In the spirit of the thin-layer quantization scheme, we give the effective Shrödinger equation for a particle confined to a corrugated torus, in which the geometric potential is substantially changed by corrugation. We find the attractive wells reconstructed by the corrugation not being at identical depths, which is strikingly different from that of a corrugated nanotube, especially in the inner side of the torus. By numerically calculating the transmission probability, we find that the resonant tunneling peaks and the transmission gaps are merged and broadened by the corrugation of the inner side of torus. These results show that the quarter corrugated torus can be used not only to connect two tubes with different radiuses in different directions, but also to filter the particles with particular incident energies.

I. INTRODUCTION

With the rapid development of nanotechnology, a variety of nanostructures with complex geometries are successfully fabricated, and the related geometric effects have attracted study by both theoretical and experimental researchers^{1,2}. Specifically, the geometric effects are shown by the geometric potential^{3,4}, geometric momentum^{5,6}, geometric orbital angular momentum⁷, geometric gauge potential^{4,8,9}, geometric magnetic moment^{8,10} and so on. One of the most important geometric effects is the geometric potential that has been investigated widely. Researchers found that the geometric potential can be used to change the band-structure of the geometrically deformed systems^{11–13}, to generate localized surface states¹⁴⁻¹⁹ and prompt energy shifts^{20,21} for an electron confined to a curved surface; additionally, transport properties on a curved surface or space curve can be affected $^{21-24}$. Experimentally, the geometric po $tential^{25}$ and the geometric momentum²⁶ have been observed. These results provide evidence on the validity of the confining potential method.

A nanotube has nonvanishing curvature that contributes an attractive scalar potential for a particle moving on the tube. When the nanotube is deformed $^{14,27-29}$, the geometric potential will be substantially reconstructed by the deformation. In other words, the deformation plays an important role in the effective quantum dynamics, like Dirac comb³⁰, with attractive wells. Particularly, the geometric potential is mainly induced by the deformation, such as the case for corrugations on the $surface^{31-34}$. The corrugation extremely affects the geometric potential, and further influences the corresponding electronic transport. Usually, corrugations appear in the bend of a tube. To connect smoothly two tubes with different radiuses in different directions, we can consider a part torus with corrugation, a quarter corrugated torus particularly in the present paper.

This paper is organized as follows. In Section II, we deduce the effective quantum equation for a particle confined to a periodically corrugated torus by the confining potential approach, and analyze the associated geometric potential. In Section ??, we investigate the effects of the corrugations on transmission probability. Finally, in Section ??, the conclusions are given.

II. QUANTUM DYNAMICS OF A PARTICLE CONFINED TO A PERIODICALLY CORRUGATED TORUS

A torus reconstructed by corrugation (see Figure 1b) that is parametrized by

$$r = (r_x, r_y, r_z), \tag{1}$$

where r_x, r_y and r_z are

$$\begin{aligned}
 r_x &= r_{x_0} + r'_x, \\
 r_y &= r_{y_0} + r'_y, \\
 r_z &= r_{z_0} + r'_z,
 \end{aligned}$$
(2)

respectively, with

$$\begin{aligned} r_{x_0} &= (R + r\cos\theta)\cos\phi, \quad r'_x = \frac{\varepsilon}{2}(1 - \cos n\phi)\cos\theta\cos\phi, \\ r_{y_0} &= (R + r\cos\theta)\sin\phi, \quad r'_y = \frac{\varepsilon}{2}(1 - \cos n\phi)\cos\theta\sin\phi, \\ r_{z_0} &= r\sin\theta, \quad r'_z = \frac{\varepsilon}{2}(1 - \cos n\phi)\sin\theta, \end{aligned}$$

wherein R and ϕ are the large radius and azimuthal angle, r and θ are the small radius and polar angle of a torus (see Figure 1a), respectively, ε is the amplitude of corrugation and n denotes the period number of corrugation. The position vector $r_0 = (r_{x_0}, r_{y_0}, r_{z_0})$ describes a torus, $r = (r_x, r_y, r_z)$ describes the torus with corrugation shown in Figure 1a,b, respectively. In addition, the vector $r' = (r'_x, r'_y, r'_z)$ describes corrugation.

FIG. 1. (a) schematic of a torus with $r_0 = (r_{x_0}, r_{y_0}, r_{z_0})$; (b) schematic of a corrugated torus described by $r = (r_x, r_y, r_z)$ with n = 6. Here, R and ϕ are the large radius and azimuthal angle, and r and θ are the small radius and polar angle.

From the corrugated torus Equation (1), the two tangent unit basis vectors e_{η} , e_{ξ} and the normal unit basis vector e_n are obtained as

$$e_{\eta} = (-\cos\phi\sin\theta, -\sin\theta\sin\phi, \cos\theta),$$

$$e_{\xi} = \frac{1}{U}(-T\sin\phi + S\cos\theta\cos\phi, T\cos\phi + S\cos\theta\sin\phi, S\sin\theta), \quad (3)$$

$$e_{n} = -\frac{1}{U}(T\cos\theta\cos\phi + S\sin\phi, T\sin\theta), \quad T\cos\theta\sin\phi - S\cos\phi, T\sin\theta),$$

where

$$Q = 2r + \varepsilon - \varepsilon \cos n\phi,$$

$$S = \varepsilon n \sin n\phi,$$

$$T = 2R + Q \cos \theta,$$

$$U = \sqrt{S^2 + T^2}.$$

In addition, the position vector R of a point close to the deformed torus is then described by

$$R = r + q_3 e_n, \tag{4}$$

where q_3 is the coordinate that measures the normal distance away from the surface. According to the two position vectors r and R, with the definitions of two matric tensors $g_{ab} = \partial_a r \cdot \partial_b r$ (a, b = 1, 2) and $G_{ij} = \partial_i R \cdot \partial_j R$ (i, j = 1, 2, 3), we obtain their covariant elements as

$$g_{11} = 1, \quad g_{22} = 1, \quad g_{12} = g_{21} = 0,$$
 (5)

and

$$G_{11} = (1 - \frac{2T}{QU}q_3)^2 + \frac{4S^2\sin^2\theta}{U^4}q_3^2,$$

$$G_{12} = G_{21} = \frac{4S\sin\theta}{U^2}q_3 - [\frac{T}{QU^3} + \frac{(S^2 + U^2)\cos\theta - \varepsilon n^2T\cos n\phi}{U^5}]4S\sin\theta q_3^2, \quad (6)$$

$$G_{22} = [1 - \frac{(S^2 + U^2)\cos\theta - \varepsilon n^2T\cos n\phi}{U^3}2q_3]^2 + \frac{4S^2\sin^2\theta}{U^4}q_3^2,$$

$$G_{33} = 1, \quad G_{13} = G_{31} = G_{23} = G_{32} = 0,$$

respectively. It is straightforward to check the relationship between g and G as

$$G = f^2 g, (7)$$

where g and G are the determinants of g_{ab} and G_{ij} , respectively, and f is the rescaling factor, that is

$$f = 1 - \frac{Q(S^2 + U^2)\cos\theta - n^2 \varepsilon QT\cos n\phi + U^2 T}{QU^3} 2q_3 + \frac{(S^2 + U^2)T\cos\theta - n^2 \varepsilon T^2\cos n\phi - QS^2\sin^2\theta}{QU^4} 4q_3^2.$$
(8)

For a particle confined to the corrugated torus (see Figure 1b), we deduce the effective Schrödinger equation by the confining potential approach^{4,8,35} (i.e., the thinlayer quantization scheme^{3,7,36}), that is

$$-\frac{\hbar^2}{2m^*}\left(\frac{\partial^2}{\partial\eta^2} + \frac{\partial^2}{\partial\xi^2}\right)\psi + V_g\psi = E\psi,\tag{9}$$

where \hbar is the Plank constant divided by 2π , m^* is the effective mass of electron, η and ξ are two tangent coordinate variables of the deformed torus, ψ is the wave function describing the motion of the confined particle, E is the energy with respect to ψ , and V_g is the geometric potential induced by curvature, that is,

$$V_{g} = -\frac{\hbar^{2}}{2m} \{ \frac{4S^{2} \sin^{2} \theta}{U^{4}} + [\frac{Q(S^{2} + U^{2}) \cos \theta - T(U^{2} + n^{2} \varepsilon Q \cos n\phi)}{QU^{3}}]^{2} \}.$$
(10)

The geometric potential Equation (10) is still valid to a part deformed torus with ϕ ranging from ϕ_0 to ϕ_1 ($0 < \phi_0 < \phi_1 < 2\pi$). In practical terms, we consider two models, one is a quarter corrugated torus with n = 6and the other with n = 12 (see Figure 2c,d). For the sake of expressing convenience, a deformed tube and a quarter torus are also sketched (Figure 2a,b). The deformation of tube generates the geometric potential, like Dirac comb, attractive wells with identical depthes. The Dirac comb can be used to filter particles with particular incident energies²⁹. It is obvious that the quarter torus can connect two tubes with identical radiuses in different directions. The rest two quarter deformed toruses own the two features simultaneously. In what follows, we will discuss the properties of geometric potential of the quarter corrugated torus.

FIG. 2. (a) schematic of a deformed tube; (b) schematic of a quarter torus; (c) schematic of a quarter corrugated torus with n = 6; (d) schematic of a quarter corrugated torus with n = 12.

For a corrugated tube (see Figure 2a), the geometric potential is determined by the radius of tube, the periodic length and the amplitude of corrugation together. As the periodic length is fixed, it is easy to check that the amplitude is larger, and the attractive wells are deeper. When the amplitude of corrugation is fixed, it is easy to confirm that the periodic length is longer, and the wells are shallower. The corrugation can create a Dirac comb for the particle passing the deformed torus. In order to learn the differences in the four cases described in Figure 2a-d, the corresponding four geometric potentials are sketched in Figure 3a-d, respectively. In the case of a quarter torus, the geometric potential well is minimal at $\theta = \pi$, and it does not change by varying the azimuthal angle ϕ . This result means that the inner side of the quarter torus is more capable of attracting particles. According to the figures of the geometric potential versus θ and ϕ shown in Figure 3c,d, it is easy to see that the geometric potentials take their minima at $\theta = \pi$, $\phi = (i + 1/2)\frac{\pi}{3}$ and $\phi = (i + 1/2)\frac{\pi}{6}$ with $(i = 0, 1, 2, \dots)$ for n = 6, 12, respectively. The minima of the geometric potential can be in general expressed by

$$V_{g_m} = -\frac{\hbar^2}{8m^*} \left[\frac{1}{R-r-\varepsilon} + \frac{1}{r+\varepsilon} - \frac{n^2\varepsilon}{2(R-r-\varepsilon)^2}\right]^2.$$
(11)

It is obvious that the minima depends on curvature. For the quarter torus with corrugation, the geometric potential looks like the Dirac comb³⁰ that can affect the transport of the electron confined to the particular quarter torus. When the variable θ is far away from π , the wells sharply become shallow. These results are useful to control the electronic transport by tailoring the quarter

corrugated torus further. In what follows, we will consider the geometric effects of the quarter corrugated torus on transmission probability to illustrate the deduction.

FIG. 3. (a) the geometric potential versus θ and ϕ for a corrugated tube of r = 2 and $\varepsilon = 1$; (b) the geometric potential versus θ and ϕ for a quarter torus of R = 4 and r = 2; (c) the geometric potential versus θ and ϕ for a quarter corrugated torus with R = 4, r = 2, $\varepsilon = 1$ and n = 6; (d) the geometric potential versus θ and ϕ for a quarter corrugated torus with R = 4, r = 2, $\varepsilon = 1$ and n = 12. Here, $\frac{\hbar^2}{2m^*}$ is taken as an unit.

III. TRANSMISSION PROBABILITY IN PERIODICALLY CORRUGATED TORUSES

In terms of the quarter corrugated torus, from left to right, the head skirt can be taken as a free electron beam source, the first connection between the head skirt and the deformed torus plays the role of a barrier, the central part is a quarter corrugated torus that can provides a geometric potential, the second connection between the central part and the foot skirt can be taken as the other barrier, and the foot skirt plays the role of a drain. This system in the ϕ direction can be simplified as a model that has the form as^{34,37} (see Figure 4) which consists of two leads, two barriers and a geometric potential.

FIG. 4. A simplified model is sketched for a quarter corrugated torus connected with two skirts. R_1 describes the head skirt, R_2 and R_4 are two barriers, R_3 denotes a quarter torus with corrugations and R_5 stands for the foot skirt.

By setting the geometric potential equal to zero, the present model becomes one with double barriers. The double barriers resonant tunneling structure is a typical microstructure that attracted various investigations^{38–44}. A quarter corrugated torus is a mesostructure that has attracted much investigation, in which the geometric potential induced by curvature will substantially affect the resonant peaks created by the double barriers. For transport properties, the resonant peaks correspond to quasibound states, which are associated with geometric quantum wells. The electrons are primarily confined to a curved surface, and tend to stay in the attractive wells, but the electron has a certain probability to tunnel the corrugation, if the energy of the electron is nearly the energy eigenvale of the quansibound state. Physically, when the spatial dimension is reduced to a scale being comparable with the de Broglie wavelength of electron in the vicinity of Fermi energy, the wave nature of electron is expected to play an important role in transport properties. We will investigate four generic cases: a periodically corrugated nanotube with 1.5 periods, a quarter of a nanotorus, a quarter nanotorus with 1.5 corrugations and a quarter nanotorus with three corrugations.

For the effective quantum equation Equation (9), when θ is fixed with constant, the equation can be simplified as

$$-\frac{\hbar^2}{2m^*}\frac{d^2}{d\xi^2}\psi(\xi) + V(\xi)\psi(\xi) = E\psi(\xi), \qquad (12)$$

where m^* is the effective mass of electron, \hbar is the Planck constant divided by 2π , ψ is a wave function describing the motion of electron confined to the surface with θ being a constant, E is the energy with respect to ψ , and the potential $V(\xi)$ has the general form as

$$V(\xi) = \begin{cases} 0 \text{ meV}, & \xi \in R_1, \\ 20 \text{ meV}, & \xi \in R_2, \\ V_g(\xi), & \xi \in R_3, \\ 20 \text{ meV}, & \xi \in R_4, \\ 0 \text{ meV}, & \xi \in R_5, \end{cases}$$
(13)

wherein $V_g(\xi)$ denotes the geometric potential that is specifically expressed in Equation (10) and meV stands for milli electron volts. This simplified model has the same form of the effective Hamiltonian of a corrugated surface³⁴.

Repeating the calculation process³⁴, we first split R_3 up into segments instead of continuous variations of $V(\xi)$, in each segment $V_g(\xi)$ can be taken as a constant. Then, let us assume that R_3 consists of a sequence N_3 small segments, R_2 one segment ($N_2 = 1$) and R_4 one segment ($N_4 = 1$). It is straightforward to obtain that the total number of segments is $N = N_2 + N_3 + N_4$, and that of boundaries is N + 1. It is worthwhile to notice that the tangent variable ξ in the *j*-th segment of R_3 should be replaced by ξ_j , which can be described by

$$\xi_j = \frac{1}{2} \int_{\phi_{j-1}}^{\phi_j} \sqrt{T^2 + S^2} d\phi, \qquad (14)$$

with $T = 2R + (2r + \varepsilon - \varepsilon \cos n\phi) \cos \theta$ and $S = \varepsilon n \sin n\phi$. This integrated function is more complex than that of a corrugated surface³⁴. Based on the continuous conditions of the wave function and its first derivative, the transmission probability can be calculated for electron moving on the particular torus.

The transmission probabilities of the electron confined to the four curved surfaces described in Figure 2a–d are shown in Figure 5a–d, respectively. In these cases, the substrate is graphene in which the effective mass of electron is $m^* = 0.173m_0$ with m_0 being the static mass of an electron. Figure 5 shows that the geometric potential makes the strips of resonant tunneling peaks curved tend to the lower energy. In addition, the corrugation of nanotube and nanotorus deepens the geometric potential wells extremely, and the energy levels of the quasibound states shift downward, which means a shift of the resonant peaks to lower energy. As a result, there are more resonant peak strips shown in Figure 5. Comparing Figure 5c with Figure 5a, we find that the bent corrugated nanotube can create the resonant peak strips more than the straight one. In addition, it is apparent that the resonant peak strips are deformed by corrugation. The result is more significant than that of a corrugated surface³⁴. The deformation becomes more important when the number of corrugations is increased. As a consequence, the quarter corrugated nanotorus can be not only employed to connect different nanotubes, but also to control the electronic transport. These results become more straightforward when the two-dimensional (2D) figures describing the transmission probabilities versus the incident energy given by Figure 6. The transmission $gaps^{34,45-47}$ are deepened and emerged and the tunneling peaks^{48–50} are emerged and broadened (see Figure 6d).

FIG. 5. Transmission probability versus incident energy E and azimuthal angle ϕ for the model with $V(\xi) = 20$ meV in R_2 and R_4 , and for (a) $V_g(\xi)$ given by a corrugated tube; (b) $V_g(\xi)$ induced by a quarter torus; (c) $V_g(\xi)$ provided by a quarter torus with 1.5 corrugations; (d) $V_g(\xi)$ provided by a quarter torus with three corrugations, and $m^* = 0.173m_0$ and $\theta = \pi$ in R_3 , $m^* = m_0$, otherwise.

FIG. 6. Transmission probability versus incident energy E for the model with $V(\xi) = 20$ meV in R_2 and R_4 , and for (a) $V_g(\xi)$ given by a corrugated tube; (b) $V_g(\xi)$ induced by a quarter torus; (c) $V_g(\xi)$ provided by a quarter torus with 1.5 corrugations; (d) $V_g(\xi)$ provided by a quarter torus with 3 corrugations, and $\theta = \pi$ and $m^* = 0.173m_0$ in R_3 , $m^* = m_0$, otherwise.

In order to learn the difference between the transmission probabilities for $\theta = \pi/2$ and $\theta = \pi$, the transmission probabilities are described in the plane constructed by E and ϕ (see Figure 7). In the case of $\theta = \pi/2$, there are more resonant peak strips than that of the case of $\theta = \pi$. Those resonant peaks are generated by the boundaries constructed by different materials in which electrons have different effective masses. Comparing (c) and (d) with (a) and (b) in Figure 7, we find that the deeper wells are more capable of merging multiple resonant peaks into one. In other words, the geometric potential can broaden the width of the resonant peaks and the transmission gaps. The result can be used to tailor the deformed torus to filter the electrons with special incident energies.

For GaAs substrate with $m^* = 0.067m_0$ and graphene $m^* = 0.173m_0$, the transmission probability depending on the incident energy E is described in Figure 8, (a) $m^* = 0.067m_0$ and $\theta = \pi/2$, (b) $m^* = 0.173m_0$ and $\theta = \pi/2$, (c) $m^* = 0.067m_0$ and $\theta = \pi$ and (d) $m^* = 0.173m_0$ and $\theta = \pi$. It is obvious that the abovementioned results are more manifest in graphene than in the GaAs substrate. Generally, the geometric potential can influence the electronic transport of various materials. Specifically, for different materials, the geometric effects have a certain difference.

IV. CONCLUSIONS

In the present paper, the main result has been to obtain the effective quantum Hamiltonian for a particle con-

FIG. 7. Surface plot of the transmission probability as a function of E and ϕ for $V(\xi) = 20$ meV in R_2 and R_4 regions and in R_3 (a) n = 6 with $\theta = \pi/2$; (b) n = 12 with $\theta = \pi/2$; (c) n = 6 with $\theta = \pi$ and (d) n = 12 with $\theta = \pi$, and $m^* = 0.173m_0$, $m^* = m_0$, otherwise.

FIG. 8. Surface plot of the transmission probability as a function of E with (**a**) $m^* = 0.067m_0$ and $\theta = \pi/2$; (**b**) $m^* = 0.173m_0$ and $\theta = \pi/2$; (**c**) $m^* = 0.067m_0$ and $\theta = \pi$; (**d**) $m^* = 0.173m_0$ and $\theta = \pi$ and n = 12 in R_3 , $m^* = m_0$ elsewhere, $V(\xi) = V_g(\xi)$ in R_3 , $V(\xi) = 20$ meV in R_2 and R_4 and $V(\xi) = 0$ meV, otherwise.

fined to the corrugated torus. To illustrate the effects of the geometric potential on the electronic transmission, we numerically calculate the transmission probability. By researching four examples, a periodically corrugated nanotube, a quarter torus, a quarter torus with 1.5 corrugations and a quarter torus with three corrugations, we found that the corrugations can extremely deepen the geometric potential wells. It is worthwhile to point out that the integer values of the number of corrugations for an usual torus would be broken when the investigated models are taken as a quarter torus. Subsequently, a part of corrugated torus can be selected to include any number of corrugations, and it can be used to connect two nanotubes with different radiuses in different directions.

The corrugations of the deformed nanotube and nanotorus can deepen the attractive wells, and the resonant peaks and valleys can emerge to broaden them. In the resonant peaks of the transmission probability, electrons with particular incident energy can easily pass, while, in the transmission gaps, electrons with specific incident energy are almost reflected. Practically, we can adjust the widths of the resonant peaks and the transmission gaps by designing corrugation, which may be used to design some quantum electronic and photonic nanodevices. In the present models, the interactions between electrons
