-th vertex of Q_c^+ viewed as a polynomial in c. Observe

$$\widetilde{hol} \ \gamma_i = v_{i+1} + v_i - v_1 - v_0$$
 and $\widetilde{hol} \ \sigma_k = v_{k+1} - v_k$.

Using the fact that $T_c = C_t \circ R_t \circ C_t^{-1}$ and the definition of C_t in (18), we see $v_n = C_t (\cos nt, \sin nt)$. Therefore

(24)
$$\widetilde{hol} \gamma_j = C_t \Big(\cos \big((j+1)t \big) + \cos(jt) - \cos(t) - 1, \sin \big((j+1)t \big) + \sin(jt) - \sin(t) \Big),$$

$$\widetilde{hol} \sigma_k = C_t \Big(\cos \big((k+1)t \big) - \cos(kt), \sin \big((k+1)t \big) - \sin(kt) \Big).$$

The transformation C_t is affine and scales signed area by a multiplicative constant. Namely,

$$C_t(\mathbf{v}) \wedge C_t(\mathbf{w}) = \frac{1}{(1 - \cos t) \sin t} (\mathbf{v} \wedge \mathbf{w})$$
 for any $\mathbf{v}, \mathbf{w} \in \mathbb{R}^2$.

Letting $\mathbf{v} = C_t^{-1}(\widetilde{hol} \ \gamma_j)$ and $\mathbf{w} = C_t^{-1}(\widetilde{hol} \ \sigma_k)$ be the quantities in parenthesis enclosed in (24), we see that the quantity being integrated is

$$\frac{\mathbf{v} \wedge \mathbf{w}}{\sin t} = 2\cos((k-j)t) - 2\cos(kt),$$

where we have done significant simplifying using trigonometric identities. It follows that

$$\frac{1}{2\pi} \int_0^{\pi} \frac{\mathbf{v} \wedge \mathbf{w}}{\sin t} dt = \delta_{j,k} - \delta_{0,k}.$$

as desired.

For our later discussion of geometric intersection numbers, it will be useful for us to extend our notion of algebraic intersection number to a bilinear map

(25)
$$\cap: H_1(\mathbf{P}_1, \Sigma; \mathbb{R}) \times H_1(\mathbf{P}_1, \Sigma; \mathbb{R}); \quad \sigma_1 \cap \sigma_2 = \frac{1}{2\pi} \int_0^{\pi} \left((\widetilde{hol} \ \sigma_1) \wedge (\widetilde{hol} \ \sigma_2) \right) (1 - \cos t) \ dt.$$

This extension has geometric meaning for saddle connections.

Lemma 13. Let σ_1 and σ_2 be saddle connections and let $i(\sigma_1, \sigma_2)$ denote the number of (unsigned) intersections of σ_1 and σ_2 not counting those that occur at the singularities. Then

$$\left|i(\sigma_1,\sigma_2)-|\sigma_1\cap\sigma_2|\right|\leq 1.$$

Proof. There two cases to consider. First suppose one of the curves joins a singularity to itself, say σ_1 has two endpoints at the singularity s_* . Then σ_1 is really a loop and we can apply a homotopy only deforming σ_1 in a small neighborhood of the s_* which makes σ_1 into a new closed loop $\hat{\sigma}_1$. We will detail a way to obtain $\hat{\sigma}_1$ so that it is fairly easy to see what is happening. For $r \in (0, \sqrt{2})$ observe that the ball of radius r about s_* contains no complete saddle connections. By choosing $r \in (0, \sqrt{2})$ sufficiently small we can arrange that the ball $B_r(s_*)$ only intersects σ_1 and σ_2 in segments of length r at the start and end of the saddle connections. (The ball will only intersect σ_2 if it starts or ends at the same singularity.) Chop off the segments of σ_1 that are within the ball. Since this singularity is an infinite cone singularity, the boundary $\partial B_r(s_*)$ is homeomorphic to the real line, so we can join the points of where σ_1 hits the ball by a unique arc $\partial B_r(s_*)$. Call the resulting loop $\hat{\sigma}_1$. The added arc may cross σ_2 if the saddle connection σ_2 starts or ends at s_* . If σ_2 has one endpoint at s_* , we have introduced at most one new crossing so that the result holds in this case. If σ_2 both starts and ends at s_* , then the added arc may cross twice, but if it does then the signs ascribed to the intersections are opposite. Again we have shown that $|\sigma_1 \cap \sigma_2|$ is within one of $i(\sigma_1, \sigma_2)$.

If we can not arrange to be in the first case, then both σ_1 and σ_2 join distinct singularities. Orientation is irrelevant for the statement we are trying to prove, so we can assume σ_1 moves from singularity s_0 to singularity s_1 and σ_2 moves from s_1 to s_0 . Let γ_1 be the curve formed by concatenating σ_1 and σ_2 . Because our extended definition of \cap is bilinear and alternating, we have

$$\sigma_1 \cap \sigma_2 = \gamma_1 \cap \sigma_2$$
.

We can again make γ_1 into a closed curve $\hat{\gamma}_1$ following the method of the previous paragraph. This time we choose r small enough so that the two balls $B_r(s_0)$ and $B_r(s_1)$ do not intersect and

so that the balls only intersect the saddle connections in initial and terminal segments. So $\hat{\gamma}_1$ follows σ_1 outside of the two balls then wraps around the boundary of $B_r(s_1)$, then follows a σ_2 until it hits $B_r(s_1)$ and closes up following the boundary of $B_r(s_0)$. Actually, it is better not to follow σ_2 exactly, instead we follow a parallel arc which stays on one side of σ_2 . Again the arcs in the boundary of the balls may have introduced one or two new crossings, but if we introduce two then they occur with opposite signs. Again we have shown that $|\sigma_1 \cap \sigma_2|$ is within one of $i(\sigma_1, \sigma_2)$.

3.4. **Affine automorphisms.** The affine automorphism group was investigated carefully in [Hoo14].

Theorem 14 (Theorem 3 [Hoo14]). For $c \ge 1$, the group $D(Aff(\mathbf{P}_c))$ is generated by A_c , B_c , C_c and -I as defined in (5).

Since P_c never has translation automorphisms, we have the following:

Proposition 15 (Proposition 5 [Hoo14]). For $c \ge 1$, the homomorphism $D: Aff(\mathbf{P}_c) \to GL(2, \mathbb{R})$ is one-to-one.

As a consequence we see that for each $c \geq 1$, there is a canonical isomorphism

$$\Phi_c: \mathcal{G} \to Aff(\mathbf{P}_c)$$
 so that $D \circ \Phi_c(g) = \rho_c(g)$ for all $g \in \mathcal{G}$,

where G and ρ_c are defined as in (6) and (8) respectively. The actions are essentially the same in a topological sense:

Theorem 16 (Theorem 7 [Hoo14]). For $c, c' \geq 1$ and any $g \in \mathcal{G}$, the automorphisms $\Phi_c(g) : \mathbf{P}_c \to \mathbf{P}_c$ and $\Phi_{c'}(g) : \mathbf{P}_{c'} \to \mathbf{P}_{c'}$ are the same up to conjugation by the canonical homomorphism $\mathbf{P}_c \to \mathbf{P}_{c'}$ and isotopy.

This has the following consequence for our deformation holonomy map.

Proposition 17. Let $\phi = \Phi_1(g) \in Aff(\mathbf{P}_1)$. Then the induced actions of ϕ on $H_1(\mathbf{P}_1^\circ; \mathbb{Z})$ and $H_1(\mathbf{P}_1, \Sigma; \mathbb{Z})$ satisfy

$$\widetilde{hol} \circ \phi(\gamma) = \rho(g) \, \widetilde{hol}(\gamma)$$

where $\rho:\mathcal{G} o \mathit{SL}^\pm(2,\mathbb{Z}[c])$ was defined in (7).

Proof. Fixing a $c \geq 1$, we see that $hol_c \circ \Phi_c(g) = \rho_c(g) \cdot hol_c(\gamma)$ since $D \circ \Phi_c(g) = \rho_c(g)$. This expression represents the equation in the proposition evaluated at a specific $c \geq 1$, but we have verified it for uncountably many values (all $c \geq 1$). Fixing any γ , the expression claims equality of two elements of $\mathbb{Z}[c]^2$. The entries are polynomial and we have verified the equation on infinitely many values, so the equation holds for all c.

3.5. Asymptotics of algebraic intersections. In this subsection we state our main result involving asymptotic algebraic intersection numbers of homology classes. The main ideas involve using \widehat{hol} to convert the homology classes to elements of $\mathbb{R}[c]^2$, use Proposition 17 to convert an affine automorphism's action to the action of an element $\rho(g) \in SL^{\pm}(2,\mathbb{Z}[c])$, and to use our integral formula to evaluate the intersection numbers.

It is useful to notice that since $\rho_1(g)$ is hyperbolic, the matrices $\rho_c(g)$ are diagonalizable in a neighborhood of c=1. We can express this diagonalization in the form

(26)
$$\rho_c(g) = \lambda_c^u P_c^u + \lambda_c^s P_c^s$$

where λ_c^u and λ_c^s are analytic real valued functions of c corresponding to the expanding and contracting eigenvalues of $\rho_c(g)$ and P_c^u denote the projection matrices (matrices with one eigenvalue

equal one and one equal zero) with the same eigenvectors as $\rho_c(g)$. Again we just interpret these quantities as defined and analytic in a neighborhood of c=1.

Let $\mathbf{v}, \mathbf{w} \in \mathbb{R}[c]^2$. We define

$$\mathbf{v} \bar{\wedge} \mathbf{w} = (P_c^u \mathbf{v}) \wedge \mathbf{w}$$

which is a real valued analytic function defined in a neighborhood of c=1. This quantity relates to constants in our asymptotics and it will be important to know that this function can not be identically zero.

Lemma 18. Let $\rho_1(g)$ be hyperbolic and define P_c^u and $\overline{\wedge}$ as above. Then so long as $\mathbf{v}, \mathbf{w} \in \mathbb{R}[c]^2$ are both non-zero, the real analytic function $\mathbf{v} \wedge \mathbf{w}$ is not identically zero.

Proof. First observe that $P_c^u + P_c^s = I$ so that

$$\mathbf{v} \bar{\wedge} \mathbf{w} = (P_c^u \mathbf{v}) \wedge (P_c^u \mathbf{w} + P_c^s \mathbf{w}) = (P_c^u \mathbf{v}) \wedge (P_c^s \mathbf{w}).$$

Since the functions are analytic and the eigendirections are transverse, the only way $\mathbf{v} \wedge \mathbf{w}$ could be identically zero is if either $P_c^u \mathbf{v}$ was identically zero or $P_c^s \mathbf{w}$ was identically zero.

We will approach this by contradiction and without loss of generality we may assume $P_c^u \mathbf{v} \equiv 0$. This says that $\mathbf{v}(c)$ lies in the stable eigenspace of $\rho_c(g)$ for all c sufficiently close to one. That is,

$$\rho_c(g)\mathbf{v} = \lambda_c^s \mathbf{v}.$$

The entries of both $\rho_c(g)\mathbf{v}$ and \mathbf{v} lie in $\mathbb{R}[c]$. Thus it follows that λ_c^s is a rational function, i.e., there are polynomials $p,q\in\mathbb{R}[c]$ so that $\lambda_c^s=\frac{p}{q}$ in a neighborhood of c=1 wherever $q(c)\neq 0$ (which holds an open set since \mathbf{v} has non-zero polynomial entries). Furthermore, we can assume that $\frac{p}{q}$ is reduced in the sense that p and q share no roots in \mathbb{C} . Since $\det \rho_c(g)\equiv \pm 1$, we know that $\lambda_c^u=\pm\frac{q}{p}$. The sum of the eigenvalues is the trace of $\rho_c(g)$ which we will denote by $t\in\mathbb{R}[c]$. Thus we have the identity

$$(28) p^2 \pm q^2 = tpq.$$

By Lemma 5, we know $\frac{d}{dc}\lambda_c^u|_{c=1}\neq 0$, so that at least one of p and q is non-constant. This means that one of those, say p, two has a root $z\in\mathbb{C}$. Then z is also a root of tpq. Thus it follows from (28) that z must be a root of q^2 and therefore also of q, but this contradicts our assumption that p and q do not share a common root.

The following is our main technical result. It describes the asymptotics of homology classes under a hyperbolic affine automorphism.

Theorem 19. Suppose $\phi: \mathbf{P}_1 \to \mathbf{P}_1$ is hyperbolic affine automorphism with derivative $D\phi = \rho_1(g)$. Let $\gamma \in H_1(\mathbf{P}_1^\circ; \mathbb{R})$ and $\sigma \in H_1(\mathbf{P}_1, \Sigma; \mathbb{R})$ be non-zero classes. Define quantities as above in (26) and (27). Let $k \geq 0$ be an integer and $\kappa \in \mathbb{R}$ be nonzero so that the Taylor expansion of $\widetilde{hol}\gamma \wedge \widetilde{hol}\sigma$ about c = 1 is of the form

$$\widetilde{hol}\gamma \wedge \widetilde{hol}\sigma = \kappa(c-1)^k + O((c-1)^{k+1}).$$

(Note that this quantity is not identically zero by Lemma 18.) Then the sequence of algebraic intersection numbers $\phi^n_*(\gamma) \cap \sigma$ is asymptotic to a constant times $n^{-k-\frac{3}{2}}(\lambda^u_1)^n$, and in fact:

$$\lim_{n\to\infty} \frac{n^{k+\frac{3}{2}}}{(\lambda_1^u)^n} \left(\phi_*^n(\gamma)\cap\sigma\right) = \frac{(-1)^k \Gamma(k+\frac{3}{2})\kappa\sqrt{2}}{4\pi\beta^{k+\frac{3}{2}}}$$

where Γ denotes the gamma function and $\beta = \frac{1}{\lambda_1^u} \left[\frac{d}{dc} \lambda_c^u \right]_{c=1}$ as in Theorem 1 of the introduction. This result also holds for $\gamma, \sigma \in H_1(\mathbf{P}_1, \Sigma; \mathbb{R})$ with algebraic intersection numbers computed as in (25).

Proof. Fix γ and σ . We will compute intersections using the integral in Lemma 5 with this being the definition in the case $\gamma, \sigma \in H_1(\mathbf{P}_1, \Sigma; \mathbb{R})$. Let $c = \cos t$ throughout this proof. Let $\mathbf{v}_c = \widetilde{hol} \ \gamma$ and $\mathbf{w}_c = \widetilde{hol} \ \sigma$ which are both elements of $\mathbb{R}[c]^2$. Determine k and κ as stated in the theorem. By our integral formula for intersection numbers and Proposition 17,

$$\phi_*^n(\gamma) \cap \sigma = \frac{1}{2\pi} \int_0^\pi \left((\rho_c(g)^n \mathbf{v}_c) \wedge \mathbf{w}_c \right) (1 - \cos t) dt.$$

Here, the quantity $(\rho_c(g)^n \mathbf{v}_c) \wedge \mathbf{w}_c$ lies in $\mathbb{R}[c]$ and we integrate with respect to t while taking $c = \cos t$.

We will be demonstrating that

(29)
$$\frac{n^{k+\frac{3}{2}}}{2\pi(\lambda_1^u)^n} \int_0^{\pi} \left(\left(\rho_c(g)^n \mathbf{v}_c \right) \wedge \mathbf{w}_c \right) (1 - \cos t) \, dt$$

is asymptotic to the quantity on the right side of the equation in the theorem.

Let λ_c^u be an eigenvalue for $\rho_c(g)$ realizing the maximum absolute value of an eigenvalue. From Lemma 5 we know that $\frac{d}{dc}|\lambda_c^u|_{c=1}>0$ and thus we can find an interval $[0,\epsilon]$ on which $t\mapsto |\lambda_{\cos t}^u|$ is decreasing and takes values larger than one. We can split the integral of (29) into two pieces at ϵ . The contribution of the interval $[\epsilon,\pi]$ to (29) can be written as

(30)
$$\frac{n^{k+\frac{3}{2}}}{2\pi \left(\frac{\lambda_1^u}{\xi}\right)^n} \int_{\epsilon}^{\pi} \left(\xi^{-n} \rho_c(g)^n \mathbf{v}_c\right) \wedge \mathbf{w}_c \left(1 - \cos t\right) dt,$$

where ξ is some quantity so that $1 < \xi < |\lambda_1^u|$ so that $\xi^{-n} \| \rho_c(g)^n \|$ tends to zero uniformly for $t \in [\epsilon, \pi]$ as obtainable from Proposition 6. Observe that the fraction in front of (30) decays to zero because of the exponential growth of $\left(\frac{\lambda_1^u}{\xi}\right)^n$. The integral in (30) also tends to zero because \mathbf{v}_c , \mathbf{w}_c and $1 - \cos t$ are continuous in t and therefore bounded in absolute value by a constant. On the other hand, from our use of Proposition 6, the quantity $\xi^{-n}\rho_c(g)^n$ decays to zero uniformly.

Now consider the interval $[0, \epsilon]$. As in (26), on this interval we can write

$$\rho_c(g)^n = (\lambda_c^u)^n P_c^u + (\lambda_c^s)^n P_c^s \quad \text{for } n \ge 0.$$

Thus we can split the contribution of $[0,\epsilon]$ to (29) into unstable and stable parts. The stable part has the form

$$\frac{n^{k+\frac{3}{2}}}{2\pi(\lambda_1^u)^n} \int_0^{\epsilon} \left(\left((\lambda_c^s)^n P_c^s \mathbf{v}_c \right) \wedge \mathbf{w}_c \right) (1 - \cos t) dt,$$

which tends to zero exponentially since $|\lambda_c^s| = |\lambda_c^u|^{-1} < 1$ so that the integral is uniformly bounded while the fraction in front decays exponentially.

The unstable part is more interesting and using the fact that λ_c^u has constant sign for $t \in [0, \epsilon]$ we can write it as

(31)
$$\frac{n^{k+\frac{3}{2}}}{2\pi|\lambda_1^u|^n} \int_0^{\epsilon} |\lambda_c^u|^n (\mathbf{v}_c \wedge \mathbf{w}_c) (1-\cos t) \ dt$$

where $\overline{\wedge}$ is used as in (27). We will use a theorem of Erdélyi following [Olv14, Ch. 3 §8] to study the asymptotics of the sequence of integrals (temporarily ignoring the fraction in front). The

integral can be written in the form

$$\int_0^{\epsilon} e^{-np(t)} q(t) dt \quad \text{where} \quad p(t) = -\ln|\lambda_c^u| \quad \text{and} \quad q(t) = (\mathbf{v}_c \wedge \mathbf{w}_c)(1 - \cos t).$$

To apply Erdélyi's theorem we need to know the first few terms of a series expansion for p(t) and q(t) about t=0. By the chain rule, in a neighborhood of t=0 we have

$$p'(t) = \frac{-1}{|\lambda_c^u|} \left(\frac{d}{dc} |\lambda_c^u|\right) (-\sin t).$$

Thus we have $p(0)=-\ln |\lambda_1^u|,\ p'(0)=0,$ and $p''(0)=\frac{1}{|\lambda_1^u|}\cdot [\frac{d}{dc}|\lambda_c^u|]_{c=1}=\beta,$ which is positive by statement (2) of Lemma 5. In addition, we know that t=0 is the location of the minimum of p(t) on $[0,\epsilon]$. Recalling that a Taylor series expansion for $\mathbf{v}_c\ \bar{\wedge}\ \mathbf{w}_c=\widetilde{hol}\ \gamma\ \bar{\wedge}\ \widetilde{hol}\ \sigma$ in terms of c was given as a hypothesis of the Theorem, we have

$$q(t) = \frac{(-1)^k \kappa}{2^{k+1}} t^{2k+2} + O(t^{2k+4}).$$

By [Olv14, Theorem 8.1], the sequence of values of integrals has the asymptotic form

$$e^{-np(0)} \left[\Gamma\left(k + \frac{3}{2}\right) \cdot n^{-k - \frac{3}{2}} \cdot \frac{(-1)^k \kappa}{2^{k+1}} \cdot \frac{1}{2} \cdot \left(\frac{p''(0)}{2}\right)^{-k - \frac{3}{2}} + O(n^{-k-2}) \right].$$

Plugging these values in for the integral in (31), we obtain the limit stated in the theorem. \Box

Proof of Theorem 4. It suffices to prove the second statement, since the statement on convergence of projective classes to $P(\mu^u)$ and $P(\mu^s)$ follows from statement (3) in the theorem.

Fix ϕ and notation as above. Given a non-zero $\gamma \in H_1(S, \Sigma; \mathbb{R})$ observe that $P_c^u \widetilde{hol} \gamma$ has coordinates which are real analytic functions of c. As a consequence of Lemma 18, $P_c^u \widetilde{hol} \gamma$ is not identically zero. Then by analyticity, the following constant is defined

(32)
$$k = \min \left\{ k \in \mathbb{Z} : \quad k \ge 0 \quad \text{and} \quad \left[\frac{d^k}{dc^k} P_c^u \widetilde{hol} \gamma \right]_{c=1} \ne \mathbf{0} \right\}.$$

The value of k can be interpreted as a function $k: H_1(S,\Sigma;\mathbb{R}) \to \mathbb{Z} \cup \{+\infty\}$ where we assign $k(\gamma)$ as in (32) except if $\gamma = \mathbf{0}$ in which case we assign $+\infty$. Then we can define the subsets in the theorem to be $S_j = \{\gamma: k(\gamma) \geq j\}$. Fixing k we observe that the map $D_k: \gamma \mapsto \frac{d^k}{dc^k} P_c^u hol\gamma$ is linear and consequently the S_j are subspaces and each S_{j+1} is codimension at most one in S_j . Recalling Proposition 11, we see that we can construct pairs of polynomials (p,q) in the image of $hol(H_1(S,\Sigma;\mathbb{R}))$ so that the minimal $k \geq 0$ such that $[\frac{d^k}{dc^k}P_c^u(p,q)]_{c=1} \neq \mathbf{0}$ is arbitrary: Such (p(c),q(c)) need to approximate the stable direction of $\rho_c(g)$ at c=1 to order k-1 but not order k. It follows that S_{j+1} is always codimension one in S_j . Finally because of the previous paragraph we know that if $\gamma \neq \mathbf{0}$ then $k(\gamma) \neq 0$ so that $\bigcap_{j \geq 0} S_j = \{\mathbf{0}\}$. We have proved statements (1) and (2) of the theorem.

To see (3) fix a non-zero γ and let k be as in (32). We need to show that there is a constant L so that for any $\sigma \in H_1(S, \Sigma; \mathbb{R})$,

$$\lim_{n \to +\infty} \frac{n^{k+\frac{3}{2}}}{(\lambda_1^u)^n} (\phi^n(\gamma) \cap \sigma) = L\mu^u(\sigma),$$

and by definition $\mu^u(\sigma) = \mathbf{u}_1^u \wedge hol_1(\sigma)$ where \mathbf{u}^u denotes a choice of a unit unstable eigenvector of $\rho_1(g)$. It suffices to prove this for elements of the form σ_l which generate $H_1(S; \Sigma; \mathbb{R})$ by Proposition 9. Theorem 19 tells us that

(33)
$$\lim_{n \to +\infty} \frac{n^{k+\frac{3}{2}}}{(\lambda_1^u)^n} \left(\phi^n(\gamma) \cap \sigma \right) = \frac{(-1)^k \Gamma(k+\frac{3}{2}) \kappa \sqrt{2}}{4\pi \beta^{k+\frac{3}{2}}}$$

with κ chosen so that

$$\widetilde{hol}\gamma \wedge \widetilde{hol}\sigma = \kappa(c-1)^k + O((c-1)^{k+1}).$$

Let \mathbf{u}_c^u denote the continuous choice of unstable unit eigenvectors of $\rho_c(g)$ defined in a neighborhood of c=1, which extends the choice of \mathbf{u}_1^u used in the definition of μ^u . Then we can define the real-analytic function f(c) so that

$$\widetilde{hol}\gamma \wedge \widetilde{hol}\sigma_l = f(c) \left(\mathbf{u}_c^u \wedge \widetilde{hol}\sigma_l\right).$$

Here $f(c)=\pm\|P_c^u\widetilde{hol}\gamma\|$ and may be changing signs as c passes through 1. To compute κ we just need to look at the lowest order terms in this expression computed at the point c=1. Observe that $hol_1\sigma_l\in\mathbb{Z}^2$ while \mathbf{u}_1^u has quadratic irrational slope so we know that $\mathbf{u}_1^u\wedge hol_1\sigma_l$ is a non-zero constant. On the other hand using our definition of k we know that $hol_1\sigma_k \wedge hol_1\sigma_k \wedge hol_1\sigma$

$$\lim_{n \to +\infty} \frac{n^{k+\frac{3}{2}}}{|\lambda_1^u|^n} \left(\phi^n(\gamma) \cap \sigma_l \right) = \frac{(-1)^k \Gamma(k+\frac{3}{2}) \alpha \sqrt{2}}{4\pi \beta^{k+\frac{3}{2}}} \mu^u(\sigma_l).$$

The constant in front of $\mu^u(\sigma_l)$ is now independent of l so we see that

(34)
$$\lim_{n \to +\infty} \frac{n^{k+\frac{3}{2}}}{(\lambda_1^u)^n} \cap_* \circ \phi^n(\gamma) = \frac{(-1)^k \Gamma(k+\frac{3}{2}) \alpha \sqrt{2}}{4\pi \beta^{k+\frac{3}{2}}} \mu^u.$$

3.6. **Asymptotics of cylinder intersections.** The goal of this section is to prove Theorem 1 and Corollary 2 of the introduction.

We first need to make a general remark about cylinders intersection on a translation surface. Let \mathcal{C} be a cylinder on a translation surface S. A *core curve* $\gamma_{\mathcal{C}}$ of \mathcal{C} is a closed geodesic in \mathcal{C} . Such closed geodesic must wind once around the circumference of \mathcal{C} .

Proposition 20. Let A and B be cylinders on a translation surface S with core curves γ_A and γ_B . Assuming A and B are not parallel (i.e., $hol\gamma_A \wedge hol\gamma_B \neq 0$), we have

$$Area(\mathcal{A} \cap \mathcal{B}) = \frac{\left| \gamma_{\mathcal{A}} \cap \gamma_{\mathcal{B}} \middle| Area(\mathcal{A}) Area(\mathcal{B})}{\left| hol(\gamma_{\mathcal{A}}) \wedge hol(\gamma_{\mathcal{B}}) \middle|},$$

where $\gamma_A \cap \gamma_B$ denotes algebraic intersection number.

Proof. Cylinders on a translation surface intersect in a union of parallelograms, which are isometric and differ only by parallel translation. The number of these parallelograms is the absolute value of the algebraic intersection number between the core curves. Thus, we need to show that the area of one such parallelogram is given by

(35)
$$\frac{Area(\mathcal{A})Area(\mathcal{B})}{\left|hol(\gamma_{\mathcal{A}}) \wedge hol(\gamma_{\mathcal{B}})\right|}.$$

FIGURE 7. Two intersecting cylinders developed into the plane. Roman numerals indicate edge identifications, which reconstruct the cylinders.

Develop the two cylinders into the plane from an intersection as in Figure 7. Define the vectors **a**, **b**, **c**, and **d** as in the figure. Then the area of the two cylinders is given by the quantities

$$Area(\mathcal{A}) = |\mathbf{a} \wedge (\mathbf{b} + \mathbf{d})|$$
 and $Area(\mathcal{B}) = |(\mathbf{a} + \mathbf{c}) \wedge \mathbf{b}|$.

Since the pair of vectors a and c are parallel as are the pair b and d, we may write the product of areas as

$$Area(A)Area(B) = |\mathbf{a} \wedge \mathbf{b}||(\mathbf{a} + \mathbf{c}) \wedge (\mathbf{b} + \mathbf{d})|.$$

The wedge of the holonomies may be written as

$$|hol(\gamma_{\mathcal{A}}) \wedge hol(\gamma_{\mathcal{B}})| = |(\mathbf{a} + \mathbf{c}) \wedge (\mathbf{b} + \mathbf{d})|.$$

Thus, the quotient given in (35) is $|\mathbf{a} \wedge \mathbf{b}|$, the area of the parallelogram formed by the intersection.

Proof of Theorem 1. Let \mathcal{A} and \mathcal{B} be cylinders on \mathbf{P}_1 and let $\gamma_{\mathcal{A}}$ and $\gamma_{\mathcal{B}}$ be their core curves and let $\mathbf{v}, \mathbf{w} \in \mathbb{Z}^2$ be their holonomies. Let ϕ be a hyperbolic automorphism of \mathbf{P}_1 . Then $D\phi = \rho_1(g)$ is a hyperbolic element of $SL^{\pm}(2,\mathbb{Z})$. As a consequence the eigenvalues of $D\phi$ are quadratic irrationals and so $(P_1^u\mathbf{v}) \wedge \mathbf{w}$ is non-zero. In the context of Theorem 19 this implies that k=0 and $\kappa = (P_1^u\mathbf{v}) \wedge \mathbf{w}$ and so the theorem gives that

$$\phi^n(\gamma_{\mathcal{A}}) \cap \gamma_{\mathcal{B}} \sim (\lambda_1^u)^n n^{\frac{-3}{2}} \frac{\Gamma(\frac{3}{2})\kappa}{\pi \beta^{\frac{3}{2}} \sqrt{2}} = (\lambda_1^u)^n n^{\frac{-3}{2}} \frac{\kappa}{4\beta^{\frac{3}{2}} \sqrt{2\pi}}.$$

For sufficiently large values of n, the cylinders $\phi^n(A)$ and \mathcal{B} are not parallel, so we may apply Proposition 20 to obtain that

$$Area(\phi^{n}(\mathcal{A}) \cap \mathcal{B}) = \frac{\left|\phi^{n}(\gamma_{\mathcal{A}}) \cap \gamma_{\mathcal{B}}\right| Area(\mathcal{A}) Area(\mathcal{B})}{|\rho_{1}(g)^{n} \mathbf{v} \wedge \mathbf{w}|} \sim \frac{n^{\frac{-3}{2}} |\kappa| Area(\mathcal{A}) Area(\mathcal{B})}{4\beta^{\frac{3}{2}} \sqrt{2\pi} |(\lambda_{1}^{u})^{-n} \rho_{1}(g)^{n} \mathbf{v} \wedge \mathbf{w}|}.$$

The quantity $|(\lambda_1^u)^{-n}\rho_1(g)^n\mathbf{v}\wedge\mathbf{w}|$ converges to $|\kappa|$, so this gives us the expression in the statement of the theorem.

Proof of Corollary 2. Fix $\phi: \mathbf{P}_1 \to \mathbf{P}_1$ hyperbolic. We will explain how to produce the wandering sets $W_{i,k}$ so that $\mathbf{P}_1 \setminus \bigcup_{i,k} W_{i,k}$ has zero measure. Let \mathcal{A}_i be the i-th horizontal cylinder as depicted in Figure 3. By Theorem 1 applied to ϕ^{-1} we have

$$\sum_{n=0}^{\infty} \operatorname{Area} \left(\phi^{-n}(\mathcal{A}_i) \cap \mathcal{A}_i \right) < \infty.$$

This means that the set of points in \mathcal{A}_i which return infinitely often to \mathcal{A}_i has measure zero. For $k \geq 0$, let $W_{i,k}$ to be the set of points in \mathcal{A}_i which return exactly k times to \mathcal{A}_i under the action of ϕ^{-1} . From the remarks above we see that $\mathcal{A}_i \setminus \bigcup_{k \geq 0} W_{i,k}$ is measure zero. Since $\mathbf{P}_1 = \bigcup_i \mathcal{A}_i$ we see that $\mathcal{W} = \{W_{i,k}\}$ satisfies the statements in Corollary 2.

3.7. **Geometric intersection numbers.** The space P_1 is non-positively curved in the sense that its universal cover is CAT(0). This guarantees that all homotopically non-trivial closed curves have geodesic representatives in the metric sense. In particular every such curve has a realization as a sequence of saddle connections $\sigma_1, \ldots, \sigma_k$ so that the endpoint singularity of σ_i coincides with the start singularity of $\sigma_{i+1 \pmod k}$ and the angle made between the two saddle connections at this singularity is at least π . A closed metric geodesic may also be a closed non-singular straightline trajectory, but by moving to the boundary of the corresponding cylinder we can find a metric geodesic representative of this homotopy class consisting of a sequence of saddle connections.

We will now describe a way to compute the geometric intersection numbers between two non-trivial homotopy classes of closed curves in the punctured surface \mathbf{P}_1° . First we may find metric geodesic representatives $\alpha = \alpha_1 \cup \ldots \cup \alpha_k$ and $\gamma = \gamma_1 \cup \ldots \cup \gamma_l$ for the curves in \mathbf{P}_1 where the α_i and γ_j are saddle connections. There are two types of intersections between α and γ : those that occur at singularities and those that do not. The unit tangent bundle space T_1s_* at an infinite cone singularity s_* is naturally homeomorphic to a line and we can make it a metric line using angle coordinates, identifying it with the universal cover of $\mathbb{R}/2\pi\mathbb{Z}$. Two saddle connections meeting at a singularity s_* thus determine an interval I in T_1s_* . Our metric geodesics α and γ thus determine two sequences of intervals I_1, \ldots, I_k and I_1, \ldots, I_k in the pair of lines $I_1s_0 \cup I_2s_1$. We say two intervals I_1 and I_2 are linked if I_2 contains an endpoint of I_2 and I_3 contains an endpoint of I_3 .

Proposition 21. Assume the metric geodesics $\alpha = \alpha_1 \cup ... \cup \alpha_k$ and $\gamma = \gamma_1 \cup ... \cup \gamma_l$ are transverse in \mathbf{P}_1° (i.e., none of the saddle connections coincide). Then the geometric intersection number $i(\alpha, \gamma)$ is given by the sum of the number of intersections in \mathbf{P}_1° and the number of linked pairs of intervals (I, J) with $I \in \{I_i\}$ and $J \in \{J_i\}$.

Proof. We will show that we can find representatives of the classes α and γ which realize the claimed intersection number. Then we will argue that the representatives realize the intersection number.

There is an r>0 so that the open balls $B_r(s_0)$ and $B_r(s_1)$ do not intersect and only intersect the saddle connections in the set $\{\alpha_i\}\cup\{\gamma_j\}$ in segments of length r where the saddle connections enter and exit the singularities. Let $\mathbb H$ be the hyperbolic upper half plane. Because the singularities are infinite cone singularities, the balls are homeomorphic to $\mathbb H\cup\{\infty\}$ via a sending radial lines in the ball to vertical lines in $\mathbb H$ and sending the singularity to ∞ . Consecutive arcs of saddle connections of α and γ intersecting the balls $B_r(s_*)$ are then sent to a vertical geodesic headed to up infinity followed by a vertical geodesic back down to the real line in $\partial \mathbb H$. We can straighten such an arcs to a geodesic in $\mathbb H$ joining the places where the two arcs pass through the real axis. Do this for all the visits of the saddle connections to the singularities. Observe that two geodesics with distinct endpoints in $\mathbb H$ joining points in $\mathbb R$ intersect if and only if the corresponding intervals in $\mathbb R$ link. Transversality guarantees this distinct endpoint condition for the geodesics constructed as above. Thus performing this action results in a pair of curves $\hat{\alpha}$ and $\hat{\gamma}$ that intersect in precisely the number of times stated in the theorem.

We must argue that the number of intersections between $\hat{\alpha}$ and $\hat{\gamma}$ is minimal among curves in their homotopy classes. For this it suffices to show that we can not find a simple closed curve

formed from an arc of $\hat{\alpha}$ and an arc of $\hat{\gamma}$ which is homotopically trivial; see [FLP12, Proposition 3.10]. Such arcs must join together at a pair of intersections for $\hat{\alpha}$ and $\hat{\gamma}$. Existence of such a curve is ruled out by the Gauss-Bonnet theorem which promises that for a closed polygon in the plane, the total exterior angle is 2π . Indeed suppose we had two such arcs of $\hat{\alpha}$ and $\hat{\gamma}$ which formed a simple closed homotopically trivial loop $\hat{\eta}$. Then $\hat{\eta}$ bounds a topological disk. By deforming back to the flat geodesics α and γ we get a curve η that bounds a flat polygonal disk. By transversality, the interior angles at the intersections are positive, so the exterior angles at these intersection points are each strictly less than π . The other vertices of η must come from visits of α or γ to the singularities, and since they are metric geodesics the interior angles are at least π and so the exterior angles are negative. We conclude that the total exterior angle of η is less than 2π , which contradicts the existence of η .

Lemma 13 tells us how to estimate (within 1) the number of interior intersections of saddle connections. Combining this lemma with the above result yields:

Proposition 22. Let $\alpha = \alpha_1 \cup \ldots \cup \alpha_k$ and $\gamma = \gamma_1 \cup \ldots \cup \gamma_l$ be transverse closed metric geodesics in \mathbf{P}_1 . Then the geometric intersection number $i(\alpha, \gamma)$ is within 2kl of

$$\sum_{i=1}^{k} \sum_{j=1}^{l} |\alpha_i \cap \gamma_j| = \sum_{i=1}^{k} \sum_{j=1}^{l} \left| \frac{1}{2\pi} \int_0^{\pi} \left((\widetilde{hol} \ \alpha_i) \wedge (\widetilde{hol} \ \gamma_j) \right) (1 - \cos t) \ dt \right|.$$

Note that the identity in the equation above holds by definition see (25).

Proof. We get an error of up to kl from possible linked intervals in Proposition 21 and another error of up to one from comparing each integral to the number of interior intersections of the corresponding saddle connections (see Lemma 13).

Now consider an affine automorphism $\phi: \mathbf{P}_1 \to \mathbf{P}_1$. Let $\alpha = \alpha_1 \cup \ldots \cup \alpha_k$ be a closed metric geodesic on \mathbf{P}_1 . Observe that $\phi(\alpha) = \phi(\alpha_1) \cup \ldots \cup \phi(\alpha_k)$ is also a closed metric geodesic because this image satisfies the angle condition on consecutive saddle connections. As a consequence we see that when considering the geometric intersection number $i(\phi^n(\alpha), \gamma)$ we can use the integral formula above and the only effect is that we introduce a uniformly bounded error.

Fix $\phi: \mathbf{P}_1 \to \mathbf{P}_1$ with hyperbolic derivative $D\phi$. Let \mathbf{u}^u and \mathbf{u}^s be unstable and stable unit eigenvectors for $D\phi$. Then the stable and unstable elements $\mu^u, \mu^s \in \mathbb{R}^{\mathcal{S}(\mathbf{P}_1^\circ)}$ corresponding to the transverse measures on \mathbf{P}_1 to foliations parallel to the expanding and contracting directions are defined by evaluating them on a simple closed curve with metric geodesic representative $\alpha = \alpha_1 \cup \ldots \cup \alpha_k$ by

(36)
$$\mu^{u}(\alpha) = \sum_{i=1}^{k} |\mathbf{u}^{u} \wedge hol_{1}\alpha_{i}| \quad \text{and} \quad \mu^{s}(\alpha) = \sum_{i=1}^{k} |\mathbf{u}^{s} \wedge hol_{1}\alpha_{i}|.$$

Proof of Theorem 3. Statement (1) is standard: In the unstable direction we have

$$\mu^{u} \circ \phi^{-1}(\alpha) = \sum_{i=1}^{k} |\mathbf{u}^{u} \wedge D(\phi)^{-1}(hol_{1}\alpha_{i})| = \sum_{i=1}^{k} |D(\phi)(\mathbf{u}^{u}) \wedge hol_{1}\alpha_{i}|$$
$$= \sum_{i=1}^{k} |\lambda_{1}^{u}\mathbf{u}^{u} \wedge hol_{1}\alpha_{i}| = |\lambda_{1}^{u}|\mu^{u}(\alpha).$$

A similar argument works in the stable direction.

Now fix a homotopically non-trivial simple closed curve and let $\alpha = \alpha_1 \cup \ldots \cup \alpha_k$ be a metric geodesic representative. We will prove that $\frac{n^{\frac{3}{2}}}{|\lambda_1^u|^n} i_* \circ \phi^n(\alpha)$ converges to a constant times μ^s with the constant as given in the theorem. To prove this let γ be another homotopically non-trivial

simple closed curve and let $\gamma = \gamma_1 \cup \ldots \cup \gamma_k$ be a metric geodesic representative. Fixing an i and a j, and observe that $hol_1\alpha_i$ and $hol_1\gamma_j$ are non-zero vectors in \mathbb{Z}^2 so that $(P_u^1hol_1\alpha_i) \wedge hol_1\gamma_k \neq 0$. This tells us that k=0 in Theorem 19 and

$$|\kappa| = |(P_u^1 hol_1 \alpha_i) \wedge hol_1 \gamma_k| = \left| \left(\frac{\mathbf{u}^s \wedge hol_1 \alpha_i}{\mathbf{u}^s \wedge \mathbf{u}^u} \mathbf{u}^u \right) \wedge hol_1 \gamma_k \right| = \frac{\mu^s(\alpha_i) \mu^u(\gamma_j)}{|\mathbf{u}^u \wedge \mathbf{u}^s|},$$

where we are slightly abusing notation by applying (36) to saddle connections (but this is justified if we think of these functions as determining measured foliations.) Then from Theorem 19 we get

$$\lim_{n\to\infty} \frac{n^{\frac{3}{2}}}{|\lambda_1^u|^n} |\phi^{-n}(\alpha_i) \cap \gamma_j| = \frac{\mu^s(\alpha_i)\mu^u(\gamma_j)}{4\beta^{\frac{3}{2}}\sqrt{2\pi} |\mathbf{u}^u \wedge \mathbf{u}^s|}.$$

Then it follows from Proposition 22 that

$$\lim_{n\to\infty} \frac{n^{\frac{3}{2}}}{|\lambda_1^u|^n} i(\phi^n(\alpha), \gamma) = \sum_{i=1}^k \sum_{j=1}^l \frac{\mu^s(\alpha_i)\mu^u(\gamma_j)}{4\beta^{\frac{3}{2}}\sqrt{2\pi} |\mathbf{u}^u \wedge \mathbf{u}^s|} = \frac{\mu^s(\alpha)\mu^u(\gamma)}{4\beta^{\frac{3}{2}}\sqrt{2\pi} |\mathbf{u}^u \wedge \mathbf{u}^s|}.$$

This is equivalent to the first limiting statement in statement (2) of the theorem. The second limit can be obtained by switching ϕ for ϕ^{-1} and stable for unstable.

SOFTWARE USED

Software was used in several ways in this paper. SageMath [The18] and the FlatSurf SageMath Module [DH] were used to experimentally check the results in this paper. FlatSurf was also used to generate the figures of translation surfaces.

ACKNOWLEDGMENTS

Theorem 1 was first proved while the author was a postdoc at Northwestern and the author would like to thank John Franks and Amie Wilkinson for helpful conversations at the time. The author would also like to thank Barak Weiss for some more recent conversations, and the anonymous referee for suggesting a number of improvements. This article is based upon work supported by the National Science Foundation under Grant Number DMS-1500965 as well as a PSC-CUNY Award (funded by The Professional Staff Congress and The City University of New York).
