# On Polyhedral Estimation of Signals via Indirect Observations

Anatoli Juditsky <sup>∗</sup> Arkadi Nemirovski †

#### Abstract

We consider the problem of recovering linear image of unknown signal belonging to a given convex compact signal set from noisy observation of another linear image of the signal. We develop a simple generic efficiently computable nonlinear in observations "polyhedral" estimate along with computation-friendly techniques for its design and risk analysis. We demonstrate that under favorable circumstances the resulting estimate is provably nearoptimal in the minimax sense, the "favorable circumstances" being less restrictive than the weakest known so far assumptions ensuring near-optimality of estimates which are linear in observations.

### 1 Introduction

#### 1.1 Motivation

In this paper we consider the estimation problem as follows:

Given a noisy observation

<span id="page-0-0"></span>
$$
\omega = Ax + \xi \in \mathbf{R}^m,\tag{1}
$$

of linear image Ax of an unknown signal x, we want to recover the image  $w = Bx \in$  $\mathbf{R}^{\nu}$  of this signal. It is assumed that x is known to belong to a given signal set – a nonempty convex compact set  $\mathcal{X} \subset \mathbb{R}^n$ , and A and B are given  $m \times n$  and  $\nu \times n$ matrices;  $\xi$  is the observation noise with distribution  $P_x$  which may depend on x. In addition, we are given a norm  $\|\cdot\|$  on  $\mathbb{R}^{\nu}$  in which the estimation error is measured.

Estimation problem [\(1\)](#page-0-0) is a (nonparametric) linear inverse problem. Popular approaches to solving statistical inverse problems include, among others, Singular Value Decomposition (SVD), see, e.g., [\[22,](#page-28-0) [21,](#page-28-1) [30\]](#page-28-2), Galerkin projection[\[32\]](#page-28-3), Wavelet-Vaguelette Decompositions [\[8,](#page-27-0) [1,](#page-26-0) [14,](#page-27-1) [20\]](#page-28-4), adaptive Galerkin algorithms [\[6,](#page-27-2) [19\]](#page-28-5), as well as various iterative regularization techniques [\[40,](#page-29-0) [26\]](#page-28-6). When statistically analysed, those approaches usually assume a special structure of the problem, when matrix A and set  $\mathcal X$  "fit each other," e.g., there exists a sparse approximation of the set  $\mathcal X$  in a given basis/pair of bases, in which matrix A is "almost diagonal" (see, e.g. [\[8,](#page-27-0) [6\]](#page-27-2) for detail). Under these assumptions, traditional results focus on estimation algorithms which are both numerically straightforward and statistically (asymptotically) optimal with closed form

analytical description of estimates and corresponding risks. In the situation considered in this paper, where we do not assume any specific structure of  $X$  apart from convexity, compactness and "computationally tractability,"<sup>[1](#page-1-0)</sup> and  $A$ ,  $B$  are "general" matrices of appropriate dimensions, we cannot expect deriving closed form expressions for estimates and risks. Instead, we adopt an alternative approach initiated in [\[7\]](#page-27-3) and further developed in [\[23,](#page-28-7) [17,](#page-27-4) [25,](#page-28-8) [24\]](#page-28-9). Within this operational approach both the estimate and its risk are yielded by efficient computation, usually via convex optimization, rather than by an explicit closed form analytical description; what we know in advance, in good cases, is that the resulting risk, whether large or low, is nearly the best one achievable under the circumstances.

Note that a "standard choice" of statistical techniques which can be applied to solve [\(1\)](#page-0-0) is between Maximum Likelihood and Linear Estimation. Maximal Likelihood Estimation (MLE)  $[15, 16, 36]$  $[15, 16, 36]$  $[15, 16, 36]$  is a "universal" statistical tool; when the distribution  $P$  of the noise is known, the application to problem [\(1\)](#page-0-0) is straightforward. It is well known that MLE has excellent asymptotical properties in parametric models; however, it is also well known [\[2,](#page-26-1) [29,](#page-28-10) [4\]](#page-27-7) that Maximum Likelihood approach has significant drawbacks. For instance, let us consider the simple situation of direct observation where  $A = B = I_n$ , observations noise is Gaussian –  $\xi \sim \mathcal{N}(0, I_n), \|\cdot\| = \|\cdot\|_2$ , and

$$
\mathcal{X} = \{x = [x_1; ...; x_n] : |x_1| \le n^{1/4}, \|[x_2; ...; x_n]\|_2 + 2n^{-1/4}|x_1| \le 2\}.
$$

In this case, for n large enough, the squared risk of the MLE  $\hat{x}^{ML}$  satisfies [\[4\]](#page-27-7)

$$
\sup_{x \in \mathcal{X}} \mathbf{E}\{\|x - \widehat{x}^{ML}\|_2^2\} \ge \frac{3}{4}\sqrt{n},
$$

while for the minimax risk it holds

<span id="page-1-1"></span>
$$
\inf_{\hat{x}} \sup_{x \in \mathcal{X}} \mathbf{E}\{\|x - \hat{x}\|_2^2\} \le 5,\tag{2}
$$

with the upper bound [\(2\)](#page-1-1) attained at the simple linear estimator  $\hat{x} = [\omega_1; 0; \dots; 0].$ 

Aside of Maximum Likelihood, very popular, due to their relative simplicity, estimates are the linear ones – those of the form  $\omega \mapsto \hat{w}(\omega) = G^T \omega$ . Linear estimates have received much attention in the statistical literature (cf. [\[27,](#page-28-11) [28,](#page-28-12) [38,](#page-29-2) [35,](#page-28-13) [12,](#page-27-8) [13,](#page-27-9) [5,](#page-27-10) [41,](#page-29-3) [39\]](#page-29-4) among many others) When designing a linear estimate, the emphasis is on how to specify the matrix  $G$  in order to obtain the lowest possible maximal over  $\mathcal X$  estimation risk, which is then compared to the minimax risk (the infimum, taken w.r.t. all Borel estimates  $\hat{x}(\cdot)$ , of the worst case, over signals from  $X$ , expected norm of the recovery error). "Near optimality" results for the case of indirect observations (where A and B are arbitrary) are the subject of recent papers  $[25, 24]$  $[25, 24]$ , where it was shown that in the spectratopic case, where  $\mathcal X$  and the unit ball  $\mathcal B_*$  of the norm conjugate to  $\|\cdot\|$  are spectratopes<sup>[2](#page-1-2)</sup>, a properly designed, via solving an explicit convex optimization problem, linear estimate is nearly optimal.

What follows is motivated by the desire to build an alternative estimation scheme which works beyond the ellitopic/spectratopic case, where linear estimates can become "heavily nonoptimal."

<span id="page-1-2"></span><span id="page-1-0"></span><sup>&</sup>lt;sup>1</sup>For a brief outline of computational tractability, see Section [A.1](#page-29-5) of the appendix.

<sup>&</sup>lt;sup>2</sup>see [\[24\]](#page-28-9) or Section [4.5.](#page-18-0)A below; as of now, a instructive example of spectratope is the intersection of finite family of ellipsoids/elliptic cylinders with common center, or, to give a more exotic example, the unit ball of the spectral norm in the space of matrices.

**Motivating example.** Consider the simple-looking problem of recovering  $Bx = x$  in  $\|\cdot\|_2$ -norm from direct observations  $(Ax = x)$  corrupted by the standard Gaussian noise  $\xi \sim \mathcal{N}(0, \sigma^2 I)$ , and let X be the unit  $\|\cdot\|_1=\text{ball}$ :

$$
\mathcal{X} = \Big\{ x \in \mathbf{R}^n : \sum_i |x_i| \le 1 \Big\}.
$$

In this situation, building the optimal, in terms of the worst-case over  $x \in \mathcal{X}$  expected  $\|\cdot\|_2^2$ -risk, linear estimate  $\hat{x}_H(\omega) = H^T \omega$  is extremely simple. Indeed, one easily verifies that the optimal H is a scalar matrix  $hI$ , with the optimal h being the minimizer of the univariate quadratic function  $(1-h)^2 + \sigma^2 nh^2$ . Therefore, in this case, the best achievable with linear estimates expected  $\|\cdot\|_2^2$ -risk is

$$
\max_{x \in \mathcal{X}} \mathbf{E} \left\{ \| \widehat{x}_H(\omega) - x \|_2^2 \right\} = \min_h \left[ (1 - h)^2 + \sigma^2 n h^2 \right] = \frac{n \sigma^2}{1 + n \sigma^2}.
$$

On the other hand, consider nonlinear estimate as follows. Given observation  $\omega$ , we specify the estimate  $\hat{x}(\omega)$  as an optimal solution to the optimization problem

<span id="page-2-1"></span>
$$
Opt(\omega) = \min_{y \in \mathcal{X}} \|y - \omega\|_{\infty}.
$$
\n(3)

Note that for every  $\rho > 0$  the probability for the true signal to satisfy  $||x - \omega||_{\infty} \le \rho \sigma$  ("event")  $\mathcal{E}$ ") is at least  $1 - \epsilon$  for  $\epsilon = 2n \exp\{-\rho^2/2\}$ , and if this event occurs then both x and  $\hat{x}$  belong to the box  $\{y : ||y - \omega||_{\infty} \leq \rho \sigma\}$ , implying that  $||x - \hat{x}||_{\infty} \leq 2\rho\sigma$ . Combining the latter bound with the constraint  $||x - \hat{x}||_2 \le ||x - \hat{x}||_1 \le 2$ , since  $x \in \mathcal{X}$  and  $\hat{x} \in \mathcal{X}$ , we obtain

$$
||x - \widehat{x}||_2 \le \sqrt{||x - \widehat{x}||_{\infty} ||x - \widehat{x}||_1} \le \begin{cases} 2\sqrt{\rho\sigma}, & \omega \in \mathcal{E} \\ 2, & \omega \notin \mathcal{E} \end{cases}
$$

whence

$$
\mathbf{E}\left\{\|\widehat{x}-x\|_2^2\right\} \le 4\rho\sigma + 4\epsilon \le 4\rho\sigma + 8n\exp\{-\rho^2/2\}.\tag{*}
$$

Assuming  $\sigma \leq 2n/\sqrt{e}$  and specifying  $\rho$  as  $\sqrt{2\ln(2n/\sigma)}$ , we get  $\rho \geq 1$  and  $2n \exp\{-\rho^2/2\} \leq \sigma$ , implying that the right hand side in (\*) is at most  $8\rho\sigma$ . Therefore, the nonlinear estimate  $\hat{x}(\omega)$ satisfies

$$
\max_{x \in \mathcal{X}} \mathbf{E} \left\{ \| \widehat{x}(\omega) - x \|_2^2 \right\} \le 8\sqrt{\ln(2n/\sigma)} \sigma.
$$

When  $n\sigma^2$  is of order of 1, the latter bound is of order of  $\sigma\sqrt{\ln(1/\sigma)}$ , while the best expected  $\|\cdot\|_2^2$ -risk attainable with linear estimates under the circumstances is of order of 1. We conclude that when  $\sigma$  is small and n is large (specifically, is of order of  $1/\sigma^2$ ), the best linear estimate is far inferior to the nonlinear estimate – the ratio of the corresponding squared risks is as large as  $\frac{O(1)}{1}$  $\frac{O(1)}{\sigma\sqrt{\ln(1/\sigma)}}$ .

#### 1.2 Polyhedral estimate

The construction of the nonlinear estimate  $\hat{x}$  we have built in the above example<sup>[3](#page-2-0)</sup> admits a natural extension yielding what we call polyhedral estimate. The idea underlying polyhedral estimate is quite straightforward. Assuming for present that the observation noise is  $\mathcal{N}(0, \sigma^2 I_n)$ ,

<span id="page-2-0"></span><sup>&</sup>lt;sup>3</sup>In fact, this estimate is nearly optimal under the circumstances in a meaningful range of values of n and  $\sigma$ .

observe that there is a spectrum of "easy to estimate" linear forms of signal  $x$  underlying observation, namely the forms  $g_h^T x = h^T A x$  with  $h \in \mathcal{H} = \{h \in \mathbb{R}^m : ||h||_2 = 1\}$ . Indeed, for a form of this type, the "plug-in" estimate  $\hat{g}_h(\omega) = h^T \omega$  is an unbiased estimate of  $g_h^T x$  with  $\mathcal{N}(0, \sigma^2)$  receiver over the selection complexing a contract metrix  $H_{\alpha}$  on  $m \times M$  $\mathcal{N}(0, \sigma^2)$  recovery error. It follows that selecting somehow a contrast matrix  $H$  – an  $m \times M$ matrix with columns from  $H$ , the plug-in estimate  $H^T\omega$  recovers well the vector  $H^T Ax$  in the uniform norm:

$$
\text{Prob}_{\omega \sim \mathcal{N}(Ax, \sigma^2 I_m)} \left\{ \|H^T \omega - H^T A x\|_{\infty} > \sigma \rho \right\} \le 2M \exp\{-\rho^2/2\}, \ \rho \ge 0. \tag{4}
$$

As a result, given a "reliability tolerance"  $\epsilon \ll 1$  and setting  $\rho = \sqrt{2 \ln(2M/\epsilon)}$ , the estimate  $H^T\omega$  recovers the vector  $H^T Ax$ , whatever be  $x \in \mathbb{R}^n$ , within  $\|\cdot\|_{\infty}$ -accuracy  $\sigma\rho$  and reliability  $1 - \epsilon$ . When our objective is to recover  $w = Bx$ , a natural way to combine this estimate with a priori information that  $x \in \mathcal{X}$  is to set

$$
\widehat{x}^{H}(\omega) \in \operatorname*{Argmin}_{y} \{ \|H^{T}[Ay - \omega]\|_{\infty} : y \in \mathcal{X} \}, \ \widehat{w}^{H}(\omega) = B\widehat{x}(\omega). \tag{5}
$$

Note that the estimate  $\hat{w}^H(\cdot)$  of w we end up with is defined solely in terms of H and the data<br>A B Y of aux estimation problem, and that simple estimate (2) is nothing but the polyhedral  $A, B, \mathcal{X}$  of our estimation problem, and that simple estimate [\(3\)](#page-2-1) is nothing but the polyhedral estimate stemming from the unit contrast matrix. The rationale behind polyhedral estimation scheme is the desire to reduce complex estimating problems to those of estimating linear forms. To the best of our knowledge, the idea of polyhedral estimate goes back to [\[34\]](#page-28-14), see also [\[33,](#page-28-15) Chapter 2], where it was shown that when recovering smooth multivariate regression functions known to belong to Sobolev balls from their noisy observations taken along a regular grid Γ, a polyhedral estimate with ad hoc selected contrast matrix is near-optimal in a wide range of smoothness characterizations and norms  $\|\cdot\|$ . Recently, the ideas underlying the results of [\[34\]](#page-28-14) have been taken up in the MIND estimator of [\[18\]](#page-27-11), then applied in the indirect observation setting in [\[37\]](#page-29-6) in the context of multiple testing.

The goal of this paper is to investigate characteristics of the polyhedral estimate, with a particular emphasis on efficiently computable upper bounds for the risk of the estimate  $\hat{w}^H(\cdot)$ <br>and design of the contrast matrix H resulting in the (pearly) best upper risk bounds and design of the *contrast matrix H* resulting in the (nearly) best upper risk bounds.

The main body of the paper is organized as follows. We begin in Section [2](#page-4-0) with detailed formulation of the estimation problem (see Section [2.1\)](#page-4-1), and present generic polyhedral estimate along with its risk analysis (Section [2.2\)](#page-4-2). This analysis requires from the main ingredient of a polyhedral estimate – the underlying contrast matrix – to be properly adjusted to the structure and the magnitude of observation noise. To allow for this adjustment, we restrict ourselves to three types of observation schemes specifying the noise structure, referred to as sub-Gaussian, Discrete, and Poisson cases; description of these cases and of the restrictions they impose on the contrast matrices form the subject of Section [2.3.](#page-6-0) The subject of the subsequent sections is tuning the polyhedral estimate to the structure of the estimation problem – the design of the contrast matrix aimed at minimizing the risk of the associated polyhedral estimate. We propose two related approaches. The first of them, developed in Section [3,](#page-7-0) mimics, in a sense, the mechanism working in the above Motivating example. We show that this approach produces near-optimal estimates in some situations where linear estimates can be heavily nonoptimal. The second, completely different, approach to the design of contrast matrix is developed in Section [4.](#page-12-0) Based on the notion of a "cone compatible with convex set," this approach is inspired by the design of nearly optimal linear estimates in the case where the signal set and the unit ball of the norm conjugate for  $\|\cdot\|$  are ellitopes/spectratopes. While this approach is not restricted to the latter case, we show that in the spectratopic case, when the observation noise is zero mean sub-Gaussian, it results in polyhedral estimate which is provably nearly optimal in the minimax sense.

Technical proofs (which are longer than few lines) are relegated to the appendix.

# <span id="page-4-0"></span>2 Problem of interest and generic polyhedral estimate

### <span id="page-4-1"></span>2.1 The problem

Suppose that we are given

- a nonempty computationally tractable convex compact signal set  $\mathcal{X} \subset \mathbb{R}^n$ ,
- sensing matrix  $A \in \mathbb{R}^{m \times n}$ , decoding matrix  $B \in \mathbb{R}^{\nu \times n}$ , and a norm  $\|\cdot\|$  on the space  $\mathbb{R}^{\nu}$ ,
- a reliability tolerance  $\epsilon \in (0,1)$ ,
- a random observation

$$
\omega = Ax + \xi_x \tag{6}
$$

stemming from unknown signal x known to belong to  $\mathcal{X}$ ; here  $\xi_x$  is a random variable with Borel probability distribution  $P_x$ .

Given observation  $\omega$ , our goal is to recover  $w = Bx$ , where x is the signal underlying the observation. A candidate estimate is a Borel function  $\hat{w}(\omega)$  taking value in  $\mathbf{R}^{\nu}$ , and we quantify the performance of such an estimate by its  $(\epsilon, \|\cdot\|)$ -risk

$$
\text{Risk}_{\epsilon, \|\cdot\|}[\widehat{w}|\mathcal{X}] = \sup_{x \in \mathcal{X}} \inf \left\{ \rho : \text{Prob}_{\xi_x \sim P_x} \{ \|Bx - \widehat{w}(Ax + \xi_x) \| > \rho \} \le \epsilon \ \forall x \in \mathcal{X} \right\},\
$$

that is, the worst, over  $x \in \mathcal{X}$ ,  $(1 - \epsilon)$ -quantile, taken w.r.t.  $P_x$ , of the  $\|\cdot\|$ -magnitude of the recovery error.

**Notation.** In the sequel, given a convex compact set, say,  $\mathcal{Y}$ , in  $\mathbb{R}^n$ , we denote by  $\mathcal{Y}_s$  its symmeterization:

$$
\mathcal{Y}_s = \frac{1}{2}(\mathcal{Y} - \mathcal{Y}).
$$

Note that whenever  $\mathcal Y$  is symmetric w.r.t. the origin, we have  $\mathcal Y_s = \mathcal Y$ . We use "MATLAB" style" of vector/matrix notation: whenever  $H_1, ..., H_k$  are matrices of appropriate dimensions,  $[H_1, ..., H_k]$  stands for horizontal and  $[H_1, ..., H_k]$  – for their vertical concatenation.  $S^n$  stands for the space of  $n \times n$  real symmetric matrices equipped with the Frobenius inner product;  $S_{+}^{n}$ is the cone of positive semidefinite matrices from  $\mathbf{S}_n$ . Relation  $A \succeq B (\Leftrightarrow B \preceq A)$  means that A and B are real symmetric matrices of common size such that  $A - B$  is positive semidefinite, while  $A \succ B$  ( $\Leftrightarrow B \prec A$ ) means that A, B are real symmetric matrices of common size such that  $A - B$  is positive definite.

### <span id="page-4-2"></span>2.2 Generic polyhedral estimate

A generic polyhedral estimate is as follows:

Given the data  $A \in \mathbb{R}^{m \times n}, B \in \mathbb{R}^{\nu \times n}, \mathcal{X} \subset \mathbb{R}^n$  of the estimation problem stated in Section [2.1](#page-4-1) and a "reliability tolerance"  $\epsilon \in (0,1)$ , we somehow specify a positive integer N along with N linear forms  $h_{\ell}^{T} z$  on the observation space  $\mathbb{R}^{m}$ . These forms define linear forms  $g_{\ell}^T x := h_{\ell}^T A x$  on the space of signals  $\mathbb{R}^n$ . Assume that vectors  $h_{\ell}$  are selected in such a way that

<span id="page-5-0"></span>
$$
\forall (x \in \mathcal{X}) : \text{Prob}\{|h_{\ell}^T \xi_x| > 1\} \le \epsilon/N. \tag{7}
$$

When setting  $H = [h_1, ..., h_N]$  (in the sequel, H is referred to as contrast matrix), we clearly have for all  $x \in \mathcal{X}$ :

<span id="page-5-1"></span>
$$
\text{Prob}\left\{ \|H^T \omega - H^T A x\|_{\infty} > 1 \right\} \le \epsilon. \tag{8}
$$

With the polyhedral estimation scheme, we act as if all information about  $x$  contained in our observation  $\omega$  were represented by  $H^T\omega$ , and we estimate  $w = Bx$  by  $\hat{w} = B\hat{x}$ , where  $\hat{x} = \hat{x}(\omega)$  is a (whatever) vector from X compatible with this information, i.e. a solution  $\hat{x}$  to the feasibility problem

find 
$$
u \in \mathcal{X}
$$
 such that  $||H^T \omega - H^T A u||_{\infty} \leq 1$ .

Note that  $\hat{x}$  not always is well defined: the above feasibility problem may be unsolvable with positive probability (in fact, with probability  $\leq \epsilon$ , since, by construction, the true signal x underlying observation  $\omega$  is feasible with probability  $1 - \epsilon$ ). To circumvent this difficulty, we define  $\hat{x}$  according to

<span id="page-5-4"></span><span id="page-5-2"></span>
$$
\widehat{x}^{H} \in \operatorname{Argmin}_{u} \left\{ \| H^{T} \omega - H^{T} A u \|_{\infty} : u \in \mathcal{X} \right\}
$$
\n
$$
(9)
$$

so that  $\hat{x}^H$  is always well defined and belongs to X, and estimate w by  $\hat{w}^H = B\hat{x}^H$ .

We have the following immediate observation:

**Proposition 2.1** In the situation in question, given a contrast matrix  $H = [h_1, ..., h_N]$  with columns satisfying [\(7\)](#page-5-0), the quantity

<span id="page-5-3"></span>
$$
\Re[H] := \max_{z} \left\{ \|Bz\| : \|H^T Az\|_{\infty} \le 2, z \in 2\mathcal{X}_s \right\}
$$
\n<sup>(10)</sup>

is an upper bound on the  $(\epsilon, \|\cdot\|)$ -risk of the polyhedral estimate  $\widehat{w}^H(\cdot)$ :

$$
\text{Risk}_{\epsilon, \|\cdot\|}[\widehat{w}^H|\mathcal{X}] \le \Re[H].\tag{11}
$$

**Proof** is immediate. Let us fix  $x \in \mathcal{X}$ , and let  $\mathcal{E}$  be the set of all realizations of  $\xi_x$  such that  $||H^T \xi_x||_{\infty} \leq 1$ , so that  $P_x(\mathcal{E}) \geq 1 - \epsilon$  by [\(8\)](#page-5-1). Let us fix a realization  $\xi \in \mathcal{E}$  of the observation noise, let  $\omega = Ax + \xi$ , and let  $\hat{x} = \hat{x}^H(Ax + \xi)$ . Then  $u = x$  is a feasible solution to the optimization problem (0) with the value of the objective  $\leq 1$  implying that the value of this optimization problem [\(9\)](#page-5-2) with the value of the objective  $\leq 1$ , implying that the value of this objective at the optimal solution  $\hat{x}$  to the problem is  $\leq 1$  as well, so that  $\|H^T A[x - \hat{x}]\|_{\infty} \leq 2$ . Besides this,  $z = x - \hat{x} \in 2\mathcal{X}_s$ . We see that z is a feasible solution to [\(10\)](#page-5-3), whence

$$
||B[x - \widehat{x}]|| = ||Bx - \widehat{w}^H(\omega)|| \leq \Re[H].
$$

It remains to note that the latter relation holds true whenever  $\omega = Ax + \xi$  with  $\xi \in \mathcal{E}$ , and for any  $x \in \mathcal{X}$  the  $P_x$ -probability of the latter inclusion is at least  $1 - \epsilon$ .

What is ahead. In what follows our focus will be on answering the following questions underlying the construction of the polyhedral estimate:

1. Suppose that, given the data of our estimation problem and a tolerance  $\delta \in (0,1)$ , we can construct a set  $\mathcal{H}_{\delta}$  of vectors  $h \in \mathbb{R}^m$  satisfying the relation

<span id="page-6-1"></span>
$$
\forall (x \in \mathcal{X}) : \text{Prob}\left\{|h^T\xi_x| > 1\right\} \le \delta. \tag{12}
$$

With our approach, after the number  $N$  of columns in a contrast matrix has been selected, we are free to select these columns  $\mathcal{H}_{\delta}$ , with  $\delta = \epsilon/N$ ,  $\epsilon$  being a given reliability tolerance of the estimate we are designing. Thus, the problem of building sets  $\mathcal{H}_{\delta}$  satisfying [\(12\)](#page-6-1) arises, the larger  $\mathcal{H}_{\delta}$ , the better.

- 2. The upper bound  $\mathfrak{R}[H]$  on the  $(\epsilon, \|\cdot\|)$ -risk of the polyhedral estimate  $\hat{w}^H$  is, in general, difficult to compute this is the maximum of a convex function can a computationally difficult to compute – this is the maximum of a convex function over a computationally tractable convex set. Thus, we need to provide computationally efficient upper bounding of  $\mathfrak{R}[\cdot]$ .
- 3. Finally, given the "raw materials" set  $\mathcal{H}_{\delta}$  and an efficiently computable upper bound on the risk of a candidate polyhedral estimate - how to design the best, in terms of (the upper bound on) its risk, polyhedral estimate?

We are about to consider these questions one by one.

#### <span id="page-6-0"></span>2.3 Specifying sets  $\mathcal{H}_{\delta}$  for basic observation schemes

To specify sets  $\mathcal{H}_{\delta}$  we are to make assumptions on the distributions of observation noise we want to handle. For the sake of conciseness, in the sequel we restrict ourselves with 3 special observation schemes (below called "cases") as follows:

• Sub-Gaussian case: For every  $x \in \mathcal{X}$ , the observation noise  $\xi_x$  is sub-Gaussian with parameters  $(0, \sigma^2 I_m)$ ,  $\sigma > 0$  (denoted  $\xi_x \sim \mathcal{SG}(0, \sigma^2 I_m)$ ).

Let us denote

$$
\pi_G(h) = \vartheta_G \|h\|_2 \text{ where } \vartheta_G = \sigma \sqrt{2\ln(2/\delta)}.
$$

In the sub-Gaussian case we set

<span id="page-6-2"></span>
$$
\mathcal{H}_{\delta} = \mathcal{H}_{\delta}^G := \{ h : \pi_G(h) \le 1 \}. \tag{13}
$$

• Discrete case: X is a convex compact subset of the probabilistic simplex  $\Delta_n = \{x \in \mathbb{R}^n :$  $x \geq 0, \sum_i x_i = 1$ , A is column-stochastic matrix, and

$$
\omega = \frac{1}{K} \sum_{k=1}^{K} \zeta_k
$$

with independent across  $k \leq K$  random vectors  $\zeta_k$ , with  $\zeta_k$  taking values  $e_i$  with probabilities  $[Ax]_i$ ,  $i = 1, ..., m$ ,  $e_i$  being the basic orths in  $\mathbb{R}^m$ .

In this case we put

$$
\pi_D(h) = 2 \sqrt{\vartheta_D \max_{x \in \mathcal{X}} \sum_i [Ax_i]_i h_i^2 + \frac{16}{9} \vartheta_D^2 \|h\|_\infty^2} \text{ with } \vartheta_D = \frac{\ln(2/\delta)}{K},
$$

and

$$
\mathcal{H}_{\delta} = \mathcal{H}_{\delta}^D := \{ h : \pi_D(h) \le 1 \}. \tag{14}
$$

• Poisson case: X is a convex compact subset of the nonnegative orthant  $\mathbb{R}^n_+$ , A is entrywise nonnegative, and the observation  $\omega$  stemming from  $x \in \mathcal{X}$  is random vector with independent across *i* entries  $\omega_i \sim \text{Poisson}([Ax]_i)$ . In the Poisson case we set

$$
\pi_P(h) = 2 \sqrt{\vartheta_P \max_{x \in \mathcal{X}} \sum_i [Ax]_i h_i^2 + \frac{4}{9} \vartheta_P^2 \|h\|_{\infty}^2} \quad \text{with} \quad \vartheta_P = \ln(2/\delta),
$$

and

<span id="page-7-1"></span>
$$
\mathcal{H}_{\delta} = \mathcal{H}_{\delta}^{P} := \{ h : \pi_{P}(h) \le 1 \}. \tag{15}
$$

We verify in Section [A.3.1](#page-30-0) that the sets  $\mathcal{H}_{\delta}^G$ ,  $\mathcal{H}_{\delta}^D$  and  $\mathcal{H}_{\delta}^P$  as given by [\(13\)](#page-6-2)–(15) indeed satisfy

$$
\forall (h \in \mathcal{H}_\delta, \ x \in \mathcal{X}) \quad \text{Prob}_x\{|h^T \xi_x| \ge 1\} \le \delta,
$$

provided that the observation noises  $\xi_x$ ,  $x \in \mathcal{X}$ , stem from the respective observation schemes.

# <span id="page-7-0"></span>3 Efficient upper-bounding of  $\mathfrak{R}[H]$  and contrast design, I.

The scheme for upper-bounding  $\mathfrak{R}[H]$  to be presented in this section is inspired by the motivating example from the introduction. Indeed, there is a special case of [\(10\)](#page-5-3) where  $\Re[H]$  is easy to compute – the case when  $\|\cdot\|$  is the uniform norm  $\|\cdot\|_{\infty}$ , whence

$$
\mathfrak{R}[H] = \widehat{\mathfrak{R}}[H] := 2 \max_{i \le \nu} \max_x \left\{ \text{Row}_i^T[B]x : x \in \mathcal{X}_s, \|H^T Ax\|_{\infty} \le 1 \right\}
$$

is just the maximum of  $\nu$  efficiently computable convex functions. It turns out that when  $\|\cdot\| = \|\cdot\|_{\infty}$ , it is easy not only to compute  $\mathfrak{R}[H]$ , but to optimize this risk bound in H as well. These observations underly the forthcoming developments in this section: under appropriate assumptions, we bound the risk of a polyhedral estimate stemming from a contrast matrix H via the efficiently computable quantity  $\mathfrak{R}[H]$  and then show that the resulting risk bounds can be efficiently optimized w.r.t.  $H$ . We shall also see that in some simple situations which allow for analytical analysis, like the one in the motivating example, the resulting estimates turn out to be nearly minimax optimal.

Assumptions. We continue to stay within the setup introduced in Section [2.1](#page-4-1) which we now augment with the following assumptions:

- **A.1.**  $\|\cdot\| = \|\cdot\|_r$  with  $r \in [1, \infty]$ .
- **A.2.** We have at our disposal a sequence  $\gamma = \{\gamma_i > 0, 1 \le i \le \nu\}$  and  $\rho \in [1, \infty]$  such that the image of  $\mathcal{X}_s$  under the mapping  $x \mapsto Bx$  is contained in the "scaled  $\|\cdot\|_{\rho}$ -ball"

<span id="page-7-3"></span><span id="page-7-2"></span>
$$
\mathcal{Y} = \{ y \in \mathbf{R}^{\nu} : ||\text{Diag}\{\gamma\}y||_{\rho} \le 1 \}. \tag{16}
$$

#### <span id="page-7-4"></span>3.1 Simple observation

Let  $B_{\ell}^T$  be  $\ell$ -th row in  $B, 1 \leq \ell \leq \nu$ . Let us make the following observation:

Proposition 3.1 In the situation described in Section [2.1,](#page-4-1) assuming that Assumptions A.1-2 hold, let  $\epsilon \in (0,1)$  and a positive real  $N \geq \nu$  be given, and let  $\pi(\cdot)$  be a norm on  $\mathbb{R}^m$  such that

$$
\forall (h: \pi(h) \le 1, x \in \mathcal{X}) : \text{Prob}\{|h^T \xi_x| > 1\} \le \epsilon/N. \tag{17}
$$

Let, next, a matrix  $H = [H_1, ..., H_\nu]$  with  $H_\ell \in \mathbf{R}^{m \times m_\ell}$ ,  $m_\ell \ge 1$ , and positive reals  $\varsigma_\ell$ ,  $1 \le \ell \le \nu$ , satisfy the relations

<span id="page-8-0"></span>(a) 
$$
\pi(\text{Col}_j[H]) \le 1, 1 \le j \le N;
$$
  
(b)  $\max_x \{ B_{\ell}^T x : x \in \mathcal{X}_s, \| H_{\ell}^T A x \|_{\infty} \le 1 \} \le \varsigma_{\ell}, 1 \le \ell \le \nu.$  (18)

Then the quantity  $\mathfrak{R}[H]$  as defined in [\(10\)](#page-5-3) can be upper-bounded as follows:

<span id="page-8-1"></span>
$$
\Re[H] \le \Psi(\varsigma) := 2 \max_{v} \left\{ \left\| [v_1/\gamma_1; \dots; v_{\nu}/\gamma_{\nu}] \right\|_{r} : \|v\|_{\rho} \le 1, 0 \le v_{\ell} \le \gamma_{\ell} \varsigma_{\ell}, 1 \le \ell \le \nu \right\}.
$$
 (19)

This combines with Proposition [2.1](#page-5-4) to imply that

<span id="page-8-2"></span>
$$
\text{Risk}_{\epsilon, \|\cdot\|}[\widehat{w}^H|\mathcal{X}] \le \Psi(\varsigma). \tag{20}
$$

Function  $\Psi$  is nondecreasing on the nonnegative orthant and is easy to compute.

**Proof.** Let  $z = 2\overline{z}$  be a feasible solution to [\(10\)](#page-5-3), so that  $\overline{z} \in \mathcal{X}_s$  and  $||H^T A \overline{z}||_{\infty} \leq 1$ . Let  $y = B\overline{z}$ , so that  $y \in \mathcal{Y}$  (see [\(16\)](#page-7-2)) due to  $\overline{z} \in \mathcal{X}_s$  and **A.2**. Thus,  $\|\text{Diag}\{\gamma\}y\|_p \leq 1$ . Besides this, by [\(18.](#page-8-0)b) relations  $\bar{z} \in \mathcal{X}_s$  and  $||H^T A \bar{z}||_{\infty} \leq 1$  combine with the symmetry of  $\mathcal{X}_s$  to imply that

$$
|y_{\ell}| = |B_{\ell}^T \bar{z}| \leq \varsigma_{\ell}, \, \ell \leq \nu.
$$

Taking into account that  $\|\cdot\| = \|\cdot\|_r$  by **A.1**, we see that

$$
\mathfrak{R}[H] = \max_{z} \{ ||Bz||_{r} : z \in 2\mathcal{X}_{s}, ||H^{T} A z||_{\infty} \leq 2 \}\leq 2 \max_{y} \{ ||y||_{r} : |y_{\ell}| \leq \varsigma_{\ell}, \ell \leq \nu \& ||\text{Diag}\{\gamma\}y||_{\rho} \leq 1 \}= 2 \max_{v} \{ ||[v_{1}/\gamma_{1};...;v_{\nu}/\gamma_{\nu}]||_{r} : ||v||_{\rho} \leq 1, 0 \leq v_{\ell} \leq \gamma_{\ell} \varsigma_{\ell}, \ell \leq \nu \},
$$

as stated in [\(19\)](#page-8-1).

It is evident that  $\Psi$  is nondecreasing on the nonnegative orthant. Computation of  $\Psi$  can be carried out as follows:

- 1. When  $r = \infty$ , we need to compute  $\max_{\ell \leq \nu} \max_{v} \{v_{\ell}/\gamma_{\ell} : ||v||_{\rho} \leq 1, 0 \leq v_j \leq \gamma_j \varsigma_j, j \leq \nu\},\$ so that evaluating  $\Psi$  reduces to solving  $\nu$  simple convex optimization problems;
- 2. When  $\rho = \infty$ , we clearly have  $\Psi(\zeta) = ||[\bar{v}_1/\gamma_1; ...; \bar{v}_\nu/\gamma_\nu]||_r$ ,  $\bar{v}_\ell = \min[1, \gamma_\ell \varsigma_\ell];$
- 3. When  $1 \leq r, \rho < \infty$ , passing from variables  $v_{\ell}$  to variables  $u_{\ell} = v_{\ell}^{\rho}$  $^{\rho}_{\ell}$ , we get

$$
\Psi^r(\varsigma) = 2^r \max_u \left\{ \sum_{\ell} \gamma_{\ell}^{-r} u_{\ell}^{r/\rho} : \sum_{\ell} u_{\ell} \leq 1, \ 0 \leq u_{\ell} \leq (\gamma_{\ell} \varsigma_{\ell})^{\rho} \right\}.
$$

When  $r \leq \rho$ , the problem on the right hand side is an easily solvable problem of maximizing a simple concave function over a simple convex compact set. When  $\infty > r > \rho$ , this problem can be solved by Dynamic Programming.

#### <span id="page-9-3"></span>3.2 Specifying contrasts

Risk bound [\(20\)](#page-8-2) allows for a straightforward design of contrast matrices. Recalling that  $\Psi$  is monotone on the nonnegative orthant, all we need is to select  $h_{\ell}$ 's satisfying [\(18\)](#page-8-0) and resulting in the smallest possible  $\varsigma_{\ell}$ 's, which is what we are about to do now.

**Preliminaries.** Given a vector  $b \in \mathbb{R}^m$  and a norm  $s(\cdot)$  on  $\mathbb{R}^m$ , consider convex-concave saddle point problem

$$
Opt = \inf_{g \in \mathbf{R}^m} \max_{x \in \mathcal{X}_S} \left\{ \phi(g, x) := [b - A^T g]^T x + s(g) \right\} \tag{SP}
$$

along with the induced primal and dual problems

$$
\begin{array}{rcl}\n\text{Opt}(P) & = & \inf_{g \in \mathbf{R}^m} \left[ \overline{\phi}(g) := \max_{x \in \mathcal{X}_s} \phi(g, x) \right] \\
& = & \inf_{g \in \mathbf{R}^m} \left[ s(g) + \max_{x \in \mathcal{X}_s} [b - A^T g]^T x \right]\n\end{array} \tag{P}
$$

and

$$
Opt(D) = \max_{x \in \mathcal{X}_s} [\underline{\phi(g)} := \inf_{g \in \mathbf{R}^m} \phi(g, x)]
$$
  
= 
$$
\max_{x \in \mathcal{X}_s} [\inf_{g \in \mathbf{R}^m} [b^T x - [Ax]^T g + s(g)]]
$$
  
= 
$$
\max_x [b^T x : x \in \mathcal{X}_s, q(Ax) \le 1]
$$
 (D)

where  $q(\cdot)$  is the norm conjugate to  $s(\cdot)$  (we have used the evident fact that  $\inf_{g \in \mathbf{R}^m} [f^T g + s(g)]$ is either  $-\infty$  or 0 depending on whether  $q(f) > 1$  or  $q(f) \leq 1$ . Since  $\mathcal{X}_s$  is compact, we have  $Opt(P) = Opt(D) = Opt$  by the Sion-Kakutani theorem. Besides this,  $(D)$  is solvable (this is evident) and (P) is solvable as well, since  $\overline{\phi}(g)$  is continuous due to the compactness of  $\mathcal{X}_s$ , and  $\overline{\phi}(q) \geq s(q)$ , so that  $\overline{\phi}(\cdot)$  has bounded level sets. Let  $\overline{g}$  be an optimal solution to  $(P)$ , let  $\overline{x}$  be an optimal solution to  $(D)$ , and let  $\bar{h} = \bar{g}/s(\bar{g})$ , so that  $s(\bar{h}) = 1$  and  $\bar{g} = s(\bar{g})\bar{h}$ . Now let us make the observation as follows:

Proposition 3.2 In the situation in question, we have

<span id="page-9-2"></span><span id="page-9-0"></span>
$$
\max_{x} \left\{ |b^T x| : x \in \mathcal{X}_s, |\bar{h}^T A x| \le 1 \right\} \le \text{Opt.}
$$
\n(21)

In addition, for any matrix  $G = [g^1, ..., g^M] \in \mathbf{R}^{m \times M}$  with  $s(g^j) \leq 1, 1 \leq j \leq M$ , one has

<span id="page-9-1"></span>
$$
\max_{x} \left\{ |b^T x| : x \in \mathcal{X}_s, \|G^T A x\|_{\infty} \le 1 \right\} = \max_{x} \left\{ b^T x : x \in \mathcal{X}_s, \|G^T A x\|_{\infty} \le 1 \right\} \ge \text{Opt.} \tag{22}
$$

**Proof.** Let x be a feasible solution to the problem in the left hand side of  $(21)$ . Replacing, if necessary, x with  $-x$ , we can assume that  $|b^T x| = b^T x$ . We now have

$$
|b^T x| = b^T x = [\bar{g}^T A x - s(\bar{g})] + \underbrace{[b - A^T \bar{g}]^T x + s(\bar{g})}_{\leq \overline{\phi}(\bar{g}) = \text{Opt}(P)} \leq \text{Opt}(P) + [s(\bar{g})\bar{h}^T A x - s(\bar{g})]
$$
  
 
$$
\leq \text{Opt}(P) + s(\bar{g}) \underbrace{|\bar{h}^T A x|}_{\leq 1} - s(\bar{g}) \leq \text{Opt}(P) = \text{Opt},
$$

as claimed in [\(21\)](#page-9-0). Now, the equality in [\(22\)](#page-9-1) is due to the symmetry of  $\mathcal{X}_s$  w.r.t. the origin. To verify the inequality in [\(22\)](#page-9-1), note that  $\bar{x}$  satisfies the relations  $\bar{x} \in \mathcal{X}_s$  and  $q(A\bar{x}) \leq 1$ , implying, due to the fact that the columns of G are of  $s(\cdot)$ -norm  $\leq 1$ , that  $\bar{x}$  is a feasible solution to optimization problems in [\(22\)](#page-9-1). As a result, the second quantity in [\(22\)](#page-9-1) is at least  $b^T \bar{x} = \text{Opt}(D) = \text{Opt}, \text{ and } (22) \text{ follows.}$  $b^T \bar{x} = \text{Opt}(D) = \text{Opt}, \text{ and } (22) \text{ follows.}$  $b^T \bar{x} = \text{Opt}(D) = \text{Opt}, \text{ and } (22) \text{ follows.}$  Designing contrasts. Propositions [3.1](#page-7-3) and [3.2](#page-9-2) allow for a straightforward solution of the associated contrast design problem, at least in the case of Sub-Gaussian, Discrete, and Poisson observation schemes. Indeed, in these cases, when designing a contrast matrix with  $N$  columns, we are supposed to select its columns in the respective sets  $\mathcal{H}_{\epsilon/N}$ , see Section [2.3.](#page-6-0) Note that these sets are "nearly independent" of N, because the norms  $\pi_G$ ,  $\pi_D$ ,  $\pi_P$  in the description of the respective sets  $\mathcal{H}_{\delta}^G$ ,  $\mathcal{H}_{\delta}^D$ ,  $\mathcal{H}_{\delta}^P$  depend on  $1/\delta$  only via logarithmic in  $1/\delta$  factors. Thus, we lose nearly nothing when assuming that  $N \geq \nu$ . So, let us act as follows:

We set  $N = \nu$ , specify  $\overline{\pi}(\cdot)$  as the norm  $(\pi_G, \text{ or } \pi_D, \text{ or } \pi_P)$  associated with the observation scheme (Sub-Gaussian, or Discrete, or Poisson) in question and  $\delta = \epsilon/\nu$ , and solve  $\nu$  convex optimization problems

$$
\begin{array}{rcl}\n\text{Opt}_{\ell} & = & \min_{g \in \mathbf{R}^m} \left[ \overline{\phi}_{\ell}(g) := \max_{x \in \mathcal{X}_s} \phi_{\ell}(g, x) \right] \\
\phi_{\ell}(g, x) & = & \left[ B_{\ell} - A^T g \right]^T x + \overline{\pi}(g)\n\end{array} \tag{P_{\ell}}
$$

Next, we convert optimal solution  $g_\ell$  to  $(P_\ell)$  into a vector  $h_\ell \in \mathbb{R}^m$  by representing  $g_{\ell} = \overline{\pi}(g_{\ell})h_{\ell}$  with  $\overline{\pi}(h_{\ell}) = 1$ , and set  $H_{\ell} = h_{\ell}$ . As a result, we get an  $m \times \nu$  contrast matrix  $H = [h_1, ..., h_\nu]$  which, taken along with  $N = \nu$ , quantities

$$
\varsigma_{\ell} = \mathrm{Opt}_{\ell}, \ 1 \le \ell \le \nu,\tag{23}
$$

and  $\pi(\cdot) \equiv \overline{\pi}(\cdot)$ , in view of the first claim in Proposition [3.2](#page-9-2) as applied with  $s(\cdot) \equiv$  $\overline{\pi}(\cdot)$ , satisfies the premise of Proposition [3.1.](#page-7-3)

Consequently, by Proposition [3.1](#page-7-3) we have

$$
\text{Risk}_{\epsilon, \|\cdot\|}[\widehat{w}^H|\mathcal{X}] \le \Psi([\text{Opt}_1; \dots; \text{Opt}_\nu]).\tag{24}
$$

Discussion. Within the framework set in Proposition [3.1,](#page-7-3) optimality of the outlined contrast design for Sub-Gaussian, Discrete and Poisson observation schemes stems from the second claim in Proposition [3.2](#page-9-2) which states that when  $N \geq \nu$  and the columns of the contrast matrix  $H = [H_1, ..., H_\nu]$  belong to the set  $\mathcal{H}_{\epsilon/N}$  associated with the observation scheme in question, i.e., the norm  $\pi(\cdot)$  in the proposition is the norm  $\pi_G$ , or  $\pi_D$ , or  $\pi_P$  associated with  $\delta = \epsilon/N$ , the quantities  $\varsigma_{\ell}$  participating in [\(18.](#page-8-0)b) cannot be less than  $\mathrm{Opt}_{\ell}$ .

Indeed, the norm  $\pi(\cdot)$  from Proposition [3.1](#page-7-3) is  $\geq$  the norm  $\overline{\pi}(\cdot)$  participating in  $(P_{\ell})$  (since the value of  $\epsilon/N$  corresponding to  $\pi(\cdot)$  is at most  $\epsilon/\nu$ , implying, by [\(18.](#page-8-0)*a*), that the columns of matrix H obeying the premise of the proposition satisfy the relation  $\overline{\pi}(\text{Col}_i[H]) \leq 1$ . Invoking the second part of Proposition [3.2](#page-9-2) with  $s(\cdot) \equiv \overline{\pi}(\cdot)$ ,  $b = B_{\ell}$ , and  $G = H_{\ell}$ , and taking [\(18.](#page-8-0)*b*) into account, we conclude that  $\varsigma_{\ell} \geq \mathrm{Opt}_{\ell}$  for all  $\ell$ , as claimed.

Since the bound on the risk of a polyhedral estimate offered by Proposition [3.1](#page-7-3) is the better the less are  $\zeta_{\ell}$ 's, we see that as far as this bound is concerned, the outlined design procedure is the best possible, provided  $N \geq \nu$ .

An attractive feature of the contrast design we have just presented is that it is completely independent of the entities participating in assumptions  $\mathbf{A}.\mathbf{1-2}$  – these entities affect theoretical risk bounds of the resulting polyhedral estimate, but not the estimate itself.

#### <span id="page-11-2"></span>3.3 Illustration: diagonal case

Let us consider the *diagonal* case of our estimation problem, where

- $\mathcal{X} = \{x \in \mathbb{R}^n : ||Dx||_\rho \leq 1\}$ , where D is a diagonal matrix with positive diagonal entries  $D_{\ell\ell} =: d_{\ell};$
- $m = \nu = n$ , and A and B are diagonal matrices with diagonal entries  $0 < A_{\ell\ell} =: a_{\ell}$ ,  $0 < B_{\ell\ell} =: b_{\ell};$
- $\|\cdot\| = \|\cdot\|_r;$
- We are in Sub-Gaussian case, that is,  $\xi_x \sim \mathcal{SG}(0, \sigma^2 I_n)$  for every  $x \in \mathcal{X}$ .

Let us implement the approach developed in Sections  $3.1 - 3.2$ .

1. Given reliability tolerance  $\epsilon$ , we set

<span id="page-11-0"></span>
$$
\delta = \epsilon/n, \quad \vartheta_G := \sigma \sqrt{2\ln(2/\delta)} = \sigma \sqrt{2\ln(2n/\epsilon)} \tag{25}
$$

and

$$
\mathcal{H} = \mathcal{H}_{\delta}^G = \{ h \in \mathbf{R}^n : \pi_G(h) := \vartheta_G ||h||_2 \le 1 \};
$$

2. We solve  $\nu = n$  convex optimization problems  $(P_\ell)$  associated with  $\overline{\pi}(\cdot) \equiv \pi_G(\cdot)$ , which is immediate: the resulting contrast matrix is

$$
H = \vartheta_G^{-1} I_n,
$$

and

<span id="page-11-4"></span>
$$
Opt_{\ell} = \varsigma_{\ell} := b_{\ell} \min[\vartheta_G/a_{\ell}, 1/d_{\ell}]. \tag{26}
$$

**Risk analysis.** The  $(\epsilon, \|\cdot\|)$ -risk of the resulting polyhedral estimate  $\hat{w}(\cdot)$  can be bounded by Proposition [3.1.](#page-7-3) Note that setting  $\gamma_{\ell} = d_{\ell}/b_{\ell}$ ,  $1 \leq \ell \leq n$ , we meet assumptions **A.1-2**, and the above choice of H,  $N = n$  and  $\varsigma_{\ell}$  satisfies the premise of Proposition [3.1.](#page-7-3) By this proposition,

<span id="page-11-3"></span>
$$
\text{Risk}_{\epsilon, \|\cdot\|_r}[\widehat{w}^H|\mathcal{X}] \le \Psi := 2 \max_v \{ \| [v_1/\gamma_1; \dots; v_n/\gamma_n] \|_r : \|v\|_\rho \le 1, 0 \le v_\ell \le \gamma_\ell \epsilon_\ell \}.
$$
 (27)

Let us work out what happens in the *simple case* where

<span id="page-11-5"></span>
$$
(a) \t 1 \le \rho \le r < \infty
$$
  
\n
$$
(b) \t a_{\ell}/d_{\ell} \text{ and } b_{\ell}/a_{\ell} \text{ are nonincreasing in } \ell
$$
\n
$$
(28)
$$

<span id="page-11-1"></span>**Proposition 3.3** In the just defined simple case, let  $\mathfrak{n} = n$  when

$$
\sum_{\ell=1}^n \left(\vartheta_G d_\ell / a_\ell\right)^{\rho} \le 1,
$$

otherwise let n be the smallest integer such that

$$
\sum_{\ell=1}^n \left(\vartheta_G d_\ell / a_\ell\right)^{\rho} > 1,
$$

with  $\vartheta_G$  given by [\(25\)](#page-11-0). Then for the contrast matrix  $H = \vartheta_G^{-1}$  $G^1I_n$  one has

Risk<sub>$$
\epsilon, \|\cdot\|_r
$$</sub>[ $\widehat{w}^H|\mathcal{X}] \leq \Psi \leq 2 \left[ \sum_{\ell=1}^n (\vartheta_G b_\ell/a_\ell)^r \right]^{1/r}$ .

For proof, see Section [A.3.2](#page-33-0)

Application. Let us apply the result of Proposition [3.3](#page-11-1) to the "standard case" (cf., e.g., [\[9,](#page-27-12) [10,](#page-27-13) [18\]](#page-27-11)) where

$$
0 < \sqrt{\ln(2n/\epsilon)}\sigma \le 1, \ a_{\ell} = \ell^{-\alpha}, \ b_{\ell} = \ell^{-\beta}, \ d_{\ell} = \ell^{\delta}
$$

with  $\beta \ge \alpha \ge 0$ ,  $\delta \ge 0$  and  $(\beta - \alpha)r < 1$ . In this case, for large enough *n*, namely, for

$$
n \ge c \vartheta_G^{-\frac{1}{\alpha + \delta + 1/\rho}} \qquad [\vartheta_G = \sigma \sqrt{2\ln(2n/\epsilon)}]
$$
\n(29)

(here and in what follows, the factors denoted c and C depend solely on  $\alpha, \beta, \delta, r, \rho$ ) we get

$$
\mathfrak{n}\leq C\vartheta_G^{-\frac{1}{\alpha+\delta+1/\rho}}
$$

resulting in

<span id="page-12-1"></span>
$$
\text{Risk}_{\epsilon, \|\cdot\|_{r}}[\widehat{w}|\mathcal{X}] \le C\vartheta_G^{\frac{\beta+\delta+1/\rho-1/r}{\alpha+\delta+1/\rho}}.\tag{30}
$$

Note that when setting  $x = D^{-1}y$ ,  $\bar{\alpha} = \alpha + \delta$ ,  $\bar{\beta} = \beta + \delta$  and treating y, rather than x, as the signal underlying the observation, we obtain an estimation problem which is similar to the original one, in which  $\alpha, \beta, \delta$  and X are replaced, respectively, with  $\bar{\alpha}$ ,  $\bar{\beta}$ ,  $\bar{\delta} = 0$ , and  $\mathcal{Y} = \{y :$  $||y||_{\rho} \leq 1$ , and A, B are replaced with  $\overline{A} = \text{Diag}\{\ell^{-\bar{\alpha}}, \ell \leq n\}$ , and  $\overline{B} = \text{Diag}\{\ell^{-\bar{\beta}}, \ell \leq n\}$ . When *n* is large enough, namely,  $n \ge \sigma^{-\frac{1}{\alpha+1/\rho}}$ ,  $\mathcal Y$  contains the "coordinate box"

$$
\overline{\mathcal{Y}} = \{x : |x_{\ell}| \le \mathfrak{m}^{-1/\rho}, \mathfrak{m}/2 \le \ell \le \mathfrak{m}, x_{\ell} = 0 \text{ otherwise}\}
$$

of dimension  $\geq \frac{m}{2}$ , where

$$
\mathfrak{m} \geq c \sigma^{-\frac{1}{\bar{\alpha}+1/\rho}}.
$$

Observe that for all  $y \in \overline{\mathcal{Y}}$ ,  $\|\overline{A}y\|_2 \leq C \mathfrak{m}^{-\overline{\alpha}} \|y\|_2$ , and  $\|\overline{B}y\|_r \geq c \mathfrak{m}^{-\overline{\beta}} \|y\|_r$ . This observation, when combined with the Fano inequality, implies that for  $\epsilon \ll 1$  (cf. [\[12\]](#page-27-8)) the minimax optimal w.r.t. the family of all Borel estimates  $(\epsilon, \|\cdot\|_r)$ -risk on the signal set  $\overline{\mathcal{X}} = D^{-1}\overline{\mathcal{Y}} \subset \mathcal{X}$  is at least

$$
c\sigma^{\frac{\bar{\beta}+1/\rho-1/r}{\bar{\alpha}+1/\rho}}.
$$

In other words, in this situation, the upper bound [\(30\)](#page-12-1) on the risk of the polyhedral estimate is within a logarithmic in  $n/\epsilon$  factor from the minimax risk. In particular, without surprise, in the case of  $\beta = 0$  the polyhedral estimates attain well known optimal rates [\[9,](#page-27-12) [11,](#page-27-14) [18\]](#page-27-11).

# <span id="page-12-0"></span>4 Efficient upper-bounding of  $\mathfrak{R}[H]$  and contrast design, II.

### <span id="page-12-2"></span>4.1 Outline

In this section we develop an approach to the design of polyhedral estimates which is an alternative to that discussed in Section [3.](#page-7-0) Our present strategy can be outlined as follows. Let us denote by

$$
\mathcal{B}_* = \{u \in \mathbf{R}^{\nu} : ||u||_* \leq 1\}
$$

the unit ball of the norm  $\|\cdot\|_*$  conjugate to the norm  $\|\cdot\|$  in the formulation of the estimation problem in Section [2.1.](#page-4-1) Assume that we have at our disposal a technique for bounding quadratic forms on the set  $\mathcal{B}_* \times \mathcal{X}_s$ , so that there is an efficiently computable convex function  $\mathcal{M}(M)$  on  $S^{\nu+n}$  such that

<span id="page-13-2"></span>
$$
\mathcal{M}(M) \ge \max_{[u,z] \in \mathcal{B}_* \times \mathcal{X}_\mathbf{S}} [u; z]^T M [u; z] \ \forall M \in \mathbf{S}^{\nu+n}.\tag{31}
$$

Note that the upper bound  $\mathfrak{R}[H]$ , as defined in [\(10\)](#page-5-3), on the risk of a candidate polyhedral estimate  $\hat{w}^H$  given by [\(10\)](#page-5-3) is nothing but

<span id="page-13-0"></span>
$$
\mathfrak{R}[H] = 2 \max_{[u;z]} \left\{ [u;z]^T \underbrace{\left[\frac{1}{2}B^T\right]}_{B_+} [u;z] : \begin{array}{l} u \in \mathcal{B}_*, z \in \mathcal{X}_s, \\ z^T A^T h_\ell h_\ell^T A z \le 1, \ell \le N \end{array} \right\}.
$$
 (32)

When  $\lambda \in \mathbf{R}^N_+$ , the constraints  $z^T A^T h_\ell h^T_\ell A z \leq 1$  in [\(32\)](#page-13-0) can be aggregated to yield the quadratic constraint

$$
z^T A^T \Theta_\lambda Az \le \mu_\lambda, \ \Theta_\lambda = H \text{Diag}\{\lambda\} H^T, \ \mu_\lambda = \sum_{\ell} \lambda_\ell.
$$

Observe that for every  $\lambda \geq 0$  we have

<span id="page-13-1"></span>
$$
\Re[H] \le 2\mathcal{M}\left(\underbrace{\left[\frac{\frac{1}{2}B^{T}}{\frac{1}{2}B^{T}}\middle| -A^{T}\Theta_{\lambda}A\right]}_{B_{+}[\Theta_{\lambda}]}\right) + 2\mu_{\lambda}.
$$
\n(33)

Indeed, let  $[u, z]$  be a feasible solution to the optimization problem [\(32\)](#page-13-0) specifying  $\mathfrak{R}[H]$ . Then

 $[u; z]^T B_+[u; z] = [u; z]^T B_+[\Theta_\lambda][u; z] + z^T A^T \Theta_\lambda A z;$ 

the first term in the right hand side is  $\leq \mathcal{M}(B_+[\Theta_\lambda])$  since  $[u; z] \in \mathcal{B}_* \times \mathcal{X}_s$ , and the second term in the right hand side, as we have already seen, is  $\leq \mu_{\lambda}$ , and [\(33\)](#page-13-1) follows.

Now assume that we have at our disposal a computationally tractable cone

$$
\mathbf{H}\subset \mathbf{S}^N_+\times \mathbf{R}_+
$$

satisfying the following assumption

Assumption C. Whenever  $(\Theta, \mu) \in H$ , we can efficiently find an  $n \times N$  matrix  $H = [h_1, ..., h_N]$  and a nonnegative vector  $\lambda \in \mathbb{R}^N_+$  such that

<span id="page-13-4"></span>\n- (a) the columns 
$$
h_{\ell}
$$
 of  $H$  satisfy (7)
\n- (b)  $\Theta = H \text{Diag}\{\lambda\} H^T$
\n- (c)  $\sum_i \lambda_i \leq \mu$
\n

The following simple observation is crucial to what follows:

**Proposition 4.1** Consider the estimation problem posed in Section [2.1,](#page-4-1) and let efficiently computable convex function M and computationally tractable closed convex cone  $\bf{H}$  satisfy [\(31\)](#page-13-2) and Assumption C, respectively. Consider the convex optimization problem

<span id="page-13-3"></span>
$$
Opt = \min_{\tau, \Theta, \mu} \{ 2\tau + 2\mu : (\Theta, \mu) \in \mathbf{H}, \mathcal{M}(B_+[\Theta]) \le \tau \}
$$

$$
\left[ B_+[\Theta] = \left[ \frac{\frac{1}{2}B}{\frac{1}{2}B^T \left| -A^T \Theta A \right|} \right] \right]
$$
(35)

Given a feasible solution  $(\tau, \Theta, \mu)$  to this problem, by C we can efficiently convert it to  $(H, \lambda)$ such that  $H = [h_1, ..., h_N]$  with  $h_\ell$  satisfying [\(7\)](#page-5-0) and  $\lambda \geq 0$  with  $\sum_{\ell} \lambda_{\ell} \leq \mu$ . We have

$$
\Re[H] \leq 2\tau + 2\mu,
$$

whence the  $(\epsilon, \|\cdot\|)$ -risk of the polyhedral estimate  $\widehat{w}^{H}$  satisfies the bound

<span id="page-14-0"></span>
$$
\text{Risk}_{\epsilon, \|\cdot\|}[\widehat{w}^H|\mathcal{X}] \le 2\tau + 2\mu. \tag{36}
$$

As a result, we can construct efficiently a polyhedral estimate with  $(\epsilon, \|\cdot\|)$ -risk arbitrarily close to Opt (and with risk exactly Opt if problem [\(35\)](#page-13-3) is solvable).

**Proof** is readily given by the reasoning preceding the proposition. Indeed, with  $\tau$ ,  $\Theta$ ,  $\mu$ ,  $H$ ,  $\lambda$  as in the premise of the proposition, the columns  $h_{\ell}$  of H satisfy [\(7\)](#page-5-0) by C, implying, by Proposition [2.1,](#page-5-4) that  $Risk_{\epsilon,\|\cdot\|}[\widehat{w}^H|\mathcal{X}] \leq \mathfrak{R}[H]$ . Besides this, **C** says that for these  $H, \lambda$  it holds  $\Theta = \Theta_{\lambda}$  and  $\mu, \leq \mu$ . Therefore, (23) combines with the constraints of (25) to imply that  $\mathfrak{R}[H] \leq 2\pi + 2$  $\mu_{\lambda} \leq \mu$ . Therefore, [\(33\)](#page-13-1) combines with the constraints of [\(35\)](#page-13-3) to imply that  $\Re[H] \leq 2\tau + 2\mu$ , and [\(36\)](#page-14-0) follows by Proposition [2.1.](#page-5-4)

The approach to the design of polyhedral estimate we develop in this section amounts to reducing the construction of the estimate (i.e., construction of the contrast matrix  $H$ ) to finding (nearly) optimal solutions to [\(35\)](#page-13-3). Implementing the proposed approach requires devising techniques for constructing cones  $H$  satisfying  $C$  along with efficiently computable functions  $\mathcal{M}(\cdot)$  satisfying [\(31\)](#page-13-2). These tasks are the subjects of the sections to follow.

#### <span id="page-14-1"></span>4.2 Specifying cones H

We specify cones  $\bf{H}$  in the case when the number N of columns in the candidate contrast matrices is m and under the following assumption on the observation scheme in question:

**Assumption D.** There is a computationally tractable convex compact subset  $Z \subset$  $\mathbf{R}^m_+$  intersecting int $\mathbf{R}^m_+$  such that the norm  $\pi(\cdot)$ 

$$
\pi(h) = \sqrt{\max_{z \in Z} \sum_{i} z_i h_i^2}
$$

induced by Z satisfies the relation

$$
\pi(h) \le 1 \ \Rightarrow \ \text{Prob}\{|h^T \xi_x| > 1\} \le \epsilon/m \ \forall x \in \mathcal{X}.
$$

Note that Assumption D is satisfied for Sub-Gaussian, Discrete, and Poisson observation schemes: according to the results of Section [2.3,](#page-6-0)

• in the Sub-Gaussian case, it suffices to take

$$
Z = \{2\sigma^2 \ln(2m/\epsilon)[1; \dots; 1]\};
$$

• in the Discrete case, it suffices to take

$$
Z = \frac{4 \ln(2m/\epsilon)}{K} A\mathcal{X} + \frac{64 \ln^2(2m/\epsilon)}{9K^2} \Delta_m
$$

where

$$
A\mathcal{X} = \{Ax : x \in \mathcal{X}\}, \ \ \Delta_m = \{y \in \mathbf{R}^m : y \ge 0, \sum_i y_i = 1\};
$$

• finally, in the Poisson case, it suffices to take

$$
Z = 4\ln(2m/\epsilon)A\mathcal{X} + \frac{16}{9}\ln^2(2m/\epsilon)\Delta_m,
$$

with  $A\mathcal{X}$  and  $\Delta_m$  as above.

Note that in all these cases Z only "marginally" – logarithmically – depends on  $\epsilon$  and m. Under Assumption  $D$ , the cone  $H$  can be built as follows:

• When Z is a singleton:  $\mathcal{Z} = \{\bar{z}\}\$ , so that  $\pi(\cdot)$  is a scaled Euclidean norm, we set

$$
\mathbf{H} = \{(\Theta, \mu) \in \mathbf{S}_{+}^{m} \times \mathbf{R}_{+} : \mu \geq \sum_{i} \bar{z}_{i} \Theta_{ii} \}.
$$

Given  $(\Theta, \mu) \in \mathbf{H}$ , the  $m \times m$  matrix H and  $\lambda \in \mathbf{R}_{+}^{m}$  are defined as follows. We set Siven  $(\heartsuit, \mu) \in \mathbb{R}$ , the  $m \times m$  matrix  $H$  and  $\lambda \in \mathbb{R}^+$  are defined as follows. We set  $S = \text{Diag}\{\sqrt{\bar{z}_1}, ..., \sqrt{\bar{z}_m}\}$  and compute the eigenvalue decomposition of the matrix  $S\Theta S$ :

$$
S\Theta S = U \text{Diag}\{\lambda\} U^T,
$$

where U is orthogonal, and set  $H = S^{-1}U$ , thus ensuring that  $\Theta = H\text{Diag}\{\lambda\}H^T$ . Since  $\mu \geq \sum_i \bar{z}_i \Theta_{ii}$ , we have  $\sum_i \lambda_i = \text{Tr}(S \Theta S) \leq \mu$ . Finally, a column h of H is of the form  $S^{-1}f$  with a  $\|\cdot\|_2$ -unit vector f, implying that

$$
\pi(h) = \sqrt{\sum_{i} \bar{z}_i [S^{-1}f]_i^2} = \sqrt{\sum_{i} f_i^2} = 1,
$$

so that h satisfies  $(7)$  by Assumption D.

• When  $Z$  is not a singleton, we set

<span id="page-15-1"></span>
$$
\begin{array}{rcl}\n\phi(r) & = & \max_{z \in Z} z^T r, \\
\kappa & = & 6 \ln(2\sqrt{3}m^2), \\
\mathbf{H} & = & \{(\Theta, \mu) \in \mathbf{S}_+^m \times \mathbf{R}_+ : \mu \geq \varkappa \phi(\text{diag}(\Theta))\},\n\end{array} \tag{37}
$$

where diag(Q) is the diagonal of a (square) matrix Q. Note that  $\phi(r) > 0$  whenever  $r \geq 0$ ,  $r \neq 0$ , since Z contains a positive vector.

<span id="page-15-0"></span>The justification of this construction and the efficient (randomized) algorithm for converting a pair  $(\Theta, \mu) \in \mathbf{H}$  into  $(H, \lambda)$  satisfying, along with  $(\Theta, \mu)$ , Assumption C are given by the following

**Lemma 4.1** Let the norm  $\pi(\cdot)$  satisfies Assumption D. (i) Whenever H is an  $m \times m$  matrix with columns  $h_\ell$  satisfying  $\pi(h_\ell) \leq 1$  and  $\lambda \in \mathbb{R}^m_+$ , we have

$$
(\Theta_{\lambda} = H \text{Diag}\{\lambda\}H^T, \ \mu = \varkappa \sum_{i} \lambda_i) \in \mathbf{H}.
$$

(ii) Given  $(\Theta, \mu) \in \mathbf{H}$  with  $\Theta \neq 0$ , we find decomposition  $\Theta = QQ^T$  with  $m \times m$  matrix  $Q$  and fix an orthogonal  $m \times m$  matrix  $V$  with magnitudes of entries not exceeding  $\sqrt{2/m}$ (e.g., the orthogonal scaling of the matrix of the cosine transform).

When  $\mu > 0$ , let us set  $\lambda = \frac{\mu}{m}$  $\frac{\mu}{m}[1;...;1] \in \mathbf{R}^m$  and consider the random matrix

$$
H_\chi = \sqrt{\frac{m}{\mu}} Q \text{Diag}\{\chi\} V,
$$

where  $\chi$  is the m-dimensional Rademacher random vector (i.e., the entries in  $\chi$  are independent of each other random variables taking values  $\pm 1$  with probabilities  $1/2$ ). We have

<span id="page-16-3"></span>
$$
H_{\chi} \text{Diag}\{\lambda\} H_{\chi}^{T} \equiv \Theta, \lambda \ge 0, \sum_{i} \lambda_{i} = \mu. \tag{38}
$$

Moreover, probability of the event

<span id="page-16-0"></span>
$$
\pi(\text{Col}_{\ell}[H_{\chi}]) \le 1 \quad \forall \ell \le m \tag{39}
$$

is at least 1/2. Thus, generating independent samples of  $\chi$  and terminating with  $H = H_{\chi}$ when the latter matrix satisfies [\(39\)](#page-16-0), we with probability 1 terminate with  $(H, \lambda)$  satisfying Assumption  $C$ . Moreover, the probability for the procedure to terminate in course of the first  $M = 1, 2, ...$  steps is at least  $1 - 2^{-M}$ .

When  $\mu = 0$ , we have  $\Theta = 0$  (since  $\mu = 0$  implies  $\phi(\text{diag}(\Theta)) = 0$ , which with  $\Theta \succeq 0$  is possible only when  $\Theta = 0$ ); thus, when  $\mu = 0$ , we set  $H = 0_{m \times m}$  and  $\lambda = 0_{m \times 1}$ .

For proof, see Section [A.3.3.](#page-33-1)

Note that the lemma states, essentially, that the cone H is a tight, up to a logarithmic in m factor, inner approximation of the set

$$
\left\{ (\Theta, \mu) : \exists (\lambda \in \mathbf{R}_{+}^{m}, H \in \mathbf{R}^{m \times m}) : \begin{array}{l} \Theta = H \text{Diag}\{\lambda\} H^{T}, \\ \pi(\text{Col}_{\ell}[H]) \leq 1, \, \ell \leq m, \\ \mu \geq \sum_{\ell} \lambda_{\ell} \end{array} \right\}
$$

#### 4.3 Specifying functions M

In this section we focus on computationally efficient upper-bounding of maxima of quadratic forms over symmetric w.r.t. the origin convex compact sets, our goal being to specify efficiently computable convex function  $\mathcal{M}(\cdot)$  satisfying [\(31\)](#page-13-2).

Cones compatible with convex sets. Given a nonempty convex compact set  $\mathcal{Y} \subset \mathbb{R}^N$ , we say that a cone Y is compatible with  $\mathcal{Y}$ , if

- Y is a closed convex computationally tractable cone contained in  $S^N_+ \times \mathbf{R}_+$
- one has

<span id="page-16-2"></span>
$$
\forall (V, \tau) \in \mathbf{Y} : \max_{y \in \mathcal{Y}} y^T V y \le \tau \tag{40}
$$

- **Y** contains a pair  $(V, \tau)$  with  $V \succ 0$ .
- <span id="page-16-1"></span>• relations  $(V, \tau) \in \mathbf{Y}$  and  $\tau' \geq \tau$  imply that  $(V, \tau') \in \mathbf{Y}^{4}$  $(V, \tau') \in \mathbf{Y}^{4}$  $(V, \tau') \in \mathbf{Y}^{4}$ .

<sup>&</sup>lt;sup>4</sup>The latter requirement is "for free" – passing from a computationally tractable closed convex cone Y ⊂  $\mathbf{S}_+^N\times\mathbf{R}_+$  satisfying [\(40\)](#page-16-2) to the cone  $\mathbf{Y}^+=\{(V,\tau):\exists\bar{\tau}\leq\tau:(V,\bar{\tau})\in\mathbf{Y}\},$  we get a larger than  $\mathbf Y$  cone compatible with  $\mathcal Y$ . It will be clear from the sequel that in our context, the larger is a cone compatible with  $\mathcal Y$ , the better, so that this extension makes no harm.

We call a cone Y sharp, if Y is a closed convex cone contained in  $S^N_+ \times \mathbb{R}_+$  and such that the only pair  $(V, \tau) \in \mathbf{Y}$  with  $\tau = 0$  is the pair  $(0, 0)$ , or, equivalently, a sequence  $\{(V_i, \tau_i) \in \mathbf{Y}, i \geq 1\}$ is bounded if and only if the sequence  $\{\tau_i, i \geq 1\}$  is bounded.

Note that whenever the linear span of  $\mathcal Y$  is the entire  $\mathbb R^N$ , every compatible with  $\mathcal Y$  cone is sharp.

Observe that if  $\mathcal{Y} \subset \mathbb{R}^N$  is a nonempty convex compact set and Y is a cone compatible with a shift  $\mathcal{Y} - a$  of  $\mathcal{Y}$ , then Y is compatible with  $\mathcal{Y}_s$  (a symmetrisation of  $\mathcal{Y}$ ).

Indeed, when shifting a set  $\mathcal{Y}$ , its symmeterization  $\frac{1}{2}[\mathcal{Y} - \mathcal{Y}]$  remains intact, so that we can assume that Y is compatible with  $\mathcal{Y}$ . Now let  $(V, \tau) \in Y$  and  $y, y' \in \mathcal{Y}$ . We have

$$
[y - y']^T V [y - y'] + \underbrace{[y + y']^T V [y + y']}_{\geq 0} = 2 [y^T V y + [y']^T V y'] \leq 4\tau,
$$

whence for  $z = \frac{1}{2}[y - y']$  it holds  $z^T V z \leq \tau$ . Since every  $z \in \mathcal{Y}_s$  is of the form  $\frac{1}{2}[y - y']$  with  $y, y' \in \mathcal{Y}$ , the claim follows.

Note that the claim can be "nearly inverted:" if  $0 \in \mathcal{Y}$  and Y is compatible with  $\mathcal{Y}_s$ , then the "widening" of  $Y - the cone$ 

$$
\mathbf{Y}^{+} = \{ (V, \tau) : (V, \tau/4) \in \mathbf{Y} \}
$$

is compatible with  $\mathcal Y$  (evident, since when  $0 \in \mathcal Y$ , every vector from  $\mathcal Y$  is proportional, with coefficient 2, to a vector from  $\mathcal{Y}_s$ ).

**Constructing functions**  $M$ **.** The role of compatibility in our context becomes clear from the following observation:

**Proposition 4.2** In the situation described in Section [2.1,](#page-4-1) assume that we have at our disposal cones **X** and **U** compatible, respectively, with  $\mathcal{X}_s$  and with the unit ball

<span id="page-17-1"></span>
$$
\mathcal{B}_* = \{ v \in \mathbf{R}^{\nu} : ||u||_* \le 1 \}
$$

of the norm  $\|\cdot\|_*$  conjugate to  $\|\cdot\|$ . Given  $M \in \mathbf{S}^{\nu+n}$ , let us set

<span id="page-17-0"></span>
$$
\mathcal{M}(M) = \inf_{X,t,U,s} \{ t+s : (X,t) \in \mathbf{X}, (U,s) \in \mathbf{U}, \text{Diag}\{U,X\} \succeq M \}
$$
(41)

Then M is a real-valued efficiently computable convex function on  $S^{\nu+n}$  such that [\(31\)](#page-13-2) takes place: for every  $M \in \mathbf{S}^{n+\nu}$  it holds

$$
\mathcal{M}(M) \ge \max_{[u; z] \in \mathcal{B}_* \times \mathcal{X}_\mathbf{S}} [u; z]^T M[u; z].
$$

In addition, when  $X$  and  $U$  are sharp, the infimum in [\(41\)](#page-17-0) is attained.

**Proof** is immediate. Given that the objective of the optimization problem specifying  $\mathcal{M}(M)$ is nonnegative on the feasible set, the fact that  $\mathcal M$  is real-valued is equivalent to problem's feasibility, and the latter is readily given by that fact that **X** is a cone containing a pair  $(X, t)$ with  $X \succ 0$  and similarly for U. Convexity of M is evident. To verify [\(31\)](#page-13-2), let  $(X, t, U, s)$  form a feasible solution to the optimization problem in [\(41\)](#page-17-0). When  $[u; z] \in \mathcal{B}_* \times \mathcal{X}_s$  we have

$$
[u; z]^T M [u; z] \le u^T U u + z^T X z \le s + t,
$$

where the first inequality is due to the  $\succeq$ -constraint in [\(41\)](#page-17-0), and the second is due to the fact that U is compatible with  $\mathcal{B}_*$ , and X is compatible with  $\mathcal{X}_s$ . Since the resulting inequality holds true for all feasible solutions to the optimization problem in  $(41)$ ,  $(31)$  follows. Finally, when **X** and  **are sharp,**  $(41)$  **is a feasible conic problem with bounded level sets of the objective and** as such is solvable.  $\Box$ 

### <span id="page-18-5"></span>4.4 Putting things together

<span id="page-18-3"></span>The following statement summarizes our second approach to the design of polyhedral estimate.

Proposition 4.3 In the situation of Section [2.1,](#page-4-1) assume that we have at our disposal cones **X** and U compatible, respectively, with  $\mathcal{X}_s$  and with the unit ball  $\mathcal{B}_*$  of the norm conjugate to  $\|\cdot\|$ . Given reliability tolerance  $\epsilon \in (0,1)$ , assume that we have at our disposal a positive integer N and a computationally tractable cone **H** satisfying, along with  $\epsilon$ , Assumption C. Consider (clearly feasible) convex optimization problem

<span id="page-18-1"></span>
$$
Opt = \min_{\Theta, \mu, X, t, U, s} \left\{ f(t, s, \mu) := 2(t + s + \mu) : \begin{array}{c} (\Theta, \mu) \in \mathbf{H}, (X, t) \in \mathbf{X}, (U, s) \in \mathbf{U} \\ \frac{U}{\frac{1}{2}B^T} \left[ \frac{U}{A^T \Theta A + X} \right] \succeq 0 \end{array} \right\} \tag{42}
$$

Given a feasible solution  $\Theta, \mu, X, t, U, s$  to [\(42\)](#page-18-1), due to C, we can convert, in a computationally efficient manner,  $(\Theta, \mu)$  into  $(H, \lambda)$  such that the columns of the  $m \times N$  contrast matrix H satisfy  $(7)$ ,  $\Theta = H\text{Diag}\{\lambda\}H^T$ , and  $\mu \geq \sum_{\ell} \lambda_{\ell}$ . In this case, the  $(\epsilon, \|\cdot\|)$ -risk of the polyhedral estimate  $\widehat{w}^{H}$  satisfies the bound

<span id="page-18-2"></span>
$$
\text{Risk}_{\epsilon, \|\cdot\|}[\widehat{w}^H|\mathcal{X}] \le f(t, s, \mu). \tag{43}
$$

In particular, we can build, in a computationally efficient manner, polyhedral estimates with risks arbitrarily close to Opt (and with risk Opt, provided that [\(42\)](#page-18-1) is solvable).

**Proof.** Let  $\Theta, \mu, X, t, U, s$  form a feasible solution to [\(42\)](#page-18-1). By the semidefinite constraint in [\(42\)](#page-18-1) we have

$$
0 \preceq \left[ \begin{array}{c|c} U & -\frac{1}{2}B \\ \hline -\frac{1}{2}B^T & A^T \Theta A + X \end{array} \right] = \text{Diag}\{U, X\} - \underbrace{\left[ \begin{array}{c|c} \frac{1}{2}B & \frac{1}{2}B \\ \hline \frac{1}{2}B^T & -A^T \Theta A \end{array} \right]}_{=:M}.
$$

Hence, for the function  $\mathcal M$  defined in [\(41\)](#page-17-0) one has

$$
\mathcal{M}(M) \leq t + s.
$$

Since, by Proposition [4.2,](#page-17-1)  $M$  satisfies [\(31\)](#page-13-2), invoking Proposition [4.1](#page-13-4) we arrive at

$$
\Re[H] \le 2(\mu + \mathcal{M}(M)) \le f(t, s, \mu).
$$

By Proposition [2.1,](#page-5-4) this implies the target relation  $(43)$ .

#### <span id="page-18-0"></span>4.5 Compatibility

The approach to design of polyhedral estimates utilizing the recipe described in Proposition [4.3](#page-18-3) relies upon our ability to equip convex "sets of interest" (in our context, these are the symmeterization  $\mathcal{X}_s$  of the signal set and the unit ball  $\mathcal{B}_*$  of the norm conjugate to the norm  $\|\cdot\|$ ) with compatible cones.<sup>[5](#page-18-4)</sup> Below, we discuss two principal sources of such cones, namely (a) spectratopes/ellitopes, and (b) absolute norms.

More examples of compatible cones can be constructed using a "compatibility calculus." Namely, let us assume that we are given a collection of convex sets (operands) and apply to them

<span id="page-18-4"></span> ${}^{5}$ Recall that we already know how to specify the second element of the construction, the cone **H**.

some basic operation, such as taking a finite intersection, or arithmetic sum, direct or inverse linear image, or convex hull of a finite union of the sets. It turns out that cones compatible with the results of such operations can be easily (in a fully algorithmic fashion) obtained from the cones compatible with the operands; see Appendix [A.2](#page-29-7) for principal calculus rules.

In view of Proposition [4.3,](#page-18-3) the larger are the cones **X** and **U** compatible with  $\mathcal{X}_s$  and  $\mathcal{B}_*$ , thebetter – the wider is the optimization domain in  $(42)$  and, consequently, the less is (the best) attainable risk bound. Given convex compact set  $\mathcal{Y} \in \mathbb{R}^{N}$ , the "ideal" – the largest candidate to the role of the cone compatible with  $\mathcal Y$  would be

$$
\mathbf{Y}^* = \{ (V, \tau) \in \mathbf{S}_+^N \times \mathbf{R}_+ : \ \tau \ge \max_{y \in \mathcal{Y}} y^T V y \}.
$$

However, this cone is typically intractable; therefore we look for "as large as possible" tractable inner approximations of  $Y^*$ .

#### 4.5.1 Cones compatible with ellitopes/spectratopes

The ellitopes and spectratopes as introduced in [\[25,](#page-28-8) [24\]](#page-28-9) are sets  $\mathcal{X} \subset \mathbb{R}^n$  representable as linear images

$$
\mathcal{X}=M\mathcal{Y}
$$

of basic ellitopes/spectratopes, that is, bounded sets  $\mathcal Y$  representable as

<span id="page-19-1"></span>(a) 
$$
\mathcal{Y} = \{y \in \mathbb{R}^N : \exists r \in \mathcal{R} : y^T R_\ell y \le r_\ell, \ell \le L\}
$$
 [basic elliptope]  
\n $R_\ell \ge 0, \ell \le L,$   
\n(b)  $\mathcal{Y} = \{y \in \mathbb{R}^N : \exists r \in \mathcal{R} : R_\ell^2[y] \preceq r_\ell I_{d_\ell}, \ell \le L\}$  [basic spectratope]  
\n $R_\ell[y] = \sum_{i=1}^N y_i R^{\ell i}, R^{\ell i} \in \mathbf{S}^{d_\ell},$  (44)

where  $\mathcal{R} \subset \mathbf{R}^L_+$  is a convex compact set intersecting with  $\text{int} \mathbf{R}^L_+$  and such that  $0 \le r' \le r \in \mathcal{R}$ implies that  $r' \in \mathcal{R}$ .

An ellitope/spectratope is a convex compact set symmetric w.r.t. the origin; as shown in [\[25,](#page-28-8) [24\]](#page-28-9), the families of ellitopes/spectratopes admit a kind of fully algorithmic "calculus" which demonstrates that these families are closed w.r.t. nearly all basic operations preserving convexity, compactness, and symmetry w.r.t. the origin, including taking finite intersections, direct products, linear images, inverse linear images under linear embeddings, and arithmetic summation. The "raw materials" this calculus can be applied to include: for ellitopes –  $\|\cdot\|_{p}$ balls with  $p \in [2,\infty]$ , and for spectratopes – the unit ball of the spectral norm in the space of matrices. In addition, every ellitope is a spectratope as well.

The importance of ellitopes/spectratopes in our context stems from the fact that it is easy to point out cones compatible with these sets. Specifically, it is shown in [\[24\]](#page-28-9)<sup>[6](#page-19-0)</sup> that if  $\mathcal{X} = M\mathcal{Y}$ , with  $\mathcal Y$  given by  $(44.b)$ , is a spectratope, then the set

<span id="page-19-2"></span>
$$
\mathbf{X} = \left\{ (V, \tau) \in \mathbf{S}_{+}^{n} \times \mathbf{R}_{+} : \exists \Lambda = \{ \Lambda_{\ell} \in \mathbf{S}_{+}^{d_{\ell}}, \ell \leq L \} : M^{T}VM \preceq \sum_{\ell} \mathcal{R}_{\ell}^{*}[\Lambda_{\ell}], \ \phi_{\mathcal{R}}(\lambda[\Lambda]) \leq \tau \right\} (45)
$$

where

$$
[\mathcal{R}_{\ell}^{*}[\Lambda_{\ell}]]_{ij} = \text{Tr}(R^{\ell i}\Lambda_{\ell}R^{\ell j}), \lambda[\Lambda] = [\text{Tr}(\Lambda_1);\ldots;\text{Tr}(\Lambda_L)], \text{ and } \phi_{\mathcal{R}}(\lambda) = \max_{r \in \mathcal{R}} r^T \lambda,
$$

<span id="page-19-0"></span> ${}^{6}$ To make the paper self-contained, we reproduce the derivations in Section [A.3.4](#page-34-0)

is a closed convex cone which is compatible with  $\mathcal{Y}$ . Similarly, when  $\mathcal{X} = M\mathcal{Y}$  with  $\mathcal{Y}$  given by  $(44.a)$  $(44.a)$ , is an ellitope, the set

<span id="page-20-2"></span>
$$
\mathbf{X} = \left\{ (V, \tau) \in \mathbf{S}_+^n \times \mathbf{R}_+ : \exists \lambda \in \mathbf{R}_+^L : M^T V M \preceq \sum_{\ell} \lambda_{\ell} R_{\ell}, \ \phi_{\mathcal{R}}(\lambda) \le \tau \right\}
$$
(46)

is a closed convex cone compatible with  $\mathcal Y$ . In both cases,  $\mathbf X$  is sharp, provided that the image space of M is the entire  $\mathbf{R}^n$ .

Note that in both these cases  $X$  is a reasonably tight inner approximation of

$$
\mathbf{X}^* = \{ (V, \tau) \in \mathbf{S}_+^n \times \mathbf{R}_+ : \ \tau \ge \max_{x \in \mathcal{X}} x^T V x \},
$$

whenever  $(V, \tau) \in \mathbf{X}^*$ , we have  $(V, \theta \tau) \in \mathbf{X}$ , with a moderate  $\theta$  (namely,  $\theta = O(1) \ln(2 \sum_{\ell} d_{\ell})$ in the spectratopic, and  $\theta = O(1) \ln(2L)$  in the ellitopic case, see [\[24,](#page-28-9) Proposition 2.1] and [\[25,](#page-28-8) Proposition 3.3], respectively).

#### 4.5.2 Compatibility via absolute norms

**Preliminaries.** Recall that a norm  $p(.)$  on  $\mathbb{R}^N$  is called absolute, if  $p(x)$  is a function of the vector  $\text{abs}[x] := [|x_1|; ...; |x_N|]$  of the magnitudes of entries in x. It is well known that an absolute norm p is monotone on  $\mathbb{R}^N_+$ , so that  $\text{abs}[x] \leq \text{abs}[x']$  implies that  $p(x) \leq p(x')$ , and that the norm

$$
p_*(x) = \max_{y: \, p(y) \le 1} x^T y
$$

conjugate to  $p(\cdot)$  is absolute along with p.

Let us say that an absolute norm  $r(\cdot)$  fits an absolute norm  $p(\cdot)$  on  $\mathbb{R}^N$ , if for every vector x with  $p(x) \leq 1$  the entrywise square  $[x]^2 = [x_1^2; \dots; x_N^2]$  of x satisfies  $r([x]^2) \leq 1$ . For example, the largest norm  $r(\cdot)$  which fits the absolute norm  $p(\cdot) = || \cdot ||_s, s \in [1, \infty],$  is

$$
r(\cdot) = \begin{cases} \|\cdot\|_1, & 1 \le s \le 2 \\ \|\cdot\|_{s/2}, & s \ge 2 \end{cases}
$$

An immediate observation is that an absolute norm  $p(.)$  on  $\mathbb{R}^{N}$  can be "lifted" to a norm on  $S^N$ , specifically, the norm

<span id="page-20-0"></span>
$$
p^{+}(Y) = p([p(\text{Col}_{1}[Y]);...;p(\text{Col}_{N}[Y])]): \mathbf{S}^{N} \to \mathbf{R}_{+},
$$
\n(47)

where  $Col<sub>i</sub>[Y]$  is jth column in Y. It is immediately seen that when p is an absolute norm, the right hand side in [\(47\)](#page-20-0) indeed is a norm on  $S<sup>N</sup>$  satisfying the identity

<span id="page-20-1"></span>
$$
p^{+}(xx^{T}) = p^{2}(x), x \in \mathbf{R}^{N}.
$$
\n(48)

Absolute norms and compatibility. Our interest in absolute norms is motivated by the following immediate

**Proposition 4.4** Let  $p(\cdot)$  be an absolute norm on  $\mathbb{R}^N$ , and  $r(\cdot)$  be another absolute norm which fits  $p(\cdot)$ , both norms being computationally tractable. These norms give rise to the computationally tractable and sharp closed convex cone

$$
\mathbf{P} = \mathbf{P}_{p,r} = \left\{ (V,\tau) \in \mathbf{S}_+^N \times \mathbf{R}_+ : \exists (W \in \mathbf{S}^N, w \in \mathbf{R}_+^N) : \begin{array}{l} V \preceq W + \text{Diag}\{w\} \\ [p^+]_*(W) + r_*(w) \le \tau \end{array} \right\},\tag{49}
$$

where  $[p^+]_*(\cdot)$  is the norm on  $S^N$  conjugate to the norm  $p^+(\cdot)$ , and  $r_*(\cdot)$  is the norm on  $\mathbf{R}^N$ conjugate to the norm  $r(\cdot)$ , and this cone is compatible with the unit ball of the norm  $p(\cdot)$  (and thus – with any convex compact subset of this ball).

Verification is immediate. The fact that  $P$  is a computationally tractable and closed convex cone is evident. Now let  $(V, \tau) \in \mathbf{P}$ , so that  $V \succeq 0$  and  $V \preceq W + \text{Diag}\{w\}$  with  $[p^+]_*(W) + r_*(w) \leq \tau$ . For x with  $p(x) \leq 1$  we have

$$
x^T V x \leq x^T [W + \text{Diag}\{w\}]x = \text{Tr}(W[x x^T]) + w^T [x]^2
$$
  
\n
$$
\leq p^+(xx^T)[p^+]_*(W) + r([x]^2)r_*(w) = p^2(x)[p^+]_*(W) + r_*(w)
$$
  
\n
$$
\leq [p^+]_*(W) + r_*(w) \leq \tau,
$$

whence  $x^T V x \leq \tau$  for all x with  $p(x) \leq 1$ .

Let us look at the proposed construction in the case where  $p(\cdot) = || \cdot ||_s, s \in [1, \infty],$  and let  $r(\cdot) = || \cdot ||_{\bar{s}}, \bar{s} = \max[s/2, 1].$  Setting  $s_* = \frac{s}{s-1}, \bar{s}_* = \frac{\bar{s}}{\bar{s}-1}$ , we clearly have

$$
[p^+]_*(W) = \|W\|_{s_*} := \begin{cases} \left(\sum_{i,j} |W_{ij}|^{s_*}\right)^{1/s_*}, & s_* < \infty \\ \max_{i,j} |W_{ij}|, & s_* = \infty \end{cases}, r_*(w) = \|w\|_{\bar{s}_*},
$$

resulting in

<span id="page-21-0"></span>
$$
\mathbf{P}^{s} := \mathbf{P}_{\|\cdot\|_{s},\|\cdot\|_{\bar{s}}} \n= \left\{ (V,\tau) : V \in \mathbf{S}_{+}^{N}, \exists (W \in \mathbf{S}^{N}, w \in \mathbf{R}_{+}^{N}) : \begin{array}{l} V \preceq W + \text{Diag}\{w\}, \\ \|W\|_{s_{*}} + \|w\|_{\bar{s}_{*}} \leq \tau \end{array} \right\}.
$$
\n(50)

By Proposition [4.4,](#page-20-1)  $\mathbf{P}^s$  is compatible with the unit ball of  $\|\cdot\|_s$ -norm on  $\mathbf{R}^N$  (and therefore with every closed convex subset of this ball).

When  $s = 1$ , that is,  $s_* = \bar{s}_* = \infty$ , [\(50\)](#page-21-0) results in

$$
\mathbf{P}^{1} = \left\{ (V, \tau) : V \succeq 0, \exists (W \in \mathbf{S}^{N}, w \in \mathbf{R}_{+}^{N}) : \begin{array}{l} V \preceq W + \text{Diag}\{w\}, \\ \|W\|_{\infty} + \|w\|_{\infty} \leq \tau \end{array} \right\}
$$
(51)  
= \left\{ (V, \tau) : V \succeq 0, \|V\|\_{\infty} \leq \tau \right\},

and it is easily seen that the situation is a good as it could be, namely,

$$
\mathbf{P}^1 = \left\{ (V, \tau) : V \succeq 0, \max_{\|x\|_1 \le 1} x^T V x \le \tau \right\}.
$$

It can be shown (see Section [A.3.5\)](#page-35-0) that when  $s \in [2, \infty]$ , so that  $\bar{s}_* = \frac{s}{s-2}$ , [\(50\)](#page-21-0) results in

<span id="page-21-1"></span>
$$
\mathbf{P}^{s} = \left\{ (V, \tau) : V \succeq 0, \exists (w \in \mathbf{R}_{+}^{N}) : V \preceq \text{Diag}\{w\} \& \|w\|_{\frac{s}{s-2}} \leq \tau \right\}.
$$
 (52)

Note that

$$
\mathbf{P}^2 = \{ (V, \tau) : \ V \succeq 0, \ ||V||_{\text{sp}} \le \tau \}
$$

where  $\|\cdot\|_{\text{sp}}$  is the spectral norm, and this is exactly the largest cone compatible with the unit Euclidean ball.

When  $s \geq 2$ , the unit ball  $\mathcal Y$  of the norm  $\|\cdot\|_s$  is an ellitope:

$$
\{y \in \mathbf{R}^N : ||y||_s \le 1\} = \{y \in \mathbf{R}^N : \exists (t \ge 0, ||t||_{\bar{s}} \le 1) : y^T R_\ell y := y_\ell^2 \le t_\ell, \ell \le L = N\},\
$$

so that a compatible with  $\mathcal Y$  cone is given by [\(46\)](#page-20-2) with  $M = I_N$ . It comes as no surprise that, as it is immediately seen, the latter cone is nothing but the cone given by [\(52\)](#page-21-1).

## 4.6 Near-optimality of polyhedral estimate in the spectratopic sub-Gaussian case

As an instructive application of the design of polyhedral estimate developed in this section, consider the special case of the estimation problem stated in Section [2.1,](#page-4-1) where

1. The signal set X and the unit ball  $\mathcal{B}_*$  of the norm conjugate to  $\|\cdot\|$  are spectratopes:

$$
\mathcal{X} = \{x \in \mathbf{R}^n : \exists t \in \mathcal{T} : R_k^2[x] \preceq t_k I_{d_k}, 1 \le k \le K\},\newline \mathcal{B}_* = \{z \in \mathbf{R}^\nu : \exists y \in \mathcal{Y} : z = My\},\newline \mathcal{Y} := \{y \in \mathbf{R}^q : \exists r \in \mathcal{R} : S_\ell^2[y] \preceq r_\ell I_{f_\ell}, 1 \le \ell \le L\},\newline
$$

2. For every  $x \in \mathcal{X}$ , observation noise is sub-Gaussian, i.e.  $\xi_x \sim \mathcal{SG}(0, \sigma^2 I_m)$ .

We are about to show that in the present situation, the polyhedral estimate yielded by the approach described in Sections [4.1–](#page-12-2)[4.4,](#page-18-5) i.e., yielded by the efficiently computable (high accuracy near-) optimal solution to the optimization problem [\(42\)](#page-18-1) is near-optimal in the minimax sense.

Given reliability tolerance  $\epsilon \in (0, 1)$ , the recipe for constructing a  $m \times m$  contrast matrix H as prescribed by Proposition [4.3](#page-18-3) is as follows:

• We set

$$
Z = \{\vartheta^2[1; ...; 1]\}, \vartheta = \sigma\kappa, \,\kappa = \sqrt{2\ln(2m/\epsilon)},
$$

and utilize the construction from Section [4.2,](#page-14-1) thus arriving at the cone

$$
\mathbf{H} = \{(\Theta, \mu) \in \mathbf{S}_{+}^{m} \times \mathbf{R}_{+} : \sigma^{2} \kappa^{2} \text{Tr}(\Theta) \le \mu\}
$$

satisfying the requirements of Assumption C.

• We specify the cones **X** and **U** compatible with  $\mathcal{X}_s = \mathcal{X}$ , and  $\mathcal{B}_*$ , respectively, according to [\(45\)](#page-19-2).

The resulting problem [\(42\)](#page-18-1), after immediate straightforward simplifications, reads

<span id="page-22-0"></span>
$$
\begin{array}{rcl}\n\text{Opt} &=& \min_{\Theta, U, \Lambda, \Upsilon} \left\{ 2 \left[ \phi_{\mathcal{R}}(\lambda[\Upsilon]) + \phi_{\mathcal{T}}(\lambda[\Lambda]) + \sigma^2 \kappa^2 \text{Tr}(\Theta) \right] : \right. \\
& & \Theta \succeq 0, U \succeq 0, \Lambda = \{ \Lambda_k \succeq 0, k \le K \}, \ \Upsilon = \{ \Upsilon_\ell \succeq 0, \ell \le L \}, \\
& & \left[ \frac{U}{\frac{1}{2} B^T} \left[ \frac{1}{A^T \Theta A + \sum_k \mathcal{R}_k^* [\Lambda_k]} \right] \succeq 0, \ M^T U M \le \sum_\ell \mathcal{S}_\ell^* [\Upsilon_\ell] \right. \end{array} \tag{53}
$$

where

$$
[\mathcal{R}_k^*[\Lambda_k]]_{ij} = \text{Tr}(R^{ki}\Lambda_k R^{kj}) \left[R_k[x] = \sum_i x_i R^{ki}\right],
$$
  

$$
[\mathcal{S}_\ell^*[\Upsilon_\ell]]_{ij} = \text{Tr}(S^{\ell i}\Upsilon_\ell S^{\ell j}) \left[S_\ell[u] = \sum_i u_i S^{\ell i}\right],
$$

and

$$
\lambda[\Lambda] = [\text{Tr}(\Lambda_1); \dots; \text{Tr}(\Lambda_K)], \lambda[\Upsilon] = [\text{Tr}(\Upsilon_1); \dots; \text{Tr}(\Upsilon_L)], \phi_W(f) = \max_{w \in W} w^T f.
$$

Let now

RiskOpt<sub>$$
\epsilon
$$</sub> = inf sup inf { $\rho$ : Prob <sub>$\xi \sim \mathcal{N}(0, \sigma^2 I)$</sub> { $||Bx - \widehat{w}(Ax + \xi)|| > \rho$ }  $\leq \epsilon \forall x \in \mathcal{X}$ },

be the minimax optimal  $(\epsilon, \|\cdot\|)$ -risk of estimating  $w = Bx$  in Gaussian observation scheme where  $\xi_x \sim \mathcal{N}(0, \sigma^2 I_m)$  independently of  $x \in X$ .

**Proposition 4.5** When  $\epsilon \leq 1/8$ , the polyhedral estimate  $\hat{w}^H$  yielded by a feasible near optimal, in terms of the objective solution to realism. (53) is minimax optimal within the locarithmic in terms of the objective, solution to problem [\(53\)](#page-22-0) is minimax optimal within the logarithmic factor, namely

<span id="page-23-2"></span>
$$
\begin{array}{rcl}\n\text{Risk}_{\epsilon, \|\cdot\|}[\widehat{w}|\mathcal{X}] & \leq & O(1) \sqrt{\ln\Big(\sum_{k} d_k\Big) \ln\Big(\sum_{\ell} f_{\ell}\Big) \ln(2m/\epsilon)} \text{RiskOpt}_{\frac{1}{8}} \\
& \leq & O(1) \sqrt{\ln\Big(\sum_{k} d_k\Big) \ln\Big(\sum_{\ell} f_{\ell}\Big) \ln(2m/\epsilon)} \text{RiskOpt}_{\epsilon},\n\end{array}
$$

where  $O(1)$  is an absolute constant.

For proof, see Section [A.3.6.](#page-36-0)

**Discussion.** It is worth mentioning that the approach described in Section [3](#page-7-0) is complementary to the approach discussed in this section. In fact, it is easily seen that the bound Opt for the risk of the polyhedral estimate stemming from [\(42\)](#page-18-1) is suboptimal in the simple situation described in the motivating example from Introduction. Indeed, let X be the unit  $\|\cdot\|_1$ -ball, let  $\|\cdot\| = \|\cdot\|_2$ , and let us consider the problem of estimating  $x \in \mathcal{X}$  from the direct observation  $\omega = x + \xi$  with Gaussian observation noise  $\xi \sim \mathcal{N}(0, \sigma^2 I)$ . We equip the ball  $\mathcal{B}_* = \{u \in \mathbb{R}^n : ||u_2||_2 \leq 1\}$  with the cone

$$
\mathbf{U} = \mathbf{P}^2 = \{ (U, \tau) : U \succeq 0, ||U||_{\text{sp}} \le \tau \}
$$

and  $\mathcal{X}$  – with the cone

$$
\mathbf{X} = \mathbf{P}^1 = \{ (X, t) : X \succeq 0, ||X||_{\infty} \le t \},
$$

(note that both cones are the largest w.r.t. inclusion cones compatible with the respective sets). The corresponding problem [\(42\)](#page-18-1) reads

<span id="page-23-0"></span>
$$
\begin{split}\n\text{Opt} &= \min_{\Theta, X, U} \left\{ 2 \Big( \kappa^2 \sigma^2 \text{Tr}(\Theta) + \max_i X_{ii} + \|U\|_{\text{sp}} \Big) : \begin{array}{l} \Theta \succeq 0, \ X \succeq 0, \ U \succeq 0, \ \frac{U}{2} I_n \ \frac{1}{2} I_n \Theta + X \end{array} \right\} \\
&= \min_{\Theta, X, U} \left\{ 2 \Big( \kappa^2 \sigma^2 \text{Tr}(\Theta) + \max_i X_{ii} + \tau \Big) : \begin{array}{l} \Theta \succeq 0, \ X \succeq 0, \ U \succeq 0, \ \frac{1}{2} I_n \ \Theta + X \end{array} \right\} \succeq 0 \right\}\n\end{split} \tag{54}
$$

Observe that every  $n \times n$  matrix of the form  $Q = EP$ , where E is diagonal with diagonal entries  $\pm 1$ , and P is a permutation matrix, induces a symmetry  $(\Theta, X, \tau) \mapsto (Q \Theta Q^T, Q X Q^T, \tau)$  of the second optimization problem in [\(54\)](#page-23-0), that is, a transformation which maps the feasible set onto itself and keeps the objective intact. Since the problem is convex and solvable, we conclude that it has an optimal solution which remains intact under the symmetries in question, i.e., solution with scalar matrices  $\Theta = \theta I_n$  and  $X = uI_n$ . As a result,

<span id="page-23-1"></span>
$$
\text{Opt} = \min_{\theta \ge 0, u \ge 0, \tau} \left\{ 2(\kappa^2 \sigma^2 n \theta + u + \tau) : \ \tau(\theta + u) \ge \frac{1}{4} \right\} = 2 \min \left[ \kappa \sigma \sqrt{n}, 1 \right],\tag{55}
$$

A similar derivation shows that the value Opt remains intact if we replace the set  $\mathcal{X} = \{x :$  $||x||_1 \leq 1$  with  $\mathcal{X} = \{x : ||x||_s \leq 1\}, s \in [1, 2]$ , and the cone  $\mathbf{X} = \mathbf{P}^1$  with  $\mathbf{X} = \mathbf{P}^s$ , see [\(50\)](#page-21-0). Since the Θ-component of an optimal solution to [\(54\)](#page-23-0) can be selected to be scalar, the contrast matrix  $H$  we end up with can be selected to be the unit matrix. An unpleasant observation is that when  $s < 2$ , the quantity Opt given by  $(55)$  "heavily overestimates" the actual risk of the polyhedral estimate with  $H = I_n$ . Indeed, the analysis of this estimate in Section [3.3](#page-11-2) results in polyhedral estimate with  $H = I_n$ . Indeed, the analysis of this estimate in section 3.5 results in the risk bound (up to a logarithmic in n factor)  $\min[\sigma^{1-s/2}, \sigma\sqrt{n}]$ , what can be much less than Opt =  $2 \min[\kappa \sigma \sqrt{n}, 1]$ , e.g., in the case of large n, and  $\sigma \sqrt{n} = O(1)$ .

The good news is that whenever the approaches developed in this section and in Section [3](#page-7-0) are applicable, they can be utilized simultaneously. The underlying observation is that

(!) In the problem setting described in Section [2,](#page-4-0) a collection of K candidate polyhedral estimates can be assembled into a single polyhedral estimate with the (upper bound on the) risk, as given by Proposition [2.1,](#page-5-4) being nearly the minimum of the risks of estimates we aggregate.

Indeed, given an observation scheme (that is, collection of probability distributions  $P_x$  of noises  $\xi_x, x \in \mathcal{X}$ , assume we have at our disposal norms

$$
\pi_\delta(\cdot): \mathbf{R}^m \to \mathbf{R}
$$

parameterized by  $\delta \in (0,1)$  such that  $\pi_{\delta}(h)$ , for every h, is the larger the less is  $\delta$ , and (cf. Section [4.2\)](#page-14-1)

$$
\forall (x \in \mathcal{X}, \delta \in (0, 1), h \in \mathbf{R}^m) : \pi_{\delta}(h) \leq 1 \Rightarrow \text{Prob}_{\xi \sim P_x} \{\xi : |h^T \xi| > 1\} \leq \delta.
$$

Assume also (as indeed is the case in all our constructions) that we ensure [\(7\)](#page-5-0) by imposing on the columns  $h_\ell$  of an  $m \times N$  contrast matrix H in question the restrictions  $\pi_{\epsilon/N}(h_\ell) \leq 1$ .

Now suppose that given the risk tolerance  $\epsilon \in (0,1)$ , we have generated somehow K candidate contrast matrices  $H_k \in \mathbb{R}^{m \times N_k}$  such that

$$
\pi_{\epsilon/N_k}(\text{Col}_j[H_k]) \le 1, \, j \le N_k,
$$

so that the  $(\epsilon, \|\cdot\|)$ -risk of the polyhedral estimate yielded by the contrast matrix  $H_k$  does not exceed

$$
\mathfrak{R}_k = \max_x \left\{ \|Bx\| : x \in 2\mathcal{X}_s, \|H_k^T Ax\|_{\infty} \le 2 \right\}.
$$

Let us combine the contrast matrices  $H_1, ..., H_K$  into a single contrast matrix H with  $N =$  $N_1 + ... + N_K$  columns by normalizing the columns of the matrix  $[H_1, ..., H_K]$  to have  $\pi_{\epsilon/N}$ norms equal to 1, so that

$$
H = [\bar{H}_1, ..., \bar{H}_K], \text{Col}_j[\bar{H}_k] = \theta_{jk} \text{Col}_j[H_k] \ \forall (k \leq K, j \leq N_k)
$$

with

$$
\theta_{jk} = \frac{1}{\pi_{\epsilon/N}(\text{Col}_j[H_k])} \ge \vartheta_k := \min_{h \neq 0} \frac{\pi_{\epsilon/N_k}(h)}{\pi_{\epsilon/N}(h)},
$$

where the concluding  $\geq$  is due to  $\pi_{\epsilon/N_k}(\text{Col}_j[H_k]) \leq 1$ . We claim that in terms of  $(\epsilon, \|\cdot\|)$ -risk, the polyhedral estimate yielded by  $H$  is " almost as good" as the best of the polyhedral estimates yielded by the contrast matrices  $H_1, ..., H_K$ , specifically,

$$
\Re[H] := \max_x \left\{ \|Bx\| : x \in 2\mathcal{X}_s, \|H^T Ax\|_{\infty} \le 2 \right\} \le \min_k \vartheta_k^{-1} \Re_k.
$$
<sup>7</sup>

The justification is readily given by the following observation: when  $\vartheta \in (0,1)$ , we have

$$
\mathfrak{R}_{k,\vartheta} := \max_{x} \left\{ \|Bx\| : x \in 2\mathcal{X}_s, \|H_k^T Ax\|_{\infty} \le 2/\vartheta \right\} \le \mathfrak{R}_k/\vartheta.
$$

Indeed, when x is a feasible solution to the maximization problem specifying  $\mathfrak{R}_{k,\vartheta}$ ,  $\vartheta x$  is a feasible solution to the problem specifying  $\mathfrak{R}_k$ , implying that  $\vartheta \|Bx\| \leq \mathfrak{R}_k$ . It remains to note that we clearly have  $\Re[H] \leq \min_k \Re_{k,\vartheta_k}$ .

The bottom line is that the just described aggregation of contrast matrices  $H_1, ..., H_K$  into a single contrast matrix H results in polyhedral estimate which in terms of upper bound  $\mathfrak{R}[\cdot]$  on its  $(\epsilon, \|\cdot\|)$ -risk is, up to the factor  $\bar{\vartheta} = \max_k \vartheta_k^{-1}$  $k^{-1}$ , not worse than the best of the K estimates yielded by the original contrast matrices. Consequently, whenever  $\pi_{\delta}(\cdot)$  grows slowly as  $\delta$  decreases, the "price"  $\bar{\vartheta}$  of assembling the original estimates is quite moderate. For example, in the case of basic observation schemes (Sub-Gaussian, Discrete, and Poisson) described in Section [2.3,](#page-6-0)  $\bar{\vartheta}$  is logarithmic in  $\max_k N_k^{-1}$  $k_k^{-1}(N_1 + ... + N_K)$ , and  $\bar{\vartheta} = 1 + o(1)$  as  $\epsilon \to +0$  for  $N_1, ..., N_K$  fixed.

#### 4.7 Numerical illustration

To illustrate the performance of the polyhedral estimates we compare it numerically with a "presumably good" linear estimate. Our setup is deliberately simple: the signal set  $\mathcal X$  is just the unit box  $\{x \in \mathbb{R}^n : ||x||_{\infty} \leq 1\}, B \in \mathbb{R}^{n \times n}$  is "numerical double integration:" for a  $\delta > 0$ ,

$$
B_{ij} = \begin{cases} \delta^2(i-j+1), & j \leq i \\ 0, & j > i \end{cases}
$$

so that x, modulo boundary effects, is the second order finite difference derivative of  $w = Bx$ :

$$
x_i = \frac{w_i - 2w_{i-1} + w_{i-2}}{\delta^2}, \ 2 < i \le n,
$$

and  $Ax$  is comprised of m randomly selected entries of  $Bx$ . The observation is

$$
\omega = Ax + \xi, \, \xi \sim \mathcal{N}(0, \sigma^2 I_m).
$$

and the recovery norm is  $\|\cdot\|_2$ . In other words, we want to recover a restriction of twice differentiable function of one variable on the n-point regular grid on the segment  $\Delta = [0, n\delta]$ from noisy observations of this restriction taken along  $m$  randomly selected points of the grid. A priori information on the function is that the magnitude of its second order derivative does not exceed 1.

Note that in the considered situation both linear estimate  $\hat{w}_H$  yielded by Proposition 3.3 in [\[24\]](#page-28-9) and polyhedral estimate  $\hat{w}^H$  yielded by Proposition [4.2,](#page-17-1) are near-optimal in the minimax sense in terms of their  $\|\cdot\|_2$ -, resp.,  $(\epsilon, \|\cdot\|_2)$ -risk.

In the experiments reported in Figure [1,](#page-26-2) we used  $n = 64$ ,  $m = 32$ , and  $\delta = 4/n$  (i.e.,  $\Delta = [0, 4]$ ; the reliability parameter for the polyhedral estimate was set to  $\epsilon = 0.1$ . For different noise levels  $\sigma = \{0.1, 0.01, 0.001, 0.0001\}$  we generate at random 20 signals x from X and record the  $\|\cdot\|_2$ -recovery errors of the linear and the polyhedral estimates. In addition to testing the nearly optimal polyhedral estimate PolyI yielded by Proposition [4.2,](#page-17-1) we also record the performance of the polyhedral estimate PolyII yielded the construction from Section [3.](#page-7-0) The observed  $\|\cdot\|_2$ -recovery errors of the three estimates, sorted in the non-descending order, are plotted in Figure [1.](#page-26-2)

<span id="page-25-0"></span><sup>&</sup>lt;sup>7</sup>This is the precise "quantitative expression" of the observation (!).

In these simulations, the three estimates exhibit similar empirical performance. However, when the noise level becomes small, polyhedral estimates seem to outperform the linear one. In addition, the estimate PolyII seems to "work" better than or, at the very worst, similarly to PolyI in spite of the fact that in the situation in question the estimate PolyI, in contrast to PolyII, is provably near-optimal.

<span id="page-26-2"></span>Figure 1: Recovery errors for near-optimal linear estimate (left) and for polyhedral estimates yielded by Proposition [4.2](#page-17-1) (*PolyI*, middle) and by the construction from Section [3](#page-7-0) (*PolyII*, right), 20 simulations per each value of  $\sigma$ .

# A Appendix

#### <span id="page-29-5"></span>A.1 Executive summary on computationally tractable convex sets

Detailed description of what "computationally tractable convex set/function" is goes beyond the scope of this paper; an interested reader is referred to [\[3\]](#page-27-15). Here we restrict ourselves with "executive summary" as follows: "for all practical purposes" (including all applications considered in this paper), a computationally tractable convex set is a set  $X \subset \mathbb{R}^N$  given by semidefinite representation

$$
X = \{x \in \mathbf{R}^N : \exists u \in \mathbf{R}^M : \mathcal{A}(x, u) \succeq 0\},\
$$

where  $\mathcal{A}(\cdot)$  is a symmetric matrix affinely depending on [x; u]; sets of this type automatically are convex. In simple words: if you can feed the problem of minimizing a linear function over X to CVX  $^8$  $^8$ , your X is computationally tractable, and nearly vice versa.

#### <span id="page-29-7"></span>A.2 Calculus of compatibility

The principal rules of the calculus of compatibility are as follows (verification of the rules is straightforward and is therefore skipped):

- 1. [passing to a subset] When  $\mathcal{Y}' \subset \mathcal{Y}$  are convex compact subsets of  $\mathbb{R}^N$  and a cone Y is compatible with  $\mathcal{Y}$ , the cone is compatible with  $\mathcal{Y}'$  as well.
- 2. [finite intersection] Let cones Y<sup>j</sup> be compatible with convex compact sets  $\mathcal{Y}_j \subset \mathbb{R}^N$ ,  $j = 1, ..., J$ . Then the cone

$$
\mathbf{Y} = \mathrm{cl}\left\{ (V, \tau) \in \mathbf{S}_+^N \times \mathbf{R}_+ : \exists ((V_j, \tau_j) \in \mathbf{Y}^j, j \leq J) : V \preceq \sum_j V_j, \sum_j \tau_j \leq \tau \right\}
$$

is compatible with  $\mathcal{Y} = \bigcap \mathcal{Y}_j$ . The closure operation can be skipped when all cones  $\mathbf{Y}^j$ j are sharp, in which case  $\dot{\mathbf{Y}}$  is sharp as well.

<span id="page-29-8"></span> $8$ M. Grant and S. Boyd. The CVX Users Guide. Release 2.1, 2014. <http://web.cvxr.com/cvx/doc/CVX.pdf>

3. [convex hulls of finite union] Let cones Y<sup>j</sup> be compatible with convex compact sets  $\mathcal{Y}_j \subset$  $\mathbf{R}^{N}$ ,  $j = 1, ..., J$ , and let there exist  $(V, \tau)$  such that  $V \succ 0$  and

$$
(V,\tau)\in \mathbf{Y}:=\bigcap_j \mathbf{Y}^j.
$$

Then Y is compatible with  $\mathcal{Y} = \text{Conv} \setminus \cup$ j  $\mathcal{Y}_j$  and, in addition, is sharp provided that at least one of  $\mathbf{Y}^j$  is sharp.

<span id="page-30-1"></span>4. [direct product] Let cones  $\mathbf{Y}^j$  be compatible with convex compact sets  $\mathcal{Y}_j \subset \mathbf{R}^{N_j}$ ,  $j =$  $1, \ldots, J$ . Then the cone

$$
\mathbf{Y} = \{ (V, \tau) \in \mathbf{S}_+^{N_1 + \ldots + N_J} \times \mathbf{R}_+ : \exists (V_j, \tau_j) \in \mathbf{Y}^j : V \preceq \text{Diag}\{V_1, \ldots, V_J\} \& \tau \ge \sum_j \tau_j \}
$$

is compatible with  $\mathcal{Y} = \mathcal{Y}_1 \times ... \times \mathcal{Y}_J$ . This cone is sharp, provided that all  $\mathbf{Y}^j$  are so.

<span id="page-30-2"></span>5. [linear image] Let cone Y be compatible with convex compact set  $\mathcal{Y} \subset \mathbb{R}^N$ , let A be a  $K \times N$  matrix, and let  $\mathcal{Z} = A \mathcal{Y}$ . The cone

$$
\mathbf{Z} = \text{cl}\left\{ (V, \tau) \in \mathbf{S}_+^K \times \mathbf{R}_+ : \exists U \succeq A^T V A : (U, \tau) \in \mathbf{Y} \right\}
$$

is compatible with  $\mathcal Z$ . The closure operation can be skipped whenever Y is either sharp, or complete, completeness meaning that  $(V, \tau) \in \mathbf{Y}$  and  $0 \leq V' \leq V$  imply that  $(V', \tau) \in \mathbf{Y}$ . The cone  $\mathbf Z$  is sharp, provided  $\mathbf Y$  is so and the rank of  $A$  is  $K$ .

6. [inverse linear image] Let cone Y be compatible with convex compact set  $\mathcal{Y} \subset \mathbb{R}^N$ , let A be a  $N \times K$  matrix with trivial kernel, and let  $\mathcal{Z} = A^{-1}\mathcal{Y} := \{z \in \mathbf{R}^K : Az \in \mathcal{Y}\}\.$  The cone

$$
\mathbf{Z} = \mathrm{cl} \left\{ (V, \tau) \in \mathbf{S}_+^K \times \mathbf{R}_+ : \exists U : A^T U A \succeq V \ \& \ (U, \tau) \in \mathbf{Y} \right\}
$$

is compatible with  $\mathcal{Z}$ . The closure operations can be skipped whenever Y is sharp, in which case **Z** is sharp as well.

7. [arithmetic summation] Let cones Y<sup>j</sup> be compatible with convex compact sets  $\mathcal{Y}_j \subset \mathbb{R}^N$ ,  $j = 1, ..., J$ . Then the arithmetic sum  $\mathcal{Y} = \mathcal{Y}_1 + ... + \mathcal{Y}_J$  of the sets  $\mathcal{Y}_j$  can be equipped with compatible cone readily given by the cones  $\mathbf{Y}^j$ ; this cone is sharp, provided all  $\mathbf{Y}^j$ are so.

Indeed, the arithmetic sum of  $\mathcal{Y}_j$  is the linear image of the direct product of  $\mathcal{Y}_j$ 's under the mapping  $[y^1; ...; y^J] \mapsto y^1 + ... + y^J$ , and it remains to combine rules [4](#page-30-1) and [5;](#page-30-2) note the cone yielded by rule [4](#page-30-1) is complete, so that when applying rule [5,](#page-30-2) the closure operation can be skipped.

### A.3 Proofs

#### <span id="page-30-0"></span>A.3.1 Proofs for Section [2.3](#page-6-0)

1<sup>o</sup> Sub-Gaussian case. Note that when  $h \in \mathbb{R}^n$  is deterministic and  $\xi \sim \mathcal{SG}(0, \sigma^2 I_m)$  we have

$$
Prob\{|h^T\xi| > 1\} \le 2 \exp\left\{-\frac{1}{2\sigma^2 \|h\|_2^2}\right\}.
$$

Indeed, when  $h \neq 0$  and  $\gamma > 0$ ,

$$
\text{Prob}\{h^T\xi > 1\} \le \exp\{-\gamma\}\mathbf{E}\left\{\exp\{\gamma h^T\xi\}\right\} \le \exp\{\frac{1}{2}\sigma^2\gamma^2\|h\|_2^2 - \gamma\}.
$$

When minimizing the resulting bound in  $\gamma > 0$ , we get Prob $\{h^T \xi > 1\} \leq \exp \left\{-\frac{1}{2|h|h|}\right\}$  $\overline{2\|h\|_2^2\sigma^2}$  $\}$ ; and the same reasoning as applied to  $-h$  in the role of h results in Prob $\{h^T\xi \leq -1\}$  $\exp \left\{-\frac{1}{2\|h\|}\right\}$  $\overline{2\|h\|_2^2\sigma^2}$ }. Consequently

$$
\pi_G(h) := \underbrace{\sigma \sqrt{2\ln(2/\delta)}}_{\vartheta_G} ||h||_2 \le 1 \Rightarrow \text{Prob}\{|h^T \xi| > 1\} \le \delta,
$$

implying that for  $\mathcal{H}_{\delta}^G$  as in [\(13\)](#page-6-2) we indeed have

$$
h \in \mathcal{H}_{\delta}^G \Rightarrow \text{Prob}\{|h^T\xi| > 1\} \le \delta.
$$

**2<sup>o</sup> Discrete case.** Given  $x \in \mathcal{X}$ , setting  $\mu = Ax$  and  $\eta_k = \zeta_k - \mu$ , we get

$$
\omega = Ax + \underbrace{\frac{1}{K} \sum_{k=1}^{K} \eta_k}_{\xi_x}.
$$

Given  $h \in \mathbf{R}^m$ ,

$$
h^T \xi_x = \frac{1}{K} \sum_k \underbrace{h^T \eta_k}_{\chi_k}.
$$

Random variables  $\chi_1, ..., \chi_K$  are independent zero mean and clearly satisfy

$$
\mathbf{E}\left\{\chi_k^2\right\} \le \sum_i [Ax]_i h_i^2, \ |\chi_k| \le 2||h||_{\infty}.
$$

Applying the Bernstein inequality we get

<span id="page-31-0"></span>
$$
\text{Prob}\{|h^T\xi_x| > 1\} = \text{Prob}\left\{|\sum_{k} \chi_k| > K\right\} \le 2 \exp\left\{-\frac{K}{2\sum_{i} [Ax]_i h_i^2 + \frac{4}{3} \|h\|_{\infty}}\right\}.\tag{56}
$$

Let now

$$
\pi_D(h) = 2 \sqrt{\vartheta_D \max_{x \in \mathcal{X}} \sum_i [Ax_i]_i h_i^2 + \frac{16}{9} \vartheta_D^2 \|h\|_\infty^2} \quad \text{with} \quad \vartheta_D = \frac{\ln(2/\delta)}{K}.
$$

After a straightforward computation, we conclude from [\(56\)](#page-31-0) that

$$
\pi_D(h) \le 1 \;\; \Rightarrow \;\; \text{Prob}\{|h^T \xi_x| > 1\} \le \delta, \; \forall x \in \mathcal{X}.
$$

Thus, in the Discrete case we can set

$$
\mathcal{H}_{\delta} = \mathcal{H}_{\delta}^D := \{ h : \pi_D(h) \le 1 \}.
$$

**Poisson case.** In the Poisson case, for  $x \in \mathcal{X}$ , setting  $\mu = Ax$ , we have

$$
\omega = Ax + \xi_x, \, \xi_x = \omega - \mu.
$$

In this case, for all  $h \in \mathbb{R}^m$  one has

<span id="page-32-1"></span>
$$
\forall t \ge 0: \text{Prob}\left\{ |h^T \xi_x| \ge t \right\} \le 2 \exp\left\{-\frac{t^2}{2\left[\sum_i h_i^2 \mu_i + \|h\|_\infty t/3\right]} \right\} \tag{57}
$$

Indeed, let  $h \in \mathbb{R}^m$ , and let  $\omega$  be random vector with independent across i entries  $\omega_i \sim$ Poisson $(\mu_i)$ . We have

$$
\mathbf{E} \left\{ \exp \{ \gamma h^T \omega \} \right\} = \prod_i \mathbf{E} \left\{ \gamma h_i \omega_i \right\} = \prod_i \exp \{ \left[ \exp \{ \gamma h_i \} - 1 \right] \mu_i \}
$$

$$
= \exp \left\{ \sum_i \left[ \exp \{ \gamma h_i \} - 1 \right] \mu_i \right\}.
$$

Hence, due to the Markov inequality for  $\gamma \geq 0$  it holds

<span id="page-32-0"></span>
$$
\text{Prob}\{h^T\omega > h^T\mu + t\} = \text{Prob}\{\gamma h^T\omega > \gamma h^T\mu + \gamma t\}
$$
  

$$
\leq \mathbf{E}\left\{\exp\{\gamma h^T\omega\}\right\}\exp\{-\gamma h^T\mu - \gamma t\} \leq \exp\left\{\sum_i \left[\exp\{\gamma h_i\} - \gamma h_i - 1\right]\mu_i - \gamma t\right\}. (58)
$$

Now the standard computation (see, e.g., [\[31\]](#page-28-16)) shows that

$$
\gamma \le 3/\|h\|_{\infty} \Rightarrow |e^{\gamma h_i} - \gamma h_i - 1| \le \frac{\gamma^2 h_i^2}{2(1 - \gamma \|h\|_{\infty}/3)}
$$

which combines with [\(58\)](#page-32-0) to imply

$$
\ln\left(\text{Prob}\{h^T\omega > h^T\mu + t\}\right) \le \frac{\gamma^2 \sum_i h_i^2 \mu_i}{2(1 - \gamma \|h\|_{\infty}/3)} - \gamma t. \tag{59}
$$

For  $\gamma_* = \frac{t}{\sum_i h_i^2 \mu_i + ||h||_\infty t/3} \in [0, 3/||h||_\infty]$  we get:

$$
\text{Prob}\left\{h^T\omega > h^T\mu + t\right\} \le \exp\left\{-\frac{t^2}{2\left[\sum_i h_i^2\mu_i + \|h\|_\infty t/3\right]}\right\}.
$$

This inequality combines with the same inequality applied to  $-h$  in the role of h to imply [\(57\)](#page-32-1).

From [\(57\)](#page-32-1), we conclude via a straightforward computation that setting

$$
\pi_P(h) = \sqrt{4\vartheta_P \max_{x \in \mathcal{X}} \sum_i [Ax]_i h_i^2 + \frac{16}{9} \vartheta_P^2 \|h\|_{\infty}^2} \text{ with } \vartheta_P = \ln(2/\delta),
$$

we ensure that

$$
\pi_P(h) \le 1 \Rightarrow \text{Prob}\{|h^T \xi_x| > 1\} \le \delta, \ \forall x \in \mathcal{X}.
$$

Thus, in the Poisson case we can set

$$
\mathcal{H}_{\delta} = \mathcal{H}_{\delta}^{P} := \{ h : \pi_{P}(h) \leq 1 \}.
$$

#### <span id="page-33-0"></span>A.3.2 Proof of Proposition [3.3](#page-11-1)

Consider optimization problem specifying  $\Psi$  in [\(27\)](#page-11-3). Setting  $\theta = r/\rho \geq 1$ , let us pass in this problem from variables  $v_{\ell}$  to variables  $z_{\ell} = v_{\ell}^{\rho}$  $^{\rho}_{\ell}$ , so that

$$
\Psi^r = 2^r \max_z \left\{ \sum_\ell z_\ell^\theta (b_\ell / d_\ell)^r : \sum_\ell z_\ell \le 1, \ 0 \le z_\ell \le (d_\ell \varsigma_\ell / b_\ell)^{\rho} \right\} \le 2^r \Gamma,
$$

where

$$
\Gamma = \max_{z} \left\{ \sum_{\ell} z_{\ell}^{\theta} (b_{\ell}/d_{\ell})^{r} : \sum_{\ell} z_{\ell} \leq 1, 0 \leq z_{\ell} \leq \chi_{\ell} := (\vartheta_{G} d_{\ell}/a_{\ell})^{\rho} \right\}
$$

(we have used [\(26\)](#page-11-4)). Note that  $\Gamma$  is the optimal value in the problem of maximizing a convex (since  $\theta \geq 1$ ) function  $\sum_{\ell} z_{\ell}^{\theta} (b_{\ell}/d_{\ell})^r$  over a bounded polyhedral set, so that the maximum is achieved at an extreme point  $\bar{z}$  of the feasible set. By the standard characterization of extreme points, the (clearly nonempty) set I of positive entries in  $\bar{z}$  is as follows: denoting by I' the set of indexes  $\ell \in I$  such that  $\bar{z}_{\ell}$  is on its upper bound  $\bar{z}_{\ell} = \chi_{\ell}$ , its cardinality  $|I'|$  is at least  $|I| - 1$ . Since  $\sum_{\ell \in I'} \bar{z}_{\ell} = \sum_{\ell \in I'} \chi_{\ell} \leq 1$  and  $\chi_{\ell}$  are nondecreasing in  $\ell$  by [\(28.](#page-11-5)b), we conclude that

$$
\sum_{\ell=1}^{|I'|} \chi_{\ell} \le 1,
$$

implying that  $|I'| < n$  when  $n < n$ , so that in this case  $|I| \leq n$ ; and of course  $|I| \leq n$  when  $\mathfrak{n} = n$ . Next, we have

$$
\Gamma = \sum_{\ell \in I} \bar{z}_{\ell}^{\theta} (b_{\ell}/d_{\ell})^r \leq \sum_{\ell \in I} \chi_{\ell}^{\theta} (b_{\ell}/d_{\ell})^r = \sum_{\ell \in I} (\vartheta_G b_{\ell}/a_{\ell})^r,
$$

and since  $b_\ell/a_\ell$  is nonincreasing in  $\ell$  and  $|I| \leq \mathfrak{n}$ , the latter quantity is at most  $\sum_{\ell=1}^{\mathfrak{n}} (\vartheta_G b_\ell/a_\ell)^r$ .  $\Box$ 

#### <span id="page-33-1"></span>A.3.3 Proof of Lemma [4.1](#page-15-0)

(i): When  $\pi(\text{Col}_{\ell}[H]) \leq 1$  for all  $\ell$  and  $\lambda \geq 0$ , denoting by  $[h]^2$  the vector comprised of squares of the entries in  $h$ , we have

$$
\phi(\text{diag}(H\text{Diag}\{\lambda\}H^T)) = \phi(\sum_{\ell} \lambda_{\ell}[\text{Col}_{\ell}[H]]^2) \leq \sum_{\ell} \lambda_{\ell} \phi([\text{Col}_{\ell}[H]]^2)
$$

$$
= \sum_{\ell} \lambda_{\ell} \pi^2(\text{Col}_{\ell}[H]) \leq \sum_{\ell} \lambda_{\ell},
$$

implying that  $(H^T \text{Diag}\{\lambda\} H^T, \ \varkappa \sum_{\ell} \lambda_{\ell})$  belongs to **H**.

(ii): Let  $\Theta, \mu, Q, V$  be as stated in (ii); there is nothing to prove when  $\mu = 0$ , thus assume that  $\mu > 0$ . Let  $d = \text{diag}(\Theta)$ , so that

<span id="page-33-2"></span>
$$
d_i = \sum_j Q_{ij}^2, \text{ and } \varkappa \phi(d) \le \mu \tag{60}
$$

(the second relation is due to  $(\Theta, \mu) \in \mathbf{H}$ ). [\(38\)](#page-16-3) is evident. We have

$$
[H_X]_{ij} = \sqrt{m/\mu} [G_X]_{ij}, \quad G_X = Q \text{Diag}\{\chi\} V = \left[\sum_{k=1}^m Q_{ik} \chi_k V_{kj}\right]_{i,j}.
$$

We claim that for every  $i$  it holds

<span id="page-34-1"></span>
$$
\forall \gamma > 0: \text{Prob}\left\{ [G_{\chi}]_{ij}^2 > 3\gamma d_i/m \right\} \le \sqrt{3} \exp\{-\gamma/2\}. \tag{61}
$$

Indeed, let us fix i. There is nothing to prove when  $d_i = 0$ , since in this case  $Q_{ij} = 0$  for all j and therefore  $[G_x]_{ij} \equiv 0$ . When  $d_i > 0$ , by homogeneity in Q, it suffices to verify [\(61\)](#page-34-1) when  $d_i/m = 1/3$ . Assuming that this is the case, let  $\eta \sim \mathcal{N}(0, 1)$  be independent of  $\chi$ . We have

$$
\mathbf{E}_{\eta} \left\{ \mathbf{E}_{\chi} \{ \exp \{ \eta [G_{\chi}]_{ij} \} \} \right\} = \mathbf{E}_{\eta} \left\{ \prod_{k} \cosh(\eta Q_{ik} V_{kj}) \right\} \leq \mathbf{E}_{\eta} \left\{ \prod_{k} \exp \{ \frac{1}{2} \eta^2 Q_{ik}^2 V_{kj}^2 \} \right\} \n= \mathbf{E}_{\eta} \{ \exp \{ \frac{1}{2} \eta^2 \sum_{k} Q_{ik}^2 V_{kj}^2 \} \} \leq \mathbf{E}_{\eta} \{ \eta^2 d_i / m \} = \mathbf{E}_{\eta} \{ \exp \{ \eta^2 / 3 \} \} = \sqrt{3}.
$$

On the other hand,

$$
\mathbf{E}_{\chi}\left\{\mathbf{E}_{\eta}\left\{\exp\{\eta[G_{\chi}]_{ij}\}\right\}\right\} = \mathbf{E}_{\chi}\left\{\exp\{\frac{1}{2}[G_{\chi}]_{ij}^{2}\}\right\},\
$$

implying that

$$
\mathbf{E}_{\chi}\left\{\exp\{\frac{1}{2}[G_{\chi}]_{ij}^2\}\right\} \leq \sqrt{3}.
$$

Therefore in the case of  $d_i/m = 1/3$  for all  $s > 0$  it holds

$$
Prob{\chi : [G_{\chi}]_{ij}^{2} > s} \le \sqrt{3} \exp{\{-s/2\}},
$$

and [\(61\)](#page-34-1) follows. Recalling the relation between H and G, we get from (61) that for all  $\gamma > 0$ 

$$
Prob{\chi : [H_{\chi}]_{ij}^2 > 3\gamma d_i/\mu} \le \sqrt{3} \exp{\{-\gamma/2\}}.
$$

Therefore, with  $\varkappa$  given by [\(37\)](#page-15-1), the probability of the event

$$
\forall i,j: [H_{\chi}]_{ij}^2 \leq \varkappa \frac{d_i}{\mu}
$$

is at least 1/2. Let this event take place; in this case we have  $[\text{Col}_{\ell}[H_{\chi}]]^2 \leq \varkappa d/\mu$ , whence, by definition of the norm  $\pi(\cdot), \pi^2(\text{Col}_{\ell}[H_{\chi}]) \leq \varkappa \phi(d)/\mu \leq 1$  (see the inequality in [\(60\)](#page-33-2)). Thus, the probability of the event [\(39\)](#page-16-0) is at least  $1/2$ .

#### <span id="page-34-0"></span>A.3.4 Verification of [\(45\)](#page-19-2), [\(46\)](#page-20-2)

Let us verify that [\(45\)](#page-19-2) is a closed convex cone compatible with the spectratope  $\mathcal{X} = M\mathcal{Y}$ , with  $\mathcal Y$  given by  $(44.b)$ ; verification of the "ellitopic" version of this claim can be obtained from what follows by straightforward simplifications. The only non-evident fact in the claim is that whenever  $(V, \tau) \in \mathbf{X}$ , we have

<span id="page-34-2"></span>
$$
x^T V x \le \tau \ \forall x \in \mathcal{X}.\tag{62}
$$

To justify [\(62\)](#page-34-2), let  $(V, \tau) \in \mathbf{X}$ , so that

<span id="page-35-2"></span>
$$
M^T V M \preceq \sum_{\ell} \mathcal{R}_{\ell}^* [\Lambda_{\ell}] \text{ and } \phi_{\mathcal{R}}(\lambda[\Lambda]) \le \tau \tag{63}
$$

for properly selected  $\Lambda_\ell \in \mathbf{S}^{d_\ell}$ , and let  $x \in \mathcal{X}$ , so that  $x = My$  for some y satisfying the relations

<span id="page-35-1"></span>
$$
\sum_{i,j} y_i y_j R^{\ell i} R^{\ell j} = R^2_{\ell}[y] \preceq r_{\ell} I_{d_{\ell}}, \ \ell \leq L \tag{64}
$$

for some properly selected  $r \in \mathcal{R}$ . Taking into account that  $R^{\ell i}$  are symmetric and  $\Lambda_{\ell} \succeq 0$ , [\(64\)](#page-35-1) implies that

$$
y^T \mathcal{R}_{\ell}^* [\Lambda_{\ell}] y = \sum_{i,j} y_i y_j \text{Tr}(R^{\ell i} \Lambda_{\ell} R^{\ell j}) = \text{Tr}(R_{\ell}[y] \Lambda_{\ell} R_{\ell}[y]) = \text{Tr}(\Lambda_{\ell} R_{\ell}^2[y]) \le r_{\ell} \text{Tr}(\lambda_{\ell}),
$$

which combines with the first relation in [\(63\)](#page-35-2) to imply that

$$
x^T V x = y^T [M^T V M] y \le \sum_{\ell} y^T \mathcal{R}_{\ell}^* [\Lambda_{\ell}] y \le \sum_{\ell} r_{\ell} \text{Tr}(\lambda_{\ell}) \le \phi_{\mathcal{R}}(\lambda[\Lambda]),
$$

where the concluding inequality is due to  $r \in \mathcal{R}$ . Invoking the second relation in [\(63\)](#page-35-2) and recalling that  $x \in \mathcal{X}$  is arbitrary, we arrive at [\(62\)](#page-34-2).

#### <span id="page-35-0"></span>A.3.5 Verification of [\(52\)](#page-21-1)

Given  $s \in [2, \infty]$  and setting  $\bar{s} = s/2$ ,  $s_* = \frac{s}{s-1}$ ,  $\bar{s}_* = \frac{\bar{s}}{\bar{s}-1}$ , we want to prove that

$$
\{(V,\tau) \in \mathbf{S}_{+}^{N} \times \mathbf{R}_{+} : \exists (W \in \mathbf{S}_{+}^{N}, w \in \mathbf{R}_{+}^{N}) : V \preceq W + \text{Diag}\{w\} \& \|W\|_{s_{*}} + \|w\|_{\bar{s}_{*}} \leq \tau\}
$$
  
=  $\{(V,\tau) \in \mathbf{S}_{+}^{N} \times \mathbf{R}_{+} : \exists w \in \mathbf{R}_{+}^{N} : V \preceq \text{Diag}\{w\}, \|w\|_{\bar{s}_{*}} \leq \tau\}.$ 

To this end it suffices to check that whenever  $W \in \mathbf{S}^{N}$  there exists  $w \in \mathbf{R}^{N}$  satisfying

$$
W \preceq \text{Diag}\{w\}, \ \ \|w\|_{\bar{s}_*} \le \|W\|_{s_*}.
$$

The latter claim is nothing but the claim that whenever  $W \in \mathbf{S}^{N}$ , and  $||W||_{s_*} \leq 1$ , the conic optimization problem

<span id="page-35-3"></span>
$$
Opt = \min_{t,w} \{ t : t \ge ||w||_{\bar{s}_*}, \text{Diag}\{w\} \succeq W \}
$$
(65)

is solvable (which is evident) with optimal value  $\leq 1$ . To see that the latter indeed is the case, note that the problem clearly is strictly feasible, whence its optimal value is the same as the optimal value in the conic problem

$$
Opt = \max_{P} \{ \text{Tr}(PW) : P \succeq 0, ||\text{diag}(P)||_{\bar{s}_{*}/(\bar{s}_{*}-1)} \le 1 \}
$$
  
 
$$
[\text{diag}(P) = [P_{11}; P_{22}; ...; P_{NN}]]
$$

dual to [\(65\)](#page-35-3). Since

$$
\text{Tr}(PW) \leq \|P\|_{s_*/(s_*-1)} \|W\|_{s_*} \leq \|P\|_{s_*/(s_*-1)},
$$

when recalling what  $s_*$  and  $\bar{s}_*$  are, our task boils down to verifying that whenever a matrix  $P \succeq 0$  satisfies  $\|\text{diag}(P)\|_{s/2} \leq 1$ , one has also  $\|P\|_{s} \leq 1$ . This is immediate: since P is positive semidefinite, we have  $|P_{ij}| \leq P_{ii}^{1/2} P_{jj}^{1/2}$ , whence, assuming  $s < \infty$ ,

$$
||P||_s^s = \sum_{i,j} |P_{ij}|^s \le \sum_{i,j} P_{ii}^{s/2} P_{jj}^{s/2} = \left(\sum_i P_{ii}^{s/2}\right)^2 \le 1.
$$

When  $s = \infty$ , the same argument leads to

$$
||P||_{\infty} = \max_{i,j} |P_{ij}| = \max_{i} |P_{ii}| = ||\text{diag}(P)||_{\infty}.
$$

#### <span id="page-36-0"></span>A.3.6 Proof of Proposition [4.5](#page-23-2)

1<sup>o</sup>. Let us consider the optimization problem, as defined in [\[24,](#page-28-9) relation (26)] (where one should set  $\mathcal{Q} = \sigma^2 I_m$ ) which under the circumstances is responsible for building a nearly optimal linear estimate of  $w = Bx$ , namely,

<span id="page-36-1"></span>
$$
\begin{array}{ll}\n\text{Opt}_{*} &= \min_{\Theta, H, \Lambda, \Upsilon', \Upsilon''} \left\{ \phi_{\mathcal{T}}(\lambda[\Lambda]) + \phi_{\mathcal{R}}(\lambda[\Upsilon']) + \phi_{\mathcal{R}}(\lambda[\Upsilon'']) + \sigma^{2} \text{Tr}(\Theta) : \right. \\
\Lambda = \left\{ \Lambda_{k} \succeq 0, k \leq K \right\}, \Upsilon' = \left\{ \Upsilon'_{\ell} \succeq 0, \ell \leq L \right\}, \Upsilon'' = \left\{ \Upsilon''_{\ell} \succeq 0, \ell \leq L \right\}, \\
& \left[ \frac{\sum_{\ell} \mathcal{S}_{\ell}^{*}[\Upsilon'_{\ell}]}{\frac{1}{2}[B - H^{T}A]^{T}M} \frac{\frac{1}{2}M^{T}[B - H^{T}A]}{\sum_{k} \mathcal{R}_{k}^{*}[\Lambda_{k}]} \right] \succeq 0, \left[ \frac{\sum_{\ell} \mathcal{S}_{\ell}^{*}[\Upsilon''_{\ell}]}{\frac{1}{2}HM} \frac{\frac{1}{2}M^{T}H^{T}}{\Theta} \right] \succeq 0 \right\}\n\end{array} \tag{66}
$$

Let us show that the optimal value Opt of  $(53)$  satisfies

<span id="page-36-2"></span>
$$
Opt \le 2\kappa Opt_* = 2\sqrt{2\ln(2m/\epsilon)} Opt_*.
$$
 (67)

To this end, observe that the matrices

$$
Q:=\left[\begin{array}{c|c} U & \frac{1}{2}B \\ \hline \frac{1}{2}B^T & A^T\Theta A + \sum_k \mathcal{R}_k^* [\Lambda_k] \end{array}\right]
$$

and

$$
\left[\begin{array}{c|c} M^TUM & \frac{1}{2}M^TB \\ \hline \frac{1}{2}B^TM & A^T\Theta A + \sum_{k} \mathcal{R}_{k}^* [\Lambda_k] \end{array}\right] = \left[\begin{array}{c|c} M^T & \\ \hline & I_n \end{array}\right] Q \left[\begin{array}{c|c} M & \\ \hline & I_n \end{array}\right]
$$

simultaneously are/are not positive semidefinite due to the fact that the image space of  $M$ contains the full-dimensional set  $\mathcal{B}_*$  and thus is the entire  $\mathbb{R}^{\nu}$ , so that the image space of  $\lceil M$  $I_n$ is the entire  $\mathbf{R}^{\nu} \times \mathbf{R}^{n}$ . Therefore

$$
Opt = \min_{\Theta, U, \Lambda, \Upsilon} \left\{ 2 \left[ \phi_{\mathcal{R}}(\lambda[\Upsilon]) + \phi_{\mathcal{T}}(\lambda[\Lambda]) + \sigma^2 \kappa^2 \text{Tr}(\Theta) \right] : \right.\n\Theta \succeq 0, U \succeq 0, \Lambda = \left\{ \Lambda_k \succeq 0, k \le K \right\}, \Upsilon = \left\{ \Upsilon_\ell \succeq 0, \ell \le L \right\},\n\left[ \frac{M^T U M}{\frac{1}{2} B^T M} \left| \frac{\frac{1}{2} M^T B}{A^T \Theta A + \sum_k \mathcal{R}_k^* [\Lambda_k]} \right| \succeq 0, M^T U M \preceq \sum_{\ell} \mathcal{S}_{\ell}^* [\Upsilon_{\ell}] \right\} \tag{68}
$$

Further, note that if a collection  $\Theta, U, {\{\Lambda_k\}, {\{\Upsilon_\ell\}}\}$  is a feasible solution to the latter problem and  $\theta > 0$ , the scaled collection  $\theta \Theta$ ,  $\theta^{-1} U$ ,  $\{\theta \Lambda_k\}$ ,  $\{\theta^{-1} \Upsilon_\ell\}$  is also a feasible solution. When optimizing with respect to the scaling, we get

<span id="page-37-2"></span>
$$
\begin{split}\n\text{Opt} &= \inf_{\Theta, U, \Lambda, \Upsilon} \left\{ 4\sqrt{\phi_{\mathcal{R}}(\lambda[\Upsilon]) \left[ \phi_{\mathcal{T}}(\lambda[\Lambda] + \sigma^2 \kappa^2 \text{Tr}(\Theta) \right]} : \right. \\
&\quad \Theta \succeq 0, U \succeq 0, \Lambda = \left\{ \Lambda_k \succeq 0, k \le K \right\}, \Upsilon = \left\{ \Upsilon_\ell \succeq 0, \ell \le L \right\}, \\
&\quad \left[ \frac{M^T U M}{\frac{1}{2} B^T M} \left[ \frac{1}{A^T \Theta A + \sum_k \mathcal{R}_k^* [\Lambda_k]} \right] \succeq 0, \ M^T U M \le \sum_\ell \mathcal{S}_\ell^* [\Upsilon_\ell] \right. \right\} \\
&\le 2\kappa \text{Opt}_+, \tag{69}\n\end{split}
$$

where

<span id="page-37-1"></span>
$$
Opt_{+} = \inf_{\Theta, U, \Lambda, \Upsilon} \left\{ 2\sqrt{\phi_{\mathcal{R}}(\lambda[\Upsilon]) \left[ \phi_{\mathcal{T}}(\lambda[\Lambda]) + \sigma^2 \text{Tr}(\Theta) \right]} : \right\}
$$
\n
$$
\Theta \succeq 0, U \succeq 0, \Lambda = \left\{ \Lambda_k \succeq 0, k \le K \right\}, \Upsilon = \left\{ \Upsilon_\ell \succeq 0, \ell \le L \right\},
$$
\n
$$
\left[ \frac{M^T U M}{\frac{1}{2} B^T M} \left| \frac{\frac{1}{2} M^T B}{A^T \Theta A + \sum_k \mathcal{R}_k^* [\Lambda_k]} \right| \right\} \succeq 0, \ M^T U M \preceq \sum_\ell \mathcal{S}_\ell^* [\Upsilon_\ell] \right\} \tag{70}
$$
\nnote that  $\kappa > 1$ 

On the other hand, when strengthening the constraint  $\Lambda_k \succeq 0$  of [\(66\)](#page-36-1) to  $\Lambda_k \succ 0$ , we still have

<span id="page-37-0"></span>
$$
\text{Opt}_{*} = \inf_{\Theta, H, \Lambda, \Upsilon', \Upsilon''} \left\{ \phi_{\mathcal{T}}(\lambda[\Lambda]) + \phi_{\mathcal{R}}(\lambda[\Upsilon']) + \phi_{\mathcal{R}}(\lambda[\Upsilon'']) + \sigma^{2} \text{Tr}(\Theta) : \Delta = \{ \Lambda_{k} \succ 0, k \leq K \}, \Upsilon' = \{ \Upsilon'_{\ell} \succeq 0, \ell \leq L \}, \Upsilon'' = \{ \Upsilon''_{\ell} \succeq 0, \ell \leq L \}, \left[ \frac{\sum_{\ell} \mathcal{S}_{\ell}^{*} [\Upsilon'_{\ell}] - \frac{1}{2} M^{T} [B - H^{T} A]}{\frac{1}{2} [B - H^{T} A]^{T} M} \right] \succeq 0, \left[ \frac{\sum_{\ell} \mathcal{S}_{\ell}^{*} [\Upsilon''_{\ell}] - \frac{1}{2} M^{T} H^{T}}{\frac{1}{2} H M} \right] \succeq 0 \right\}. \tag{71}
$$

Now let  $\Theta, H, \Lambda, \Upsilon', \Upsilon''$  be a feasible solution to the latter problem. By the second semidefinite constraint in [\(71\)](#page-37-0) we have

$$
\left[\frac{\sum_{\ell} \mathcal{S}_{\ell}^* [\Upsilon_{\ell}''] \mid \frac{1}{2} M^T H^T A}{\frac{1}{2} A^T H M} \right] = \left[\begin{array}{c|c} I & X_{\ell}^* \end{array} \right]^T \left[\begin{array}{c|c} \sum_{\ell} \mathcal{S}_{\ell}^* [\Upsilon_{\ell}''] \mid \frac{1}{2} M^T H^T \end{array} \right] \left[\begin{array}{c|c} I & X_{\ell}^* \end{array} \right] \geq 0
$$

which combines with the first semidefinite constraint in  $(71)$  to imply that

$$
\left[\frac{\sum_{\ell} S_{\ell}^* [\Upsilon_{\ell}'+\Upsilon_{\ell}'']}{\frac{1}{2}B^T M} \middle| \frac{\frac{1}{2}M^T B}{A^T \Theta A + \sum_{k} \mathcal{R}_k^* [\Lambda_k]} \right] \succeq 0.
$$

Next, by the Schur Complement Lemma (which is applicable due to

$$
A^T \Theta A + \sum_k \mathcal{R}_k^* [\Lambda_k] \succeq \sum_k \mathcal{R}_k^* [\Lambda_k] \succ 0,
$$

where the concluding  $\succ$  is due to [\[24,](#page-28-9) Lemma 5.1] combined with  $\Lambda_k \succ 0$ ), this relation implies that for

$$
\Upsilon_\ell=\Upsilon'_\ell+\Upsilon''_\ell,
$$

we have

$$
\sum_{\ell} \mathcal{S}_{\ell}^*[\Upsilon_{\ell}] \succeq M^T \underbrace{\left[ \frac{1}{4} B[A^T \Theta A + \sum_{k} \mathcal{R}_{k}^* [\Lambda_k]]^{-1} B^T \right]}_{U} M.
$$

Using the Schur Complement Lemma again, for the just defined  $U \succeq 0$  we obtain

$$
\left[\begin{array}{c|c}\nM^TUM & \frac{1}{2}M^TB \\
\hline\n\frac{1}{2}B^TM & A^T\Theta A + \sum_k \mathcal{R}_k^* [\Lambda_k]\n\end{array}\right] \succeq 0,
$$

and in addition, by the definition of  $U$ ,

$$
M^TUM \preceq \sum_{\ell} \mathcal{S}_{\ell}^*[\Upsilon_{\ell}].
$$

We conclude that

$$
(\Theta, U, \Lambda, \Upsilon := \{\Upsilon_\ell = \Upsilon'_\ell + \Upsilon''_\ell, \ell \leq L\})
$$

is a feasible solution to optimization problem [\(70\)](#page-37-1) specifying  $Opt_+$ . The value of the objective of the latter problem at this feasible solution is

$$
2\sqrt{\phi_{\mathcal{R}}(\lambda[\Upsilon'] + \lambda[\Upsilon''])[\phi_{\mathcal{T}}(\lambda[\Lambda]) + \sigma^2 \text{Tr}(\Theta)]} \leq \phi_{\mathcal{R}}(\lambda[\Upsilon'] + \lambda[\Upsilon'']) + \phi_{\mathcal{T}}(\lambda[\Lambda]) + \sigma^2 \text{Tr}(\Theta) \leq \phi_{\mathcal{R}}(\lambda[\Upsilon']) + \phi_{\mathcal{R}}(\lambda[\Upsilon'']) + \phi_{\mathcal{T}}(\lambda[\Lambda]) + \sigma^2 \text{Tr}(\Theta),
$$

the concluding quantity in the chain being the value of the objective of problem [\(71\)](#page-37-0) at the feasible solution  $\Theta, H, \Lambda, \Upsilon', \Upsilon''$  to this problem. Since the resulting inequality holds true for every feasible solution to [\(71\)](#page-37-0), we conclude that  $Opt_+ \leq Opt_*$ , and we arrive at [\(67\)](#page-36-2) due to [\(69\)](#page-37-2).

 $2^o$ . Now, from Proposition 3.3 in the latest arXiv version of [\[24,](#page-28-9) Section 5.7], we conclude that Opt<sub>∗</sub> is within a logarithmic factor of the minimax optimal  $(\frac{1}{8}, \| \cdot \|)$ -risk corresponding to the case of Gaussian noise  $\xi_x \sim \mathcal{N}(0, \sigma^2 I_m)$  for all x:

$$
Opt_* \leq \theta_*RiskOpt_{1/8},
$$

where

$$
\theta_* = 8\sqrt{(2\ln F + 10\ln 2)(2\ln D + 10\ln 2)},
$$
  $F = \sum_{\ell} f_{\ell}, D = \sum_{k} d_k.$ 

Since the minimax optimal  $(\epsilon, \|\cdot\|)$ -risk clearly only grows when  $\epsilon$  decreases, we conclude that for  $\epsilon \leq 1/8$  a feasible near optimal solution to [\(53\)](#page-22-0) is minimax optimal within the factor  $2\theta^* \kappa$ .  $\Box$
