(Received xx; revised xx; accepted xx)

In this two-part study, we present the development and analysis of a stochastic theory for characterizing the relative positions of monodisperse, low-inertia particle pairs that are settling rapidly in homogeneous isotropic turbulence. In the limits of small Stokes number and Froude number such that $F r \ll S t_{\eta} \ll 1$, closures are developed for the drift and diffusion fluxes in the probability density function (PDF) equation for the pair relative positions. The theory focuses on the relative motion of particle pairs in the dissipation regime of turbulence, i.e., for pair separations smaller than the Kolmogorov length scale. In this regime, the theory approximates the fluid velocity field in a reference frame following the primary particle as locally linear.

In this Part I paper, we present the derivation of closure approximations for the drift and diffusion fluxes in the PDF equation for the relative positions $\boldsymbol{r}$. The drift flux contains the time integral of the third and fourth moments of the "seen" fluid velocity gradients along the trajectories of primary particles. These moments may be analytically resolved by making approximations regarding the "seen" velocity gradient. Accordingly, two closure forms are derived specifically for the drift flux. The first invokes the assumption that the fluid velocity gradient along particle trajectories has a Gaussian distribution. In the second drift closure, we instead assume that the "seen" strain-rate and rotation-rate tensors scaled by the turbulent dissipation rate and enstrophy, respectively, are normally distributed. A key feature of the second closure is that it accounts for the two-time autocorrelations and cross-correlations of dissipation rate and enstrophy. These correlations quantify, as well as illustrate the mechanisms driving particle clustering. Analytical solution to the $\operatorname{PDF}\langle P\rangle(r, \theta)$ is then derived, where the $\theta$ is spherical polar angle. It is seen that the PDF has a power-law dependence on separation $r$ of the form $\langle P\rangle(r, \theta) \sim r^{\beta}$, with $\beta \sim S t_{\eta}^{2}$ and $\beta<0$, analogous to that for the radial distribution function of non-settling pairs. An explicit expression is derived for $\beta$ in terms of the drift and diffusion closures. The $\langle P\rangle(r, \theta)$ solution also shows that for a given $r$, the clustering of $S t_{\eta} \ll 1$ particles is only weakly anisotropic, which is in conformity with prior observations from direct numerical simulations of isotropic turbulence containing settling particles.

## 1. Introduction

This paper presents a stochastic theory for inertial particle clustering that incorporates the effects of settling on the sampling of turbulence. The theory focuses on the relative motion of low-Stokes-number pairs for sub-Kolmogorov separations. The study is principally motivated by the desire to understand the microphysical processes influencing the relative motion of water droplets in cumulus clouds.

The growth of droplets in a cloud from a radius of $10-20 \mu \mathrm{~m}$ to raindrop size ( $>100 \mu \mathrm{~m}$ radius) is a central problem in cloud physics. Cloud microphysical models describe droplet growth through two main mechanisms: (1) condensation, and (2) droplet collision and coalescence. For radii $<20 \mu \mathrm{~m}$, droplet growth is principally driven by condensation (Bartlett 1966). For larger radii, collision and coalescence play an increasingly important role, eventually becoming the dominant mechanism for radii $>40 \mu \mathrm{~m}$. Interestingly, in the $15-40 \mu \mathrm{~m}$ radius range, droplet Stokes numbers $S t_{\eta}$ are in the 0.1-1 range. The relative motion of such droplet pairs is strongly susceptible to the effects of air turbulence. For instance, it is now well established that for $S t_{\eta}<1$, particles exhibit strong spatial clustering arising from the complex interactions between turbulent eddies and particle inertia (Chun et al. 2005; Bragg \& Collins 2014a, b). Turbulence-induced clustering of droplets may lead to increased collision rates, potenially playing a key role in droplet growth. In addition to turbulence, differential gravitational settling among droplets is an important driver of collisions, particularly for pairs of larger drops whose size ratio departs substantially from one. Differential settling also reduces the clustering of particles with different radii so that the most pronounced inertial clustering occurs in drops of nearly equal size (Ayala et al. 2008b; Parishani et al. 2015).

In cumulus and stratocumulus clouds, the Kolmogorov-scale fluid acceleration $\left(a_{\eta}\right)$ is small relative to gravitational acceleration $(g)$ so that the Froude number $F r=a_{\eta} / g \sim$ 0.009-0.06 (Ayala et al. 2008a; Fouxon et al. 2015). Therefore, the present study focuses on the relative motion of monodisperse, low-inertia particle pairs that are undergoing rapid settling in isotropic turbulence. While Fr characterizes fluid accelerations, the settling velocity parameter $S v_{\eta}$ is used to quantify particle settling, where $S v_{\eta}$ is defined as the ratio of particle terminal velocity to the Kolmogorov velocity scale. Therefore, by rapid settling, we mean $S v_{\eta} \gg 1$. Recognizing that $S v_{\eta}=S t_{\eta} / F r$, the current stochastic theory is derived in the regime characterized by $F r \ll S t_{\eta} \ll 1$. Here Stokes number $S t_{\eta}$ is the ratio of the particle viscous relaxation time $\tau_{v}$ and the Kolmogorov time scale $\tau_{\eta}$. In these parametric limits, the transport equation for the probability density function (PDF) of pair separations $(\boldsymbol{r})$ is of the drift-diffusion form. In this Part I paper, we derive closure approximations for the drift and diffusion fluxes. The PDF equation is also solved analytically, giving rise to a PDF with a power-law dependence on pair separation $r$ with a negative exponent. An explicit expression is obtained for the exponent in terms of the drift and diffusion fluxes.

Turbulence-driven inhomogeneities in the spatial distribution of inertial particles are believed to play an important role in locally enhancing particle collision rates. Preferential concentration is one of the mechanisms of particle clustering, wherein inertial particles denser than the fluid are ejected out of vorticity-dominated regions, and accumulate in strain-dominated regions. Numerous computational, experimental and theoretical studies of aerosol dynamics in isotropic turbulence have established that inertial particles preferentially concentrate in regions of excess strain-rate over rotation-rate (Maxev 1987; Squires \& Eaton 1991; Eaton \& Fessler 1994; Druzhinin 1995; Druzhinin \& Elghobashi 1999; Rani \& Balachandar 2003; Ferry et al. 2003; Rani \& Balachandar 2004; Chun et al. 2005; Ray \& Collins 2011).

Since the characteristic length scales of strain rate and rotation rate in isotropic turbulence scale with the Kolmogorov length scale $(\eta)$, it may be expected that preferential concentration enhances the probability of finding a pair of particles at separations comparable to $\eta$. However, Reade \& Collins (2000) showed through direct numerical simulations (DNS) of particle-laden isotropic turbulence that inertial particles continued to exhibit clustering at separations much smaller than $\eta$. In fact, they found that for separations $r \ll \eta$, the radial distribution function (RDF), an important measure of clustering, followed a power law given by

$$
\begin{equation*}
g(r)=c_{0}\left(\frac{\eta}{r}\right)^{c_{1}} \tag{1.1}
\end{equation*}
$$

where $g(r)$ is the RDF. The existence of power law for $r / \eta \approx 10^{-3}$ in the DNS of Reade \& Collins (2000) suggests that the mechanism of preferential concentration alone is insufficient to explain clustering at such small separations.

Chun et al. (2005) investigated the continued clustering of monodisperse particles at sub-Kolmogorov separations, wherein we developed a theory for the RDF of low $S t_{\eta}$, nonsettling $(\mathrm{Fr} \rightarrow \infty)$ particle pairs. Motivated by the observation that much of the growth of the RDF occurs for separations $r<\eta$, Chun et al. (2005) focused on the dynamics of pair separations in the disspation regime of turbulence. Analytical closures were derived for the drift and diffusion fluxes in the PDF equation of pair relative positions. The balance of these two fluxes determines the steady state value of the RDF at a given separation. Of particular interest in that theory is the closure form for the drift flux $q_{i}^{d}(r)$ of monodisperse pairs, given by

$$
\begin{equation*}
q_{i}^{d}(r)=-\frac{S t_{\eta}^{2}}{3} r_{i}\langle P\rangle(\boldsymbol{r}) \int_{-\infty}^{t}\left\langle\left[S^{2}(t)-R^{2}(t)\right]\left[S^{2}\left(t^{\prime}\right)-R^{2}\left(t^{\prime}\right)\right]\right\rangle d t^{\prime} \tag{1.2}
\end{equation*}
$$

where $S^{2}=S_{i j} S_{i j}$ and $R^{2}=R_{i j} R_{i j}$ are the second invariants of the strain-rate and rotation-rate tensors, respectively, along particle paths.

It is evident from (1.2) that the net drift flux will be negative or radially inward provided the primary particles sample more strain than rotation along their trajectories, a mechanism referred to as preferential concentration. One can also deduce from (1.2) a second mechanism of clustering that is particularly relevant for sub-Kolmogorov scale separations. We can see from (1.2) that the drift flux will continue to be negative even for $r<\eta$ provided we have a positive two-time correlation of $\left[S^{2}(t)-R^{2}(t)\right]$ along the trajectory of the primary particle. Thus, the sub-Kolmogorov scale clustering is driven by a path-history effect in that the pair separation at time $t$ continues to be influenced by the preferential sampling of strain-rate over rotation-rate by the primary particle at earlier times (and at larger separations, on average). It is this path history effect that is responsible for the power-law behavior of the RDF at $r \ll \eta$. To the authors' knowledge, the Chun et al. (2005) study is the first to provide an explicit relation for this effect through the integral in (1.2).

Chun et al. (2005) also derived the drift-diffusion equation of the radial distribution function (RDF) for bidisperse, non-settling pairs. Bidispersity, or more generally polydispersity, of the particle population is a key factor in determining clustering, and thereby the rate of particle collisions. Bidispersity is also important when considering the effects of gravitational settling, since differential sedimentation is thought to be a key contributing factor to enhanced collision frequency. In the current study, we consider a monodisperse population of settling particles. However, our theory accounts for the effects of gravity through the modified sampling of turbulence by the settling particles. Although cloud droplets would be polydisperse, it is noteworthy that: (a) condensation tends to narrow
the size distribution; (b) turbulence-induced coalescence is most important for nearly equal-sized drops for which differential sedimentation is weak, and (c) clustering is strongest for nearly equal-sized drops. In the rapid settling limit, particles experience an essentially frozen turbulence, so that the flow time scales along particle trajectories may be approximated as the Eulerian correlation length scales divided by the particle terminal velocity.

A detailed review of stochastic theories for the relative motion of inertial particle pairs is provided in Rani et al. (2014) and Dhariwal et al. (2017). An important study is that of Zaichik \& Alipchenkov (2003), who developed a stochastic theory for describing the relative velocities and positions of monodisperse particle pairs. Their theory was conceived to be applicable for all Stokes numbers and for pair separations spanning all three regimes of turbulence, i.e., the integral, inertial and dissipation scale ranges. Zaichik \& Alipchenkov derived a closure for the phase space diffusion current by using the Furutsu-Novikov-Donsker (FND) formula. The FND formula relates the diffusion current to a series expansion in the cumulants of the fluid relative velocities seen by the pairs $(\Delta \boldsymbol{u})$ multiplied by the functional derivatives of the PDF with respect to $\Delta \boldsymbol{u}$ (Bragg \& Collins 2014a). Zaichik \& Alipchenkov (2003) then computed the statistics of pair separation and relative velocity by solving the equations for the zeroeth, first and second relative-velocity moments of the master PDF equation.
Bragg \& Collins (2014a) performed a rigorous, quantitative comparison of the Chun et al. (2005) and Zaichik \& Alipchenkov (2007) stochastic models for inertial pair dynamics in isotropic turbulence. The focus of the Bragg \& Collins study was to compare and analyze the predictions of particle clustering at sub-Kolmogorov scale separations by the two theories. The Zaichik \& Alipchenkov (2007) study improved upon their earlier study (Zaichik \& Alipchenkov 2003) by accounting for the unequal Lagrangian correlation timescales of the strain-rate and rotation-rate tensors. Bragg \& Collins showed that the power-law exponents in the RDFs predicted by the two theories were in good agreement for $S t_{\eta} \ll 1$ at $r \ll \eta$. Through a detailed theoretical analysis, they proved that this agreement was a consequence of the Chun et al. drift velocity being the same as the leading order term in the Zaichik \& Alipchenkov (2007) drift velocity. As is to be expected, for $S t_{\eta} \sim 1$, the theories diverge.
In a recent analytical study, Fouxon et al. (2015) considered the clustering behavior of fast-sedimenting particles in isotropic turbulence. For a broad range of Stokes numbers $\left(S t_{\eta} \gtrsim 1, S t_{\eta} \ll 1\right)$ and small Froude numbers ( $F r \ll 1$ ), they derived the power-law exponents characterizing the dependence of pair clustering on separation $r$. The exponent that is applicable in the same parametric regime as in our study is (Fouxon et al. 2015)

$$
\begin{equation*}
D_{K Y}=\frac{4 \tau_{\eta}^{2} \int_{0}^{\infty} \kappa^{3} E_{p}(\kappa) d \kappa}{\int_{0}^{\infty} \kappa E(\kappa) d \kappa} \propto S t_{\eta}^{2} \tag{1.3}
\end{equation*}
$$

where $D_{K Y}$ is the Lyapunov power-law exponent (known as the Kaplan-Yorke codimension), $E(\kappa)$ is the energy spectrum of isotropic turbulence, and $E_{p}(\kappa)$ is the spectrum of pressure fluctuations. It may be noted that $D_{K Y}$ scales as $S t_{\eta}^{2}$, and is independent of $F r$. The exponent $\beta$ derived in the current study also shows the same dependence on $S t_{\eta}$. In our study, the first drift closure results in a $\beta$ that is independent of Fr . However, the second drift closure can include the effects of Fr through the two-time correlations of dissipation rate and enstrophy along particle trajectories. Fouxon et al. (2015) did not quantify $D_{K Y}$, as the spectrum $E_{p}(\kappa)$ is not known. In our study, however, $\beta_{2}$ is both quantified and compared with DNS data.

In this Part I paper, we present the derivation of closures for the drift and diffusion
fluxes in the probability density function (PDF) equation for pair separations $r$ of rapidly setting, low-inertia, monodisperse particle pairs in isotropic turbulence. This study extends the Chun et al. (2005) work by including the effects of particle settling in high gravity conditions. Motivated by the Chun et al. (2005) study, we approximate the fluid velocity field following the primary particle as locally linear. An additional assumption regarding the fluid velocity gradient "seen" by the primary particle is also necessitated to resolve the third and fourth moments of the velocity gradient that appear in the drift flux. Two types of assumption regarding the velocity gradient lead to two separate closures for the drift flux, while the diffusion flux has only one closure. The first closure of the drift flux entails assuming the "seen" fluid velocity gradient to be Gaussian, while in the second, the scaled strain-rate and rotation-rate tensors "seen" by the primary particle are assumed to be normally distributed. In addition to the closures, an analytical solution is also derived for the $\operatorname{PDF}\langle P\rangle(r, \theta)$, allowing us to quantify both the $r$-dependence and the anisotropy of clustering due to gravity.

The organization of the paper is as follows. Section 2 presents the stochastic theory, including the derivation of the drift and diffusion flux closures. In section 3, analytical solution to the $\operatorname{PDF}\langle P\rangle(r, \theta)$ is derived, with a power law dependence on $r$. The results obtained from the first drift closure (in conjunction with the diffusion closure) are presented in section 4 These results are based on using the analytical form of the energy spectrum that is valid in the high Reynolds-number limit. The advantages of using this spectrum are that it obviates the need for DNS inputs, and importantly allows us to quantify the drift and diffusion fluxes in a universal manner (i.e., independent of $R e_{\lambda}$ ). Section 5ummarizes the key findings of the Part I paper.

## 2. Stochastic Theory

In this section, we derive closure approximations for the drift and diffusion fluxes in the PDF equation for the relative positions $\boldsymbol{r}$ of monodisperse, low-inertia particle pairs that are settling rapidly in stationary isotropic turbulence. The theory is applicable in the $F r \ll S t_{\eta} \ll 1$ regime, and for pair separations in the dissipation regime of turbulence, i.e., $r<\eta$, where $\eta$ is the Kolmogorov length scale. This restriction, however, allows us to approximate the fluid velocity field as being locally linear. The effects of hydrodynamic and interparticle interactions on pair probability are neglected.

We begin with the drift-diffusion equation derived by Chun et al. (2005) for the PDF $\langle P\rangle(\boldsymbol{r} ; t)$ :

$$
\begin{equation*}
\frac{\partial\langle P\rangle}{\partial t}+\frac{\partial}{\partial r_{i}}\left(q_{i}^{d}+q_{i}^{D}\right)=0 \tag{2.1}
\end{equation*}
$$

where the drift flux

$$
\begin{equation*}
q_{i}^{d}(\boldsymbol{r}, t)=-\int_{-\infty}^{t}\left\langle W_{i}(\boldsymbol{r}, \boldsymbol{x} ; t) \frac{\partial W_{l}}{\partial r_{l}}\left[\boldsymbol{r}\left(t^{\prime}\right), \boldsymbol{x}\left(t^{\prime}\right) ; t^{\prime}\right]\right\rangle\langle P\rangle\left(\boldsymbol{r}^{\prime} ; t^{\prime}\right) d t^{\prime} \tag{2.2}
\end{equation*}
$$

and the diffusive flux

$$
\begin{equation*}
q_{i}^{D}(\boldsymbol{r}, t)=-\int_{-\infty}^{t}\left\langle W_{i}(\boldsymbol{r}, \boldsymbol{x} ; t) W_{j}\left[\boldsymbol{r}\left(t^{\prime}\right), \boldsymbol{x}\left(t^{\prime}\right) ; t^{\prime}\right]\right\rangle \frac{\partial\langle P\rangle}{\partial r_{j}^{\prime}}\left(\boldsymbol{r}^{\prime} ; t^{\prime}\right) d t^{\prime} \tag{2.3}
\end{equation*}
$$

In (2.2) and (2.3), $\boldsymbol{r}^{\prime}=\boldsymbol{r}\left(t^{\prime}\right)$ is the pair separation at time $t^{\prime}$, and $\boldsymbol{x}=\boldsymbol{x}(t)$ is the primary particle position at time $t$. As the drift and diffusion fluxes at $\boldsymbol{r}$ depend on the pair probability and its derivative, respectively, at earlier pair separations $\boldsymbol{r}^{\prime}$, equation (2.1) is non-local and accounts for the path history effects.

The governing equations for the relative position (separation vector) $r_{i}$ and relative velocity $W_{i}$ of a settling, like-particle pair are:

$$
\begin{gather*}
\frac{d r_{i}}{d t}=W_{i}  \tag{2.4}\\
\frac{d W_{i}}{d t}=-\frac{1}{\tau_{v}}\left[W_{i}(t)-\Delta u_{i}(\boldsymbol{r}(t), \boldsymbol{x}(t) ; t)\right]  \tag{2.5}\\
\approx-\frac{1}{\tau_{v}}\left[W_{i}(t)-\Gamma_{i k}(\boldsymbol{x}(t) ; t) r_{k}\right] \tag{2.6}
\end{gather*}
$$

where $\boldsymbol{x}(t)$ is the location of the primary particle, and $\Delta u_{i}(\boldsymbol{r}(t), \boldsymbol{x}(t) ; t)$ is the difference in the fluid velocities seen by the secondary and primary particles of a pair. Using the approximation of a locally linear flow field, we write $\Delta u_{i} \approx \Gamma_{i k} r_{k}$, where $\Gamma_{i k}=\partial u_{i} / \partial x_{k}$ is the fluid velocity gradient at the location of the primary particle, $\boldsymbol{x}(t)$. In the case of monodisperse particle pairs, gravity influences pair relative motion only through the modified sampling of fluid velocity gradient by the primary particle.

We now discuss the modeling of the drift and diffusion fluxes. Two separate closures will be considered for the drift flux, whereas a single closure is obtained for the diffusion flux. The two drift closures, DF1 and DF2, differ in the nature of the approximation made to analytically resolve the moments of the fluid velocity gradient tensor. It will be seen that DF2 has the advantage of capturing key mechanisms of particle clustering.

### 2.1. Drift Flux Closure 1 (DF1)

Based on Chun et al. (2005), we express the pair relative velocity $W_{i}$ as a perturbation expansion with the Stokes number $S t_{\eta}$ as the small parameter, as follows.

$$
\begin{equation*}
W_{i}=W_{i}^{[0]}+S t_{\eta} W_{i}^{[1]}+\ldots \tag{2.7}
\end{equation*}
$$

Substituting this expansion into (2.5) and equating terms of equal order in $S t_{\eta}$ yields

$$
\begin{align*}
& W_{i}^{[0]}=\Gamma_{i k} r_{k}  \tag{2.8}\\
& W_{i}^{[1]}=-\frac{1}{\Gamma_{\eta}}\left[\frac{d \Gamma_{i k}}{d t}+\Gamma_{i j} \Gamma_{j k}\right] r_{k} \tag{2.9}
\end{align*}
$$

where $\Gamma_{\eta}=1 / \tau_{\eta}$ is the inverse of the Kolmogorov time scale $\tau_{\eta}$. We have also used $d r_{k} / d t \approx W_{k}^{[0]}$ in deriving the expression for $W_{i}^{[1]}$. Thus, we can write

$$
\begin{gather*}
W_{i}(\boldsymbol{r}(t), \boldsymbol{x}(t) ; t)=\Gamma_{i k}(\boldsymbol{x}(t) ; t) r_{k}-\frac{S t_{\eta}}{\Gamma_{\eta}}\left[\frac{d \Gamma_{i k}}{d t}+\Gamma_{i j}(\boldsymbol{x}(t), t) \Gamma_{j k}(\boldsymbol{x}(t) ; t)\right] r_{k}  \tag{2.10}\\
\frac{\partial W_{l}}{\partial r_{l}}\left(\boldsymbol{r}\left(t^{\prime}\right), \boldsymbol{x}\left(t^{\prime}\right) ; t^{\prime}\right)=\Gamma_{l l}-\frac{S t_{\eta}}{\Gamma_{\eta}}\left[\frac{d \Gamma_{l l}}{d t}+\Gamma_{l m} \Gamma_{m l}\right]=-\frac{S t_{\eta}}{\Gamma_{\eta}} \Gamma_{l m}\left(\boldsymbol{x}\left(t^{\prime}\right) ; t^{\prime}\right) \Gamma_{m l}\left(\boldsymbol{x}\left(t^{\prime}\right) ; t^{\prime}\right) \tag{2.11}
\end{gather*}
$$

where $\Gamma_{l l}=0$ due to continuity.
Since the Stokes numbers of interest are small ( $S t_{\eta} \ll 1$ ), the fluid velocity gradients seen by the primary particle will be replaced by those of a collocated fluid particle. With this approximation, we substitute (2.10) and (2.11) into the drift flux given by (2.2),
yielding

$$
\begin{array}{r}
q_{i}^{d}(\boldsymbol{r}, t)=-\langle P\rangle(\boldsymbol{r} ; t) r_{k} \int_{-\infty}^{t}\left\{-\frac{S t_{\eta}}{\Gamma_{\eta}}\left\langle\Gamma_{i k}(t) \Gamma_{l m}\left(t^{\prime}\right) \Gamma_{m l}\left(t^{\prime}\right)\right\rangle+\right. \\
\left.\frac{S t_{\eta}^{2}}{\Gamma_{\eta}^{2}}\left[\left\langle\frac{d \Gamma_{i k}}{d t}(t) \Gamma_{l m}\left(t^{\prime}\right) \Gamma_{m l}\left(t^{\prime}\right)\right\rangle+\left\langle\Gamma_{i j}(t) \Gamma_{j k}(t) \Gamma_{l m}\left(t^{\prime}\right) \Gamma_{m l}\left(t^{\prime}\right)\right\rangle\right]\right\} d t^{\prime} \tag{2.12}
\end{array}
$$

where $\Gamma_{i j}(t)$ and $\Gamma_{i j}\left(t^{\prime}\right)$ are the fluid velocity gradients at $t$ and $t^{\prime}$ seen by a fluid particle at the same location as the inertial particle. In (2.12), $r_{k}$ and $\langle P\rangle(\boldsymbol{r} ; t)$ have been brought out of the integral. This is reasonable given the parametric limits under consideration, and can be explained as follows. In the rapid settling limit, the correlation times of $\Gamma_{i j}$ along particle trajectories scale as $\eta / g \tau_{v}$, whereas pair separation evolves over $\tau_{v} \gg \eta / g \tau_{v}$. Thus, the pair separation remains essentially unchanged during the time the velocity gradient remains correlated. This allows us to pull $r_{k}$ out of the ensemble averaging $\langle\cdots\rangle$, as well as the time integral. Further, we are able to write $\langle P\rangle\left(\boldsymbol{r}^{\prime} ; t^{\prime}\right) \approx\langle P\rangle(\boldsymbol{r} ; t)$, and then bring the PDF out of the time integral. In Section (4.3), we will explicitly quantify the times over which the $\mathrm{PDF}\langle P\rangle$ evolves, and show that this is $\gg \eta / g \tau_{v}$, implying that the PDF is relatively unchanged during the $\Gamma_{i j}$ correlation times.

The drift flux in (2.12) contains the time integral of the third and fourth moments of fluid velocity gradient tensor along fluid particle trajectories. To analytically resolve these moments, we apply the approximation that the velocity gradient tensor $\boldsymbol{\Gamma}$ is Gaussian. The resulting closure is referred to as DF1. Consequently, the two triple moment terms on the RHS of (2.37) would drop out. Further, the fourth moment term may be written in terms of second moments as follows:

$$
\begin{align*}
\left\langle\Gamma_{i j}(t) \Gamma_{j k}(t) \Gamma_{l m}\left(t^{\prime}\right) \Gamma_{m l}\left(t^{\prime}\right)\right\rangle & =\left\langle\Gamma_{i j}(t) \Gamma_{j k}(t)\right\rangle\left\langle\Gamma_{l m}\left(t^{\prime}\right) \Gamma_{m l}\left(t^{\prime}\right)\right\rangle \\
& +2\left\langle\Gamma_{i j}(t) \Gamma_{l m}\left(t^{\prime}\right)\right\rangle\left\langle\Gamma_{j k}(t) \Gamma_{m l}\left(t^{\prime}\right)\right\rangle \tag{2.13}
\end{align*}
$$

The first term on the RHS of (2.13) can be resolved by writing $\Gamma_{l m}=S_{l m}+R_{l m}$, where $S_{l m}$ and $R_{l m}$ are the fluid strain-rate and rotation-rate tensors. Thus, we have

$$
\begin{equation*}
\left\langle\Gamma_{i j}(t) \Gamma_{j k}(t)\right\rangle\left\langle\Gamma_{l m}\left(t^{\prime}\right) \Gamma_{m l}\left(t^{\prime}\right)\right\rangle=\left\langle\Gamma_{i j}(t) \Gamma_{j k}(t)\right\rangle\left\langle S^{2}\left(t^{\prime}\right)-R^{2}\left(t^{\prime}\right)\right\rangle=0 \tag{2.14}
\end{equation*}
$$

since $\left\langle S^{2}-R^{2}\right\rangle=0$ for fluid particles, where $S^{2}=S_{l m} S_{l m}$ and $R^{2}=R_{l m} R_{l m}$.
Let us now consider the second term on the RHS of (2.13):

$$
\begin{equation*}
2 \underbrace{\left\langle\Gamma_{i j}(t) \Gamma_{l m}\left(t^{\prime}\right)\right\rangle}_{\text {(I) }} \underbrace{\left\langle\Gamma_{j k}(t) \Gamma_{m l}\left(t^{\prime}\right)\right\rangle}_{\text {II }} \tag{2.15}
\end{equation*}
$$

We will analyze the correlations (I) and (II) separately. In the rapid settling limit, particles fall through Kolmogorov-scale eddies in the time $\eta /\left(g \tau_{v}\right) \ll \tau_{\eta}$. This enables us to express the two-time correlation of fluid velocity gradients as a two-point correlation with a spatial separation of $\boldsymbol{x}_{g}=\boldsymbol{g} \tau_{v}\left(t^{\prime}-t\right)$. Therefore,

$$
\begin{align*}
(\mathrm{I})=\left\langle\Gamma_{i j}(\boldsymbol{x}(t), t) \Gamma_{l m}\left(\boldsymbol{x}\left(t^{\prime}\right), t^{\prime}\right)\right\rangle & =\left\langle\Gamma_{i j}(\boldsymbol{x}(t), t) \Gamma_{l m}\left(\boldsymbol{x}(t)+\boldsymbol{x}_{g}, t\right)\right\rangle \\
& =\left\langle\frac{\partial u_{i}}{\partial x_{j}}(\boldsymbol{x}, t) \frac{\partial u_{l}}{\partial x_{m}}\left(\boldsymbol{x}+\boldsymbol{x}_{g}, t\right)\right\rangle . \tag{2.16}
\end{align*}
$$

Expressing fluid velocities $u_{i}$ and $u_{l}$ in terms of Fourier coefficients in the wavenumber
space yields

$$
\begin{array}{r}
\frac{\partial u_{i}}{\partial x_{j}}(\boldsymbol{x})=\int \mathrm{i} \kappa_{j} \widehat{u}_{k}(\boldsymbol{\kappa}) e^{\mathrm{i} \boldsymbol{\kappa} \cdot \boldsymbol{x}} d \boldsymbol{\kappa} \\
\frac{\partial u_{l}}{\partial x_{m}}\left(\boldsymbol{x}+\boldsymbol{x}_{g}\right)=\int \mathrm{i} \kappa_{m}^{\prime} \widehat{u}_{l}\left(\boldsymbol{\kappa}^{\prime}\right) e^{\mathrm{i} \boldsymbol{\kappa}^{\prime} \cdot\left(\boldsymbol{x}+\boldsymbol{x}_{g}\right)} d \boldsymbol{\kappa}^{\prime} \tag{2.18}
\end{array}
$$

where $\mathrm{i}=\sqrt{-1}$.
Using the spatial homogeneity of fluid particle statistics, we can further average the correlation in (I) over $\boldsymbol{x}$-space giving (Pope 2000)

$$
\begin{align*}
(\mathrm{I})=\left\langle\left\langle\frac{\partial u_{i}}{\partial x_{j}}(\boldsymbol{x}) \frac{\partial u_{l}}{\partial x_{m}}\left(\boldsymbol{x}+\boldsymbol{x}_{g}\right)\right\rangle_{\mathcal{L}}\right\rangle & =-\iint d \boldsymbol{\kappa} d \boldsymbol{\kappa}^{\prime} \kappa_{j} \kappa_{m}^{\prime}\left\langle\widehat{u}_{i}(\boldsymbol{\kappa}) \widehat{u}_{l}\left(\boldsymbol{\kappa}^{\prime}\right)\right\rangle\left\langle e^{\mathrm{i} \cdot \boldsymbol{\kappa} \cdot \boldsymbol{x}} e^{\mathrm{i} \boldsymbol{\kappa}^{\prime} \cdot\left(\boldsymbol{x}+\boldsymbol{x}_{g}\right)}\right\rangle_{\mathcal{L}} \\
& =-\iint d \boldsymbol{\kappa} d \boldsymbol{\kappa}^{\prime} \kappa_{j} \kappa_{m}^{\prime}\left\langle\widehat{u}_{i}(\boldsymbol{\kappa}) \widehat{u}_{l}\left(\boldsymbol{\kappa}^{\prime}\right)\right\rangle \delta\left(\boldsymbol{\kappa}+\boldsymbol{\kappa}^{\prime}\right) e^{\mathrm{i} \boldsymbol{\kappa}^{\prime} \cdot \boldsymbol{x}_{g}} \\
& =\int d \boldsymbol{\kappa} \kappa_{j} \kappa_{m}\left\langle\widehat{u}_{i}(\boldsymbol{\kappa}) \widehat{u}_{l}^{*}(\boldsymbol{\kappa})\right\rangle e^{-\mathrm{i} \boldsymbol{\kappa} \cdot \boldsymbol{x}_{g}} \\
& =\int d \boldsymbol{\kappa} \kappa_{j} \kappa_{m} \Phi_{i l}(\boldsymbol{\kappa}) e^{-\mathrm{i} \boldsymbol{\kappa} \cdot \boldsymbol{x}_{g}} \tag{2.19}
\end{align*}
$$

where $\langle\ldots\rangle_{\mathcal{L}}$ denotes averaging over $\boldsymbol{x}, \delta(\cdots)$ denotes the Diract delta function, $\boldsymbol{\kappa}$ and $\boldsymbol{\kappa}^{\prime}$ are both wavenumber vectors, $\widehat{u}_{i}(\boldsymbol{\kappa})$ is a Fourier component of the fluid velocity corresponding to the wavenumber $\boldsymbol{\kappa}$, and $\widehat{u}_{l}^{*}$ is the complex conjugate of $\widehat{u}_{l}$. The velocity spectrum tensor $\Phi_{i l}(\boldsymbol{\kappa})$ can be written in terms of energy spectrum $E(\kappa)$ (Pope 2000)

$$
\begin{equation*}
\Phi_{i l}(\boldsymbol{\kappa})=\frac{E(\kappa)}{4 \pi \kappa^{2}}\left(\delta_{i l}-\frac{\kappa_{i} \kappa_{l}}{\kappa^{2}}\right) \tag{2.20}
\end{equation*}
$$

Similarly,

$$
\begin{align*}
\text { (II) }=\left\langle\Gamma_{j k}(\boldsymbol{x}(t), t) \Gamma_{m l}\left(\boldsymbol{x}(t)+\boldsymbol{x}_{g}, t\right)\right\rangle & =\left\langle\frac{\partial u_{j}}{\partial x_{k}}(\boldsymbol{x}) \frac{\partial u_{m}}{\partial x_{l}}\left(\boldsymbol{x}+\boldsymbol{x}_{g}\right)\right\rangle \\
& =\int d \boldsymbol{\kappa}^{\prime} \kappa_{k}^{\prime} \kappa_{l}^{\prime} \Phi_{j m}\left(\boldsymbol{\kappa}^{\prime}\right) e^{-\mathrm{i} \boldsymbol{\kappa}^{\prime} \cdot \boldsymbol{x}_{g}} \tag{2.21}
\end{align*}
$$

The time integral of the product of (I) and (II) is

$$
\begin{array}{r}
\int_{-\infty}^{0} d t\left\langle\Gamma_{i j}(\boldsymbol{x}(0), 0) \Gamma_{l m}\left(\boldsymbol{x}(0)+\boldsymbol{x}_{g}, 0\right)\right\rangle\left\langle\Gamma_{j k}(\boldsymbol{x}(0), 0) \Gamma_{m l}\left(\boldsymbol{x}(0)+\boldsymbol{x}_{g}, 0\right)\right\rangle \\
=\iint d \boldsymbol{\kappa} d \boldsymbol{\kappa}^{\prime} \kappa_{j} \kappa_{m} \Phi_{i l}(\boldsymbol{\kappa}) \kappa_{k}^{\prime} \kappa_{l}^{\prime} \Phi_{j m}\left(\boldsymbol{\kappa}^{\prime}\right) \int_{-\infty}^{0} d t e^{-\mathrm{i}\left(\boldsymbol{\kappa}+\boldsymbol{\kappa}^{\prime}\right) \cdot \boldsymbol{g} \tau_{v} t} \\
=\iint d \boldsymbol{\kappa} d \boldsymbol{\kappa}^{\prime} \kappa_{j} \kappa_{m} \Phi_{i l}(\boldsymbol{\kappa}) \kappa_{k}^{\prime} \kappa_{l}^{\prime} \Phi_{j m}\left(\boldsymbol{\kappa}^{\prime}\right)\left\{\frac{1}{2} \delta\left[-\frac{\left(\boldsymbol{\kappa}+\boldsymbol{\kappa}^{\prime}\right) \cdot \boldsymbol{g} \tau_{v}}{2 \pi}\right]-\frac{1}{\mathrm{i}\left(\boldsymbol{\kappa}+\boldsymbol{\kappa}^{\prime}\right) \cdot \boldsymbol{g} \tau_{v}}\right\} \tag{2.22}
\end{array}
$$

where we have used the Fourier transform identity for the time integral $\int_{-\infty}^{0} d t e^{-\mathrm{i}\left(\boldsymbol{\kappa}+\boldsymbol{\kappa}^{\prime}\right) \cdot \boldsymbol{g} \tau_{v} t}$. Let us consider the two terms in the above integral separately. The first term given by the integral

$$
\begin{equation*}
\frac{1}{2} \iint d \boldsymbol{\kappa} d \boldsymbol{\kappa}^{\prime} \kappa_{j} \kappa_{m} \Phi_{i l}(\boldsymbol{\kappa}) \kappa_{k}^{\prime} \kappa_{l}^{\prime} \Phi_{j m}\left(\boldsymbol{\kappa}^{\prime}\right) \delta\left[-\frac{\left(\boldsymbol{\kappa}+\boldsymbol{\kappa}^{\prime}\right) \cdot \boldsymbol{g} \tau_{v}}{2 \pi}\right] \tag{2.23}
\end{equation*}
$$

is non-zero only when $\left(\boldsymbol{\kappa}+\boldsymbol{\kappa}^{\prime}\right) \cdot \boldsymbol{g}=0$, or $\left(\boldsymbol{\kappa}+\boldsymbol{\kappa}^{\prime}\right)$ is $\perp$ to $\boldsymbol{g}=-g \hat{\boldsymbol{e}}_{3}$. Let $\left(\boldsymbol{\kappa}+\boldsymbol{\kappa}^{\prime}\right)=$
$\boldsymbol{\xi}=\left(\xi_{1}, \xi_{2}, 0\right)$ such that this property is satisfied. Using the sifting property of the Diract delta function, as well as the identity $\delta(a x)=(1 /|a|) \delta(x)$, the integral in (2.23) now becomes

$$
\begin{equation*}
\frac{1}{2} \frac{2 \pi}{g \tau_{v}} \iint d \boldsymbol{\kappa} d \xi_{1} d \xi_{2} \kappa_{j} \kappa_{m} \Phi_{i l}(\boldsymbol{\kappa})\left(\xi_{k}-\kappa_{k}\right)\left(\xi_{l}-\kappa_{l}\right) \Phi_{j m}(\boldsymbol{\xi}-\boldsymbol{\kappa}) \tag{2.24}
\end{equation*}
$$

Next, we consider the second term in the integral in the last line of (2.22). Unlike the first term, it will be seen subsequently that this term does not make any contribution to the drift.

Recognizing that the particles preferentially sample the velocity gradients along the $x_{3}$ or gravity direction, we apply the tensorial constraints for a field that is homogeneous along the $x_{1}$ and $x_{2}$ directions. Expressing the integral in Eq. (2.24) in terms of these tensor constraints, we have

$$
\begin{array}{r}
\frac{\pi}{g \tau_{v}} \iint d \boldsymbol{\kappa} d \xi_{1} d \xi_{2} \kappa_{j} \kappa_{m} \Phi_{i l}(\boldsymbol{\kappa})\left(\xi_{k}-\kappa_{k}\right)\left(\xi_{l}-\kappa_{l}\right) \Phi_{j m}(\boldsymbol{\xi}-\boldsymbol{\kappa})= \\
\lambda_{1}\left(\delta_{i k}-\delta_{i 3} \delta_{k 3}\right)+\lambda_{2} \delta_{i 3} \delta_{k 3} \tag{2.25}
\end{array}
$$

Multiplying the above equation with $\left(\delta_{i k}-\delta_{i 3} \delta_{k 3}\right)$ gives $\lambda_{1}$ and with $\delta_{i 3} \delta_{k 3}$ gives $\lambda_{2}$.

$$
\begin{gather*}
\lambda_{1}=\frac{\pi}{2 g \tau_{v}} \iint d \boldsymbol{\kappa} d \xi_{1} d \xi_{2} \kappa_{j} \kappa_{m} \Phi_{j m}(\boldsymbol{\xi}-\boldsymbol{\kappa})\left(\xi_{l}-\kappa_{l}\right)\left[\Phi_{i l}(\boldsymbol{\kappa})\left(\xi_{i}-\kappa_{i}\right)+\Phi_{3 l}(\boldsymbol{\kappa}) \kappa_{3}\right]  \tag{2.26}\\
\lambda_{2}=-\frac{\pi}{g \tau_{v}} \iint d \boldsymbol{\kappa} d \xi_{1} d \xi_{2} \kappa_{j} \kappa_{m} \Phi_{3 l}(\boldsymbol{\kappa}) \kappa_{3}\left(\xi_{l}-\kappa_{l}\right) \Phi_{j m}(\boldsymbol{\xi}-\boldsymbol{\kappa}) \tag{2.27}
\end{gather*}
$$

Using spherical coordinates to represent the $\boldsymbol{\kappa}$ vector and cylindrical coordinates to represent $\boldsymbol{\xi}$, we have

$$
\begin{gather*}
\boldsymbol{\kappa}=\left(\kappa_{1}, \kappa_{2}, \kappa_{3}\right)=(\kappa \sin \theta \cos \phi, \kappa \sin \theta \sin \phi, \kappa \cos \theta) \\
\boldsymbol{\xi}=\left(\xi_{1}, \xi_{2}, 0\right)=(\xi \cos \psi, \xi \sin \psi, 0) \tag{2.28}
\end{gather*}
$$

Using (2.28) in the equations for $\lambda_{1}$ and $\lambda_{2}$, i.e. Eqs. (2.26) and (2.27),

$$
\begin{align*}
\lambda_{1} & \left.=\frac{\pi}{2 g \tau_{v}} \int_{\phi=0}^{2 \pi} d \phi \int_{\theta=0}^{\pi} d \theta \int_{\kappa=0}^{\infty} d \kappa \int_{\psi=0}^{2 \pi} d \psi \int_{\xi=0}^{\infty} d \xi \times \text { [Integrand (1) }\right]  \tag{2.29}\\
\lambda_{2} & =\frac{\pi}{g \tau_{v}} \int_{\phi=0}^{2 \pi} d \phi \int_{\theta=0}^{\pi} d \theta \int_{\kappa=0}^{\infty} d \kappa \int_{\psi=0}^{2 \pi} d \psi \int_{\xi=0}^{\infty} d \xi \times[\text { Integrand (2) }] \tag{2.30}
\end{align*}
$$

where

$$
\begin{align*}
& \text { Integrand (1) }=\frac{E(|\boldsymbol{\xi}-\boldsymbol{\kappa}|)}{4 \pi\left[\xi^{2}+\kappa^{2}-2 \xi \kappa \sin \theta \cos (\psi-\phi)\right]} \frac{\xi^{3} \kappa^{4}\left[1-\sin ^{2} \theta \cos ^{2}(\psi-\phi)\right] \sin \theta}{\xi^{2}+\kappa^{2}-2 \xi \kappa \sin \theta \cos (\psi-\phi)} \times \\
& \qquad \frac{E(\kappa)}{4 \pi \kappa^{2}}\left\{\xi^{2}\left[1-\sin ^{2} \theta \cos ^{2}(\psi-\phi)\right]-\frac{\xi \kappa \cos \theta}{2} \sin 2 \theta \cos (\psi-\phi)\right\}  \tag{2.31}\\
& \text { Integrand (2) }=\frac{E(|\boldsymbol{\xi}-\boldsymbol{\kappa}|)}{4 \pi\left[\xi^{2}+\kappa^{2}-2 \xi \kappa \sin \theta \cos (\psi-\phi)\right]} \frac{\xi^{3} \kappa^{4}\left[1-\sin ^{2} \theta \cos ^{2}(\psi-\phi)\right] \sin \theta}{\xi^{2}+\kappa^{2}-2 \xi \kappa \sin \theta \cos (\psi-\phi)} \times \\
& \frac{E(\kappa)}{4 \pi \kappa^{2}} \frac{\xi \kappa \cos \theta}{2} \sin 2 \theta \cos (\psi-\phi) \tag{2.32}
\end{align*}
$$

Let us now consider the second term in the integral of Eq. (2.22) (it has already been
mentioned earlier that this term goes to zero), given by

$$
\begin{align*}
-\iint d \boldsymbol{\kappa} d \boldsymbol{\kappa}^{\prime} \kappa_{j} \kappa_{m} \Phi_{i l}(\boldsymbol{\kappa}) \kappa_{k}^{\prime} \kappa_{l}^{\prime} \Phi_{j m}\left(\boldsymbol{\kappa}^{\prime}\right) \frac{1}{\mathrm{i}\left(\boldsymbol{\kappa}+\boldsymbol{\kappa}^{\prime}\right) \cdot \boldsymbol{g} \tau_{v}} & =\lambda_{3}\left(\delta_{i k}-\delta_{i 3} \delta_{k 3}\right)+\lambda_{4} \delta_{i 3} \delta_{k 3} \\
& =\lambda_{3}\left(\delta_{i k}-\frac{g_{i} g_{k}}{g^{2}}\right)+\lambda_{4} \frac{g_{i} g_{k}}{g^{2}} \tag{2.33}
\end{align*}
$$

where $g_{i}$ is the gravity vector that is non-zero only when $i=3$. The integral on the LHS of (2.33) is odd in $\mathbf{g}$, but the RHS is even in $\mathbf{g}$. Hence the integral will be zero. The final form of drift flux in DF1 is given by

$$
\begin{equation*}
q_{i}^{d}(\boldsymbol{r}, t)=-\langle P\rangle(r, \theta) 2 r_{k} \frac{S t_{\eta}^{2}}{\Gamma_{\eta}^{2}}\left[\lambda_{1}\left(\delta_{i k}-\delta_{i 3} \delta_{k 3}\right)+\lambda_{2} \delta_{i 3} \delta_{k 3}\right] \tag{2.34}
\end{equation*}
$$

where $\theta$ is the spherical polar angle that accounts for the anisotropy in the radial distribution function (RDF), and $\lambda_{1}$ and $\lambda_{2}$ are given by (2.29) and (2.30).

### 2.2. Drift Flux Closure 2 (DF2)

We now present the development of the second drift closure (DF2). It is evident from (2.14) that the first closure (DF1) does not capture the two-time autocorrelations and cross-correlations of the strain-rate and rotation-rate invariants- $\left\langle S^{2}(t) S^{2}\left(t^{\prime}\right)\right\rangle$, $\left\langle R^{2}(t) R^{2}\left(t^{\prime}\right)\right\rangle,\left\langle S^{2}(t) R^{2}\left(t^{\prime}\right)\right\rangle$ and $\left\langle R^{2}(t) S^{2}\left(t^{\prime}\right)\right\rangle$. As seen in (1.2), the drift flux of nonsettling pairs involves the time integration of these correlations. We anticipate that the mechanism(s) driving the accumulation of pairs for $F r \ll 1$ will be related to those for Fr>>1 (zero gravity case), albeit modulated by gravity. Therefore, our objective is to derive a closure (DF2) that accounts for the above correlations.

The closures DF1 and DF2 differ in the assumption made to resolve the moments of the fluid velocity gradient tensor. In DF1, we had assumed the velocity gradient tensor to be Gaussian, whereas in DF2, we regard the dimensionless strain-rate and rotation-rate tensors to be normally distributed.

Referring to the drift flux $q_{i}^{d}$ in (2.12), we first decompose the velocity gradient tensor $\Gamma_{i j}(t)$ into the sum of the strain-rate and rotation-rate tensors, $S_{i j}(t)$ and $R_{i j}(t)$. Subsequently, we non-dimensionalize $S_{i j}$ and $R_{i j}$ using the instantaneous dissipation rate and enstrophy, $\epsilon(t)$ and $\zeta(t)$ respectively. These two steps allow us to write $\Gamma_{i j}(t)$ as

$$
\begin{align*}
\Gamma_{i j}(t) & =S_{i j}(t)+R_{i j}(t)  \tag{2.35}\\
& =\frac{1}{\sqrt{2 \nu}}\left[\sqrt{\epsilon(t)} \sigma_{i j}(t)+\sqrt{\zeta(t)} \rho_{i j}(t)\right] \tag{2.36}
\end{align*}
$$

where $\epsilon(t)=2 \nu S_{i j}(t) S_{i j}(t), \zeta(t)=2 \nu R_{i j}(t) R_{i j}(t)$ [ $\nu$ is the kinematic viscosity], and $\sigma_{i j}(t)$ and $\rho_{i j}(t)$ are the dimensionless strain-rate and rotation-rate tensors, respectively.

Substituting (2.36) for $\boldsymbol{\Gamma}$ in (2.12), and assuming $\sigma_{i j}(t)$ and $\rho_{i j}(t)$ to be normally distributed, we can drop the third moments of $\boldsymbol{\Gamma}$ as they, in turn, give rise to third moments of $\boldsymbol{\sigma}, \boldsymbol{\rho}$, and to cross correlations of third order involving $\boldsymbol{\sigma}$ and $\boldsymbol{\rho}$. With these simplifications, the drift flux in (2.12) reduces to

$$
\begin{equation*}
q_{i}^{d}(\boldsymbol{r}, t)=-\langle P\rangle(\boldsymbol{r} ; t) \frac{S t_{\eta}^{2}}{\Gamma_{\eta}^{2}} r_{k} \int_{-\infty}^{t} d_{i k} d t^{\prime} \tag{2.37}
\end{equation*}
$$

where

$$
\begin{gather*}
d_{i k}=\left\langle\Gamma_{i j}(t) \Gamma_{j k}(t) \Gamma_{l m}\left(t^{\prime}\right) \Gamma_{m l}\left(t^{\prime}\right)\right\rangle \approx \\
\frac{1}{4 \nu^{2}}\left\{\left\langle\epsilon(t) \epsilon\left(t^{\prime}\right)\right\rangle\left[\left\langle\sigma_{i j}(t) \sigma_{j k}(t)\right\rangle\left\langle\sigma_{l m}\left(t^{\prime}\right) \sigma_{l m}\left(t^{\prime}\right)\right\rangle+2\left\langle\sigma_{i j}(t) \sigma_{l m}\left(t^{\prime}\right)\right\rangle\left\langle\sigma_{j k}(t) \sigma_{l m}\left(t^{\prime}\right)\right\rangle\right]\right. \\
-\left\langle\epsilon(t) \zeta\left(t^{\prime}\right)\right\rangle\left\langle\sigma_{i j}(t) \sigma_{j k}(t)\right\rangle\left\langle\sigma_{l m}\left(t^{\prime}\right) \sigma_{l m}\left(t^{\prime}\right)\right\rangle+\left\langle\zeta(t) \epsilon\left(t^{\prime}\right)\right\rangle\left\langle\rho_{i j}(t) \rho_{j k}(t)\right\rangle\left\langle\sigma_{l m}\left(t^{\prime}\right) \sigma_{l m}\left(t^{\prime}\right)\right\rangle \\
\left.-\left\langle\zeta(t) \zeta\left(t^{\prime}\right)\right\rangle\left[\left\langle\rho_{i j}(t) \rho_{j k}(t)\right\rangle\left\langle\rho_{l m}\left(t^{\prime}\right) \rho_{l m}\left(t^{\prime}\right)\right\rangle+2\left\langle\rho_{i j}(t) \rho_{l m}\left(t^{\prime}\right)\right\rangle\left\langle\rho_{j k}(t) \rho_{l m}\left(t^{\prime}\right)\right\rangle\right]\right\} \tag{2.38}
\end{gather*}
$$

In (2.38), we have also assumed that $\epsilon(t)$ and $\boldsymbol{\sigma}(t)$ are weakly correlated, and so are $\zeta(t)$ and $\boldsymbol{\rho}(t)$. This is a reasonable approximation since the dissipation rate and enstrophy vary over characteristic time scales that are quite different from those of strain-rate and rotation-rate tensors, respectively. The former two have scales of the order of largeeddy time scales (Chun et al. 2005). But, the components of strain rate have time scales $\sim 2.3 \tau_{\eta}$ and those of rotation rate $\sim 7.2 \tau_{\eta}$ (Chun et al. 2005; Zaichik \& Alipchenkov 2007), where $\tau_{\eta}$ is the Kolmogorov time scale.

Due to isotropy, the one-time correlations of the $\boldsymbol{\sigma}$ and $\boldsymbol{\rho}$ tensors in (2.38) can be written as (Chun et al. 2005)

$$
\begin{gather*}
\left\langle\sigma_{i j}(t) \sigma_{j k}(t)\right\rangle=\frac{1}{3} \delta_{i k}  \tag{2.39}\\
\left\langle\sigma_{l m}(t) \sigma_{l m}(t)\right\rangle=1  \tag{2.40}\\
\left\langle\rho_{i j}(t) \rho_{j k}(t)\right\rangle=-\frac{1}{3} \delta_{i k}  \tag{2.41}\\
\left\langle\rho_{l m}(t) \rho_{l m}(t)\right\rangle=1 \tag{2.42}
\end{gather*}
$$

We now have

$$
\begin{align*}
d_{i k}=\frac{1}{4 \nu^{2}}\{ & \frac{1}{3} \delta_{i k}\left[\left\langle\epsilon(t) \epsilon\left(t^{\prime}\right)\right\rangle+\left\langle\epsilon(t) \zeta\left(t^{\prime}\right)\right\rangle-\left\langle\zeta(t) \epsilon\left(t^{\prime}\right)\right\rangle-\left\langle\zeta(t) \zeta\left(t^{\prime}\right)\right\rangle\right]+ \\
& 2\left\langle\epsilon(t) \epsilon\left(t^{\prime}\right)\right\rangle\left\langle\sigma_{i j}(t) \sigma_{l m}\left(t^{\prime}\right)\right\rangle\left\langle\sigma_{j k}(t) \sigma_{l m}\left(t^{\prime}\right)\right\rangle- \\
& \left.2\left\langle\zeta(t) \zeta\left(t^{\prime}\right)\right\rangle\left\langle\rho_{i j}(t) \rho_{l m}\left(t^{\prime}\right)\right\rangle\left\langle\rho_{j k}(t) \rho_{l m}\left(t^{\prime}\right)\right\rangle\right\} \tag{2.43}
\end{align*}
$$

In (2.43), we will express the two-time correlation of dissipation rate as (Chun et al. 2005)

$$
\begin{equation*}
\left\langle\epsilon(t) \epsilon\left(t^{\prime}\right)\right\rangle=\left\langle\epsilon^{2}\right\rangle \exp \left(-\frac{t-t^{\prime}}{T_{\epsilon \epsilon}}\right) \tag{2.44}
\end{equation*}
$$

so that

$$
\begin{equation*}
\int_{-\infty}^{t}\left\langle\epsilon(t) \epsilon\left(t^{\prime}\right)\right\rangle d t^{\prime}=\left\langle\epsilon^{2}\right\rangle T_{\epsilon \epsilon} \tag{2.45}
\end{equation*}
$$

where $T_{\epsilon \epsilon}$ is the correlation time scale of $\epsilon$. In a similar manner, the correlations $\left\langle\epsilon(t) \zeta\left(t^{\prime}\right)\right\rangle$, $\left\langle\zeta(t) \epsilon\left(t^{\prime}\right)\right\rangle$ and $\left\langle\zeta(t) \zeta\left(t^{\prime}\right)\right\rangle$ are expressed in terms of the correlation time scales $T_{\epsilon \zeta}, T_{\zeta \epsilon}$
and $T_{\zeta \zeta}$, respectively. Thus, we have

$$
\begin{gather*}
\int_{-\infty}^{t} d_{i k} d t^{\prime}=\frac{1}{4 \nu^{2}}\left\{\frac{1}{3} \delta_{i k}\left[\left\langle\epsilon^{2}\right\rangle T_{\epsilon \epsilon}+\langle\epsilon \zeta\rangle T_{\epsilon \zeta}-\langle\zeta \epsilon\rangle T_{\zeta \epsilon}-\left\langle\zeta^{2}\right\rangle T_{\zeta \zeta}\right]+\right. \\
2\left\langle\epsilon^{2}\right\rangle \int_{-\infty}^{t} \exp \left(-\frac{t-t^{\prime}}{T_{\epsilon \epsilon}}\right)\left\langle\sigma_{i j}(t) \sigma_{l m}\left(t^{\prime}\right)\right\rangle\left\langle\sigma_{j k}(t) \sigma_{l m}\left(t^{\prime}\right)\right\rangle d t^{\prime}- \\
\left.2\left\langle\zeta^{2}\right\rangle \int_{-\infty}^{t} \exp \left(-\frac{t-t^{\prime}}{T_{\zeta \zeta}}\right)\left\langle\rho_{i j}(t) \rho_{l m}\left(t^{\prime}\right)\right\rangle\left\langle\rho_{j k}(t) \rho_{l m}\left(t^{\prime}\right)\right\rangle d t^{\prime}\right\} \tag{2.46}
\end{gather*}
$$

In the rapid settling limit, the time scales $T_{\epsilon \epsilon}, T_{\epsilon \zeta}, T_{\zeta \epsilon}$ and $T_{\zeta \zeta}$ can be approximated as the ratio of the corresponding Eulerian correlation length and the particle terminal velocity. For example,

$$
\begin{equation*}
T_{\epsilon \epsilon} \approx \frac{L_{\epsilon \epsilon}}{g \tau_{v}} \tag{2.47}
\end{equation*}
$$

where $L_{\epsilon \epsilon}$ is the Eulerian length scale of $\epsilon$. The various Eulerian length scales are evaluated via DNS of isotropic turbulence.

To evaluate the two integrals on the RHS of (2.46), we need to resolve the twotime correlations of $\boldsymbol{\sigma}$ and $\boldsymbol{\rho}-\left\langle\sigma_{i j}(t) \sigma_{l m}\left(t^{\prime}\right)\right\rangle,\left\langle\sigma_{j k}(t) \sigma_{l m}\left(t^{\prime}\right)\right\rangle,\left\langle\rho_{i j}(t) \rho_{l m}\left(t^{\prime}\right)\right\rangle$, and $\left\langle\rho_{j k}(t) \rho_{l m}\left(t^{\prime}\right)\right\rangle$. Analogous to the process leading to (2.19), we will transform the twotime correlations of $\boldsymbol{\sigma}$ and $\rho$ into two-point correlations with a spatial separation of $\boldsymbol{x}_{g}=\boldsymbol{g} \tau_{v}\left(t^{\prime}-t\right)$, and express the two-point correlations as Fourier integrals. Subsequently, we apply the tensorial constraints arising from the particles sampling the flow field preferentially along the $x_{3}$ direction, but homogeneously in the $x_{1}-x_{2}$ plane. Accordingly, $\left\langle\sigma_{i j}(t) \sigma_{l m}\left(t^{\prime}\right)\right\rangle$ can be expressed as

$$
\begin{array}{r}
\left\langle\sigma_{i j}(\boldsymbol{x}, t) \sigma_{l m}\left(\boldsymbol{x}^{\prime}, t^{\prime}\right)\right\rangle=\int d \boldsymbol{\kappa}\left\langle\widehat{\sigma}_{i j}(\boldsymbol{\kappa}, t) \widehat{\sigma}_{l m}^{*}(\boldsymbol{\kappa}, t)\right\rangle e^{-\mathrm{i} \boldsymbol{\kappa} \cdot \boldsymbol{x}_{g}}=\mathscr{L}_{i j l m}= \\
\alpha_{1} \delta_{i j} \delta_{l m}+\alpha_{2}\left(\delta_{i m} \delta_{j l}+\delta_{i l} \delta_{j m}\right)+\alpha_{4} \delta_{i 3} \delta_{j 3} \delta_{l 3} \delta_{m 3}+ \\
\alpha_{5}\left(\delta_{i 3} \delta_{j 3} \delta_{l m}+\delta_{i j} \delta_{l 3} \delta_{m 3}\right)+\alpha_{6}\left(\delta_{i 3} \delta_{l 3} \delta_{j m}+\delta_{i 3} \delta_{m 3} \delta_{j l}+\delta_{j 3} \delta_{l 3} \delta_{i m}+\delta_{j 3} \delta_{m 3} \delta_{i l}\right) \tag{2.48}
\end{array}
$$

where

$$
\begin{gather*}
\alpha_{1}=-\frac{1}{8}\left(2 B_{1}-B_{2}-4 B_{3}\right) ; \quad \alpha_{2}=\frac{1}{8}\left(2 B_{1}+B_{2}-4 B_{3}\right) \\
\alpha_{4}=\frac{1}{8}\left(2 B_{1}+35 B_{2}-20 B_{3}\right) ; \quad \alpha_{5}=\frac{1}{8}\left(2 B_{1}-5 B_{2}-4 B_{3}\right) \\
\alpha_{6}=-\frac{1}{8}\left(2 B_{1}+5 B_{2}-8 B_{3}\right) \\
B_{1}=\frac{\nu}{2\langle\epsilon\rangle}\left[\frac{1}{\pi} \int d \boldsymbol{\kappa} E(\kappa) e^{-\mathrm{i} \boldsymbol{\kappa} \cdot \boldsymbol{x}_{g}}\right]  \tag{2.49}\\
B_{2}=\frac{\nu}{2\langle\epsilon\rangle}\left[4 \int d \boldsymbol{\kappa} \kappa_{3}^{2} \frac{E(\kappa)}{4 \pi \kappa^{2}}\left(1-\frac{\kappa_{3}^{2}}{\kappa^{2}}\right) e^{-\mathrm{i} \boldsymbol{\kappa} \cdot \boldsymbol{x}_{g}}\right]  \tag{2.50}\\
B_{3}=\frac{\nu}{2\langle\epsilon\rangle}\left[\int d \boldsymbol{\kappa} \kappa_{j} \kappa_{j} \frac{E(\kappa)}{4 \pi \kappa^{2}}\left(1+\frac{\kappa_{3}^{2}}{\kappa^{2}}\right) e^{-\mathrm{i} \boldsymbol{\kappa} \cdot \boldsymbol{x}_{g}}\right] \tag{2.51}
\end{gather*}
$$

In the equations (2.49)-(2.51), $E(\kappa)$ is the energy spectrum of isotropic turbulence, and $\kappa_{3}$ is the component of $\kappa$ along the $x_{3}$ direction. Appendix A presents the process for determining the form of the tensorial constraints in (2.48), as well as the coefficients $\alpha_{1}, \alpha_{2}$ and others. Appendix B presents the evaluation of $\left\langle\widehat{\sigma}_{i j}(\boldsymbol{\kappa}, t) \widehat{\sigma}_{l m}^{*}(\boldsymbol{\kappa}, t)\right\rangle$.

The term $\left\langle\sigma_{j k}(\boldsymbol{x}, t) \sigma_{l m}\left(\boldsymbol{x}^{\prime}, t^{\prime}\right)\right\rangle$ may also be expressed analogous to (2.48). Thus, the product $\left\langle\sigma_{i j}(t) \sigma_{l m}\left(t^{\prime}\right)\right\rangle\left\langle\sigma_{j k}(t) \sigma_{l m}\left(t^{\prime}\right)\right\rangle$ in (2.46) can now be written as

$$
\begin{align*}
& \left\langle\sigma_{i j}(t) \sigma_{l m}\left(t^{\prime}\right)\right\rangle\left\langle\sigma_{j k}(t) \sigma_{l m}\left(t^{\prime}\right)\right\rangle=\delta_{i k}\left(3 \alpha_{1} \alpha_{1}+4 \alpha_{1} \alpha_{2}+2 \alpha_{1} \alpha_{5}+8 \alpha_{2} \alpha_{2}+4 \alpha_{2} \alpha_{6}+\right. \\
& \left.\alpha_{5} \alpha_{5}+2 \alpha_{6} \alpha_{6}\right)+\delta_{i 3} \delta_{k 3}\left(2 \alpha_{1} \alpha_{4}+6 \alpha_{1} \alpha_{5}+8 \alpha_{1} \alpha_{6}+4 \alpha_{2} \alpha_{4}+8 \alpha_{2} \alpha_{5}+\right. \\
& \left.20 \alpha_{2} \alpha_{6}+\alpha_{4} \alpha_{4}+4 \alpha_{4} \alpha_{5}+8 \alpha_{4} \alpha_{6}+5 \alpha_{5} \alpha_{5}+16 \alpha_{5} \alpha_{6}+18 \alpha_{6} \alpha_{6}\right) \tag{2.52}
\end{align*}
$$

Terms such as $\alpha_{1} \alpha_{1}, \alpha_{1} \alpha_{2}$ and others give rise to wavenumber integration of the form $\int d \boldsymbol{\kappa} d \boldsymbol{\kappa}^{\prime} e^{-\mathrm{i}\left(\boldsymbol{\kappa}+\boldsymbol{\kappa}^{\prime}\right) \cdot \boldsymbol{x}_{g}} \times(\cdots)$, which upon substitution into (2.46) leads to time integrals of the following form.

$$
\begin{align*}
\int_{-\infty}^{t} \exp \left(-\frac{t-t^{\prime}}{T_{\epsilon \epsilon}}\right) e^{-\mathrm{i}\left(\boldsymbol{\kappa}+\boldsymbol{\kappa}^{\prime}\right) \cdot \boldsymbol{x}_{g}} d t^{\prime} & =\frac{1}{\left(\frac{1}{T_{\epsilon \epsilon}}\right)-\mathrm{i}\left(\boldsymbol{\kappa}+\boldsymbol{\kappa}^{\prime}\right) \cdot \boldsymbol{g} \tau_{v}} \\
& =\frac{\left(\frac{1}{T_{\epsilon \epsilon}}\right)+\mathrm{i}\left(\boldsymbol{\kappa}+\boldsymbol{\kappa}^{\prime}\right) \cdot \boldsymbol{g} \tau_{v}}{\left(\frac{1}{T_{\epsilon \epsilon}}\right)^{2}+\left[\left(\boldsymbol{\kappa}+\boldsymbol{\kappa}^{\prime}\right) \cdot \boldsymbol{g} \tau_{v}\right]^{2}} \tag{2.53}
\end{align*}
$$

It may be noted that in (2.53), the imaginary part on the RHS is odd in $\boldsymbol{g}$, whereas the drift flux is tensorially constrained to be even in $\boldsymbol{g}$. Thus, the imaginary part does not contribute to the overall drift flux. Further details of the evaluation of the RHS of (2.52) are presented in Appendix C.

Next we evaluate the term $\left\langle\rho_{i j}(t) \rho_{l m}\left(t^{\prime}\right)\right\rangle\left\langle\rho_{j k}(t) \rho_{l m}\left(t^{\prime}\right)\right\rangle$ in (2.46). This again involves applying the appropriate tensorial constraints on each of the two correlations as follows.

$$
\begin{gather*}
\left\langle\rho_{i j}(\boldsymbol{x}, t) \rho_{l m}\left(\boldsymbol{x}^{\prime}, t^{\prime}\right)\right\rangle=\int d \boldsymbol{\kappa}\left\langle\widehat{\rho}_{i j}(\boldsymbol{\kappa}, t) \widehat{\rho}_{l m}^{*}(\boldsymbol{\kappa}, t)\right\rangle e^{-\mathrm{i} \boldsymbol{\kappa} \cdot \boldsymbol{x}_{g}}=\mathscr{M}_{i j l m}= \\
\beta_{2}\left(\delta_{i m} \delta_{j l}-\delta_{i l} \delta_{j m}\right)+\beta_{6}\left(\delta_{i 3} \delta_{l 3} \delta_{j m}-\delta_{i 3} \delta_{m 3} \delta_{j l}-\delta_{j 3} \delta_{l 3} \delta_{i m}+\delta_{j 3} \delta_{m 3} \delta_{i l}\right) \tag{2.54}
\end{gather*}
$$

The criteria for determining $\beta$ 's-provided in Appendix A yield

$$
\begin{equation*}
\beta_{2}=\frac{1}{2}\left(2 C_{2}-C_{1}\right) ; \quad \beta_{6}=\frac{1}{2}\left(3 C_{2}-C_{1}\right) \tag{2.55}
\end{equation*}
$$

where

$$
\begin{gather*}
C_{1}=\frac{\nu}{2\langle\zeta\rangle}\left[\frac{1}{\pi} \int d \boldsymbol{\kappa} E(\kappa) e^{-\mathrm{i} \boldsymbol{\kappa} \cdot \boldsymbol{x}_{g}}\right]  \tag{2.56}\\
C_{2}=\frac{\nu}{2\langle\zeta\rangle}\left[\int d \boldsymbol{\kappa} \kappa_{j} \kappa_{j} \frac{E(\kappa)}{4 \pi \kappa^{2}}\left(1+\frac{\kappa_{3}^{2}}{\kappa^{2}}\right) e^{-\mathrm{i} \boldsymbol{\kappa} \cdot \boldsymbol{x}_{g}}\right] \tag{2.57}
\end{gather*}
$$

Thus, the product $\left\langle\rho_{i j}(t) \rho_{l m}\left(t^{\prime}\right)\right\rangle\left\langle\rho_{j k}(t) \rho_{l m}\left(t^{\prime}\right)\right\rangle$ in (2.46) can now be written as

$$
\begin{equation*}
\left\langle\rho_{i j}(t) \rho_{l m}\left(t^{\prime}\right)\right\rangle\left\langle\rho_{j k}(t) \rho_{l m}\left(t^{\prime}\right)\right\rangle=\delta_{i k}\left(-4 \beta_{2} \beta_{2}+4 \beta_{2} \beta_{6}-2 \beta_{6} \beta_{6}\right)+\delta_{i 3} \delta_{k 3}\left(4 \beta_{2} \beta_{6}-2 \beta_{6} \beta_{6}\right) \tag{2.58}
\end{equation*}
$$

Terms on the RHS of (2.58) such as $\beta_{2} \beta_{2}, \beta_{2} \beta_{6}$ and $\beta_{6} \beta_{6}$ contain wavenumber integration of the form $\int d \boldsymbol{\kappa} d \boldsymbol{\kappa}^{\prime} e^{-\mathrm{i}\left(\boldsymbol{\kappa}+\boldsymbol{\kappa}^{\prime}\right) \cdot \boldsymbol{x}_{g}} \times(\cdots)$, which upon substitution into (2.46) leads to a time integration similar to that in (2.53), with the $T_{\epsilon \epsilon}$ replaced by $T_{\zeta \zeta}$.

Recalling the integral $\int_{-\infty}^{t} d_{i k} d t^{\prime}$ in (2.46), we can evaluate terms such as

$$
\begin{equation*}
\int_{-\infty}^{t} d t^{\prime}\left\langle\epsilon(t) \epsilon\left(t^{\prime}\right)\right\rangle\left\langle\sigma_{i j}(t) \sigma_{l m}\left(t^{\prime}\right)\right\rangle\left\langle\sigma_{j k}(t) \sigma_{l m}\left(t^{\prime}\right)\right\rangle \tag{2.59}
\end{equation*}
$$

by applying the time integral in (2.53) along with (2.48)-(2.52). The final form of drift
flux for DF2 is analogous to that in (2.34) and is given by

$$
\begin{equation*}
q_{i}^{d}(\boldsymbol{r}, t)=-\langle P\rangle(r, \theta) 2 r_{k} \frac{S t_{\eta}^{2}}{\Gamma_{\eta}^{2}}\left[\lambda_{1}^{\prime}\left(\delta_{i k}-\delta_{i 3} \delta_{k 3}\right)+\lambda_{2}^{\prime} \delta_{i 3} \delta_{k 3}\right] \tag{2.60}
\end{equation*}
$$

where $\lambda_{1}^{\prime}$ and $\lambda_{2}^{\prime}$ are the coefficients for DF2. The expressions for $\lambda_{1}^{\prime}$ and $\lambda_{2}^{\prime}$ are extremely involved and are not explicitly presented. In fact, (2.52) gives rise to thirteen separate integrations of the general form shown in (2.53), while (2.58) gives rise to three more such integrals. Each of these integrals is evaluated through numerical quadrature, and then assembled using (2.52) and (2.58) during runtime (of the computational code).

### 2.3. Diffusion Flux

Applying (2.10) in the diffusion flux given by (2.3), and retaining only the leading order term yields the following form of the diffusion flux (Chun et al. |2005)

$$
\begin{equation*}
q_{i}^{D}(\boldsymbol{r})=-\mathscr{D}_{i j} \frac{\partial\langle P\rangle}{\partial r_{j}} \tag{2.61}
\end{equation*}
$$

with the diffusivity tensor

$$
\begin{equation*}
\mathscr{D}_{i j}=r_{m} r_{n} \int_{-\infty}^{t}\left\langle\Gamma_{i m}(t) \Gamma_{j n}\left(t^{\prime}\right)\right\rangle d t^{\prime}=r_{m} r_{n} Q_{i m j n} \tag{2.62}
\end{equation*}
$$

where $\Gamma_{i m}(t)=\Gamma_{i m}(\boldsymbol{x}(t), t), \Gamma_{j n}\left(t^{\prime}\right)=\Gamma_{j n}\left(\boldsymbol{x}\left(t^{\prime}\right), t^{\prime}\right)$.
In writing (2.61), we have invoked the assumption that the pair separation does not change appreciably over the correlation time for the "seen" fluid velocity gradient. Such an approximation has been referred to as the local diffusion analysis in the Chun et al. (2005) study, and is particularly suitable for the case of rapidly settling particle pairs. As noted by Ireland et al. (2016), gravity reduces the Lagrangian time scales of strainrate and rotation-rate along the particle trajectories. Therefore, in the rapidly settling limit, one would anticipate these time scales to be significantly smaller than those in the zero gravity case. Thus, it is reasonable to assume the pair separation to be essentially constant in these reduced correlation times of the fluid velocity gradient.

Analogous to the drift analysis, we can express the two-time correlation $\left\langle\Gamma_{i m}(t) \Gamma_{j n}\left(t^{\prime}\right)\right\rangle$ in terms of two-point Eulerian correlation as

$$
\begin{align*}
\left\langle\Gamma_{i m}(t) \Gamma_{j n}\left(t^{\prime}\right)\right\rangle & =\left\langle\Gamma_{i m}(\boldsymbol{x} ; t) \Gamma_{j n}\left[\boldsymbol{x}+\boldsymbol{g} \tau_{v}\left(t^{\prime}-t\right) ; t\right]\right\rangle \\
& =\int d \boldsymbol{\kappa} \kappa_{m} \kappa_{n} \Phi_{i j}(\boldsymbol{\kappa}) e^{\mathrm{i} \boldsymbol{\kappa} \cdot \boldsymbol{g} \tau_{v}\left(t^{\prime}-t\right)} \\
& =\int d \boldsymbol{\kappa} \kappa_{m} \kappa_{n} \frac{E(\kappa)}{4 \pi \kappa^{2}}\left(\delta_{i j}-\frac{\kappa_{i} \kappa_{j}}{\kappa^{2}}\right) e^{\mathrm{i} \boldsymbol{\kappa} \cdot \boldsymbol{g} \tau_{v}\left(t^{\prime}-t\right)} \tag{2.63}
\end{align*}
$$

Thus, the diffusivity tensor may be written as

$$
\begin{align*}
\mathscr{D}_{i j}(\boldsymbol{r}) & =r_{m} r_{n} \int d \boldsymbol{\kappa} \kappa_{m} \kappa_{n} \frac{E(\kappa)}{4 \pi \kappa^{2}}\left(\delta_{i j}-\frac{\kappa_{i} \kappa_{j}}{\kappa^{2}}\right) \int_{-\infty}^{0} e^{\mathrm{i} \boldsymbol{\kappa} \cdot \boldsymbol{g} \tau_{v} t} d t \\
& =\frac{1}{2} r_{m} r_{n} \int d \boldsymbol{\kappa} \kappa_{m} \kappa_{n} \frac{E(\kappa)}{4 \pi \kappa^{2}}\left(\delta_{i j}-\frac{\kappa_{i} \kappa_{j}}{\kappa^{2}}\right) \delta\left(\boldsymbol{\kappa} \cdot \boldsymbol{g} \tau_{v}\right) \\
& =r_{m} r_{n} \frac{1}{2 g \tau_{v}} \int d \boldsymbol{\xi} \xi_{m} \xi_{n} \frac{E(\xi)}{4 \pi \xi^{2}}\left(\delta_{i j}-\frac{\xi_{i} \xi_{j}}{\xi^{2}}\right) \tag{2.64}
\end{align*}
$$

where $\boldsymbol{\xi}=\left(\xi_{1}, \xi_{2}, 0\right)$ is the wavenumber vector in the homogeneous $x_{1}-x_{2}$ plane.
Using (2.62) and (2.64), and applying the tensor constraints on the fourth order tensor
$Q_{i m j n}$ yields (details of the tensor analysis are in Appendix ( D

$$
\begin{align*}
& Q_{i m j n}=\frac{1}{2 g \tau_{v}} \int d \boldsymbol{\xi} \xi_{m} \xi_{n} \frac{E(\xi)}{4 \pi \xi^{2}}\left(\delta_{i j}-\frac{\xi_{i} \xi_{j}}{\xi^{2}}\right)=\lambda_{5}\left(\delta_{i 3} \delta_{m 3} \delta_{j 3} \delta_{n 3}-\delta_{i 3} \delta_{j 3} \delta_{m n}\right)+ \\
& \lambda_{6}\left(\delta_{i n} \delta_{m j}+\delta_{i m} \delta_{j n}-3 \delta_{i j} \delta_{m n}-\delta_{i 3} \delta_{n 3} \delta_{m j}-\delta_{j 3} \delta_{n 3} \delta_{i m}-\delta_{i 3} \delta_{m 3} \delta_{j n}-\delta_{m 3} \delta_{j 3} \delta_{i n}+\right. \\
& \left.2 \delta_{i 3} \delta_{j 3} \delta_{m n}+3 \delta_{m 3} \delta_{n 3} \delta_{i m}\right) \tag{2.65}
\end{align*}
$$

which gives

$$
\begin{align*}
& \lambda_{5}=-\frac{3 \pi}{16 g \tau_{v}} \int_{\xi=0}^{\infty} \xi E(\xi) d \xi,  \tag{2.66}\\
& \lambda_{6}=\frac{\lambda_{5}}{3} \tag{2.67}
\end{align*}
$$

Therefore,

$$
\begin{align*}
\mathscr{D}_{i j}(\boldsymbol{r}) & =r_{m} r_{n} A_{i m j n} \\
& =\lambda_{6}\left[\left(3 r_{3}^{2}-r^{2}\right) \delta_{i 3} \delta_{j 3}+2 r_{i} r_{j}+3\left(r_{3}^{2}-r^{2}\right) \delta_{i j}-2 r_{3}\left(r_{j} \delta_{i 3}+r_{i} \delta_{j 3}\right)\right] \tag{2.68}
\end{align*}
$$

Having derived closures for the drift and diffusion fluxes, we present the analytical solution to the PDF equation (2.1).

## 3. Solution of the PDF Equation

We will solve the PDF equation (2.1) in spherical coordinates. At steady state, the governing equation for $\langle P\rangle(r, \theta)$ is given by

$$
\begin{equation*}
\frac{1}{r^{2}} \frac{\partial}{\partial r}\left(r^{2} q_{r}\right)+\frac{1}{r \sin \theta} \frac{\partial}{\partial \theta}\left(\sin \theta q_{\theta}\right)=0 \tag{3.1}
\end{equation*}
$$

where $q_{r}$ and $q_{\theta}$ are fluxes along the radial and polar directions. These contain both the drift and diffusion fluxes, and are given by

$$
\begin{aligned}
q_{r} & =v_{r}\langle P\rangle-\mathscr{D}_{r r} \frac{\partial\langle P\rangle}{\partial r}-\mathscr{D}_{r \theta} \frac{1}{r} \frac{\partial\langle P\rangle}{\partial \theta} \\
q_{\theta} & =v_{\theta}\langle P\rangle-\mathscr{D}_{r \theta} \frac{\partial\langle P\rangle}{\partial r}-\mathscr{D}_{\theta \theta} \frac{1}{r} \frac{\partial\langle P\rangle}{\partial \theta} \\
v_{r} & =-2 r\left(\lambda_{1} \sin ^{2} \theta+\lambda_{2} \cos ^{2} \theta\right) S t_{\eta}^{2} \\
v_{\theta} & =-2 r\left(\lambda_{1}-\lambda_{2}\right) S t_{\eta}^{2} \sin \theta \cos \theta \\
\mathscr{D}_{r r} & =\lambda_{6} r^{2}\left(3 \sin ^{4} \theta-4 \sin ^{2} \theta\right) \\
\mathscr{D}_{r \theta} & =3 \lambda_{6} r^{2} \sin ^{3} \theta \cos \theta \\
\mathscr{D}_{\theta \theta} & =-\lambda_{6} r^{2}\left(\sin ^{2} \theta+3 \sin ^{4} \theta\right)
\end{aligned}
$$

The coefficients $\lambda_{1}, \lambda_{2}$ and $\lambda_{6}$ in the above equations are given in (2.29), (2.30) and (2.67) respectively, while $\mathscr{D}_{r r}, \mathscr{D}_{r \theta}$ and $\mathscr{D}_{\theta \theta}$ are the components in spherical coordinates of the diffusivity tensor $\mathscr{D}_{i j}(\boldsymbol{r})$ in (2.68). When applying DF2, we use $\lambda_{1}^{\prime}$ and $\lambda_{2}^{\prime}$ in place of $\lambda_{1}$ and $\lambda_{2}$.
It is evident from the $q_{r}$ and $q_{\theta}$ equations that the variables $r$ and $\theta$ are separable. Also, the form of the PDF equation (3.1) suggests a solution with a power law dependence on separation $r$. Accordingly, we write $\langle P\rangle(r, \theta)=r^{\beta} f(\theta)$ and substitute this form into (3.1). A change of variable $\mu=\cos \theta$ leads to the following equation for $f(\mu)$

$$
\begin{equation*}
a(\mu) \frac{d^{2} f}{d \mu^{2}}+b(\mu) \frac{d f}{d \mu}+c(\mu) f=0 \tag{3.2}
\end{equation*}
$$

where

$$
\begin{aligned}
a(\mu)= & \lambda_{6}\left(3 \mu^{2}-4\right)\left(1-\mu^{2}\right)^{2} \\
b(\mu)= & 2\left(\lambda_{2}-\lambda_{1}\right) S t^{2} \mu\left(1-\mu^{2}\right)-3 \lambda_{6} \beta \mu\left(1-\mu^{2}\right)^{2}- \\
& \lambda_{6} \mu\left(18 \mu^{2}-22\right)\left(1-\mu^{2}\right)-3 \lambda_{6}(\beta+3) \mu\left(1-\mu^{2}\right)^{2} \\
c(\mu)= & 2\left(\lambda_{2}-\lambda_{1}\right) S t^{2}\left(1-3 \mu^{2}\right)-3 \lambda_{6} \beta\left(1-\mu^{2}\right)\left(1-5 \mu^{2}\right)+ \\
& (\beta+3)\left\{2\left[\lambda_{1}\left(1-\mu^{2}\right)+\lambda_{2} \mu^{2}\right] S t^{2}-\lambda_{6} \beta\left(1+3 \mu^{2}\right)\left(1-\mu^{2}\right)\right\}
\end{aligned}
$$

### 3.1. Power Law Exponent $\beta$

To find the power law exponent, we apply the constraint that at steady state, the net radial flux through a spherical surface of radius $r$ is zero, given by

$$
\begin{equation*}
\int_{-1}^{1} q_{r} d \mu=0 \tag{3.3}
\end{equation*}
$$

leading to

$$
\begin{equation*}
\beta=\frac{\int_{-1}^{1}\left(A_{r} f(\mu)+B_{r \theta} \sqrt{1-\mu^{2}} \frac{d f}{d \mu}\right) d \mu}{\int_{-1}^{1} B_{r r} f(\mu) d \mu} \tag{3.4}
\end{equation*}
$$

where

$$
\begin{aligned}
A_{r} & =-2\left[\lambda_{1}\left(1-\mu^{2}\right)+\lambda_{2} \mu^{2}\right] S t_{\eta}^{2} \\
B_{r r} & =-\lambda_{6}\left(1-\mu^{2}\right)\left(1+3 \mu^{2}\right) \\
B_{r \theta} & =3 \lambda_{6} \mu\left(1-\mu^{2}\right) \sqrt{1-\mu^{2}} .
\end{aligned}
$$

Since the drift flux scales as $S t_{\eta}^{2}$, we seek $\beta=\beta_{2} S t_{\eta}^{2}\left(\beta_{2}>0\right)$, which then means that the numerator of (3.4), $\int_{-1}^{1}\left(A_{r} f(\mu)+B_{r \theta} \sqrt{1-\mu^{2}} \frac{d f}{d \mu}\right) d \mu$, should also scale as $S t_{\eta}^{2}$. With these arguments, we seek a perturbation solution to (3.2) of the form

$$
\begin{equation*}
f(\mu)=f_{0}(\mu)+S t_{\eta}^{2} f_{2}(\mu) \tag{3.5}
\end{equation*}
$$

### 3.2. Perturbation Solution for $f(\mu)$

Substitution of $f(\mu)=f_{0}(\mu)+S t_{\eta}^{2} f_{2}(\mu)$ into (3.2) and gathering terms that are $O\left(S t^{0}\right)$ gives

$$
\begin{equation*}
a_{0}(\mu) \frac{d^{2} f_{0}}{d \mu^{2}}+b_{0}(\mu) \frac{d f_{0}}{d \mu}=0 \tag{3.6}
\end{equation*}
$$

where

$$
\begin{aligned}
a_{0}(\mu) & =\lambda_{6}\left(3 \mu^{2}-4\right)\left(1-\mu^{2}\right)^{2} \\
b_{0}(\mu) & =-\lambda_{6} \mu\left(18 \mu^{2}-22\right)\left(1-\mu^{2}\right)-9 \lambda_{6} \mu\left(1-\mu^{2}\right)^{2}
\end{aligned}
$$

Equation (3.6) can be integrated to give

$$
\frac{d f_{0}}{d \mu}=k_{1} \frac{\left(4-3 \mu^{2}\right)^{1 / 2}}{\left(1-\mu^{2}\right)^{2}}
$$

which upon further integration leads to

$$
f_{0}(\mu)=k_{2}+k_{1}\left[\frac{1}{2} \frac{\mu\left(4-3 \mu^{2}\right)^{1 / 2}}{\left(1-\mu^{2}\right)}+2 \tanh ^{-1} \mu+\ln \left(\frac{4-3 \mu+\sqrt{4-3 \mu^{2}}}{4+3 \mu+\sqrt{4-3 \mu^{2}}}\right)\right]
$$

Recalling that $\mu=\cos \theta \in[-1,1]$, it can be seen that $f_{0} \rightarrow \infty$ as $\mu \rightarrow \pm 1$. These singularities prevent the normalization of the probability density $f_{0}$, suggesting that the integration constant $k_{1}=0$. Hence, we have $f_{0}(\mu)=k_{2}$. Using the normalization constraint $\int_{0}^{1} f_{0} d \mu=\frac{1}{4 \pi}$ leads to $f_{0}=\frac{1}{4 \pi}$.

Having determined $f_{0}$, we now gather terms that are $O\left(S t^{2}\right)$ as well as use $f_{0}=\frac{1}{4 \pi}$, giving us

$$
a_{0}(\mu) \frac{d^{2} f_{2}}{d \mu^{2}}+b_{0}(\mu) \frac{d f_{2}}{d \mu}+\frac{c_{2}(\mu)}{4 \pi}=0
$$

where

$$
\begin{align*}
c_{2}(\mu)= & 2\left(\lambda_{2}-\lambda_{1}\right)\left(1-3 \mu^{2}\right)-3 \lambda_{6} \beta_{2}\left(1-\mu^{2}\right)\left(1-5 \mu^{2}\right)+ \\
& 6\left[\lambda_{1}\left(1-\mu^{2}\right)+\lambda_{2} \mu^{2}\right]-3 \lambda_{6} \beta_{2}\left(1+3 \mu^{2}\right)\left(1-\mu^{2}\right) \tag{3.7}
\end{align*}
$$

Equation (3.7) is a linear, inhomogeneous first order ordinary differential equation in $\frac{d f_{2}}{d \mu}$, and can be integrated using the integrating factor

$$
\text { Integrating Factor } I=\exp \left[\int \frac{Q_{0}(\mu)}{P_{0}(\mu)} d \mu\right]=\frac{\left(1-\mu^{2}\right)^{2}}{\left(4-3 \mu^{2}\right)^{1 / 2}}
$$

Thus, we have

$$
\begin{equation*}
I \frac{d f_{2}}{d \mu}=\int I \frac{-R_{2}(\mu)}{P_{0}(\mu) 4 \pi} d \mu+k_{3} \tag{3.8}
\end{equation*}
$$

where $k_{3}$ is a constant of integration. To find $k_{3}$, we enforce symmetry $\frac{d f}{d \mu}=0$ at $\mu=0$. Since the first term on the RHS of (3.8) is zero at $\mu=0$, it follows that $k_{3}=0$ in order to satisfy the symmetry requirement. Thus

$$
\begin{equation*}
\frac{d f_{2}}{d \mu}=\frac{1}{4 \pi} \frac{\mu\left[\lambda_{2}+2 \lambda_{1}+\lambda_{6} \beta_{2}\left(-3+2 \mu^{2}\right)\right]}{2 \lambda_{6}\left(1-\mu^{2}\right)^{2}} \tag{3.9}
\end{equation*}
$$

Referring to (3.4), in order for $\beta$ to scale as $S t_{\eta}^{2}$, we use $f(\mu)=f_{0}=1 / 4 \pi$ and $d f / d \mu=d f_{2} / d \mu$ in the numerator of (3.4), giving us

$$
\begin{equation*}
\beta_{2}=\frac{\int_{0}^{1}\left(\frac{a_{r}}{4 \pi}+b_{r \theta} \frac{d f_{2}}{d \mu}\right) d \mu}{\int_{0}^{1} \frac{B_{r r}}{4 \pi} d \mu} \tag{3.10}
\end{equation*}
$$

where

$$
\begin{aligned}
a_{r} & =-2\left[\lambda_{1}\left(1-\mu^{2}\right)+\lambda_{2} \mu^{2}\right] \\
B_{r r} & =-\lambda_{6}\left(1-\mu^{2}\right)\left(1+3 \mu^{2}\right) \\
b_{r \theta} & =3 \lambda_{6} \mu\left(1-\mu^{2}\right)^{2} .
\end{aligned}
$$

Substitution of (3.9) into (3.10) and simplification thereafter leads to

$$
\begin{equation*}
\beta_{2}=\frac{\lambda_{2}+2 \lambda_{1}}{\lambda_{6}} \tag{3.11}
\end{equation*}
$$

It may noted that $\beta_{2}<0$ as both $\lambda_{1}$ and $\lambda_{2}$ are $<0$.
Using the above form of $\beta_{2}$ in (3.9) we get

$$
\frac{d f_{2}}{d \mu}=-\frac{1}{4 \pi} \frac{\mu \beta_{2}}{\left(1-\mu^{2}\right)}
$$

which leads to

$$
f_{2}=\frac{\beta_{2}}{8 \pi} \ln \left(1-\mu^{2}\right)+k_{4}
$$

The unknown constant $k_{4}$ may be determined using $\int_{0}^{1} f_{2} d \mu=0$, yielding

$$
\begin{equation*}
k_{4}=-\frac{1}{4 \pi} \beta_{2}(\ln 2-1) \tag{3.12}
\end{equation*}
$$

Thus the complete solution for $f(\mu)$ is given by

$$
f(\mu)=\frac{1}{4 \pi}\left[1+S t_{\eta}^{2} \beta_{2}\left(\frac{1}{2} \ln \left(1-\mu^{2}\right)-(\ln 2-1)\right)\right] .
$$

Therefore $\langle P\rangle(r, \mu)$ is given by

$$
\begin{equation*}
\langle P\rangle(r, \mu)=r^{\beta_{2} S t^{2}} \frac{1}{4 \pi}\left[1+S t_{\eta}^{2} \beta_{2}\left(\frac{1}{2} \ln \left(1-\mu^{2}\right)-(\ln 2-1)\right)\right] \tag{3.13}
\end{equation*}
$$

where $\beta_{2}$ is given by (3.11).

## 4. Results

### 4.1. Discussion of the PDF Solution

The PDF solution $\langle P\rangle(r, \mu)$ in (3.13) quantifies the dependence of particle clustering on separation $r$ and direction $\operatorname{cosine} \mu(=\cos \theta)$, the latter quantifying anisotropy due to particle settling. In the DNS by Ireland et al. (2016), they referred to $\langle P\rangle$ as the angular distribution function (ADF) $g(\boldsymbol{r})$, and expressed it in terms of the Legendre spherical harmonic functions, as below.

$$
\begin{equation*}
\frac{g(\boldsymbol{r})}{g(r)}=\sum_{l=1}^{\infty} \frac{\mathscr{C}_{2 l}^{0}(r)}{\mathscr{C}_{0}^{0}(r)} Y_{2 l}^{0}(\cos \theta) \tag{4.1}
\end{equation*}
$$

where

$$
\begin{equation*}
g(r)=\mathscr{C}_{0}^{0}(r)=\int_{0}^{\pi} d \theta \sin \theta g(\boldsymbol{r}) \tag{4.2}
\end{equation*}
$$

Applying the orthogonality of Legendre polynomials to 4.1), we get

$$
\begin{equation*}
\frac{\mathscr{C}_{2}^{0}(r)}{\mathscr{C}_{0}^{0}(r)}=\frac{5}{2} \frac{\int_{0}^{\pi} d \theta \sin \theta g(\boldsymbol{r}) Y_{2}^{0}(\cos \theta)}{g(r)} \tag{4.3}
\end{equation*}
$$

The corresponding value from the theory is

$$
\begin{equation*}
\left[\frac{\mathscr{C}_{2}^{0}(r)}{\mathscr{C}_{0}^{0}(r)}\right]_{\text {theory }}=\frac{5 \beta_{2} S t_{\eta}^{2}}{12} \tag{4.4}
\end{equation*}
$$

Ireland et al. (2016) plotted the ratio $\mathscr{C}_{2}^{0}(r) / \mathscr{C}_{0}^{0}(r)$ as a function of $r$ for various $S t_{\eta}>$ 0.3 . These curves show that for $r \ll \eta$, the coefficient ratio becomes independent of $r$, suggesting that both $g(\boldsymbol{r})$ and $g(r)$ have the same functionality in $r$ for sub-Kolmogorov separations. This was particularly the case for lower Stokes numbers. The current theory also predicts that for $r \ll \eta$, the coefficient ratio is independent of $r$. However, we could not directly compare the DNS and theory values of the coefficient ratio, as the theory is applicable for $S t_{\eta} \ll 1$ and the DNS values of Ireland et al. (2016) were for $S t_{\eta}>0.3$. It is evident from (4.4) that anisotropy due to gravity is small for $S t_{\eta} \ll 1$. A similar trend is noticed in the DNS of Ireland et al. (2016).

### 4.2. Time Scale of PDF $\langle P\rangle$

We have seen in Section 3 that the radial component, $\mathscr{D}_{r r}$, of the diffusivity tensor scales as $\lambda_{6} r^{2}$. Thus, a good estimate of the time over which the PDF $\langle P\rangle$ evolves may be obtained using the coefficient $\lambda_{6}$ which has the dimensions of inverse time. To calculate $\lambda_{6}$ from (2.67), we need the energy spectrum $E(\kappa)$. A fully analytical and universal result may be obtained by using the following dimensionless form of $E(\kappa)$-valid in the limit $R e_{\lambda} \rightarrow \infty$-that follows from Kolmogorov's first similarity hypothesis (Pope 2000).

$$
\begin{gather*}
\frac{E(\kappa \eta)}{\eta u_{\eta}^{2}}=1.5(\kappa \eta)^{-5 / 3} f_{\eta}(\kappa \eta)  \tag{4.5}\\
f_{\eta}(\kappa \eta)=\exp \left\{-5.2\left(\left[(\kappa \eta)^{4}+c_{\eta}^{4}\right]^{1 / 4}-c_{\eta}\right)\right\} \tag{4.6}
\end{gather*}
$$

where $c_{\eta} \approx 0.4$ for $R e_{\lambda} \rightarrow \infty$, and $\eta$ and $u_{\eta}$ are the Kolmogorov length and velocity scales. The integral in (2.67) is then evaluated through numerical quadrature. The characteristic time scale of $\langle P\rangle$ is thus obtained to be $\approx 1.43118 \times\left(S t_{\eta} / F r\right) \times \tau_{\eta} \gg \eta / g \tau_{v}$. Thus, the PDF evolves over time scales that are much longer than the settling time of a pair through a Kolmogorov-scale eddy.

### 4.3. Prediction of Clustering through Universal Scaling

The first drift closure DF1, and the diffusion flux have the advantage that the only statistical input they require is the energy spectrum $E(\kappa)$. In contrast, DF2 requires the correlation length scales of dissipation rate and enstrophy as well. The spectrum in (4.5) enables us to obtain universal values of the drift and diffusion fluxes. To determine the power law exponent $\beta_{2}$ for the spatial clustering of particles, we first non-dimensionalize the drift and diffusion fluxes using the Kolmogorov length and time scales. We then substitute (4.5) into the integrals in (2.29) and (2.30) for $\lambda_{1}$ and $\lambda_{2}$ of DF1 and also in (2.65) and (2.67) for the diffusion flux. Finally, the integrals are evaluated through numerical quadrature.

The $\beta_{2}$ 's obtained using the above process are shown as a function of Stokes number in figure 1. Also shown are the DNS data from Ireland et al. (2016) both with and without gravity $\left(F r=0.052\right.$ and $F r=\infty$, respectively) at $R e_{\lambda}=398$. We see that the theorypredicted $\beta_{2}$ 's are lower than the DNS values for both $F r=0.052$ and $F r=\infty$. It may noted that the theory is derived for $F r \ll 1$. In addition, DF1 does not capture the two-time auto- and cross-correlations of strain-rate and rotation-rate invariants, which constitute the mechanisms responsible for particle clustering.

In the Part II paper, we present a direct comparison of theory predictions of particle clustering with our DNS data. Results obtained using both DF1 and DF2 will be presented. Turbulence and particle statistics needed as inputs to the theory will be obtained from the DNS runs. The dependence of clustering on both separation and angular direction will be quantified.

## 5. Conclusions

In Part I of this two-part study, we presented the derivation of closures for the drift and diffusion fluxes in the PDF equation for the pair relative positions $\boldsymbol{r}$. The theory focuses on pair separations smaller than the Kolmogorov length scale, at which separations the theory approximates the fluid velocity field as being locally linear. This allows us to express the fluid velocity differences between the secondary and primary particles of a pair in terms of the fluid velocity gradient at the location of the primary particle and

Figure 1: Power-law exponent $\beta_{2}$ obtained from DF1 in conjunction with the universal energy spectrum (referred as Theory 1). Also shown are the DNS data of Ireland et al. (2016) for $F r=\infty$ and $F r=0.052$ at $R e_{\lambda}=398$.
their relative position. Drift closures are obtained by expressing the pair relative velocity $W_{i}$ as a perturbation expansion in the Stokes number $S t_{\eta}$.

The drift flux contains the time integral of the third and fourth moments of the "seen" fluid velocity gradients along the trajectories of primary particles. These moments are analytically resolved by making approximations regarding the "seen" velocity gradient. Accordingly, two closure forms, DF1 and DF2, are derived specifically for the drift flux. DF1 is based on the assumption that the fluid velocity gradient "seen" by the primary particle has a Gaussian distribution. In DF2, we assume that the "seen" strainrate and rotation-rate tensors scaled by the dissipation rate and enstrophy, respectively, are normally distributed. Unlike DF1, DF2 captures the two-time autocorrelations and cross-correlations of the strain-rate and rotation-rate invariants. Time integrals of these correlations quantify the radially inward drift flux responsible for particle clustering. Analytical form of the $\operatorname{PDF}\langle P\rangle(r, \theta)$ is then obtained with a power-law dependence on separation $r$. Analogous to the theoretical result of Chun et al. (2005) for non-settling pairs, and that of Fouxon et al. (2015) for rapidly settling pairs, the power-law exponent scales as $S t_{\eta}^{2}$. The anisotropy in clustering due to gravity is also quantified by deriving an analytical expression for the ratio of coefficients in the spherical harmonics expansion of the PDF. As observed in the DNS of Ireland et al. (2016), when $S t_{\eta}<1$, the PDF obtained from the theory is only weakly anisotropic. Predictions of particle clustering obtained from DF1 in conjunction with the universal Kolmogorov energy spectrum are
presented, and compared with the DNS data of Ireland et al. (2016). A more detailed and rigorous comparison of theory and DNS results is presented in the Part II paper.

## Appendix A. Tensorial Constraints

$$
\text { A.1. }\left\langle\sigma_{i j}(t) \sigma_{l m}\left(t^{\prime}\right)\right\rangle=\mathscr{L}_{i j l m}
$$

Gravitational acceleration induces anisotropy along the $x_{3}$ direction, but homogeneity is satisfied along the $x_{1}$ and $x_{2}$ directions. Accordingly, the fourth order tensor $A_{i j l m}$ in (2.48) may be represented as

$$
\begin{align*}
& \mathscr{L}_{i j l m}=\alpha_{1} \delta_{i j} \delta_{l m}+\alpha_{2} \delta_{i m} \delta_{j l}+\alpha_{3} \delta_{i l} \delta_{j m}+\alpha_{4} \delta_{i 3} \delta_{j 3} \delta_{l 3} \delta_{m 3}+\alpha_{5} \delta_{i 3} \delta_{j 3} \delta_{l m}+ \\
& \alpha_{6} \delta_{i 3} \delta_{l 3} \delta_{j m}+\alpha_{7} \delta_{i 3} \delta_{m 3} \delta_{j l}+\alpha_{8} \delta_{j 3} \delta_{l 3} \delta_{i m}+\alpha_{9} \delta_{j 3} \delta_{m 3} \delta_{i l}+\alpha_{10} \delta_{l 3} \delta_{m 3} \delta_{i j} \tag{A1}
\end{align*}
$$

where

$$
\begin{equation*}
\mathscr{L}_{i j l m}=\int d \boldsymbol{\kappa}\left\langle\widehat{\sigma}_{i j}(\boldsymbol{\kappa}, t) \widehat{\sigma}_{l m}^{*}(\boldsymbol{\kappa}, t)\right\rangle e^{-\mathrm{i} \boldsymbol{\kappa} \cdot \boldsymbol{x}_{g}} \tag{A2}
\end{equation*}
$$

Evaluation of the correlation $\left\langle\widehat{\sigma}_{i j}(\boldsymbol{\kappa}, t) \widehat{\sigma}_{l m}^{*}(\boldsymbol{\kappa}, t)\right\rangle$ is presented in Appendix ??. The coefficients $\alpha_{1}$ through $\alpha_{10}$ in (A1) are determined using the following criteria.

- Continuity: $\mathscr{L}_{i i l m}=0 ; \mathscr{L}_{i j m m}=0$
- Symmetry: $\mathscr{L}_{i j l m}=\mathscr{L}_{i j m l} ; \mathscr{L}_{j i l m}=\mathscr{L}_{\text {lmij }}$
- Additional Independent Equations:

$$
\begin{aligned}
\mathscr{L}_{i j i j} & =B_{1} \\
\mathscr{L}_{3333} & =B_{2} \\
\mathscr{L}_{3 j 3 j} & =B_{3}
\end{aligned}
$$

where

$$
\begin{gather*}
B_{1}=\frac{\nu}{2\langle\epsilon\rangle}\left[\frac{1}{\pi} \int d \boldsymbol{\kappa} E(\kappa) e^{-\mathrm{i} \boldsymbol{\kappa} \cdot \boldsymbol{x}_{g}}\right]  \tag{A3}\\
B_{2}=\frac{\nu}{2\langle\epsilon\rangle}\left[4 \int d \boldsymbol{\kappa} \kappa_{3}^{2} \frac{E(\kappa)}{4 \pi \kappa^{2}}\left(1-\frac{\kappa_{3}^{2}}{\kappa^{2}}\right) e^{-\mathrm{i} \boldsymbol{\kappa} \cdot \boldsymbol{x}_{g}}\right]  \tag{A4}\\
B_{3}=\frac{\nu}{2\langle\epsilon\rangle}\left[\int d \boldsymbol{\kappa} \kappa_{j} \kappa_{j} \frac{E(\kappa)}{4 \pi \kappa^{2}}\left(1+\frac{\kappa_{3}^{2}}{\kappa^{2}}\right) e^{-\mathrm{i} \boldsymbol{\kappa} \cdot \boldsymbol{x}_{g}}\right] \tag{A5}
\end{gather*}
$$

$$
\text { A.2. }\left\langle\rho_{i j}(t) \rho_{l m}\left(t^{\prime}\right)\right\rangle=\mathscr{M}_{i j l m}
$$

$\mathscr{M}_{i j l m}$ may be represented as

$$
\begin{align*}
& \mathscr{M}_{i j l m}=\beta_{1} \delta_{i j} \delta_{l m}+\beta_{2} \delta_{i m} \delta_{j l}+\beta_{3} \delta_{i l} \delta_{j m}+\beta_{4} \delta_{i 3} \delta_{j 3} \delta_{l 3} \delta_{m 3}+\beta_{5} \delta_{i 3} \delta_{j 3} \delta_{l m}+ \\
& \beta_{6} \delta_{i 3} \delta_{l 3} \delta_{j m}+\beta_{7} \delta_{i 3} \delta_{m 3} \delta_{j l}+\beta_{8} \delta_{j 3} \delta_{l 3} \delta_{i m}+\beta_{9} \delta_{j 3} \delta_{m 3} \delta_{i l}+\beta_{10} \delta_{l 3} \delta_{m 3} \delta_{i j} \tag{A6}
\end{align*}
$$

where

$$
\begin{equation*}
\mathscr{M}_{i j l m}=\int d \boldsymbol{\kappa}\left\langle\widehat{\rho}_{i j}(\boldsymbol{\kappa}, t) \widehat{\rho}_{l m}^{*}(\boldsymbol{\kappa}, t)\right\rangle e^{-\mathrm{i} \boldsymbol{\kappa} \cdot \boldsymbol{x}_{g}} \tag{A7}
\end{equation*}
$$

The unknown $\beta$ 's are determined using the following constraints.

- Continuity: $\mathscr{M}_{i i l m}=0 ; \mathscr{M}_{i j m m}=0$
- Symmetry: $\mathscr{M}_{i j l m}=\mathscr{M}_{l m i j} ; \mathscr{M}_{l m i j}=-\mathscr{M}_{i j m l}$
- Additional Independent Equations:

$$
\begin{aligned}
\mathscr{M}_{i j i j} & =C_{1} \\
\mathscr{M}_{3 j 3 j} & =C_{2}
\end{aligned}
$$

where

$$
\begin{gather*}
C_{1}=\frac{\nu}{2\langle\zeta\rangle}\left[\frac{1}{\pi} \int d \boldsymbol{\kappa} E(\kappa) e^{-\mathrm{i} \boldsymbol{\kappa} \cdot \boldsymbol{x}_{g}}\right]  \tag{A8}\\
C_{2}=\frac{\nu}{2\langle\zeta\rangle}\left[\int d \boldsymbol{\kappa} \kappa_{j} \kappa_{j} \frac{E(\kappa)}{4 \pi \kappa^{2}}\left(1+\frac{\kappa_{3}^{2}}{\kappa^{2}}\right) e^{-\mathrm{i} \boldsymbol{\kappa} \cdot \boldsymbol{x}_{g}}\right] \tag{A9}
\end{gather*}
$$

## Appendix B. Evaluation of $\left\langle\widehat{\sigma}_{i j}(\boldsymbol{\kappa}, t) \widehat{\sigma}_{l m}^{*}(\boldsymbol{\kappa}, t)\right\rangle$

Using the normalization of the strain-rate tensor defined in (2.36), we can write $\widehat{\sigma}_{i j}$ in terms of the Fourier coefficients of the fluid velocity as

$$
\begin{equation*}
\widehat{\sigma}_{i j}(\boldsymbol{\kappa}, t)=\sqrt{\frac{2 \nu}{\epsilon(t)}} \frac{1}{2}\left[\mathrm{i} \kappa_{j} \widehat{u}_{i}(\boldsymbol{\kappa}, t)+\mathrm{i} \kappa_{i} \widehat{u}_{j}(\boldsymbol{\kappa}, t)\right] \tag{B1}
\end{equation*}
$$

where $\mathrm{i}=\sqrt{-1}$. We now have

$$
\begin{array}{r}
\left\langle\widehat{\sigma}_{i j}(\boldsymbol{\kappa}, t) \widehat{\sigma}_{l m}^{*}(\boldsymbol{\kappa}, t)\right\rangle=-\frac{\nu}{2}\left\langle\frac{1}{\epsilon(t)}\left(\mathrm{i} \kappa_{j} \widehat{u}_{i}+\mathrm{i} \kappa_{i} \widehat{u}_{j}\right)\left(\mathrm{i} \kappa_{m} \widehat{u}_{l}^{*}+\mathrm{i} \kappa_{l} \widehat{u}_{m}^{*}\right)\right\rangle \\
\approx \frac{\nu}{2\langle\epsilon\rangle}\left[\kappa_{j} \kappa_{m}\left\langle\widehat{u}_{i} \widehat{u}_{l}^{*}\right\rangle+\kappa_{j} \kappa_{l}\left\langle\widehat{u}_{i} \widehat{u}_{m}^{*}\right\rangle+\kappa_{i} \kappa_{m}\left\langle\widehat{u}_{j} \widehat{u}_{l}^{*}\right\rangle+\kappa_{i} \kappa_{l}\left\langle\widehat{u}_{j} \widehat{u}_{m}^{*}\right\rangle\right] \\
=\frac{\nu}{2\langle\epsilon\rangle}\left[\kappa_{j} \kappa_{m} \Phi_{i l}(\boldsymbol{\kappa}, t)+\kappa_{j} \kappa_{l} \Phi_{i m}(\boldsymbol{\kappa}, t)+\kappa_{i} \kappa_{m} \Phi_{j l}(\boldsymbol{\kappa}, t)+\kappa_{i} \kappa_{l} \Phi_{j m}(\boldsymbol{\kappa}, t)\right] \tag{B2}
\end{array}
$$

where we have applied $\widehat{\sigma}_{l m}^{*}(\boldsymbol{\kappa}, t)=\widehat{\sigma}_{l m}(-\boldsymbol{\kappa}, t)$, and $\Phi_{i l}(\boldsymbol{\kappa}, t)=\left\langle\widehat{u}_{i}(\boldsymbol{\kappa}, t) \widehat{u}_{l}^{*}(\boldsymbol{\kappa}, t)\right\rangle$ is the velocity spectrum tensor (see equation (2.20)).

The constraint $\mathscr{L}_{i j i j}=B_{1}$ can now be obtained from ( (B2) as follows.

$$
\begin{gather*}
B_{1}=\int d \boldsymbol{\kappa}\left\langle\widehat{\sigma}_{i j}(\boldsymbol{\kappa}, t) \widehat{\sigma}_{i j}^{*}(\boldsymbol{\kappa}, t)\right\rangle e^{-\mathrm{i} \boldsymbol{\kappa} \cdot \boldsymbol{x}_{g}}= \\
\frac{\nu}{2\langle\epsilon\rangle} \int d \boldsymbol{\kappa}\left[\kappa_{j} \kappa_{j} \Phi_{i i}(\boldsymbol{\kappa}, t)+\kappa_{j} \kappa_{i} \Phi_{i j}(\boldsymbol{\kappa}, t)+\kappa_{i} \kappa_{j} \Phi_{j i}(\boldsymbol{\kappa}, t)+\kappa_{i} \kappa_{i} \Phi_{j j}(\boldsymbol{\kappa}, t)\right] e^{-\mathrm{i} \boldsymbol{\kappa} \cdot \boldsymbol{x}_{g}} \tag{B3}
\end{gather*}
$$

Using in (B3) the velocity spectrum tensor $\Phi_{i j}(\boldsymbol{\kappa}, t)$ (see equation (2.20)), it is relatively straightforward to show that $\kappa_{j} \kappa_{i} \Phi_{i j}(\kappa, t)=0$, and the remaining terms together are equal to $B_{1}$ in (A3). The integrals contained in $B_{2}$ and $B_{3}$ (equations (A4) and A5)) can be arrived at in a similar manner.

Analogous to ( (B2), we can also write

$$
\begin{gather*}
\left\langle\widehat{\sigma}_{j k}(\boldsymbol{\kappa}, t) \widehat{\sigma}_{l m}^{*}(\boldsymbol{\kappa}, t)\right\rangle= \\
\frac{\nu}{2\langle\epsilon\rangle}\left[\kappa_{k} \kappa_{m}\left\langle\Phi_{j l}(\boldsymbol{\kappa}, t)\right\rangle+\kappa_{k} \kappa_{l}\left\langle\Phi_{j m}(\boldsymbol{\kappa}, t)\right\rangle+\kappa_{j} \kappa_{m}\left\langle\Phi_{k l}(\boldsymbol{\kappa}, t)\right\rangle+\kappa_{j} \kappa_{l}\left\langle\Phi_{k m}(\boldsymbol{\kappa}, t)\right\rangle\right]  \tag{B4}\\
\left\langle\widehat{\rho}_{i j}(\boldsymbol{\kappa}, t) \widehat{\rho}_{l m}^{*}(\boldsymbol{\kappa}, t)\right\rangle= \\
\frac{\nu}{2\langle\epsilon}\left[\kappa_{j} \kappa_{m}\left\langle\Phi_{i l}(\boldsymbol{\kappa}, t)\right\rangle-\kappa_{j} \kappa_{l}\left\langle\Phi_{i m}(\boldsymbol{\kappa}, t)\right\rangle-\kappa_{i} \kappa_{m}\left\langle\Phi_{j l}(\boldsymbol{\kappa}, t)\right\rangle+\kappa_{i} \kappa_{l}\left\langle\Phi_{j m}(\boldsymbol{\kappa}, t)\right\rangle\right]  \tag{B5}\\
\left\langle\widehat{\rho}_{j k}(\boldsymbol{\kappa}, t) \widehat{\rho}_{l m}^{*}(\boldsymbol{\kappa}, t)\right\rangle= \\
\frac{\nu}{2\langle\epsilon\rangle}\left[\kappa_{k} \kappa_{m}\left\langle\Phi_{j l}(\boldsymbol{\kappa}, t)\right\rangle-\kappa_{k} \kappa_{l}\left\langle\Phi_{j m}(\boldsymbol{\kappa}, t)\right\rangle-\kappa_{j} \kappa_{m}\left\langle\Phi_{k l}(\boldsymbol{\kappa}, t)\right\rangle+\kappa_{j} \kappa_{l}\left\langle\Phi_{k m}(\boldsymbol{\kappa}, t)\right\rangle\right] \tag{B6}
\end{gather*}
$$

Appendix C. Evaluation of time integrals containing $\alpha_{1} \alpha_{1}, \alpha_{1} \alpha_{2}, \ldots$
Reproducing (2.46)

$$
\begin{gather*}
\int_{-\infty}^{t} d_{i k} d t^{\prime}=\frac{1}{4 \nu^{2}}\left\{\frac{1}{3} \delta_{i k}\left[\left\langle\epsilon^{2}\right\rangle T_{\epsilon \epsilon}+\langle\epsilon \zeta\rangle T_{\epsilon \zeta}-\langle\zeta \epsilon\rangle T_{\zeta \epsilon}-\langle\zeta \zeta\rangle T_{\zeta \zeta}\right]+\right. \\
2\left\langle\epsilon^{2}\right\rangle \int_{-\infty}^{t} \exp \left(-\frac{t-t^{\prime}}{T_{\epsilon \epsilon}}\right)\left\langle\sigma_{i j}(t) \sigma_{l m}\left(t^{\prime}\right)\right\rangle\left\langle\sigma_{j k}(t) \sigma_{l m}\left(t^{\prime}\right)\right\rangle d t^{\prime}- \\
\left.2\left\langle\zeta^{2}\right\rangle \int_{-\infty}^{t} \exp \left(-\frac{t-t^{\prime}}{T_{\zeta \zeta}}\right)\left\langle\rho_{i j}(t) \rho_{l m}\left(t^{\prime}\right)\right\rangle\left\langle\rho_{j k}(t) \rho_{l m}\left(t^{\prime}\right)\right\rangle d t^{\prime}\right\} \tag{C1}
\end{gather*}
$$

the term $\int_{-\infty}^{t} \exp \left(-\frac{t-t^{\prime}}{T_{\epsilon \epsilon}}\right)\left\langle\sigma_{i j}(t) \sigma_{l m}\left(t^{\prime}\right)\right\rangle\left\langle\sigma_{j k}(t) \sigma_{l m}\left(t^{\prime}\right)\right\rangle d t^{\prime}$, in turn, contains integrals such as (see equations (A1) and (A2 2))

$$
\begin{equation*}
\int_{-\infty}^{t} \exp \left(-\frac{t-t^{\prime}}{T_{\epsilon \epsilon}}\right) \alpha_{1} \alpha_{1} \tag{C2}
\end{equation*}
$$

which leads to integrals of the form

$$
\begin{align*}
\int_{-\infty}^{t} & \exp \left(-\frac{t-t^{\prime}}{T_{\epsilon \epsilon}}\right) e^{-\mathrm{i}\left(\boldsymbol{\kappa}+\boldsymbol{\kappa}^{\prime}\right) \cdot \boldsymbol{x}_{g}} d t^{\prime} \int d \boldsymbol{\kappa} d \boldsymbol{\kappa}^{\prime} E(\kappa) E\left(\kappa^{\prime}\right)  \tag{C3}\\
& =\int d \boldsymbol{\kappa} d \boldsymbol{\kappa}^{\prime} E(\kappa) E\left(\kappa^{\prime}\right) \frac{\left(\frac{1}{T_{\epsilon \epsilon}}\right)}{\left(\frac{1}{T_{\epsilon \epsilon}}\right)^{2}+\left[\left(\boldsymbol{\kappa}+\boldsymbol{\kappa}^{\prime}\right) \cdot \boldsymbol{g} \tau_{v}\right]^{2}} \tag{C4}
\end{align*}
$$

The integral $\int d \boldsymbol{\kappa} d \boldsymbol{\kappa}^{\prime} E(\kappa) E\left(\kappa^{\prime}\right) \times(\cdots)$ is then evaluated in spherical coordinates through numerical quadrature.

## Appendix D. Diffusion Flux Tensor Constraints

The fourth order tensor $Q_{i m j n}$ may be represented as

$$
\begin{align*}
& Q_{i m j n}=\alpha_{1} \delta_{i m} \delta_{j n}+\alpha_{2} \delta_{i n} \delta_{m j}+\alpha_{3} \delta_{i j} \delta_{m n}+\alpha_{4} \delta_{i 3} \delta_{m 3} \delta_{j 3} \delta_{n 3}+\alpha_{5} \delta_{i 3} \delta_{m 3} \delta_{j n}+ \\
& \alpha_{6} \delta_{i 3} \delta_{j 3} \delta_{m n}+\alpha_{7} \delta_{i 3} \delta_{n 3} \delta_{m j}+\alpha_{8} \delta_{i n} \delta_{m 3} \delta_{j 3}+\alpha_{9} \delta_{i j} \delta_{m 3} \delta_{n 3}+\alpha_{10} \delta_{i m} \delta_{j 3} \delta_{n 3} \tag{D1}
\end{align*}
$$

where the coefficients $\alpha_{1}$ through $\alpha_{10}$ are determined using the following criteria.

- Continuity: $Q_{i i j n}=0, Q_{i m j j}=0, Q_{i i j j}=0$
- Symmetry: $Q_{i m j n}=Q_{j m i n}, Q_{i m j n}=Q_{j n i m}$
- Additional Independent Equations:

$$
\begin{aligned}
Q_{3 m 3 m} & =\frac{\pi}{2 g \tau_{v}} \int_{\xi=0}^{\infty} \xi E(\xi) d \xi \\
Q_{i m i m} & =\frac{\pi}{g \tau_{v}} \int_{\xi=0}^{\infty} \xi E(\xi) d \xi
\end{aligned}
$$
