What is Nonreciprocity? – Part II

Christophe Caloz, Fellow, IEEE, Andrea Alù, Fellow, IEEE, Sergei Tretyakov, Fellow, IEEE, Dimitrios Sounas, Senior Member, IEEE, Karim Achouri, Student Member, IEEE, and Zoé-Lise Deck-Léger

Abstract—This paper is the second part of a two-part paper on Electromagnetic (EM) Nonreciprocity (NR). Part I has defined NR, pointed out that linear NR is a stronger form of NR than nonlinear (NL) NR, explained EM Time-Reversal (TR) Symmetry (TRS) Breaking (TRS-B), described linear Time-Invariant (TI) NR media, generalized the Lorentz reciprocity theorem for NR, and provided a physical interpretation of the resulting Onsager-Casimir relations [1]. This part first explains the TR specificity of lossy and open systems. Next, it proposes an extended version of the S-parameters for all NR systems. Then, it presents the fundamentals of linear-TI (LTI) NR, linear Time-Variant (LTV) Space-Time (ST) modulated NR and NL NR systems. Finally, it addresses confusions between with systems.

Index Terms—Nonreciprocity (NR), Time Reversal Symmetry Breaking (TRS-B), loss irreversibility, Onsager-Casimir relations, extended scattering parameters, Linear Time-Invariant (LTI) and Linear Time-Variant (LTV) systems, Space-Time (ST) varying systems, nonlinear (NL) systems, metamaterials, asymmetry.

I. INTRODUCTION

Part I [1] has introduced the overall paper and covered the topics enumerated in the abstract. This second part, after subdividing the linear category of NR systems (Tab. [1].I) into Linear Time-Invariant (LTI) and Linear Time-Variant (LTV)¹ systems, expands the concepts of Part I to lossy and open systems, extends the scattering parameter concept from LTI systems to LTV Space-Time (ST) and NL systems, presents the fundamental NR characteristics and devices for these three types of systems, and finally warns against fallacious similarities between NR and other forms of asymmetric transmission.

FUNDAMENTAL CONCEPT APPLICABILITY TO DIFFERENT NR SYSTEMS.

Table I, with generic susceptibility $\overline{\chi}$ ($\overline{\chi}^T$: opposite dir.), presents *Time Reversal Symmetry Breaking* (*TRS-B*) and *Onsager-Casimir relations* as a common descriptor for all **NR systems**, points out that the Lorentz theorem is applicable only to LTI systems, and indicates that the extended Sparameter apply to the three systems with growing restriction.

II. RECIPROCITY DESPITE TRS-B IN LOSSY SYSTEMS

Figure 1 monitors the process of EM wave propagation in a *lossy bias-less waveguide system*. Let us see how such a system responds to TR (Secs. [1].III to [1].IV) by applying the **TRS-B test** in Sec. [1].V, as for the Faraday system in Figs. [1].2(b),(c).

Fig. 1. TRS-B in a lossy reciprocal waveguide of length ℓ (Sec. [1].V). Assuming that the process under consideration is the propagation of a modulated pulse, we have $\Psi'(-t) = [\psi'_{P_1}(-t), \psi'_{P_2}(-t)]^T \neq [\psi_{P_1}(t), \psi_{P_2}(t)]^T = \Psi(-t)$, and in particular $\Psi'(0) = [P_0/4, 0]^T \neq [P_0, 0]^T = \Psi(0)$.

In the direct part of the process, the wave is attenuated by dissipation as it propagates from port P₁ to port P₂ (red curve), say from P_0 to $P_0/2$ (3 dB loss). Upon TR, the propagation direction is reversed, *and* loss is transformed into gain (Tab. [1].II). As a result, the wave propagates back from P₂ to P₁ *and* its power level is restored (green curve), from $P_0/2$ to P_0 . However, the system has been altered. Maintaining lossy leads to further attenuation on the return trip, from $P_0/2$ to $P_0/4$ (6 dB loss), and hence **breaks TRS**. According to Sec. [1].V, this would imply NR, which is at odds with the generalized reciprocity theorem (Sec. [1].IX)!

This paradox originates in the looseness² of the assumption that "**TRS/A is equivalent to reciprocity/NR**" in Sec. [1].III. This assumption is, as pointed out in Fn. [1].8, stricto senso incorrect, as the equivalence **only holds in terms of absolute field levels** but not field ratios! In the case of loss, as just seen, the field ratios are equal $[(P_0/4)/(P_0/2) = 0.5 = (P_0/2)/P_0]$, consistently with the general definition of reciprocity in Sec. [1].II, but the field levels are not $(P_0/4 \neq P_0)$, in contradiction with the definition of TR in Sec. [1].III. In this sense, *a simple lossy system is perfectly reciprocal despite breaking TRS*. This TRA may be seen as an expression of *thermodynamical macroscopic irreversibility*³.

²This looseness has been tolerated because it is the *ratio* definition of Sec. [1].II, and not its restricted *level* form, that is commonly used in practice.

³Consider for instance an empty metallic waveguide. The transfer of charges from the waveguide lossy walls results in EM energy being transformed into heat (Joule first law) [3]. In theory, a *Maxwell demon* [4] could reverse the velocities of all the molecules of the system, which would surely reconvert that heat into EM energy. In this sense, *all systems are microscopically reversible*, which is the fundamental assumption underpinning Onsager reciprocity relations [5]–[8] (Fn. [1].6). However, such reconversion is prohibited by the second law of thermodynamics, which stipulates that *the total entropy in an isolated system cannot decrease over time*. It would at the least require injecting energy from the outside of the system! So, such a lossy system is *macroscopically – and hence practically! – irreversible*. Loss cannot be undone; it ever accumulates over time, as in Fig. 1.

Alù is with the CUNY Advanced Science Research Center, NY 10031, USA. D. Sounas and A. Alù are with the University of Texas at Austin, Austin, TX 78712, USA. S. Tretyakov is with Aalto University, Aalto, FI-00076, Finland. K. Achouri is with EPFL, Lausanne, CH-1015, Switzerland.

¹Consider the isotropic dielectric medium system: $\mathbf{D} = \epsilon \mathbf{E}$. The system is clearly *NL* if $\epsilon = \epsilon(\mathbf{E})$, since it excludes superposition because $\epsilon = \epsilon(\mathbf{E}_1 + \mathbf{E}_2)$ [2]. However, we call here *linear*-TV a system with $\epsilon = \epsilon(t) \neq \epsilon(\mathbf{E})$ insofar such a system *supports superposition*, although it is often called NL due to the generation of new frequencies.

III. OPEN SYSTEMS AND THEIR TR-"LOSSY" BEHAVIOR

ing the original [Fig. 2(a)], TR [Fig. 2(b)] and recipi [Fig. 2(c)] problems. The nature of the system is clearly altered upon TR, where the intrinsic impedance of the surrounding medium becomes negative (Tab. [1].II). This results from the fact that the radiated and scattered energy escaping the antennas in the original problem is equivalent to loss relatively to the two-port system. Such loss transforms into gain upon TR, as in Sec. II, leading to fields emerging from infinity. Upon replacing TR by restricted-TR so as to avoid denaturing the system, one would find, as in the lossy case, reduced field levels but conserved field ratios⁴. An open

Fig. 2. TRA and apparent (restricted) nonreciprocity of an open system composed of a dipole antenna and a patch antenna in free space.

IV. EXTENDED SCATTERING PARAMETER MODELING

The lossy/open system paradox (Secs. II/III) and the common definition in Sec. [1].II, suggest describing LTI (non)reciprocal systems in terms of *field ratios*. This leads to the scattering parameters or S-parameters, introduced in quantum physics in 1937 [9], used for over 70 years in microwave engineering [10]–[12], extended to power parameters for arbitrary loads in the 1960ies [12], [13], and to the crosscoupled matrix theory for topologically-coupled resonators in the 2000s [14], [15]. We shall attempt here an *extension* of these parameters to LTV and NL systems.

Figure 3 defines an *extended arbitrary P*-port network as an electromagnetic structure delimited by a surface S with Nwaveguide terminals, T_n , supporting each a number of modefrequency⁵ ports, $P_p = P_{\mu,\omega}^n$ with p = 1, 2, ..., P (e.g. if T_1 is a waveguide with the $M_1 = 2$ modes TE₁₀ and TM₁₁ and the $\Omega_1 = 2$ frequencies ω and 2ω , it includes the $M_1\Omega_1 = 4$ ports

⁴However, the restricted-TR problem is still *distinct* from the reciprocity problem [Fig. 2(c)] insofar as it does not reset the field level.

⁵"Frequency" here refers to the new frequency set (possibly infinite or continuous) in LTV and NL systems, practically restricted to discrete spectra.

II. OPEN SYSTEMS AND THEIR TR-"LOSSY" BEHAVIOR $P_1 = P_{TE_{10},\omega}^1$, $P_2 = P_{TE_{10},2\omega}^1$, $P_3 = P_{TM_{11},\omega}^1$ and $P_4 = P_{TM_{11},2\omega}^1$.) Consider the two-antenna open system in Fig. 2 show-g the original [Fig. 2(a)], TR [Fig. 2(b)] and reciprocal *domain form* [11], extended here to LTV and NL systems,

$$\begin{cases} \mathbf{E}_{t,p}(x,y,z) \\ \tilde{\mathbf{H}}_{t,p}(x,y,z) \end{cases} = \left(a_p e^{-j\beta_p z} \pm b_p e^{+j\beta_n z} \right) \begin{cases} \tilde{\mathbf{e}}_{t,p}(x,y) \\ \tilde{\mathbf{h}}_{t,p}(x,y) \end{cases},$$
(1)

where $\oiint_{S}(\tilde{\mathbf{e}}_{t,p} \times \tilde{\mathbf{h}}_{t,q}) \cdot \hat{\mathbf{n}} ds = 2\delta_{pq}^{6}$, and where a_{p}/b_{p} (p = $1, \ldots, P$) are the port input/output complex wave amplitudes, related by the *extended S-matrix*, S, as

Fig. 3. Arbitrary P-port network and extended scattering matrix, S.

If the system is *linear*, each entry of the matrix can be expressed by the simple transfer function $S_{ij} = b_i/a_j|_{a_k=0, k\neq j}$, which corresponds to the **conventional definition** of the Sparameters, except for the frequency port definition extension in the ST (LTV) case. If the system is NL, then S_{ii} = $S_{ij}(a_1, a_2, \ldots, a_P)$, and therefore *all* the (significant) input signals must be simultaneously present in the measurement of the transfer function S_{ij} , as done in Broadband Poly-Harmonic Distortion (PHD), used in the Keysight microwave Nonlinear Vector Network Analyzer (NVNA) [16]–[18]⁷.

In a *LTI medium*, the bianisotropic reciprocity relations [19], [20] excited by the two states \mathbf{a}' and \mathbf{a}'' with responses \mathbf{b}' and \mathbf{b}'' read now (sources are outside of the system.) [21]

$$\nabla \cdot \left(\tilde{\mathbf{E}}' \times \tilde{\mathbf{H}}'' - \tilde{\mathbf{E}}'' \times \tilde{\mathbf{H}}'\right) = j\omega \left[\tilde{\mathbf{E}}'' \cdot \left(\tilde{\bar{\bar{\epsilon}}} - \tilde{\bar{\bar{\epsilon}}}^T\right) \cdot \tilde{\mathbf{E}}' - \tilde{\mathbf{H}}'' \cdot \left(\tilde{\bar{\bar{\mu}}} - \tilde{\bar{\bar{\mu}}}^T\right) \cdot \tilde{\mathbf{H}}' + \tilde{\mathbf{E}}'' \cdot \left(\tilde{\bar{\bar{\xi}}} + \tilde{\bar{\bar{\zeta}}}^T\right) \cdot \tilde{\mathbf{H}}' - \tilde{\mathbf{H}}'' \cdot \left(\tilde{\bar{\bar{\zeta}}} + \tilde{\bar{\bar{\xi}}}^T\right) \cdot \tilde{\mathbf{E}}'\right] = 0.$$
(3)

Inserting the sum $(\sum_{p=1}^{P})$ of fields (1) into this equation, taking the volume integral of the resulting relation, applying the Gauss theorem and the orthogonality relation, and using the Onsager-Casimir relations [Eqs. [1].(11)], yields [21]

$$\sum_{p} \left(b'_{p} a''_{p} - a'_{p} b''_{p} \right) = \mathbf{b} \mathbf{a}''^{T} - \mathbf{a} \mathbf{b}''^{T} = \mathbf{a}' \mathbf{a}''^{T} \left(\mathbf{S}^{T} - \mathbf{S} \right), \quad (4)$$

where (2) has been used to eliminate $\mathbf{b}^{(\prime,\prime\prime)}$ in the last equality. This leads to the reciprocity condition $\mathbf{S} = \mathbf{S}^T$, and hence to the convenient scattering-parameter NR condition

$$\mathbf{S} \neq \mathbf{S}^T \text{ or } \exists (i,j) \mid S_{ij} \neq S_{ji}, i = 1, 2, \dots, N,$$
 (5)

(e.g. $S_{21} \neq S_{12}$) which also applies to LTV and NL systems, although the current demonstration is restricted to LTI media.

In the microwave regime, these S-parameters can be directly measured (magnitude and phase) with a VNA [12] or with an NVNA. In contrast, in the optical regime no specific instrumentation is available for that and a special setup, with nontrivial phase handling, is therefore required [22].

⁶This relation also applies when p and q differ only by frequency (same terminal/mode) assuming narrow-band, and hence independent, port detectors. ⁷E.g. $S_{21}^{\text{junction}} = b_2/a_1|_{a_2=a_3=0} \neq S_{21}(a_3); \ S_{21}^{\text{mixer}} = S_{21}^{\text{mixer}}(a_3, \text{LO}).$

V. ENERGY CONSERVATION - THERMODYNAMIC PARADOX In a lossless system, energy conservation requires that the total output power equals the total input power, or $\sum_{p=1}^{P} |b_p|^2 = \sum_{p=1}^{P} |a_p|^2$ in Fig. 3, since no power is dissipated in the system. In terms of **S-matrix**, this requirement translates into the **unitary** relation $SS^{\dagger} = I$ (I: unit matrix). Many fundamental useful facts on multi-port systems straightforwardly follow from energy conservation (e.g. [12]).

Some immediate consequences for NR are: 1) A lossless **1-port system** can be only totally reflective, from $|S_{11}|^2 = 1$, even it includes NR materials, contrary to claims in [23]. 2) A 2-port system can be magnitude-wise NR only if it is lossy; specifically, a purely reflective 2-port isolator $\mathbf{S} = [0, 0; 1, 1]$ whereas the device would exhibit $b_2^2 = a_1^2 + a_2^2 + 2a_1a_2$, with the additional term $2a_1a_2$ that may bring the total energy to be larger than the input power, depending on the relative phases of a_1 and a_2 . 3) A lossless **2-port system** can still be NR in phase, since $\mathbf{SS}^{\dagger} = I$ does not demand $\angle S_{21} = \angle S_{12}$ [24]. 4) A lossless 3-port system can be matched simultaneously at all port only if it is NR, according to the system $SS^{\dagger} = I$ [12].

The case 2) has raised much perplexity in the past⁸, and led to the so-called "thermodynamic paradox", according to which such a system would ever increase the temperature of the load at the passing end at the detriment of the load at the isolated end, hence violating the second law of thermodynamics, which prescribes heat transfer from hot to cold bodies. The paradox resurfaced in 1955, as Lax and Button pointed out the existence of lossless unidirectional eigenmodes in some ferrite-loaded waveguide structures [28], but it was resolved by Ishimaru, who showed that such a waveguide would necessarily support loss in its terminations, even in the limit of negligible material loss [29], [30].

VI. LINEAR-TI (LTI) NR SYSTEMS

LTI NR systems have the following characteristics: 1) TRS-B by TR-odd external bias F_0 , which is often a magnetic **field,** \mathbf{B}_0 [Fig. [1].2(c)]; 2) applicability, by linearity, to arbitrary excitations and intensities - strong NR (Tab. [1].I); 3) frequency conservation, and hence unrestricted frequencydomain description (Secs. [1].VII and [1].VIII), applicability of the Lorentz reciprocity theorem (Sec. [1].IX) and of Sparameters (Sec. IV); 4) generally based on LTI materials [31]-[39], including 2DEGs and graphene [40]-[46], or metamaterials [47]-[57] (Sec. [1].VII).

The main LTI NR systems are isolators, NR phase shifters and circulators [12], [31], [34]. *Isolators* ($\mathbf{S} = [0, 0; 1, 0]$)⁹ are typically used to shield equipment (e.g. VNA or laser) from detuning, interfering and even destructive reflections. *NR* phase shifters (S = $[0, e^{j\Delta\varphi}; 1, 0]$)¹⁰, such as gyrators $(\Delta \varphi = \pi)$ [58], combine with couplers to form isolators or circulators, provide compact simulated inductors and filter inverters, and enable NR pattern and scanning arrays. Circulators

⁹They may be of resonance, field-displacement or matched-port-circulator type, and may involve resistive sheets, quarter-wave plates or polarizing grids.

¹⁰They may be of *latching (hard magnetic hysteresis)* or Faraday rotation (Sec. [1].VI) type, and may involve quarter-wave plates.

 $(\mathbf{S} = [0, 0, 1; 1, 0, 0; 0, 1, 0])^{11}$ are used for isolation, duplexing (radar and communication), and reflection amplifiers.

VII. LINEAR-TV (LTV) SPACE-TIME (ST) NR SYSTEMS LTV ST^{12} NR systems have the following characteristics: 1) TRS-B by TR-odd external bias (\mathbf{F}_0) velocity, \mathbf{v}_0 ; 2) strong NR, as in Sec. VI; 3) generation of new, possibly anharmonic, frequencies, and hence restricted applicability of S-parameters (Fn. 5); 4) moving medium (moving matter, e.g. opto-mechanical) [19], [59]-[62] or modulated medium (moving perturbation, e.g. electro/acousto/NL-optic)¹³ [66], [67]; 5) pulse/periodic and abrupt/smooth mat./pert. motion.

As an illustration, Fig. 4 graphically depicts, using an is impossible, since energy conservation requires $b_2^{2PS} f_{f_{es}} + r_{es}^{2PS} |acontonded$ Minkowski diagram [65], a step ST-modulated (STM) system with interface between media of refractive indices n_1 and n_2 ($n_2 > n_1$) moving in the -z-direction with the constant velocity $\mathbf{v}_0 = v \hat{\mathbf{z}}$ (v < 0) and excited by an incident (i) wave propagating in the +z-direction. Upon full-TR, \mathbf{v}_0 is reversed, which leads to identical *Doppler shifts* [63] in the reflected (r) and transmitted (t) waves¹⁴, as in Fig. 4(a), but alters the system. The unaltered system is TRA, and hence breaks TRS, which leads to the NR scattering in Fig. $4(b)^{15}$.

A great diversity of useful STM NR systems have been reported in recent years [71]-[89]. They are all based on

¹¹They may be of 4-port Faraday rotation or 3-port junction rotation type.

¹²As will be seen, NR requires also spatial inversion symmetry breaking.

¹³Moving and modulated media both produce Doppler shifts [63] and NR. In contrast, only the former supports Fizeau drag [61], [64] and bianisotropy transformation [19], and only the latter allows superluminality [65].

¹⁴Transitions follow frequency conservation lines in the moving frame [65]. ¹⁵Purely temporal modulation (horizontal interface) [68]–[70] would clearly be insufficient for NR; spatial inversion symmetry breaking, provided here by the moving modulation, is also required to break TRS: $\overline{\overline{\chi}}(\mathbf{v}_0) \neq \overline{\overline{\chi}}^T(\mathbf{v}_0)$.

⁸This started in 1885 with the comment by Rayleigh that the system composed of two Nicols sandwiching a magnetized dielectric would be 'inconsistent with the second law of thermodynamics" [25], to be overruled by Rayleigh himself 16 years later [26], in reaction to studies of Wiener [27].

the production of *different traveling phase gradient in different directions* and are, in that sense, more or less lumped/distributed [12] variations of parametric systems developed by microwave engineers in the 1950ies¹⁶ [90]–[96].

Figure 4 shows a *NR metasurface reflector* application [85], [97] based on the ST modulation $n(x) = n_0 + n_m \cos(\beta_m x + \omega_m t)$, where $(\omega_m/\beta_m)\hat{z} = v_0$. The STM metasurface breaks reciprocity and hence provides a quite unique NR device by adding the spatial and temporal momenta \mathbf{K}_{MS} and ω_{MS} to those of the incident wave¹⁷.

VIII. NONLINEAR (NL) NR SYSTEMS

NL NR systems have the following characteristics: 1) TRS-B by *spatial asymmetry* and NL *self-biasing* (NL triggering by wave) [98], [99]; 2) limitation to restricted excitations, intensities and isolation – *weak NR* (Tab. [1].I); 3) generation of new, only harmonic, frequencies, and inapplicability g replacements superposition, and hence *very restricted* applicability of S-

parameters (Fns. 5 and 7); 4) diversity of TRS-B approaches.

Fig. 6. Principle of nonlinear nonreciprocity with the asymmetric cascade of a linear medium, $\epsilon_{\rm L} = \epsilon_1$, and a nonlinear lossy medium, $\epsilon_{\rm NL} = \epsilon_2 + [\epsilon_1'(E) - j\epsilon''(E)]$, with high mismatch, $|\Gamma| = |(\sqrt{\epsilon_{\rm NL}} - \sqrt{\epsilon_{\rm L}})/(\sqrt{\epsilon_{\rm NL}} + \sqrt{\epsilon_{\rm L}})/(\frac{\epsilon_{\rm NL}}{\epsilon_{\rm L}})|$

Figure 6 shows a simple way to achieve NL NR by pairing a linear medium and a NL lossy medium. The two media are strongly *mismatched*, with reflection Γ . A wave injected at port P₁ experiences a transmittance of $|T|^2 = 1 - |\Gamma|^2 \ll 1$, yielding a much smaller field level in the NL medium. If this level is insufficient to trigger NL loss, all the power transmitted through the interface $(|T|^2)$ reaches port P₂, so that $|S_{21}| =$ |T| and $|S_{11}| = |\Gamma|$. The same wave injected at P₂, assuming sufficient intensity to trigger NL loss, undergoes exponential attenuation $e^{-\alpha \ell_{\rm NL}}$ ($\ell_{\rm NL}$: NL length), so that $|S_{12}| = |T| e^{-\alpha \ell_{\rm NL}} \approx$ 0. The system is thus NR, but it is a *pseudo-isolator*¹⁸: 1) it is restricted to a small range of intensities; 2) it works only for one excitation direction $(P_1 \rightarrow P_2 \text{ or } P_2 \rightarrow P_1)$ at **a time**, since the $P_2 \rightarrow P_1$ wave would trigger NL loss and hence also extinct the $P_1 \rightarrow P_2$ wave¹⁹; 3) it often suffers from poor isolation $(|S_{21}|/|S_{12}| = e^{\alpha \ell_{\rm NL}})$ and poor isolation to

¹⁸The device is also *not a diode* [100], whose NR consists in different forward/backward spectra due to positive/negative wave cycle clipping.

¹⁹This precludes most of the applications of real isolators (Sec. VI) [101].

insertion loss ratio $((|S_{21}|/|S_{12}/|)/|S_{11}| = e^{\alpha \ell_{\rm NL}}/|\Gamma|)^{20}$; 4) it is reciprocal to noise [101].

Ingenious variations of the NL NR device in Fig. 6 have been reported [102]–[113]. Some of them mitigate some of the aforementioned issues, but these improvements are severely restricted by fundamental limitations of NL NR [22], [101].

IX. DISTINCTION WITH ASYMMETRIC PROPAGATION

A NR system is a system that exhibits TRA field ratios between well-defined ports [Eq. (5)], which is possible only under external biasing (linear NR) or self-biasing plus spatial asymmetry (NL NR). Any system not satisfying this condition is necessarily reciprocal, despite possible fallacious asymmetries in transmission [22], [101], [114]–[120]. For instance, the system in Fig. 7 exhibits asymmetric ray propagation, but it is fully reciprocal since only the horizontal ray gets transmitted between the array ports, the P_1 \rightarrow P_2 oblique rays symmetrically canceling out on the right array due to opposite phase gradients. Other deceptively NR cases include: asymmetric field rotation-filtering (e.g. $\pi/2$ rotator + polarizer), where $S_{21}^{yx} \neq S_{21}^{xy}$, but $S_{21}^{yx} = S_{12}^{xy}$; asymmetric waveguide junction (e.g. step width variation), with full transmission to larger side distributed over multi-modes and small transmission from the same mode to the smaller (single-mode) side, but reciprocal mode-to-mode transmission (e.g. $S_{51} = S_{15}$, 1: small side single-mode port, 2: large side mode/port 5) [22]; asymmetric mode conversion (e.g. waveguide with nonuniform load), where even mode transmits in opposite directions with and without excitation of odd mode, without breaking reciprocity, since $S_{21}^{ee} = S_{12}^{ee}$ and $S_{21}^{\text{oe}} = 0 = S_{12}^{\text{eo}}$ [117]. In all cases, reciprocity is verified upon exchanging the source and detector.

 P_1 (a) P_2 P_1 (b) P_2 Fig. 7. Asymmetric *reciprocal* system formed by a lens and a mirror sandwiched between two antenna arrays under (a) left and (b) right excitations.

X. CONCLUSION

This paper has presented, in the context of novel magnetless NR systems aiming at repelling the frontiers of NR technology, a global perspective of NR, with the following conclusions: 1) NR systems may be classified into linear (TI and TV-ST) and NL systems, based on TRS-B by external biasing and selfbiasing plus spatial asymmetry, respectively; 2) NL NR is a weaker form of NR than linear NR, as it suffers from restricted intensities, one-way-at-a-time excitations, and poor isolation and high insertion loss; 3) lossy and open systems, although reciprocal in terms of field ratios, are TRS-A, due macroscopic irreversibility; 4) S-parameters are advantageously generalized to all types of NR systems, with some restrictions; 5) Care must be exercised to avoid confusing asymmetric transmission with NR in some fallacious systems. Nonreciprocity is a rich and fascinating concept, that has already and will continue to open new scientific and technological horizons.

 $^{20} \rm These$ two parameters are typically smaller than 20dB/25dB in NR NL structures, whereas they commonly exceed 45dB/50dB in NR LTI isolators.

¹⁶The main difference is that the STM or *parametric* systems of that time were developed mostly for amplifiers or mixers, rather than NR devices.

¹⁷This system actually includes infinitely many ports, $S_{n,n+1} = 0$ and $S_{n+1,n}$ with $\omega_{n+1} > \omega_n$ $(n = 1, ..., \infty)$, but its *functional* reduction in the figure is meaningful the power transfer beyond P₃ is of no interest.
