# Linear response and moderate deviations: hierarchical approach. IV 

Boris Tsirelson

#### Abstract

The Moderate Deviations Principle (MDP) is well-understood for sums of independent random variables, worse understood for stationary random sequences, and scantily understood for random fields. Here it is established for splittable random fields integrated against test functions.

## 1 Definition, and main result formulated

The definition of a splittable random field, used in [2] and [3], is geared toward integrals $\int_{B} X_{t} \mathrm{~d} t$ of the random field $\left(X_{t}\right)_{t \in \mathbb{R}^{d}}$ over boxes $B \subset \mathbb{R}^{d}$ rather than more general integrals $\int \varphi(t) X_{t} \mathrm{~d} t$ with a test function $\varphi: \mathbb{R}^{d} \rightarrow \mathbb{R}$. In order to examine integrals with test functions, here we introduce a new definition of a splittable random field.

We still do not need random variables $X_{t}$; instead, by a random field on $\mathbb{R}^{d}$ we mean a random locally finite signed Borel measure (LFSBM) on $\mathbb{R}^{d}$, denoted (if only for convenience) by $B \mapsto \int_{B} X_{t} \mathrm{~d} t$ where $B$ runs over
bounded Borel measurable subsets of $\mathbb{R}^{d}$. The set of all such measures (LFSBMs ) is a standard measurable space; its $\sigma$-field is generated by the functions $\mu \mapsto \int f \mathrm{~d} \mu$ where $f$ runs over all compactly supported continuous functions $\mathbb{R}^{d} \rightarrow \mathbb{R}$ (or, equivalently, all bounded Borel functions with bounded support; or only indicator functions of boxes). Accordingly, a random LFSBM is a measurable map from a given probability space to the space of LFSBMs; for convenience we say "random field" instead of "random LFSBM" ${ }^{1}$ Sometimes we specify $d$ or/and $\Omega$, saying "random field on $\mathbb{R}^{d "}$, or "random field on $\mathbb{R}^{d}$ and $\Omega$ ", or "random field on $\Omega$ ". The notions "independent" and "identically distributed" for such random fields are interpreted naturally. Note that independence makes sense only for random fields on the same $\Omega$. In contrast, identically distributed random fields may live on different $\Omega$ (but the same $\left.\mathbb{R}^{d}\right)$.
1.1 Definition. A split of a random field $X\left(o n \mathbb{R}^{d}\right.$ and $\left.\Omega\right)$ is a triple of random fields $X^{0}, X^{-}, X^{+}$(all the three on $\mathbb{R}^{d}$ and the same $\tilde{\Omega}$ possibly different from $\Omega$ ) such that the two random fields $X^{-}, X^{+}$are (mutually) independent and the four random fields $X, X^{0}, X^{-}, X^{+}$are identically distributed.

Informally, a split is useful when its leak, defined below, is small. ${ }^{2}$
1.2 Definition. (a) Let $X$ be a random field on $\mathbb{R}^{d}$ and $\Omega$, and $\left(X^{0}, X^{-}, X^{+}\right)$ a split of $X$ on $\tilde{\Omega}$. The leak of this split is the random field $Y$ on $\mathbb{R}^{d}$ and $\Omega$ such that $\sqrt[3]{4 / 4} \sqrt{5}$

$$
Y_{t_{1}, \ldots, t_{d}}= \begin{cases}X_{t_{1}, \ldots, t_{d}}^{-}-X_{t_{1}, \ldots, t_{d}}^{0} & \text { when } t_{1}<0 \\ X_{t_{1}, \ldots, t_{d}}^{+}-X_{t_{1}, \ldots, t_{d}}^{0} & \text { when } t_{1} \geq 0\end{cases}
$$

that is, $\int_{A} Y_{t} \mathrm{~d} t=\int_{A}\left(X_{t}^{-}-X_{t}^{0}\right) \mathrm{d} t$ for every bounded Borel measurable set $A \subset(-\infty, 0) \times \mathbb{R}^{d-1}$, and $\int_{A} Y_{t} \mathrm{~d} t=\int_{A}\left(X_{t}^{+}-X_{t}^{0}\right) \mathrm{d} t$ for every bounded Borel measurable set $A \subset[0, \infty) \times \mathbb{R}^{d-1}$.
(b) Let $X$ be a random field on $\mathbb{R}^{d}$ and $\Omega$. A random field $Y$ on $\mathbb{R}^{d}$ and $\Omega_{1}$ is a leak for $X$, if there exists a split of $X$ on some $\tilde{\Omega}$ such that the leak of this split is distributed like $Y$ 6

[^0]Ultimately we are interested in stationary (that is, shift-invariant in distribution) random fields, but for now we waive stationary, getting in exchange a useful property, see Item 1 in the numbered list below.

The variation of a LFSBM is a locally finite Borel measure (positive, not signed). Thus, the variance of a random field is a random locally finite Borel measure; we denote it $B \mapsto \int_{B}\left|X_{t}\right| \mathrm{d} t$.

We'll define the notion "splittable random field" satisfying the following.

1. If $\left(X_{t}\right)_{t \in \mathbb{R}^{d}}$ is splittable and $\varphi: \mathbb{R}^{d} \rightarrow \mathbb{R}$ is bounded Borel measurable, then $\left(\varphi(t) X_{t}\right)_{t \in \mathbb{R}^{d}}$ is splittable 1
2. If $\left(X_{t_{1}, \ldots, t_{d}}\right)_{t_{1}, \ldots, t_{d} \in \mathbb{R}}$ is splittable and $\left(k_{1}, \ldots, k_{d}\right)$ is a permutation of $(1, \ldots, d)$, then $\left(X_{t_{k_{1}}, \ldots, t_{k_{d}}}\right)_{t_{1}, \ldots, t_{d} \in \mathbb{R}}$ is splittable ("permutation invariance") $2^{2}$
3. If $\left(X_{t}\right)_{t \in \mathbb{R}^{d}}$ is splittable and $s \in \mathbb{R}^{d}$, then $\left(X_{t+s}\right)_{t \in \mathbb{R}^{d}}$ is splittable ("shift invariance") $3^{3}$
4. If $\left(X_{t}\right)_{t \in \mathbb{R}^{d}}$ is splittable and $A \subset \mathbb{R}^{d}$ bounded Borel measurable, then $\mathbb{E} \exp \varepsilon \int_{A}\left|X_{t}\right| \mathrm{d} t<\infty$ for some $\varepsilon>0, \frac{4}{4}$ and $\mathbb{E} \int_{A} X_{t} \mathrm{~d} t=0.5$
5. If $\left(X_{t}\right)_{t \in \mathbb{R}^{d}}$ is splittable and compactly supported (that is, $\int_{\mathbb{R}^{d} \backslash B}\left|X_{t}\right| \mathrm{d} t=0$ a.s. for some bounded Borel measurable $B$ ), then there exists a splittable $\left(Y_{s}\right)_{s \in \mathbb{R}^{d-1}}$ such that $\left(\int_{-\infty}^{\infty} X_{r, s} \mathrm{~d} r\right)_{s \in \mathbb{R}^{d-1}}$ is distributed like the sum of $\left(Y_{s}\right)_{s \in \mathbb{R}^{d-1}}$ and two mutually independent random fields, one distributed like $\left(\int_{-\infty}^{0} X_{r, s} \mathrm{~d} r\right)_{s \in \mathbb{R}^{d-1}}$, the other distributed like $\left(\int_{0}^{\infty} X_{r, s} \mathrm{~d} r\right)_{s \in \mathbb{R}^{d-1}} \cdot 6$
6. In the case $d=1$ the previous item means existence of a random variable $Y$ such that $\int_{-\infty}^{\infty} X_{r} \mathrm{~d} r$ is distributed like the sum of $Y$ and two mutually independent random variables, one distributed like $\int_{-\infty}^{0} X_{r} \mathrm{~d} r$, the other distributed like $\int_{0}^{\infty} X_{r} \mathrm{~d} r$, and $\mathbb{E} \exp \varepsilon|Y|<\infty$ for some $\varepsilon>0$.
1.3 Definition. Let $d \in\{1,2, \ldots\}$ and $k \in\{1, \ldots, d\}$. A random field $\left(X_{t}\right)_{t \in \mathbb{R}^{d}}$ is $(1, k)$-splittable, if

[^1](a) for every $s \in \mathbb{R}^{k}, \sqrt{1}$
$$
\mathbb{E} \exp \int_{\left([0,1)^{k}+s\right) \times \mathbb{R}^{d-k}}\left|X_{t}\right| \mathrm{d} t \leq 2
$$
(b) $\mathbb{E} X_{t}=0$ for all $t \in \mathbb{R}^{d}$; that is, for every bounded Borel measurable set $A \subset \mathbb{R}^{d}$,
$$
\mathbb{E} \int_{A} X_{t} \mathrm{~d} t=0
$$
(this expectation is well-defined, since (a) implies $\mathbb{E} \int_{A}\left|X_{t}\right| \mathrm{d} t<\infty$ );
(c) for every $i \in\{1, \ldots, k\}$ and every $r \in \mathbb{R}$ the random field $\tilde{X}$ defined by
$$
\tilde{X}_{t_{1}, \ldots, t_{d}}=X_{t_{2}, \ldots, t_{i}, t_{1}+r, t_{i+1}, \ldots, t_{d}}
$$
has a leak $\tilde{Y}$ such that the random field $Y$ defined by ${ }^{2}$
$$
Y_{t_{1}, \ldots, t_{d}}=\tilde{Y}_{t_{k}, t_{1}, \ldots, t_{k-1}, t_{k+1}, \ldots, t_{d}}
$$
is $(1, k-1)$-splittable, provided that $k>1$; otherwise, if $k=1, Y$ is required to satisfy
$$
\mathbb{E} \exp \int_{\mathbb{R}^{d}}\left|Y_{t}\right| \mathrm{d} t \leq 2
$$
1.4 Definition. (a) Let $C \in(0, \infty)$. A random field $X=\left(X_{t}\right)_{t \in \mathbb{R}^{d}}$ is $(C, k)$-splittable, if the random field $\frac{1}{C} X=\left(\frac{1}{C} X_{t}\right)_{t \in \mathbb{R}^{d}}$ is $(1, k)$-splittable.
(b) In the case $k=d$ we say that $X$ is $C$-splittable.
(c) If $X$ is $C$-splittable for some $C \in(0, \infty)$, then we say that $X$ is splittable.
1.5 Theorem ("linear response"). For every splittable stationary random field $X$ on $\mathbb{R}^{d}$ there exists a number (evidently unique) $\sigma_{X} \in[0, \infty)$ such that for every continuous compactly supported function $\varphi: \mathbb{R}^{d} \rightarrow \mathbb{R}$ holds
$$
\lim _{\substack{r \rightarrow \infty, \lambda \rightarrow 0 \\ \lambda \log ^{d} r \rightarrow 0}} \frac{1}{r^{d} \lambda^{2}} \log \mathbb{E} \exp \lambda \int_{\mathbb{R}^{d}} \varphi\left(\frac{1}{r} t\right) X_{t} \mathrm{~d} t=\frac{1}{2}\|\varphi\|^{2} \sigma_{X}^{2}
$$
where $\|\varphi\|^{2}=\int_{\mathbb{R}^{d}} \varphi^{2}(t) \mathrm{d} t$.

[^2]1.6 Corollary (moderate deviations). For $X$ and $\varphi$ as above, if $\|\varphi\| \sigma_{X} \neq 0$, then
$$
\lim _{\substack{r \rightarrow \infty, c \rightarrow \infty \\\left(c \log ^{d} r\right)^{2} / r^{d} \rightarrow 0}} \frac{1}{c^{2}} \log \mathbb{P}\left(\int_{\mathbb{R}^{d}} \varphi\left(\frac{1}{r} t\right) X_{t} \mathrm{~d} t \geq c\|\varphi\| \sigma_{X} r^{d / 2}\right)=-\frac{1}{2} .
$$
1.7 Corollary. For $X$ and $\varphi$ as above, if $\|\varphi\| \sigma_{X} \neq 0$, then the distribution of $r^{-d / 2} \int_{\mathbb{R}^{d}} \varphi\left(\frac{1}{r} t\right) X_{t} \mathrm{~d} t$ converges (as $r \rightarrow \infty$ ) to the normal distribution $N\left(0,\|\varphi\|^{2} \sigma_{X}^{2}\right)$.

## 2 Basic observations

Notions of $(1, k)$-splittability and $(C, k)$-splittability are used in this section only (for induction in $k$ ). Further, in Sections 3 5, we use only splittability and $C$-splittability, and need only corollaries (rather than lemmas and propositions) from this section.
2.1 Proposition. If $\left(X_{t}\right)_{t \in \mathbb{R}^{d}}$ is $(1, k)$-splittable and $\varphi: \mathbb{R}^{d} \rightarrow[-1,1]$ is Borel measurable, then $\left(\varphi(t) X_{t}\right)_{t \in \mathbb{R}^{d}}$ is $(1, k)$-splittable.
2.2 Lemma. Let $\varphi: \mathbb{R}^{d} \rightarrow \mathbb{R}$ be a locally bounded Borel measurable function.
(a) If $\left(X^{0}, X^{-}, X^{+}\right)$is a split of a random field $X$, then $\left(\varphi X^{0}, \varphi X^{-}, \varphi X^{+}\right)$ is a split of the random field $\varphi X=\left(\varphi(t) X_{t}\right)_{t \in \mathbb{R}^{d}}$.
(b) If $Y$ is the leak of the split $\left(X^{0}, X^{-}, X^{+}\right)$, then $\varphi Y$ is the leak of the $\operatorname{split}\left(\varphi X^{0}, \varphi X^{-}, \varphi X^{+}\right)$.
(c) If $Y$ is a leak for $X$, then $\varphi Y$ is a leak for $\varphi X$.

Proof. (a): just from Def. 1.1, (b): just from (a) and Def. 1.2(a); (c): just from (b) and Def. 1.2(b).

Proof of Prop. 2.1. Induction in $k=1, \ldots, d$. We inspect Def. 1.3(a,b,c).
(a) Just $\left|\varphi(t) X_{t}\right| \leq\left|X_{t}\right|$.
(b) First, for an indicator function $\varphi(t)=\mathbb{1}_{B}(t)$ just $\int_{A} \varphi(t) X_{t} \mathrm{~d} t=$ $\int_{A \cap B} X_{t} \mathrm{~d} t$. Second, take linear combinations of such $\varphi$. Third, take limits of such combinations.
(c) In the notation of Def. 1.3 (c) we have $\widetilde{\varphi X}=\tilde{\varphi} \tilde{X}, \tilde{\varphi}: \mathbb{R}^{d} \rightarrow[-1,1]$; by Lemma 2.2(c), $\tilde{\varphi} \tilde{X}$ has a leak $\tilde{\varphi} \tilde{Y}$; instead of $Y$ we get $\psi Y, \psi: \mathbb{R}^{d} \rightarrow[-1,1]$; and $\psi Y$ is $(1, k-1)$-splittable by the induction hypothesis, provided that $k>1$; otherwise, for $k=1$, just $\left|\psi(t) Y_{t}\right| \leq\left|Y_{t}\right|$.
2.3 Corollary. If $\left(X_{t}\right)_{t \in \mathbb{R}^{d}}$ is $C_{1}$-splittable and $\varphi: \mathbb{R}^{d} \rightarrow\left[-C_{2}, C_{2}\right]$ Borel measurable, then $\left(\varphi(t) X_{t}\right)_{t \in \mathbb{R}^{d}}$ is $C_{1} C_{2}$-splittable.

Proof. $\frac{1}{C_{1}} X$ is $(1, d)$-splittable; by Prop. 2.1, $\frac{1}{C_{2}} \varphi \frac{1}{C_{1}} X$ is $(1, d)$-splittable.
2.4 Proposition. If $\left(X_{t_{1}, \ldots, t_{d}}\right)_{t_{1}, \ldots, t_{d} \in \mathbb{R}}$ is $(1, k)$-splittable, $\left(\ell_{1}, \ldots, \ell_{k}\right)$ is a permutation of $(1, \ldots, k)$, and $s \in \mathbb{R}^{d}$, then

$$
\left(X_{t_{\ell_{1}}+s_{1}, \ldots, t_{\ell_{k}}+s_{k}, t_{k+1}+s_{k+1}, \ldots, t_{d}+s_{d}}\right)_{t_{1}, \ldots, t_{d} \in \mathbb{R}}
$$

is $(1, k)$-splittable.
Given a random field $X$ on $\mathbb{R}^{d}$ and a homeomorphism $\alpha: \mathbb{R}^{d} \rightarrow \mathbb{R}^{d}$ that preserves Lebesgue measure, we introduce the random field $X \circ \alpha$ by $\forall t \in \mathbb{R}^{d}(X \circ \alpha)_{t}=X_{\alpha(t)}$; that is, $\int_{B}(X \circ \alpha)_{t} \mathrm{~d} t=\int_{\alpha(B)} X_{t} \mathrm{~d} t$ for all bounded Borel measurable $B \subset \mathbb{R}^{d}$.

We need only coordinate permutations and shifts; that is, homeomorphisms $\alpha$ of the form $\alpha(p, s):\left(t_{1}, \ldots, t_{d}\right) \mapsto\left(t_{p(1)}+s_{1}, \ldots, t_{p(d)}+s_{d}\right)$ where $p:\{1, \ldots, d\} \rightarrow\{1, \ldots, d\}$ is a permutation, and $s \in \mathbb{R}^{d}$. These $\alpha(p, s)$ are a group of transformations. We denote by $S_{k}$ (for $k \in\{1, \ldots, d\}$ ) the subgroup of all permutations $p$ such that $p(k+1)=k+1, \ldots, p(d)=d$. We reformulate Prop. 2.4 accordingly:
(2.5) if $X$ is $(1, k)$-splittable, then $X \circ \alpha(p, s)$ is $(1, k)$-splittable whenever $p \in S_{k}$ and $s \in \mathbb{R}^{d}$.
2.6 Lemma. If $Y$ is a leak for $X$, then $Y \circ \alpha(p, s)$ is a leak for $X \circ \alpha(p, s)$ whenever $p(1)=1$ and $s_{1}=0$.

Proof. Having a split $\left(X^{0}, X^{-}, X^{+}\right)$of $X$ such that 1

$$
Y_{t_{1}, \ldots, t_{d}}= \begin{cases}X_{t_{1}, \ldots, t_{d}}^{-}-X_{t_{1}}^{0}, \ldots, t_{d} & \text { when } t_{1}<0 \\ X_{t_{1}, \ldots, t_{d}}^{+}-X_{t_{1}, \ldots, t_{d}}^{0} & \text { when } t_{1} \geq 0\end{cases}
$$

and denoting $\alpha=\alpha(p, s)$, we observe that ( $X^{0} \circ \alpha, X^{-} \circ \alpha, X^{+} \circ \alpha$ ) is a split of $X \circ \alpha$, and

$$
(Y \circ \alpha)_{t_{1}, \ldots, t_{d}}= \begin{cases}\left(X^{-} \circ \alpha\right)_{t_{1}, \ldots, t_{d}}-\left(X^{0} \circ \alpha\right)_{t_{1}, \ldots, t_{d}} & \text { when } t_{1}<0 \\ \left(X^{+} \circ \alpha\right)_{t_{1}, \ldots, t_{d}}-\left(X^{0} \circ \alpha\right)_{t_{1}, \ldots, t_{d}} & \text { when } t_{1} \geq 0 .\end{cases}
$$

Proof of Prop. 2.4. Induction in $k=1, \ldots, d$. We inspect Def. 1.3(a,b,c).
(a) $\int_{\left([0,1)^{k}+r\right) \times \mathbb{R}^{d-k}}\left|X_{\alpha(p, s)(t)}\right| \mathrm{d} t=\int_{\left([0,1)^{k}+r^{\prime}\right) \times \mathbb{R}^{d-k}}\left|X_{t}\right| \mathrm{d} t \quad$ where $r^{\prime}=\left(r_{p(1)}+s_{1}, \ldots, r_{p(k)}+s_{k}\right)$.

[^3](b) $\int_{A} X_{\alpha(p, s)(t)} \mathrm{d} t=\int_{B} X_{t} \mathrm{~d} t$ where $B=\alpha(p, s)(A)$.
(c) We introduce transformations $\beta_{i, r}$ and $\gamma_{k}$ by
$\beta_{i, r}:\left(t_{1}, \ldots, t_{d}\right) \mapsto\left(t_{2}, \ldots, t_{i}, t_{1}+r, t_{i+1}, \ldots, t_{d}\right)$,
$\gamma_{k}:\left(t_{1}, \ldots, t_{d}\right) \mapsto\left(t_{k}, t_{1}, \ldots, t_{k-1}, t_{k+1}, \ldots, t_{d}\right)$;
or, more formally, in terms of coordinate functions $f_{1}, \ldots, f_{d}: \mathbb{R}^{d} \rightarrow \mathbb{R}$, $f_{i}:\left(t_{1}, \ldots, t_{d}\right) \mapsto t_{i}$, we have $f_{1} \circ \gamma_{k}=f_{k}, f_{j} \circ \gamma_{k}=f_{j-1}$ for $j$ such that $2 \leq j \leq k$ (if any), etc. We observe in 1.3(c) that $\tilde{X}=X \circ \beta_{i, r}$ and $Y=\tilde{Y} \circ \gamma_{k}$. We have to check 1.3(c) for $X \circ \alpha(p, s)$. Given $i \in\{1, \ldots, k\}$ and $r \in \mathbb{R}$, we note that
\[

$$
\begin{equation*}
f_{i} \circ \beta_{i, r}=f_{1}+r ; \tag{2.7}
\end{equation*}
$$

\]

taking $i^{\prime}=p^{-1}(i)$ we get

$$
f_{i^{\prime}} \circ \alpha(p, s) \circ \beta_{i, r}=f_{p\left(i^{\prime}\right)} \circ \beta_{i, r}+s_{i^{\prime}}=f_{i} \circ \beta_{i, r}+s_{i^{\prime}}=f_{1}+r+s_{i^{\prime}} .
$$

We take $r^{\prime}=r+s_{i^{\prime}}$ and get

$$
f_{i^{\prime}} \circ \beta_{i^{\prime}, r^{\prime}}=f_{1}+r^{\prime}=f_{1}+r+s_{i^{\prime}} .
$$

By (2.7), $f_{1} \circ \beta_{i, r}^{-1}=f_{i}-r\left(\right.$ since $\left.f_{i}=f_{i} \circ \beta_{i, r} \circ \beta_{i, r}^{-1}=f_{1} \circ \beta_{i, r}^{-1}+r\right)$, and similarly $f_{1} \circ \beta_{i^{\prime}, r^{\prime}}^{-1}=f_{i^{\prime}}-r^{\prime}$. We introduce $\delta=\beta_{i^{\prime}, r^{\prime}}^{-1} \circ \alpha(p, s) \circ \beta_{i, r}$ and get

$$
\begin{equation*}
f_{1} \circ \delta=f_{1} \tag{2.8}
\end{equation*}
$$

(since $f_{1} \circ \delta=f_{i^{\prime}} \circ \alpha(p, s) \circ \beta_{i, r}-r^{\prime}=f_{1}$ ), which shows that $\delta$ satisfies the condition of Lemma 2.6.

Lemma 2.6 applied to $\delta$ and the leak $\tilde{Y}$ for $\tilde{X}=X \circ \beta_{i^{\prime}, r^{\prime}}$ provides a leak $\tilde{Y} \circ \delta$ for $\tilde{X} \circ \delta=X \circ \beta_{i^{\prime}, r^{\prime}} \circ \delta=X \circ \alpha(p, s) \circ \beta_{i, r}$.

Case $k=1$. The permutation $p$ is necessarily trivial; $\alpha(p, s)$ is the shift by $s ; r^{\prime}=r+s_{1} ; \delta$ is the shift by $\left(0, s_{2}, \ldots, s_{d}\right) ; Y=\tilde{Y}$; and finally $\int_{\mathbb{R}^{d}}\left|(Y \circ \delta)_{t}\right| \mathrm{d} t=\int_{\mathbb{R}^{d}}\left|Y_{t}\right| \mathrm{d} t$.

CASE $k>1$. We know that $\tilde{Y} \circ \gamma_{k}$ is $(1, k-1)$-splittable. We have $f_{1} \circ \gamma_{k}=f_{k}$, thus

$$
f_{k} \circ \gamma_{k}^{-1}=f_{1}
$$

(since $f_{1}=f_{1} \circ \gamma_{k} \circ \gamma_{k}^{-1}=f_{k} \circ \gamma_{k}^{-1}$ ). We introduce $\varepsilon=\gamma_{k}^{-1} \circ \delta \circ \gamma_{k}$ and note that

$$
f_{k} \circ \varepsilon=f_{k}
$$

(since $f_{k} \circ \varepsilon=f_{k} \circ \gamma_{k}^{-1} \circ \delta \circ \gamma_{k}=f_{1} \circ \delta \circ \gamma_{k}=f_{1} \circ \gamma_{k}=f_{k}$ ); taking into account that $f_{m} \circ \varepsilon=f_{m}$ for all $m \in\{k+1, \ldots, d\}$ (since this relation holds for $\alpha(p, s), \gamma_{k}, \beta_{i, r}$ and $\left.\beta_{i^{\prime}, r^{\prime}}\right)$ we conclude that $\varepsilon$ is of the form $\alpha\left(p^{\prime}, s^{\prime}\right)$ with $p^{\prime} \in S_{k-1}$. By the induction hypothesis, $(1, k-1)$-splittability of $\tilde{Y} \circ \gamma_{k}$ implies $(1, k-1)$-splittability of $\tilde{Y} \circ \gamma_{k} \circ \varepsilon=\tilde{Y} \circ \delta \circ \gamma_{k}$, as required.
2.9 Corollary. If $\left(X_{t_{1}, \ldots, t_{d}}\right)_{t_{1}, \ldots, t_{d} \in \mathbb{R}}$ is $C$-splittable and $\left(\ell_{1}, \ldots, \ell_{d}\right)$ is a permutation of $(1, \ldots, d)$, then $\left(X_{t_{\ell_{1}}, \ldots, t_{\ell_{d}}}\right)_{t_{1}, \ldots, t_{d} \in \mathbb{R}}$ is $C$-splittable.

Proof. $\left(\frac{1}{C} X_{t_{1}, \ldots, t_{d}}\right)_{t_{1}, \ldots, t_{d} \in \mathbb{R}}$ is (1,d)-splittable; by Prop. 2.4. $\left(\frac{1}{C} X_{t_{\ell_{1}}, \ldots, t_{\ell_{d}}}\right)_{t_{1}, \ldots, t_{d} \in \mathbb{R}}$ is $(1, d)$-splittable.
2.10 Corollary. If $\left(X_{t}\right)_{t \in \mathbb{R}^{d}}$ is $C$-splittable and $s \in \mathbb{R}^{d}$, then $\left(X_{t+s}\right)_{t \in \mathbb{R}^{d}}$ is $C$-splittable.

Proof. $\frac{1}{C} X$ is $(1, d)$-splittable; by Prop. 2.4, its shift is $(1, d)$-splittable.
2.11 Remark. If $\left(X_{t}\right)_{t \in \mathbb{R}^{d}}$ is splittable, then $\left(X_{c t}\right)_{t \in \mathbb{R}^{d}}$ is splittable whenever $c \in(0, \infty)$. This is not evident because of the unit cube used in Def. 1.3(a); but see Prop. 4.7. Moreover, $\left(X_{c_{1} t_{1}, \ldots, c_{d} t_{d}}\right)_{t_{1}, \ldots, t_{d} \in \mathbb{R}}$ is splittable whenever $c_{1}, \ldots, c_{d} \in(0, \infty)$. However, these facts will not be used here.

Let $d_{1}, d_{2} \in\{1,2, \ldots\}, d=d_{1}+d_{2}$, and $B \subset \mathbb{R}^{d_{2}}$ be a Borel measurable set. Let $X$ be a random field on $\mathbb{R}^{d}$ such that for every bounded Borel measurable set $A \subset \mathbb{R}^{d_{1}}$ holds $\int_{A \times B}\left|X_{t}\right| \mathrm{d} t<\infty$ a.s. We introduce the random field $X^{(B)}$ on $\mathbb{R}^{d_{1}}$ by

$$
X_{s}^{(B)}=\int_{B} X_{s, t} \mathrm{~d} t \quad \text { for } s \in \mathbb{R}^{d_{1}}
$$

that is,

$$
\int_{A} X_{s}^{(B)} \mathrm{d} s=\int_{A \times B} X_{t} \mathrm{~d} t \quad \text { for bounded Borel } A \subset \mathbb{R}^{d_{1}}
$$

2.12 Lemma. (a) If $\left(X^{0}, X^{-}, X^{+}\right)$is a split of $X$, then $\left(\left(X^{0}\right)^{(B)},\left(X^{-}\right)^{(B)},\left(X^{+}\right)^{(B)}\right)$ is a split of $X^{(B)}$.
(b) If $Y$ is a leak for $X$, then $Y^{(B)}$ is a leak for $X^{(B)}$.

Proof. (a) Immediate from Def. 1.1.
(b) Immediate from (a) and Def. 1.2.

Let $X$ be a $(1, k)$-splittable random field on $\mathbb{R}^{d}$, and $k<d$, and $\ell \in$ $\{1, \ldots, d-k\}$. We treat $\mathbb{R}^{d}$ as $\mathbb{R}^{d-\ell} \times \mathbb{R}^{\ell}$, consider $X^{(B)}$ for $B=\mathbb{R}^{\ell}$ and denote it $X^{\left(\mathbb{R}^{\ell}\right)}$ or just $X^{(\ell)}$; this random field on $\mathbb{R}^{d-\ell}$ is well-defined, since for bounded Borel $A \subset \mathbb{R}^{d-\ell}$ the relation " $\int_{A \times \mathbb{R}^{d-\ell}}\left|X_{t}\right| \mathrm{d} t<\infty$ a.s." follows easily from Def. 1.3(a).

By Lemma 2.12(b), for each $\ell \in\{1, \ldots, d-k\}$, if $Y$ is a leak for $X$, then $Y^{(\ell)}$ is a leak for $X^{(\ell)}$.
2.14 Lemma. If $X$ is $(1, k)$-splittable and $1 \leq \ell \leq d-k$, then $X^{(\ell)}$ is a $(1, k)$-splittable random field on $\mathbb{R}^{d-\ell}$.

Proof. Induction in $k=1, \ldots, d-\ell$. We inspect Def. 1.3(a,b,c).
(a) $\int_{\left([0,1)^{k}+s\right) \times \mathbb{R}^{d-\ell-k}}\left|X_{t}^{(\ell)}\right| \mathrm{d} t=\int_{\left([0,1)^{k}+s\right) \times \mathbb{R}^{d-\ell-k}} \mathrm{~d} t\left|\int_{\mathbb{R}^{\ell}} X_{t, r} \mathrm{~d} r\right| \leq$ $\int_{\left([0,1)^{k}+s\right) \times \mathbb{R}^{d-k}}\left|X_{t}\right| \mathrm{d} t$, thus $\mathbb{E} \exp (\ldots) \leq 2$.
(b) $\mathbb{E} X_{s}^{(\ell)}=\mathbb{E} \int_{\mathbb{R}^{\ell}} X_{s, r} \mathrm{~d} r=\int_{\mathbb{R}^{e}} \mathbb{E} X_{s, r} \mathrm{~d} r=0$.
(c) Let $i \in\{1, \ldots, k\}$ and $r \in \mathbb{R}$; we consider the random field $\widetilde{X^{(\ell)}}$ : $\widetilde{X^{(\ell)}}{ }_{t_{1}, \ldots, t_{d-\ell}}=X_{t_{2}, \ldots, t_{i}, t_{1}+r, t_{i+1}, \ldots, t_{d-\ell}}^{(\ell)}=\int_{\mathbb{R}^{\ell}} X_{t_{2}, \ldots, t_{i}, t_{1}+r, t_{i+1}, \ldots, t_{d}} \mathrm{~d} t_{d-\ell+1} \ldots \mathrm{~d} t_{d}=$ $\int_{\mathbb{R}^{\mathbb{R}}} \tilde{X}_{t_{1}, \ldots, t_{d}} \mathrm{~d} t_{d-\ell+1} \ldots \mathrm{~d} t_{d}=\tilde{X}_{t_{1}, \ldots, t_{d-\ell}}^{(\ell)} ;$ that is, $\widetilde{X^{(\ell)}}=\tilde{X}^{(\ell)}$. We have a leak $\tilde{Y}$ of $\tilde{X}$; by (2.13), $\tilde{Y}^{(\ell)}$ is a leak of $\tilde{X}^{(\ell)}$. Now, $(1, k-1)$-splittability of $Y$ implies $(1, k-1)$-splittability of $Y^{(\ell)}$ by the induction hypothesis, provided that $k>1$; and $Y_{t_{1}, \ldots, t_{d-\ell}}^{(\ell)}=\int_{\mathbb{R}^{\ell}} Y_{t_{1}, \ldots, t_{d}} \mathrm{~d} t_{d-\ell+1} \ldots \mathrm{~d} t_{d}=$ $\int_{\mathbb{R}^{\ell}} \tilde{Y}_{t_{k}, t_{1}, \ldots, t_{k-1}, t_{k+1}, \ldots, t_{d} \mathrm{~d} t_{d-\ell+1}} \ldots \mathrm{~d} t_{d}=\tilde{Y}_{\left.t_{k}, t_{1}, \ldots, t_{k-1}, t_{k+1}, \ldots, t_{d-\ell}\right)}^{(\ell)}$, as required. Otherwise, if $k=1$, we have $\int_{\mathbb{R}^{d-\ell}}\left|Y_{t}^{(\ell)}\right| \mathrm{d} t=\int_{\mathbb{R}^{d-\ell}} \mathrm{d} t\left|\int_{\mathbb{R}^{\ell}} Y_{t, r} \mathrm{~d} r\right| \leq \int_{\mathbb{R}^{d}}\left|Y_{t}\right| \mathrm{d} t$, thus $\mathbb{E} \exp (\cdot) \leq 2$.
2.15 Corollary. If $X$ is $(C, k)$-splittable on $\mathbb{R}^{d}$ and $k<d$, then $X^{(d-k)}$ is $C$-splittable on $\mathbb{R}^{k}$.

Proof. Lemma 2.14 for $\ell=d-k$ gives $(1, k)$-splittability of $\frac{1}{C} X^{(d-k)}$ on $\mathbb{R}^{k}$.

This fact generalizes readily, as follows.
2.16 Corollary. Let $X$ be $(C, k)$-splittable on $\mathbb{R}^{d}, k<d$, and $B \subset \mathbb{R}^{d-k}$ a Borel measurable set. Then $X^{(B)}$ is $C$-splittable on $\mathbb{R}^{k}$.
Proof. 1 $\left.\mathbb{1}_{\mathbb{R}^{k} \times B}\right)^{(d-k)}$.
2.17 Lemma. ${ }^{2}$ Let $X$ be $C$-splittable on $\mathbb{R}^{d}$. Then $X$ has a leak $Y$ such that the random field $Z$ on $\mathbb{R}^{d-1}$ defined by $Z_{t_{1}, \ldots, t_{d-1}}=\int_{\mathbb{R}} Y_{s, t_{1}, \ldots, t_{d-1}} \mathrm{~d} s$ is $C$-splittable (on $\mathbb{R}^{d-1}$ ).

Proof. WLOG, $C=1$ (otherwise divide $X, Y, Z$ by $C$ ). Def. 1.3(c) for $k=d, i=1$ and $r=0$ gives a leak $\tilde{Y}$ for $\tilde{X}=X$ such that the random field $Y$ defined by $Y_{t_{1}, \ldots . t_{d}}=\tilde{Y}_{t_{d}, t_{1}, \ldots, t_{d-1}}$ is $(1, d-1)$-splittable. We have $Z_{t_{1}, \ldots, t_{d-1}}=\int_{\mathbb{R}} \tilde{Y}_{s, t_{1}, \ldots, t_{d-1}} \mathrm{~d} s=\int_{\mathbb{R}} Y_{t_{1}, \ldots, t_{d-1}, s} \mathrm{~d} s$, that is, $Z=Y^{(1)}$. We apply to $Y$ Corollary 2.15 with $k=d-1$ (and $C=1$ ).

[^4]2.18 Remark. Once again, the same holds for $Z$ defined by $Z_{t_{1}, \ldots, t_{d-1}}=$ $\int_{B} Y_{s, t_{1}, \ldots, t_{d-1}} \mathrm{~d} s$ whenever $B \subset \mathbb{R}$ is a Borel measurable set. (Just use Corollary 2.16 rather than 2.15, now $Z=Y^{(B)}$.)
2.19 Proposition. Let $X$ be a $C$-splittable random field on $\mathbb{R}^{d}, d>1$, $B \subset \mathbb{R}^{d-1}$ a box, and $r>0$. Then there exist random variables $U, V, W, Z$ (on some probability space) and a $C$-splittable random field $Y$ on $\mathbb{R}^{d-1}$ such that $U, V$ are (mutually) independent, $W+Z=U+V$, and
\[

$$
\begin{aligned}
U & \sim \int_{[-r, 0) \times B} X_{t} \mathrm{~d} t, \quad(\text { here " } \sim \text { " means "distributed as") } \\
V & \sim \int_{[0, r) \times B} X_{t} \mathrm{~d} t \\
W & \sim \int_{[-r, r) \times B} X_{t} \mathrm{~d} t \\
Z & \sim \int_{B} Y_{s} \mathrm{~d} s
\end{aligned}
$$
\]

Proof. WLOG, $X_{t_{1}, \ldots, t_{d}}=0$ whenever $t_{1} \notin[-r, r)$; otherwise we multiply $X$ by $\mathbb{1}_{[-r, r) \times \mathbb{R}^{d-1}}$ and use Corollary 2.3. By Item (c) of Def. 1.3 for $k=d, i=1$ and $r=0, \frac{1}{C} X$ has a leak $\frac{1}{C} \tilde{Y}$ such that the random field $\left(\tilde{Y}_{t_{d}, t_{1}, \ldots, t_{d-1}}\right)_{t_{1}, \ldots, t_{d} \in \mathbb{R}}$ is $(C, d-1)$-splittable. By Corollary 2.15 for $k=d-1$, the random field $Y=\left(\int_{\mathbb{R}} \tilde{Y}_{s, t_{1}, \ldots, t_{d-1}} \mathrm{~d} s\right)_{t_{1}, \ldots, t_{d-1} \in \mathbb{R}}=\left(\int_{\mathbb{R}} \tilde{Y}_{t_{1}, \ldots, t_{d}} \mathrm{~d} t_{1}\right)_{t_{2}, \ldots, t_{d} \in \mathbb{R}}$ is $C$-splittable on $\mathbb{R}^{d-1}$. We take a split $\left(X^{0}, X^{-}, X^{+}\right)$of $X$ whose leak is $\tilde{Y}$, and introduce

$$
\begin{aligned}
U & =\int_{[-r, 0) \times B} X_{t}^{-} \mathrm{d} t \\
V & =\int_{[0, r) \times B} X_{t}^{+} \mathrm{d} t \\
W & =\int_{[-r, r) \times B} X_{t}^{0} \mathrm{~d} t \\
Z & =\int_{[-r, r) \times B} \tilde{Y}_{t} \mathrm{~d} t=\int_{B} Y_{s} \mathrm{~d} s
\end{aligned}
$$

Independence of $X^{-}, X^{+}$implies independence of $U, V$. The equalities $\int_{[-r, 0) \times B}\left(X_{t}^{-}-X_{t}^{0}\right) \mathrm{d} t=\int_{[-r, 0) \times B} Y_{t} \mathrm{~d} t$ and $\int_{[0, r) \times B}\left(X_{t}^{+}-X_{t}^{0}\right) \mathrm{d} t=$ $\int_{[0, r) \times B} \tilde{Y}_{t} \mathrm{~d} t$ imply $U+V-W=Z$.
2.20 Remark. For $d=1$ we have no $B$, no $Y$, but $U \sim \int_{[-r, 0)} X_{t} \mathrm{~d} t, V \sim$ $\int_{[0, r)} X_{t} \mathrm{~d} t, W \sim \int_{[-r, r)} X_{t} \mathrm{~d} t$, and $\mathbb{E} \exp |Z| \leq 2$, and $\mathbb{E} Z=0$.

In the proof: $Y$ is just a random variable $\int_{\mathbb{R}} \tilde{Y}_{t} \mathrm{~d} t$, and $\mathbb{E} \exp \int_{\mathbb{R}}\left|\tilde{Y}_{t}\right| \mathrm{d} t \leq 2$; $Z=Y ;|Z| \leq \int_{\mathbb{R}}\left|\tilde{Y}_{t}\right| \mathrm{d} t$; thus $\mathbb{E} \exp |Z| \leq 2$.

## 3 Upper bounds: abstract nonsense

We consider functions $f: \cup_{d=0}^{\infty}\left(\mathbb{R} \times(0,+\infty)^{d}\right) \rightarrow[0,+\infty]$, where $\mathbb{R} \times(0,+\infty)^{0}$ means just $\mathbb{R}$. ${ }^{1}$

Informally, $f\left(\lambda ; r_{1}, \ldots, r_{d}\right)$ is intended to be an upper bound on the cumulant generating function

$$
\log \mathbb{E} \exp \frac{\lambda}{\sqrt{r_{1} \ldots r_{d}}} \int_{\left[0, r_{1}\right) \times \cdots \times\left[0, r_{d}\right)} X_{t} \mathrm{~d} t
$$

for a class of random fields $\left(X_{t}\right)_{t \in \mathbb{R}^{d}}$. Invariance (in distribution) under permutations (of coordinates $t_{1}, \ldots, t_{d}$ ) and shifts, not required of a random field, is required of the class of random fields, which motivates the first condition on $f$ :

$$
\begin{align*}
f\left(\lambda ; r_{1}, \ldots, r_{d}\right) & =f\left(\lambda ; r_{k_{1}}, \ldots, r_{k_{d}}\right)  \tag{3.1}\\
& \text { whenever }\left(k_{1}, \ldots, k_{d}\right) \text { is a permutation of }(1, \ldots, d) .
\end{align*}
$$

The second condition on $f$ ("duplication inequality") is more complicated; for its motivation see Prop. 4.3:
$f\left(\lambda ; r_{1}, \ldots, r_{d}\right) \leq \frac{2}{p} f\left(\frac{p \lambda}{\sqrt{2}} ; \frac{r_{1}}{2}, r_{2}, \ldots, r_{d}\right)+\frac{p-1}{p} f\left(-\frac{p}{p-1} \frac{\lambda}{\sqrt{r_{1}}} ; r_{2}, \ldots, r_{d}\right)$
whenever $p \in(1, \infty)$.
Here is the third (last) condition on $f$; for its motivation see Prop. 4.7:

$$
\begin{align*}
& \forall d \in\{1,2, \ldots\} \quad \forall C \in[1, \infty) \exists \varepsilon>0  \tag{3.3}\\
& \forall r_{1}, \ldots, r_{d} \in\left[\frac{1}{2} C, C\right] \quad \forall \lambda \in[-\varepsilon, \varepsilon] \quad \varepsilon^{2} f\left(\lambda ; r_{1}, \ldots, r_{d}\right) \leq \lambda^{2} .
\end{align*}
$$

More formally, for each $d \in\{0,1,2, \ldots\}$ we introduce condition $\mathcal{A}_{d}$ as follows. For $d \neq 0$ condition $\mathcal{A}_{d}$ is the conjunction of (3.1), (3.2) and (3.3) (for the given $d$ ). And condition $\mathcal{A}_{0}$ is just

$$
\begin{equation*}
\exists \varepsilon>0 \quad \forall \lambda \in[-\varepsilon, \varepsilon] \quad \varepsilon^{2} f(\lambda) \leq \lambda^{2} . \tag{3.4}
\end{equation*}
$$

3.5 Theorem. If $f$ satisfies condition $\mathcal{A}_{d}$ for all $d$, then for each $d$ there exists $C_{d}$ such that $f\left(\lambda ; r_{1}, \ldots, r_{d}\right) \leq C_{d} \lambda^{2}$ whenever $C_{d}|\lambda| \leq \sqrt{r_{1} \ldots r_{d}} \log ^{-d}\left(r_{1} \ldots r_{d}\right)$ and $\min \left(r_{1}, \ldots, r_{d}\right) \geq C_{d} .2$

[^5]This is basically Theorem 1.5 of [2], somewhat reformulated and generalized. For convenience, for each $d \in\{0,1,2, \ldots\}$ we introduce condition $\mathcal{B}_{d}$ as follows. For $d \neq 0$, condition $\mathcal{B}_{d}$ requires existence of $C_{d}$ such that $f\left(\lambda ; r_{1}, \ldots, r_{d}\right) \leq C_{d} \lambda^{2}$ whenever $C_{d}|\lambda| \leq \sqrt{r_{1} \ldots r_{d}} \log ^{-d}\left(r_{1} \ldots r_{d}\right)$ and $\min \left(r_{1}, \ldots, r_{d}\right) \geq C_{d}$. For $d=0$, condition $\mathcal{B}_{0}$ requires existence of $C_{0}$ such that $f(\lambda) \leq C_{0} \lambda^{2}$ whenever $C_{0}|\lambda| \leq 1$. Note that $\mathcal{B}_{0} \Longleftrightarrow \mathcal{A}_{0}$.

Thus, Theorem [3.5 says that $\left(\forall d \mathcal{A}_{d}\right) \Longrightarrow\left(\forall d \mathcal{B}_{d}\right)$. Induction in $d$, started with the trivial relation $\mathcal{A}_{0} \Longrightarrow \mathcal{B}_{0}$, reduces Theorem 3.5 to the following result (to be proved later).
3.6 Proposition. For each $d \in\{1,2, \ldots\}$ holds $\left(\mathcal{A}_{d} \wedge \mathcal{B}_{d-1}\right) \Longrightarrow \mathcal{B}_{d}$.

It is possible to translate nearly all calculations in 2 from the language of $f_{B}(\lambda)$ used there into the language of $f\left(\lambda ; r_{1}, \ldots, r_{d}\right)$ used here. Alternatively, we define $f_{B}(\lambda)$ in our terms:

$$
\begin{equation*}
f_{B}(\lambda)=f\left(\lambda ; \beta_{1}-\alpha_{1}, \ldots, \beta_{d}-\alpha_{d}\right) \quad \text { for } B=\left[\alpha_{1}, \beta_{1}\right] \times \cdots \times\left[\alpha_{d}, \beta_{d}\right] . \tag{3.7}
\end{equation*}
$$

We rewrite Lemma 2.4 of [2] in our terms and prove it in our framework. For simplicity we formulate it as a duplication inequality for the first coordinate, but it generalizes readily to $k$-th coordinate ( $k=1, \ldots, d$ ) due to (3.1).
3.8 Lemma. Let $f$ satisfy conditions $\mathcal{A}_{d}$ and $\mathcal{B}_{d-1}$ for a given $d \geq 1 ; r_{1} \in$ $(0, \infty) ; r_{2}, \ldots, r_{d} \in\left[C_{d-1}, \infty\right)$. Then for all $p \in(1, \infty)$ and $\lambda \in \mathbb{R}$ satisfying $C_{d-1}|\lambda| \leq \frac{p-1}{p} \sqrt{2 v} \log ^{-(d-1)} \frac{v}{r_{1}}$, where $v=r_{1} \ldots r_{d}$ (for $d=1$ read $C_{0}|\lambda| \leq$ $\frac{p-1}{p} \sqrt{2 r_{1}}$ ), holds

$$
f\left(\lambda ; 2 r_{1}, r_{2}, \ldots, r_{d}\right) \leq \frac{2}{p} f\left(\frac{p \lambda}{\sqrt{2}} ; r_{1}, \ldots, r_{d}\right)+C_{d-1} \frac{p}{p-1} \frac{\lambda^{2}}{2 r_{1}}
$$

Proof. By (3.2), $\quad f\left(\lambda ; 2 r_{1}, r_{2}, \ldots, r_{d}\right) \leq \frac{2}{p} f\left(\frac{p \lambda}{\sqrt{2}} ; r_{1}, \ldots, r_{d}\right)+$ $\frac{p-1}{p} f\left(-\frac{p}{p-1} \frac{\lambda}{\sqrt{2 r_{1}}} ; r_{2}, \ldots, r_{d}\right)$; it suffices to prove that $f\left(-\mu ; r_{2}, \ldots, r_{d}\right) \leq$ $C_{d-1} \mu^{2}$ where $\mu=\frac{p}{p-1} \frac{\lambda}{\sqrt{2 r_{1}}}$. Condition $\mathcal{B}_{d-1}$ reduces it to $C_{d-1}|\mu| \leq \sqrt{r_{2} \ldots r_{d}} \log ^{-(d-1)}\left(r_{2} \ldots r_{d}\right)$, that is, $C_{d-1}|\mu| \leq \sqrt{\frac{v}{r_{1}}} \log ^{-(d-1)} \frac{v}{r_{1}}$ (for $d=1$ read $C_{0}|\mu| \leq 1$ ); it remains to rewrite the latter in terms of $\lambda$.

This lemma is the only property of $f_{B}(\lambda)$ used in the proof of [2, Prop. 2.6]. The same proof applies to $f_{B}(\lambda)$ defined by (3.7), which gives Prop. 3.9 below. Similarly to [2, p. 5] we denote for convenience

$$
R(v)=v^{\frac{1}{d}} \quad \text { and } \quad S(v)=v^{\frac{d-1}{d}} \quad \text { for all } v \in(0, \infty) .
$$

3.9 Proposition. Let $f$ satisfy conditions $\mathcal{A}_{d}$ and $\mathcal{B}_{d-1}$ for a given $d \geq 1$, and $C$ be large enough. Then for every $\delta>0$ there exists natural $N$ such that for all $r_{1}, \ldots, r_{d} \in[C, 2 C]$ and $a \geq \frac{C}{R\left(r_{1} \ldots r_{d}\right)}$ satisfying

$$
f_{B_{0}}(\lambda) \leq a \lambda^{2} \quad \text { for all } \lambda \in[-\delta, \delta],
$$

where $B_{0}=\left[0, r_{1}\right] \times \cdots \times\left[0, r_{d}\right]$ (and $f_{B_{0}}(\lambda)$ is defined by (3.7)), the following holds for all $n_{1}, \ldots, n_{d} \in\{0,1,2 \ldots\}$ satisfying $n_{1}+\cdots+n_{d} \geq N$ :

$$
f_{B}(\lambda) \leq 2 a \lambda^{2} \quad \text { for all } \lambda \in[-\Delta, \Delta],
$$

where $B=\left[0,2^{n_{1}} r_{1}\right] \times \cdots \times\left[0,2^{n_{d}} r_{d}\right]$ and $\Delta=\frac{1}{C_{d-1}} \sqrt{\frac{1}{a} S(\operatorname{vol} B)} \log ^{-(d-1)} S(\operatorname{vol} B)$.
(For $d=1$, by convention, $\log ^{-(d-1)} S(\ldots)=1$, notwithstanding that $S(\ldots)=1$.

The formulation above is stronger than [2, Prop. 2.6] because it incorporates the fact that $N$ depends only on $d, C$ and $\delta$ noted in [2, Remark 2.7]. For completeness, here is the same result in terms of $f\left(\lambda ; r_{1}, \ldots, r_{d}\right)$.
3.9a Proposition. Let $f$ satisfy conditions $\mathcal{A}_{d}$ and $\mathcal{B}_{d-1}$ for a given $d \geq 1$, and $C$ be large enough. Then for every $\delta>0$ there exists natural $N$ such that the following holds for all $r_{1}, \ldots, r_{d} \in[C, 2 C], a \geq \frac{C}{R\left(r_{1} \ldots r_{d}\right)}, n_{1}, \ldots, n_{d}$ satisfying $n_{1}+\cdots+n_{d} \geq N$, provided that $\forall \lambda \in[-\delta, \delta] f\left(\lambda ; r_{1}, \ldots, r_{d}\right) \leq a \lambda^{2}$ :

$$
f\left(\lambda ; 2^{n_{1}} r_{1}, \ldots, 2^{n_{d}} r_{d}\right) \leq 2 a \lambda^{2} \quad \text { for all } \lambda \in[-\Delta, \Delta],
$$

where $\Delta=\frac{1}{C_{d-1}} \sqrt{\frac{1}{a} S\left(2^{n_{1}} r_{1} \ldots 2^{n_{d}} r_{d}\right)} \log ^{-(d-1)} S\left(2^{n_{1}} r_{1} \ldots 2^{n_{d}} r_{d}\right)$.
We define for convenience, as in [2, Sect. 2],

$$
f_{v, C}(\lambda)=\sup _{r_{1} \ldots r_{d}=v, \min \left(r_{1}, \ldots, r_{d}\right) \geq C} f\left(\lambda ; r_{1}, \ldots, r_{d}\right)
$$

for $v \geq C^{d}$.
Now we adapt Prop. 2.3 of [2].
3.10 Proposition. Let $f$ satisfy conditions $\mathcal{A}_{d}$ and $\mathcal{B}_{d-1}$ for a given $d \geq 1$. Then there exists $C \in(1, \infty)$ such that

$$
f_{v, C}(\lambda) \leq C \lambda^{2} \quad \text { whenever } \quad C|\lambda| \leq \sqrt{S(v)} \log ^{-(d-1)} v \text { and } v \geq C^{d}
$$

Proof. We take $C$ large enough according to Prop. 3.9a, Condition (3.3) gives $\varepsilon>0$ such that $\varepsilon^{2} f\left(\lambda ; r_{1}, \ldots, r_{d}\right) \leq \lambda^{2}$ whenever $r_{1}, \ldots, r_{d} \in[C, 2 C]$ and $|\lambda| \leq \varepsilon$. We take $\delta=\varepsilon, a=\max \left(1, \frac{1}{\varepsilon^{2}}\right)$. Prop. 3.9a gives $N$. We take $M=\max \left(2 a, 2 C \cdot 2^{N / d}\right)$. It is sufficient to prove that $f_{v, M}(\lambda) \leq M \lambda^{2}$ whenever $M|\lambda| \leq \sqrt{S(v)} \log ^{-(d-1)} v$ and $v \geq M^{d}$. That is, $f\left(\lambda ; r_{1}, \ldots, r_{d}\right) \leq$ $M \lambda^{2}$ whenever $r_{1} \ldots r_{d}=v, r_{1}, \ldots, r_{d} \geq M$.

Given such $r_{1}, \ldots, r_{d}$, we have $r_{1}, \ldots, r_{d} \geq M \geq C$; Lemma [3, 3.1] gives $n_{1}, \ldots, n_{d}$ such that $2^{-n_{1}} r_{1}, \ldots, 2^{-n_{d}} r_{d} \in[C, 2 C)$ and $2^{-d} r_{1} \ldots r_{d}<$ $C^{d} 2^{n_{1}+\cdots+n_{d}}$, whence $2^{n_{1}+\cdots+n_{d}}>(2 C)^{-d} r_{1} \ldots r_{d} \geq(2 C)^{-d} M^{d} \geq 2^{N}$ and so, $n_{1}+\cdots+n_{d}>N$.

Taking into account that $f\left(\lambda ; 2^{-n_{1}} r_{1}, \ldots, 2^{-n_{d}} r_{d}\right) \leq \frac{1}{\varepsilon^{2}} \lambda^{2} \leq a \lambda^{2}$ for
 $2^{-n_{1}} r_{1}, \ldots, 2^{-n_{d}} r_{d}$, getting $f\left(\lambda ; r_{1}, \ldots, r_{d}\right) \leq 2 a \lambda^{2} \leq M \lambda^{2}$ as needed.

Toward proving Prop. 3.6 we assume $\mathcal{A}_{d}$ and $\mathcal{B}_{d-1}$ for a given $d \geq 1$; we need to deduce $\mathcal{B}_{d}$. Prop. 3.10 gives a constant $C$; denote it $C_{3.10}$. WLOG, $C_{3.10} \geq C_{d-1}$. We define for convenience, as in [2, Sect. 3],

$$
f_{v}(\lambda)=f_{v, C_{3.10}}(\lambda)=\sup _{r_{1} \ldots r_{d}=v, \min \left(r_{1}, \ldots, r_{d}\right) \geq C_{3.10}} f\left(\lambda ; r_{1}, \ldots, r_{d}\right) \quad \text { for } v \geq C_{3.10}^{d}
$$

and adapt Lemma 3.2 of [2].
3.11 Lemma. For all $p \in(1, \infty)$,

$$
f_{2 v}(\lambda) \leq \frac{2}{p} f_{v}\left(\frac{p \lambda}{\sqrt{2}}\right)+C_{d-1} \frac{p}{p-1} \cdot \frac{\lambda^{2}}{R(2 v)}
$$

whenever $C_{d-1}|\lambda| \leq \frac{p-1}{p} \sqrt{2 v} \log ^{-(d-1)} S(2 v)$ and $2 v \geq\left(2 C_{3.10}\right)^{d}$.
Proof. Given $r_{1}, \ldots, r_{d} \in\left[C_{3.10}, \infty\right)$ such that $r_{1} \ldots r_{d}=2 v$, we assume that $\max \left(r_{1}, \ldots, r_{d}\right)=r_{1}$ (WLOG, due to (3.1)) and apply Lemma 3.8 to $\frac{1}{2} r_{1}, r_{2}, \ldots, r_{d}$ :

$$
f\left(\lambda ; r_{1}, \ldots, r_{d}\right) \leq \frac{2}{p} f\left(\frac{p \lambda}{\sqrt{2}} ; \frac{r_{1}}{2}, r_{2}, \ldots, r_{d}\right)+C_{d-1} \frac{p}{p-1} \frac{\lambda^{2}}{r_{1}}
$$

for $C_{d-1}|\lambda| \leq \frac{p-1}{p} \sqrt{2 v} \log ^{-(d-1)} \frac{2 v}{r_{1}}$. We note that $r_{1} \geq R(2 v) \geq R\left(\left(2 C_{3.10}\right)^{d}\right)=$ $2 C_{3.10}$, thus $f\left(\frac{p \lambda}{\sqrt{2}} ; \frac{r_{1}}{2}, r_{2}, \ldots, r_{d}\right) \leq f_{v}\left(\frac{p \lambda}{\sqrt{2}}\right)$ and $\frac{\lambda^{2}}{r_{1}} \leq \frac{\lambda^{2}}{R(2 v)}$. Also, $\frac{2 v}{r_{1}} \leq \frac{2 v}{R(2 v)}=$ $S(2 v)$, thus $\log ^{-(d-1)} S(2 v) \leq \log ^{-(d-1)} \frac{2 v}{r_{1}}$.

This lemma is the only property of $f_{v}(\lambda)$ used in [2] when proving Corollaries $3.3,3.4,3.5$, Lemmas 3.9, 3.11, 3.13, 3.14, 3.16 and ultimately Prop. 3.6 ( $C_{1}$ there is $C_{d-1}$ here; $C_{2}$ there is $C_{3.10}$ here; and (3.1) there is ensured by Prop. 3.10 here), which gives the following remake of [2, Prop. 3.6].
3.12 Proposition. There exists $C \in(1, \infty)$ such that for every $\lambda \in \mathbb{R}$, if $C|\lambda| \leq \sqrt{v} \log ^{-d} v$ and $v \geq C^{d}$, then $f_{v, C}(\lambda) \leq C \lambda^{2}$.

Denoting this $C$ by $C_{d}$ we get condition $\mathcal{B}_{d}$, thus deduced from $\mathcal{A}_{d}$ and $\mathcal{B}_{d-1}$. This completes the proof of Prop. 3.6 and Theorem 3.5.

## 4 Upper bounds, applied

We define for $d \in\{1,2, \ldots\}$

$$
\begin{equation*}
f\left(\lambda ; r_{1}, \ldots, r_{d}\right)=\sup _{X} \log \mathbb{E} \exp \frac{\lambda}{\sqrt{r_{1} \ldots r_{d}}} \int_{\left[0, r_{1}\right) \times \cdots \times\left[0, r_{d}\right)} X_{t} \mathrm{~d} t \tag{4.1}
\end{equation*}
$$

where the supremum is taken over all 1-splittable random fields $X$ on $\mathbb{R}^{d}$; and for $d=0$,

$$
f(\lambda)= \begin{cases}\lambda^{2} & \text { for }|\lambda| \leq 1  \tag{4.2}\\ +\infty & \text { for }|\lambda|>1\end{cases}
$$

Condition (3.1) is satisfied due to Corollary 2.9.
4.3 Proposition. Condition (3.2) is satisfied.

We borrow a general fact [4, Lemma 1.7].
4.4 Lemma. For all random variables $X, Y$ and all $p \in(1, \infty)$, $p \log \mathbb{E} \exp \frac{1}{p} X-(p-1) \log \mathbb{E} \exp \left(-\frac{1}{p-1} Y\right) \leq$

$$
\leq \log \mathbb{E} \exp (X+Y) \leq \frac{1}{p} \log \mathbb{E} \exp p X+\frac{p-1}{p} \log \mathbb{E} \exp \frac{p}{p-1} Y
$$

(In the lower bound we interpret $\infty-\infty$ as $-\infty$.)
Proof. By the Hölder inequality,
$\mathbb{E} \exp (X+Y)=\mathbb{E}(\exp X \cdot \exp Y) \leq(\mathbb{E} \exp p X)^{1 / p}\left(\mathbb{E} \exp \frac{p}{p-1} Y\right)^{(p-1) / p} ;$
the upper bound follows. We apply the upper bound to $\frac{1}{p}(X+Y)$ and $\left(-\frac{1}{p} Y\right)$ instead of $X, Y$ :

$$
\log \mathbb{E} \exp \frac{1}{p} X \leq \frac{1}{p} \log \mathbb{E} \exp (X+Y)+\frac{p-1}{p} \log \mathbb{E} \exp \left(-\frac{1}{p-1} Y\right)
$$

the lower bound follows.
4.5 Lemma. Let $X$ be a 1 -splittable random field on $\mathbb{R}^{d}, d>1, r, r_{2}, \ldots, r_{d}>$ 0 , and $B=\left[0, r_{2}\right) \times \cdots \times\left[0, r_{d}\right) \subset \mathbb{R}^{d-1}$. Then for all $\lambda \in \mathbb{R}$ hold $\left.]^{1}\right]$

$$
\begin{aligned}
& p \log \mathbb{E} \exp \frac{\lambda}{p} \int_{[-r, 0) \times B} X_{t} \mathrm{~d} t+p \log \mathbb{E} \exp \frac{\lambda}{p} \int_{[0, r) \times B} X_{t} \mathrm{~d} t- \\
& \quad-(p-1) f\left(\frac{\lambda}{p-1} \sqrt{\operatorname{vol} B} ; r_{2}, \ldots, r_{d}\right) \leq \\
& \leq \log \mathbb{E} \exp \lambda \int_{[-r, r) \times B} X_{t} \mathrm{~d} t \leq \frac{1}{p} \log \mathbb{E} \exp p \lambda \int_{[-r, 0) \times B} X_{t} \mathrm{~d} t+ \\
& +\frac{1}{p} \log \mathbb{E} \exp p \lambda \int_{[0, r) \times B} X_{t} \mathrm{~d} t+\frac{p-1}{p} f\left(-\frac{p}{p-1} \lambda \sqrt{\operatorname{vol} B} ; r_{2}, \ldots, r_{d}\right) .
\end{aligned}
$$

Proof. Prop. 2.19 gives a 1-splittable random field $Y$ on $\mathbb{R}^{d-1}$ and random variables $U, V, W, Z$ such that $U, V$ are independent, $W+Z=U+V$, and $U \sim \int_{[-r, 0) \times B} X_{t} \mathrm{~d} t, V \sim \int_{[0, r) \times B} X_{t} \mathrm{~d} t, W \sim \int_{[-r, r) \times B} X_{t} \mathrm{~d} t, Z \sim \int_{B} Y_{s} \mathrm{~d} s$. It remains to apply Lemma 4.4 to $X=\lambda(U+V), Y=-\lambda Z$ and use independence of $U, V$.

Another general fact, borrowed from [1, Lemma 2a8] (see also [2, Lemma 1.8]: for arbitrary random variable $Z$,
(4.6) if $\mathbb{E} \exp |Z| \leq 2$ and $\mathbb{E} Z=0$, then $\forall \lambda \in[-1,1] \log \mathbb{E} \exp \lambda Z \leq \lambda^{2}$.

Proof of Prop. 4.3. For $d>1$, Lemma 4.5 (the upper bound) applied to $r=\frac{1}{2} r_{1}$ and $\frac{\lambda}{\sqrt{r_{1} \ldots r_{d}}}$ instead of $\lambda$ gives

$$
\begin{aligned}
& \log \mathbb{E} \exp \frac{\lambda}{\sqrt{r_{1} \ldots r_{d}}} \int_{[-r, r) \times B} X_{t} \mathrm{~d} t \leq \frac{1}{p} \log \mathbb{E} \exp \frac{p \lambda}{\sqrt{r_{1} \ldots r_{d}}} \int_{[-r, 0) \times B} X_{t} \mathrm{~d} t+ \\
&+\frac{1}{p} \log \mathbb{E} \exp \frac{p \lambda}{\sqrt{r_{1} \ldots r_{d}}} \int_{[0, r) \times B} X_{t} \mathrm{~d} t+\frac{p-1}{p} f\left(-\frac{p}{p-1} \frac{\lambda}{\sqrt{r_{1}}} ; r_{2}, \ldots, r_{d}\right)
\end{aligned}
$$

the first term (in the right-hand side) does not exceed $\frac{1}{p} f\left(\frac{p \lambda}{\sqrt{2}} ; \frac{1}{2} r_{1}, r_{2}, \ldots, r_{d}\right)$; the same holds for the second term. It remains to take the supremum over all 1-splittable random fields $X$ on $\mathbb{R}^{d}$.

For $d=1$, Remark 2.20 gives $(U, V, W$ and) $Z$ such that $\mathbb{E} \exp |Z| \leq 2$ and $\mathbb{E} Z=0$. By (4.2) and (4.6), $\log \mathbb{E} \exp \lambda Z \leq f(\lambda)$ for all $\lambda$ (and all relevant $Z)$, and so, $\log \mathbb{E} \exp \frac{\lambda}{\sqrt{r}} W \leq \frac{2}{p} f\left(\frac{p \lambda}{\sqrt{2}} ; \frac{1}{2} r\right)+\frac{p-1}{p} f\left(-\frac{p}{p-1} \frac{\lambda}{\sqrt{r}}\right)$.
4.7 Proposition. Condition (3.3) is satisfied.

[^6]We introduce $\varphi:(0, \infty)^{d} \rightarrow[0, \infty]$ by

$$
\varphi\left(r_{1}, \ldots, r_{d}\right)=\limsup _{\lambda \rightarrow 0} f\left(\lambda ; r_{1}, \ldots, r_{d}\right)
$$

and prove that this function is identically zero. Note that $\varphi\left(r_{1}, \ldots, r_{d}\right)=$ $\limsup _{\lambda \rightarrow 0} f\left(\lambda \sqrt{r_{1}, \ldots, r_{d}} ; r_{1}, \ldots, r_{d}\right)$, and $f\left(\lambda \sqrt{r_{1}, \ldots, r_{d}} ; r_{1}, \ldots, r_{d}\right)=$ $\sup _{X} \log \mathbb{E} \exp \lambda \int_{\left[0, r_{1}\right) \times \cdots \times\left[0, r_{d}\right)} X_{t} \mathrm{~d} t=\log \sup _{X} \mathbb{E} \exp \lambda \int_{\left[0, r_{1}\right) \times \cdots \times\left[0, r_{d}\right)} X_{t} \mathrm{~d} t$.
4.8 Lemma. The function $\varphi$ is increasing.

Proof. Given $r_{1} \leq s_{1}, \ldots, r_{d} \leq s_{d}$ and a 1 -splittable $X$, we note that $Y=$ $X \cdot \mathbb{1}_{\left[0, r_{1}\right) \times \cdots \times\left[0, r_{d}\right)}$ is 1-splittable by Corollary 2.3, and $\int_{\left[0, s_{1}\right) \times \cdots \times\left[0, s_{d}\right]} Y_{t} \mathrm{~d} t=$ $\int_{\left[0, r_{1}\right) \times \cdots \times\left[0, r_{d}\right]} X_{t} \mathrm{~d} t$, whence $\log \mathbb{E} \exp \lambda \int_{\left[0, r_{1}\right) \times \cdots \times\left[0, r_{d}\right)} X_{t} \mathrm{~d} t=$
$\log \mathbb{E} \exp \lambda \int_{\left[0, s_{1}\right) \times \cdots \times\left[0, s_{d}\right)} Y_{t} \mathrm{~d} t \leq f\left(\lambda \sqrt{s_{1}, \ldots, s_{d}} ; s_{1}, \ldots, s_{d}\right) ;$ supremum in $X$ gives $f\left(\lambda \sqrt{r_{1}, \ldots, r_{d}} ; r_{1}, \ldots, r_{d}\right) \leq f\left(\lambda \sqrt{s_{1}, \ldots, s_{d}} ; s_{1}, \ldots, s_{d}\right)$; limsup in $\lambda$ gives $\varphi\left(r_{1}, \ldots, r_{d}\right) \leq \varphi\left(s_{1}, \ldots, s_{d}\right)$.
4.9 Lemma. For arbitrary $r_{2}, \ldots, r_{d} \in(0, \infty)$ the function $\psi: r \mapsto$ $\varphi\left(r, r_{2}, \ldots, r_{d}\right)$ satisfies $\psi(r+s) \leq(\psi(r)+\psi(s)) / 2$ for all $r, s \in(0, \infty)$.

Proof. Denoting $B=\left[0, r_{2}\right) \times \cdots \times\left[0, r_{d}\right) \subset \mathbb{R}^{d-1}$ we have
$\mathbb{E} \exp \lambda \int_{[0, r+s) \times B} X_{t} \mathrm{~d} t=\mathbb{E} \exp \left(\lambda \int_{[0, r) \times B} X_{t} \mathrm{~d} t+\lambda \int_{[r, r+s) \times B} X_{t} \mathrm{~d} t\right) \leq$ $\left(\mathbb{E} \exp 2 \lambda \int_{[0, r) \times B} X_{t} \mathrm{~d} t\right)^{1 / 2}\left(\mathbb{E} \exp 2 \lambda \int_{[r, r+s) \times B} X_{t} \mathrm{~d} t\right)^{1 / 2} \leq$ $\exp \frac{1}{2}\left(f\left(2 \lambda ; r, r_{2}, \ldots, r_{d}\right)+f\left(2 \lambda ; s, r_{2}, \ldots, r_{d}\right)\right)$; supremum in $X$ gives $f\left(\lambda ; r+s, r_{2}, \ldots, r_{d}\right) \leq \frac{1}{2}\left(f\left(2 \lambda ; r, r_{2}, \ldots, r_{d}\right)+f\left(2 \lambda ; s, r_{2}, \ldots, r_{d}\right)\right)$, and then $\lim s u p$ in $\lambda$ gives $\psi(r+s) \leq \frac{1}{2}(\psi(r)+\psi(s))$.
4.10 Lemma. The function $\varphi$ is constant.

Proof. We'll prove that the function $\psi$ (introduced in Lemma 4.9) is constant; this is sufficient due to (3.1). For every $r \in(0, \infty)$, first, $\psi(s) \leq \psi(r)$ for all $s \in(0, r]$ by Lemma 4.8: second, $\psi(s) \leq \psi(r)$ for all $s \in(0,2 r]$ by Lemma 4.9, and so on; $\psi(s) \leq \psi(r)$ for all $s \in(0, \infty)$ and all $r \in(0, \infty)$.
4.11 Lemma. $\varphi\left(r_{1}, \ldots, r_{d}\right)=0$ for all $r_{1}, \ldots, r_{d} \in(0, \infty)$.

Proof. By Lemma 4.10 it is sufficient to prove that $\varphi(1, \ldots, 1)=0$. By Def. 1.3(a) (for $k=d$ ), $\mathbb{E} \exp \int_{[0,1)^{d}}\left|X_{t}\right| \mathrm{d} t \leq 2$ for every 1-splittable $X$. We apply (4.6), taking into account that $\mathbb{E} \int_{[0,1)^{d}} X_{t} \mathrm{~d} t=0$ by 1.3(b) and $\left|\int_{[0,1)^{d}} X_{t} \mathrm{~d} t\right| \leq \int_{[0,1)^{d}}\left|X_{t}\right| \mathrm{d} t$; we get $\log \mathbb{E} \exp \lambda \int_{[0,1)^{d}} X_{t} \mathrm{~d} t \leq \lambda^{2}$ for all $\lambda \in$ $[-1,1]$. Thus, $f(\lambda ; 1, \ldots, 1) \leq \lambda^{2}$ for these $\lambda$.

Proof of Prop. 4.7. First, a general fact. For arbitrary random variable $W$,

$$
\begin{equation*}
\text { if } \mathbb{E} \mathrm{e}^{W} \leq \frac{5}{4} \text { and } \mathbb{E} \mathrm{e}^{-W} \leq \frac{5}{4}, \quad \text { then } \mathbb{E} \mathrm{e}^{|W|} \leq 2 \tag{4.12}
\end{equation*}
$$

since $\mathrm{e}^{|W|}=\frac{4}{3}\left(\mathrm{e}^{|W|}+\mathrm{e}^{-|W|}-1\right)-\frac{1}{3}\left(\mathrm{e}^{|W| / 2}-2 \mathrm{e}^{-|W| / 2}\right)^{2} \leq \frac{4}{3}\left(\mathrm{e}^{|W|}+\mathrm{e}^{-|W|}-1\right)=$ $\frac{4}{3}\left(\mathrm{e}^{W}+\mathrm{e}^{-W}-1\right)$.

Therefore, by (4.6),
(4.13) if $\mathbb{E} \mathrm{e}^{W} \leq \frac{5}{4}, \mathbb{E} \mathrm{e}^{-W} \leq \frac{5}{4}$ and $\mathbb{E} W=0$, then

$$
\forall \lambda \in[-1,1] \quad \log \mathbb{E} \exp \lambda W \leq \lambda^{2}
$$

Applying (4.13) to $W=\frac{\varepsilon}{\sqrt{r_{1} \ldots r_{d}}} \int_{\left[0, r_{1}\right) \times\left[0, r_{d}\right)} X_{t} \mathrm{~d} t$ (and taking supremum in $X$ ) we get, for arbitrary $\varepsilon>0$,

$$
\text { if } \exp f\left( \pm \varepsilon ; r_{1}, \ldots, r_{d}\right) \leq \frac{5}{4}, \quad \text { then } \quad \forall \lambda \in[-1,1] \quad f\left(\varepsilon \lambda ; r_{1}, \ldots, r_{d}\right) \leq \lambda^{2}
$$

that is,

$$
\begin{equation*}
\forall \lambda \in[-\varepsilon, \varepsilon] \quad \varepsilon^{2} f\left(\lambda ; r_{1}, \ldots, r_{d}\right) \leq \lambda^{2} \tag{4.14}
\end{equation*}
$$

Due to Lemma 4.11, for arbitrary $r_{1}, \ldots, r_{d}$ there exists $\varepsilon>0$ such that $f\left( \pm \varepsilon ; r_{1}, \ldots, r_{d}\right) \leq \log \frac{5}{4}$, and therefore (4.14) holds.

In order to obtain a single $\varepsilon$ for all $r_{1}, \ldots, r_{d} \in\left[\frac{1}{2} C, C\right]$ we recall that $f\left(\lambda \sqrt{r_{1} \ldots r_{d}} ; r_{1}, \ldots, r_{d}\right)$ is an increasing function of $r_{1}, \ldots, r_{d}$ (as noted in the proof of Lemma 4.8). We take $\varepsilon$ such that
$\forall \lambda \in[-\varepsilon, \varepsilon] \quad \varepsilon^{2} f(\lambda ; C, \ldots, C) \leq \lambda^{2}$, that is, $\varepsilon^{2} f\left(\lambda \sqrt{C^{d}} ; C, \ldots, C\right) \leq C^{d} \lambda^{2}$ for $|\lambda| \leq C^{-d / 2} \varepsilon$; then $\varepsilon^{2} f\left(\lambda \sqrt{r_{1} \ldots r_{d}} ; r_{1}, \ldots, r_{d}\right) \leq C^{d} \lambda^{2}$ for $|\lambda| \leq C^{-d / 2} \varepsilon$, that is, $\varepsilon^{2} f\left(\lambda ; r_{1}, \ldots, r_{d}\right) \leq \frac{C^{d}}{r_{1} \ldots r_{d}} \lambda^{2}$ for $|\lambda| \leq \sqrt{r_{1} \ldots r_{d}} C^{-d / 2} \varepsilon$, which implies $\left(2^{-d / 2} \varepsilon\right)^{2} f\left(\lambda ; r_{1}, \ldots, r_{d}\right) \leq \lambda^{2}$ for $|\lambda| \leq 2^{-d / 2} \varepsilon$.

We summarize.
4.15 Theorem. The function $f$ defined by (4.1) satisfies condition $\mathcal{A}_{d}$ for all $d$.
4.16 Corollary. For each $d$ there exists $C_{d}$ such that $f\left(\lambda ; r_{1}, \ldots, r_{d}\right) \leq C_{d} \lambda^{2}$ whenever $C_{d}|\lambda| \leq \sqrt{r_{1} \ldots r_{d}} \log ^{-d}\left(r_{1} \ldots r_{d}\right)$ and $\min \left(r_{1}, \ldots, r_{d}\right) \geq C_{d}$; here $f$ is defined by (4.1).

Proof. Combine theorems 3.5 and 4.15,

## 5 Proving the main result

The term "splittable" is defined both here and in [2], and the definitions are nonequivalent. In order to avoid ambiguity, below we use either " $C$-splittable" (defined here by Def. 1.4(b) and undefined in [2]) or "uniformly splittable" (defined in [2, Def. 1.4] and undefined here).

Every $C$-splittable random field $X$ on $\mathbb{R}^{d}$ leads to a centered random field $\hat{X}$ on $\mathbb{R}^{d}$ as defined in [2, Sect. 1]; it is just the family of integrals $\int_{\left[\alpha_{1}, \beta_{1}\right) \times \cdots \times\left[\alpha_{d}, \beta_{d}\right)} X_{t} \mathrm{~d} t$ indexed by boxes $\left[\alpha_{1}, \beta_{1}\right] \times \cdots \times\left[\alpha_{d}, \beta_{d}\right] \subset \mathbb{R}^{d}$; that is,

$$
\int_{\left[\alpha_{1}, \beta_{1}\right] \times \cdots \times\left[\alpha_{d}, \beta_{d}\right]} \hat{X}_{t} \mathrm{~d} t=\int_{\left[\alpha_{1}, \beta_{1}\right) \times \cdots \times\left[\alpha_{d}, \beta_{d}\right)} X_{t} \mathrm{~d} t
$$

whenever $\alpha_{1}<\beta_{1}, \ldots, \alpha_{d}<\beta_{d}$. (If puzzled, note that the left-hand side is nothing but a conventional notation used in [2] and [3]; half-open intervals could be used there equally well.) The additivity [2, (1.1)] is evidently satisfied. The zero mean condition [2, (1.2)] is ensured by Def. [1.3(b).

If, in addition, $X$ is stationary, then $\hat{X}$ is a centered measurable stationary ("CMS") random field on $\mathbb{R}^{d}$ as defined in [2, Sect. 1] (see also [3, Sect. 1]). Stationarity is evident.
5.1 Lemma. The measurability condition [2, (1.3)] is satisfied.

Proof. For arbitrary $u_{1}, \ldots, u_{d}, v_{1}, \ldots, v_{d} \in[0, \infty)$ the symmetric difference $B \Delta B_{0}$ between boxes $B=\left[\alpha_{1}-u_{1}, \beta_{1}-v_{1}\right) \times \cdots \times\left[\alpha_{d}-u_{d}, \beta_{d}-v_{d}\right)$ and $B_{0}=\left[\alpha_{1}, \beta_{1}\right) \times \cdots \times\left[\alpha_{d}, \beta_{d}\right)$ satisfies $B \Delta B_{0}=\left(B \cup B_{0}\right) \backslash\left(B \cap B_{0}\right) \subset B_{2} \backslash B_{1}$ where $B_{2}=\left[\alpha_{1}-u_{1}, \beta_{1}\right) \times \cdots \times\left[\alpha_{d}-u_{d}, \beta_{d}\right)$ and $B_{1}=\left[\alpha_{1}, \beta_{1}-v_{1}\right) \times \cdots \times$ $\left[\alpha_{d}, \beta_{d}-v_{d}\right)$. Also, $B_{2} \backslash B_{1} \subset\left(B_{2} \backslash B\right) \cup\left(B \backslash B_{1}\right)$ (equal, in fact). Thus, $\left|\int_{B} X_{t} \mathrm{~d} t-\int_{B_{0}} X_{t} \mathrm{~d} t\right| \leq \int_{B_{2} \backslash B}\left|X_{t}\right| \mathrm{d} t+\int_{B \backslash B_{1}}\left|X_{t}\right| \mathrm{d} t$. It follows that $\int_{B} X_{t} \mathrm{~d} t$ converges to $\int_{B_{0}} X_{t} \mathrm{~d} t$ (as $u_{1}, \ldots, u_{d}, v_{1}, \ldots, v_{d} \rightarrow 0+$ ) almost surely, therefore, in distribution. By stationarity, $\int_{\left[\alpha_{1}, \beta_{1}+u_{1}-v_{1}\right) \times \cdots \times\left[\alpha_{d}, \beta_{d}+u_{d}-v_{d}\right)} X_{t} \mathrm{~d} t$ is distributed like $\int_{B} X_{t} \mathrm{~d} t$ and therefore converges to $\int_{B_{0}} X_{t} \mathrm{~d} t$ in distribution. It shows that $\int_{\left[\alpha_{1}, \beta_{1}+w_{1}\right) \times \cdots \times\left[\alpha_{d}, \beta_{d}+w_{d}\right)} X_{t} \mathrm{~d} t$ converges to $\int_{B_{0}} X_{t} \mathrm{~d} t$ in distribution as $w_{1}, \ldots, w_{d} \rightarrow 0$ (not " $\rightarrow 0+$ " this time). Thus, the distribution of $\int_{\left[0, r_{1}\right) \times \cdots \times\left[0, r_{d}\right)} X_{t} \mathrm{~d} t$ as a function of $r_{1}, \ldots, r_{d}$ is continuous, therefore Borel measurable.

For every $d \in\{1,2, \ldots\}$ and $C \in(0, \infty)$ we consider the set $\operatorname{Spl}_{C}(d)$ of all $C$-splittable random fields on $\mathbb{R}^{d}$, and the family $(\hat{X})_{X \in \operatorname{Spl}_{C}(d)}$ of the corresponding centered random fields on $\mathbb{R}^{d}$.

Uniform splittability is defined (in [2]) by recursion in dimension $d \in$ $\{0,1,2, \ldots\}$, treating a centered random field on $\mathbb{R}^{0}$ as just a single random
variable of zero mean. Accordingly we define $\operatorname{Spl}_{C}(0)$ as the set of all random variables $X$ such that $\mathbb{E} \exp \frac{1}{C}|X| \leq 2$ and $\mathbb{E} X=0$. (See also the last line of Def. 1.3(c).) For $X \in \operatorname{Spl}_{C}(0)$ we define just $\hat{X}=X$.
5.2 Proposition. For every $d \in\{0,1,2, \ldots\}$ and $C \in(0, \infty)$ the family $(\hat{X})_{X \in \operatorname{Spl}_{C}(d)}$ is uniformly splittable.
5.3 Lemma. Let $X$ be a random field on $\mathbb{R}^{d},\left(X^{-}, X^{+}, X^{0}\right)$ a split of $X$, and $Y$ the leak of this split. Then, in terms of [2], $\left(\widehat{X^{-}}, \widehat{X^{+}}, \widehat{X^{0}}\right)$ is a split of $\hat{X}$, and its leak along the hyperplane $\{0\} \times \mathbb{R}^{d-1}$ on a strip $[a, b] \times \mathbb{R}^{d-1}$ (for arbitrary $a<0, b>0$ ) is $\hat{U}$ where $U$ is a random field on $\mathbb{R}^{d-1}$ defined by $U_{t_{2}, \ldots, t_{d}}=\int_{[a, b)} Y_{t_{1}, \ldots, t_{d}} \mathrm{~d} t_{1}$.

Proof. ${ }^{1}$ Clearly, $\left(\widehat{X^{-}}, \widehat{X^{+}}, \widehat{X^{0}}\right)$ is a split of $\hat{X}$. Its leak $Z$ on the given strip is defined (in [2, p. 2]) by

$$
\begin{aligned}
& \int_{\left[\alpha_{2}, \beta_{2}\right] \times \cdots \times\left[\alpha_{d}, \beta_{d}\right]} Z(t) \mathrm{d} t=\int_{[a, 0] \times\left[\alpha_{2}, \beta_{2}\right] \times \cdots \times\left[\alpha_{d}, \beta_{d}\right]} \widehat{X^{-}}(t) \mathrm{d} t+ \\
& \quad+\int_{[0, b] \times\left[\alpha_{2}, \beta_{2}\right] \times \cdots \times\left[\alpha_{d}, \beta_{d}\right]} \widehat{X^{+}}(t) \mathrm{d} t-\int_{[a, b] \times\left[\alpha_{2}, \beta_{2}\right] \times \cdots \times\left[\alpha_{d}, \beta_{d}\right]} \widehat{X^{0}}(t) \mathrm{d} t .
\end{aligned}
$$

The right-hand side is

$$
\begin{aligned}
& \int_{[a, 0) \times\left[\alpha_{2}, \beta_{2}\right) \times \cdots \times\left[\alpha_{d}, \beta_{d}\right)} X^{-}(t) \mathrm{d} t+\int_{[0, b) \times\left[\alpha_{2}, \beta_{2}\right) \times \cdots \times\left[\alpha_{d}, \beta_{d}\right]} X^{+}(t) \mathrm{d} t- \\
& -\int_{[a, b] \times\left[\alpha_{2}, \beta_{2}\right) \times \cdots \times\left[\alpha_{d}, \beta_{d}\right)} X^{0}(t) \mathrm{d} t=\int_{[a, b) \times\left[\alpha_{2}, \beta_{2}\right) \times \cdots \times\left[\alpha_{d}, \beta_{d}\right)} Y(t) \mathrm{d} t
\end{aligned}
$$

(by Def. 1.2). On the other hand,

$$
\begin{aligned}
& \int_{\left[\alpha_{2}, \beta_{2}\right] \times \cdots \times\left[\alpha_{d}, \beta_{d}\right]} \hat{U}(s) \mathrm{d} s=\int_{\left[\alpha_{2}, \beta_{2}\right) \times \cdots \times\left[\alpha_{d}, \beta_{d}\right)} U(s) \mathrm{d} s= \\
&=\int_{[a, b) \times\left[\alpha_{2}, \beta_{2}\right) \times \cdots \times\left[\alpha_{d}, \beta_{d}\right)} Y_{t} \mathrm{~d} t
\end{aligned}
$$

whenever $\alpha_{2}<\beta_{2}, \ldots, \alpha_{d}<\beta_{d}$. Thus, $Z=\hat{U}$.
Proof of Prop. 5.2. Induction in $d$. For $d=0$ we take $\varepsilon=1 / C$ and get $\mathbb{E} \exp \varepsilon|\hat{X}| \leq 2$ as required. For $d \geq 1$, Condition (a) of [2, Def. 1.4] (there

[^7]take $B=[0,1]^{d}$ and $\varepsilon=1 / C$ ) follows from Condition (a) of Def. 1.3 here (for $\frac{1}{C} X$ and $k=d$ ).

In order to check Condition (b) of [2, Def. 1.4] (for $d \geq 1$ ) we need splits of $\hat{X}$ (indexed by $k \in\{1, \ldots, d\}$ and $r \in \mathbb{R}$ ) whose leaks (as defined there) are members of the family $(\hat{Y})_{Y \in \operatorname{Spl}_{C}(d-1)}$; this is sufficient, since this family is uniformly splittable by the induction hypothesis.

WLOG, $k=1$ (the first coordinate) since, first, $\operatorname{Spl}_{C}(d)$ and $\operatorname{Spl}_{C}(d-1)$ are permutation invariant (by Corollary [2.9), and second, in [2], the class of all centered random fields is permutation invariant, and leaks on different coordinates turn into one another under coordinate permutations. Likewise, WLOG, $s=0$ (use shift invariance).

Lemma 2.17 (in combination with Remark (2.18) gives a leak $Y$ for $X$ such that for all $a<0, b>0$ the random field $U$ on $\mathbb{R}^{d-1}$ defined by $U_{t_{1}, \ldots, t_{d-1}}=\int_{[a, b)} Y_{s, t_{1}, \ldots, t_{d-1}} \mathrm{~d} s$ is $C$-splittable, that is, belongs to $\operatorname{Spl}_{C}(d-1)$. By Lemma 5.3, the leak of the corresponding split of $\hat{X}$ along the hyperplane $\{0\} \times \mathbb{R}^{d-1}$ on $[a, b] \times \mathbb{R}^{d-1}$ is $\hat{U}$.
5.4 Corollary. (a) For every splittabl ${ }^{1}$ random field $X$ on $\mathbb{R}^{d}$, the corresponding centered random field $\hat{X}$ is splittable (in the sense of [2], [3]).
(b) For every splittable ${ }^{2}$ stationary random field $X$ on $\mathbb{R}^{d}$, the corresponding CMS random field $\hat{X}$ is splittable (in the sense of [2], [3).

Our main results (Theorem 1.5 and Corollaries 1.6 and 1.7) are formulated for compactly supported continuous functions $\varphi: \mathbb{R}^{d} \rightarrow \mathbb{R}$. More generally, we may try compactly supported bounded Borel measurable functions $\varphi$ : $\mathbb{R}^{d} \rightarrow \mathbb{R}$. We introduce the space $\mathrm{BB}(d)$ of all such functions, and its subset $\mathrm{G}(d)$ of all functions $\varphi \in \mathrm{BB}(d)$ such that the claim of Theorem 1.5 holds for $\varphi$. If $\varphi \in \mathrm{G}(d)$, then the shifted function $t \mapsto \varphi(t+s)$ belongs to $\mathrm{G}(d)$ (for every $s \in \mathbb{R}^{d}$ ) due to stationarity. If $\varphi \in \mathrm{G}(d)$ and $c \in \mathbb{R}$, then $c \varphi \in$ $\mathrm{G}(d)$, since $c X$ is splittable whenever $X$ is. Also, invariance of $\mathrm{G}(d)$ under permutations of coordinates follows from such invariance of splittability.

By a box (in $\mathbb{R}^{d}$ ) we mean here a set of the form $\left[\alpha_{1}, \beta_{1}\right) \times \cdots \times\left[\alpha_{d}, \beta_{d}\right)$ for $\alpha_{1}<\beta_{1}, \ldots, \alpha_{d}<\beta_{d}$.
5.5 Proposition. For every box $B \subset \mathbb{R}^{d}$, its indicator function $\mathbb{1}_{B}$ belongs to $\mathrm{G}(d)$.

Proof. Corollary [5.4(b) in combination with [3, Theorem 1.1] gives

$$
\frac{1}{r_{1} \ldots r_{d} \lambda^{2}} \log \mathbb{E} \exp \lambda \int_{\left[0, r_{1}\right] \times \cdots \times\left[0, r_{d}\right]} \hat{X}_{t} \mathrm{~d} t \rightarrow \frac{\sigma^{2}}{2}
$$

[^8]as $r_{1}, \ldots, r_{d} \rightarrow \infty, \lambda \rightarrow 0, \lambda \log ^{d}\left(r_{1} \ldots r_{d}\right) \rightarrow 0$. In particular, for arbitrary $r_{1}, \ldots, r_{d}>0$,
$$
\frac{1}{\left(r_{1} r\right) \ldots\left(r_{d} r\right) \lambda^{2}} \log \mathbb{E} \exp \lambda \int_{\left[0, r_{1} r\right) \times \cdots \times\left[0, r_{d} r\right)} X_{t} \mathrm{~d} t \rightarrow \frac{\sigma^{2}}{2}
$$
as $r \rightarrow \infty, \lambda \rightarrow 0, \lambda \log ^{d} r \rightarrow 0$. Thus (using stationarity),
$$
\frac{1}{r^{d} \cdot \operatorname{vol} B \cdot \lambda^{2}} \log \mathbb{E} \exp \lambda \int_{r B} X_{t} \mathrm{~d} t \rightarrow \frac{\sigma^{2}}{2}
$$
as $r \rightarrow \infty, \lambda \rightarrow 0, \lambda \log ^{d} r \rightarrow 0$. That is, for $\varphi=\mathbb{1}_{B}$ and $\sigma_{X}=\sigma$,
$$
\frac{1}{r^{d} \lambda^{2}} \log \mathbb{E} \exp \lambda \int_{\mathbb{R}^{d}} \varphi\left(\frac{1}{r} t\right) X_{t} \mathrm{~d} t \rightarrow \frac{\sigma_{X}^{2}}{2} \int_{\mathbb{R}^{d}} \varphi^{2}(t) \mathrm{d} t
$$
5.6 Proposition. Let $\varphi \in \operatorname{BB}(d)$, and the two functions $\varphi \cdot \mathbb{1}_{(-\infty, 0) \times \mathbb{R}^{d-1}}$, $\varphi \cdot \mathbb{1}_{[0, \infty) \times \mathbb{R}^{d-1}}$ belong to $\mathrm{G}(d)$. Then $\varphi \in \mathrm{G}(d)$. ${ }^{1}$

Given $\varphi \in \mathrm{BB}(d)$ and a stationary splittable random field $X$ on $\mathbb{R}^{d}$, we introduce for convenience $I(r)=\int_{\mathbb{R}^{d}} \varphi\left(\frac{1}{r} t\right) X_{t} \mathrm{~d} t$ and similarly $I_{-}(r)=$ $\int_{(-\infty, 0) \times \mathbb{R}^{d-1}} \varphi\left(\frac{1}{r} t\right) X_{t} \mathrm{~d} t, I_{+}(r)=\int_{[0, \infty) \times \mathbb{R}^{d-1}} \varphi\left(\frac{1}{r} t\right) X_{t} \mathrm{~d} t$.

### 5.7 Lemma.

$$
\begin{aligned}
\limsup _{\substack{r \rightarrow \infty, \lambda \rightarrow 0 \\
\lambda \log ^{d} r \rightarrow 0}} & \frac{1}{r^{d} \lambda^{2}} \log \mathbb{E} \exp \lambda I(r) \leq \\
& \leq \limsup _{\substack{r \rightarrow \infty, \lambda \rightarrow 0 \\
\lambda \log d_{r \rightarrow 0}}} \frac{1}{r^{d} \lambda^{2}} \log \mathbb{E} \exp \lambda I_{-}(r)+\lim _{\substack{r \rightarrow \infty, \lambda \rightarrow 0 \\
\lambda \log d_{r \rightarrow 0}}} \frac{1}{r^{d} \lambda^{2}} \log \mathbb{E} \exp \lambda I_{+}(r) .
\end{aligned}
$$

Proof. We take $C \in(0, \infty)$ such that $\varphi X$ is $C$-splittable by Corollary 2.3, and $a \in(0, \infty)$ such that $\varphi(\cdot)=0$ outside $[-a, a)^{d}$. We apply Lemma 4.5 (the upper bound) to the 1-splittable random field $\left(\frac{1}{C} \varphi\left(\frac{1}{r} t\right) X_{t}\right)_{t \in \mathbb{R}^{d}}$ and the box $B=[-r a, r a)^{d-1}$ (not of the form $\left[0, r_{2}\right) \times \ldots\left[0, r_{d}\right)$, which is harmless due to shift invariance of splittability); we get

$$
\begin{aligned}
& \log \mathbb{E} \exp \frac{\lambda}{C} I(r) \leq \frac{1}{p} \log \mathbb{E} \exp \frac{p \lambda}{C} I_{-}(r)+\frac{1}{p} \log \mathbb{E} \exp \frac{p \lambda}{C} I_{+}(r)+ \\
&+\frac{p-1}{p} f(-\frac{p}{p-1} \lambda(2 r a)^{(d-1) / 2} ; \underbrace{2 r a, \ldots, 2 r a}_{d-1}) .
\end{aligned}
$$

[^9]By Corollary 4.16, the last term (in the right-hand side) does not exceed $\frac{p-1}{p} C_{d-1}\left(\frac{p}{p-1} \lambda(2 r a)^{(d-1) / 2}\right)^{2} \quad$ provided that $\quad C_{d-1}\left|\frac{p}{p-1} \lambda(2 r a)^{(d-1) / 2}\right| \leq$ $(2 r a)^{(d-1) / 2} \log ^{-d}(2 r a)^{d-1}$ and $2 r a \geq C_{d-1}$. When $r$ is large enough and $|\lambda| \log ^{d} r$ is small enough, we get $\mathcal{O}\left(r^{d-1} \lambda^{2}\right)$ for that last term, and therefore

$$
\begin{aligned}
& \frac{1}{r^{d} \lambda^{2}} \log \mathbb{E} \exp \frac{\lambda}{C} I(r) \leq \\
& \quad \leq \frac{1}{p} \cdot \frac{1}{r^{d} \lambda^{2}} \log \mathbb{E} \exp \frac{p \lambda}{C} I_{-}(r)+\frac{1}{p} \cdot \frac{1}{r^{d} \lambda^{2}} \log \mathbb{E} \exp \frac{p \lambda}{C} I_{+}(r)+\mathcal{O}\left(\frac{1}{r}\right),
\end{aligned}
$$

that is (substituting $C \lambda$ for $\lambda$ and multiplying by $C^{2}$ )

$$
\begin{aligned}
& \frac{1}{r^{d} \lambda^{2}} \\
& \quad \log \mathbb{E} \exp \lambda I(r) \leq \\
& \quad \leq \frac{1}{p} \cdot \frac{1}{r^{d} \lambda^{2}} \log \mathbb{E} \exp p \lambda I_{-}(r)+\frac{1}{p} \cdot \frac{1}{r^{d} \lambda^{2}} \log \mathbb{E} \exp p \lambda I_{+}(r)+\mathcal{O}\left(\frac{1}{r}\right) .
\end{aligned}
$$

Taking into account that (substituting $\frac{\lambda}{p}$ for $\lambda$ )

$$
\frac{1}{p} \limsup _{\substack{r \rightarrow \infty, \lambda \rightarrow 0 \\ \lambda \log d^{\lambda} \rightarrow 0}} \frac{1}{r^{d} \lambda^{2}} \log \mathbb{E} \exp p \lambda I_{-}(r)=p \limsup _{\substack{r \rightarrow \infty, \lambda \rightarrow 0 \\ \lambda \log ^{\lambda} r_{r \rightarrow 0}}} \frac{1}{r^{d} \lambda^{2}} \log \mathbb{E} \exp \lambda I_{-}(r)
$$

and the same for $I_{+}$, we get

$$
\begin{aligned}
& \limsup _{\substack{r \rightarrow \infty, \lambda \rightarrow 0 \\
\lambda \log d^{i} \rightarrow 0}} \frac{1}{r^{d} \lambda^{2}} \log \mathbb{E} \exp \lambda I(r) \leq \\
& \quad \leq p \limsup _{\substack{r \rightarrow \infty, \lambda \rightarrow 0 \\
\lambda \log ^{d} r \rightarrow 0}} \frac{1}{r^{d} \lambda^{2}} \log \mathbb{E} \exp \lambda I_{-}(r)+p \lim _{\substack{r \rightarrow \infty, \lambda \rightarrow 0 \\
\lambda \log ^{d} \mathrm{~s}_{r \rightarrow 0}}} \frac{1}{r^{d} \lambda^{2}} \log \mathbb{E} \exp \lambda I_{+}(r)
\end{aligned}
$$

for all $p>1$, therefore, also for $p=1$.
Proof of Prop. 5.6. Lemma 5.7 gives the upper bound

$$
\begin{aligned}
& \limsup _{\substack{r \rightarrow \infty, \lambda^{\rightarrow} \rightarrow 0 \\
\lambda \log d \rightarrow 0}} \frac{1}{r^{d} \lambda^{2}} \log \mathbb{E} \exp \lambda I(r) \leq \\
& \leq \frac{\sigma_{X}^{2}}{2} \int_{(-\infty, 0) \times \mathbb{R}^{d-1}} \varphi^{2}(t) \mathrm{d} t+\frac{\sigma_{X}^{2}}{2} \int_{[0, \infty) \times \mathbb{R}^{d-1}} \varphi^{2}(t) \mathrm{d} t=\frac{\sigma_{X}^{2}}{2} \int_{R^{d}} \varphi^{2}(t) \mathrm{d} t
\end{aligned}
$$

The lower bound

$$
\begin{aligned}
& \liminf _{\substack{r \rightarrow \infty \\
\lambda \log ^{\lambda} d \rightarrow 0}} \frac{1}{r^{d} \lambda^{2}} \log \mathbb{E} \exp \lambda I(r) \geq \\
& \quad \geq \lim _{\substack{r \rightarrow \infty, \lambda) \\
\lambda \log d \rightarrow 0}} \frac{1}{r^{d} \lambda^{2}} \log \mathbb{E} \exp \lambda I_{-}(r)+\lim _{\substack{r \rightarrow \infty \\
\lambda \operatorname{los} \lambda^{\prime} \rightarrow 0 \\
\lambda \log _{r \rightarrow 0}}} \frac{1}{r^{d} \lambda^{2}} \log \mathbb{E} \exp \lambda I_{+}(r)= \\
& \quad=\frac{\sigma_{X}^{2}}{2} \int_{(-\infty, 0) \times \mathbb{R}^{d-1}} \varphi^{2}(t) \mathrm{d} t+\frac{\sigma_{X}^{2}}{2} \int_{[0, \infty) \times \mathbb{R}^{d-1}} \varphi^{2}(t) \mathrm{d} t=\frac{\sigma_{X}^{2}}{2} \int_{R^{d}} \varphi^{2}(t) \mathrm{d} t
\end{aligned}
$$

is obtained similarly (via the lower bound in Lemma 4.5).
A linear combination of (finitely many) indicators of boxes will be called a step function.
5.8 Lemma. Every step function belongs to $\mathrm{G}(d)$.

Proof. A linear combination of indicators of two disjoint boxes belongs to $\mathrm{G}(d)$ by Propositions 5.5 and 5.6. (Prop. 5.6 is formulated for the hyperplane $\{0\} \times \mathbb{R}^{d-1}$, but holds for every $\mathbb{R}^{k-1} \times\{s\} \times \mathbb{R}^{d-k}$ due to shift and permutation invariance of $\mathrm{G}(d)$.) Continuing this way, every step function can be obtained in finitely many steps ${ }^{1}$
5.9 Lemma. Let $\varphi, \varphi_{1}, \varphi_{2}, \cdots \in \operatorname{BB}(D), \sup _{t \in \mathbb{R}^{d}}\left|\varphi_{n}(t)-\varphi(t)\right| \rightarrow 0$ as $n \rightarrow$ $\infty$, and $\varphi_{n}$ be uniformly compactly supported (that is, they all vanish outside a single bounded set). If $\varphi_{1}, \varphi_{2}, \cdots \in \mathrm{G}(d)$, then $\varphi \in \mathrm{G}(d)$. ${ }^{2}$

The proof is somewhat similar to that of Lemma 5.7.
Proof. Given a splittable $X$, for arbitrary $r \in(0, \infty)$ we consider $I(r)=$ $\int_{\mathbb{R}^{d}} \varphi\left(\frac{1}{r} t\right) X_{t} \mathrm{~d} t$ and $I_{n}(r)=\int_{\mathbb{R}^{d}} \varphi_{n}\left(\frac{1}{r} t\right) X_{t} \mathrm{~d} t$. WLOG, $X$ is 1 -splittable (otherwise, for a $C$-splittable $X$, turn to $C \varphi, C \varphi_{n}$ and $\left.\frac{1}{C} X\right)$. We take $a \in(0, \infty)$ such that $\forall n \varphi_{n}(\cdot)=0$ outside $[-a, a)^{d}$. Given $\varepsilon>0$, we take $n_{\varepsilon}$ such that $\forall t\left|\varphi_{n}(t)-\varphi(t)\right| \leq \varepsilon$ whenever $n \geq n_{\varepsilon}$. Lemma 4.4 applied to $p=\frac{1}{1-\varepsilon}$ and random variables $\lambda I_{n}(r)$ and $\lambda\left(I(r)-I_{n}(r)\right)$ for arbitrary $\lambda \in \mathbb{R}$ gives

$$
\begin{aligned}
& \frac{1}{1-\varepsilon} \log \mathbb{E} \exp (1-\varepsilon) \lambda I_{n}(r)-\frac{\varepsilon}{1-\varepsilon} \log \mathbb{E} \exp \left(-\frac{1-\varepsilon}{\varepsilon} \lambda\left(I(r)-I_{n}(r)\right)\right) \leq \\
& \leq \log \mathbb{E} \exp \lambda I(r) \leq(1-\varepsilon) \log \mathbb{E} \exp \frac{\lambda}{1-\varepsilon} I_{n}(r)+\varepsilon \log \mathbb{E} \exp \frac{\lambda}{\varepsilon}\left(I(r)-I_{n}(r)\right) .
\end{aligned}
$$

[^10]By Corollary 4.16 (and 2.3),
$\log \mathbb{E} \exp \frac{\lambda}{\varepsilon}\left(I(r)-I_{n}(r)\right)=\log \mathbb{E} \exp \lambda \int_{[-r a, r a)^{d}} \frac{1}{\varepsilon}\left(\varphi\left(\frac{1}{r} t\right)-\varphi_{n}\left(\frac{1}{r} t\right)\right) X_{t} \mathrm{~d} t \leq$

$$
\leq f\left((2 r a)^{d / 2} \lambda ; 2 r a, \ldots, 2 r a\right) \leq C_{d}(2 r a)^{d} \lambda^{2}
$$

whenever $n \geq n_{\varepsilon}, C_{d}\left|(2 r a)^{d / 2} \lambda\right| \leq(2 r a)^{d / 2} \log ^{-d}(2 r a)^{d}$ and $2 r a \geq C_{d}$. When $n$ and $r$ are large enough and $|\lambda| \log ^{d} r$ is small enough, we have

$$
\frac{1}{r^{d} \lambda^{2}} \log \mathbb{E} \exp \frac{\lambda}{\varepsilon}\left(I(r)-I_{n}(r)\right) \leq C_{d}(2 a)^{d}
$$

and similarly,

$$
\frac{1}{r^{d} \lambda^{2}} \log \mathbb{E} \exp \left(-\frac{1-\varepsilon}{\varepsilon} \lambda\left(I(r)-I_{n}(r)\right)\right) \leq(1-\varepsilon)^{2} C_{d}(2 a)^{d}
$$

Taking into account that

$$
\lim _{\substack{r \rightarrow \infty, \lambda, 0 \\ \lambda \log d \rightarrow 0}} \frac{1}{r^{d} \lambda^{2}} \log \mathbb{E} \exp (1-\varepsilon) \lambda I_{n}(r)=
$$

$=(1-\varepsilon)^{2} \lim _{\substack{r \rightarrow \infty \\ \lambda \log ^{d} \rightarrow 0}} \frac{1}{r^{d}((1-\varepsilon) \lambda)^{2}} \log \mathbb{E} \exp (1-\varepsilon) \lambda I_{n}(r)=(1-\varepsilon)^{2} \frac{\sigma_{X}^{2}}{2} \int_{\mathbb{R}^{d}} \varphi_{n}^{2}(t) \mathrm{d} t$,
and similarly

$$
\lim _{\substack{r \rightarrow \infty \\ \lambda \rightarrow \log ^{d} d \rightarrow 0}} \frac{1}{r^{d} \lambda^{2}} \log \mathbb{E} \exp \frac{\lambda}{1-\varepsilon} I_{n}(r)=\frac{1}{(1-\varepsilon)^{2}} \frac{\sigma_{X}^{2}}{2} \int_{\mathbb{R}^{d}} \varphi_{n}^{2}(t) \mathrm{d} t
$$

we have

$$
\begin{aligned}
&(1-\varepsilon) \frac{\sigma_{X}^{2}}{2} \int_{\mathbb{R}^{d}} \varphi_{n}^{2}(t) \mathrm{d} t-\varepsilon(1-\varepsilon) C_{d}(2 a)^{d} \leq \\
& \leq \liminf _{\substack{r \rightarrow \infty, \lambda \rightarrow 0 \\
\lambda \log d \rightarrow 0}} \frac{1}{r^{d} \lambda^{2}} \log \mathbb{E} \exp \lambda I(r) \leq \limsup _{\substack{r \rightarrow \infty, \lambda \rightarrow 0 \\
\lambda \log d \\
r \rightarrow 0}} \frac{1}{r^{d} \lambda^{2}} \log \mathbb{E} \exp \lambda I(r) \leq \\
& \leq \frac{1}{1-\varepsilon} \frac{\sigma_{X}^{2}}{2} \int_{\mathbb{R}^{d}} \varphi_{n}^{2}(t) \mathrm{d} t+\varepsilon C_{d}(2 a)^{d}
\end{aligned}
$$

for all $\varepsilon>0$ and $n \geq n_{\varepsilon}$. In the limit $n \rightarrow \infty, \int_{\mathbb{R}^{d}} \varphi_{n}^{2}(t) \mathrm{d} t$ turns into $\int_{\mathbb{R}^{d}} \varphi^{2}(t) \mathrm{d} t$. Finally, take $\varepsilon \rightarrow 0+$.

Proof of Theorem 1.5. Given a compactly supported continuous function $\varphi$ : $\mathbb{R}^{d} \rightarrow \mathbb{R}$, we take step functions $\varphi_{n}$ satisfying the conditions of Lemma 5.9, By Lemma 5.8, each $\varphi_{n}$ belongs to $\mathrm{G}(d)$. By Lemma 5.9, $\varphi$ belongs to $\mathrm{G}(d)$, which means that the claim of Theorem 1.5 holds for $\varphi$.

Corollaries 1.6 and 1.7 follow from Theorem 1.5 in the same way as [1, Corollaries 1.7, 1.8] follow from [1, Theorem 1.6]. (See also [3, Sect. 6].)
5.10 Remark. More generally,

$$
\lim _{\substack{r_{1}, \ldots, r_{d} \rightarrow \infty, \lambda \rightarrow 0 \\ \lambda \log \left(r_{1} \ldots r_{d}\right) \rightarrow 0}} \frac{1}{r_{1} \ldots r_{d} \lambda^{2}} \log \mathbb{E} \exp \lambda \int_{\mathbb{R}^{d}} \varphi\left(\frac{1}{r_{1}} t_{1}, \ldots, \frac{1}{r_{d}} t_{d}\right) X_{t} \mathrm{~d} t=\frac{1}{2}\|\varphi\|^{2} \sigma_{X}^{2},
$$

where $t=\left(t_{1}, \ldots, t_{d}\right) \in \mathbb{R}^{d}$. The proof needs only trivial modifications (starting from Prop. 5.5).

[^0]:    ${ }^{1}$ Thus, the centered Poisson point process is still an example, but the white noise is not. (Both are mentioned in 1, page 2] for $d=1$.)
    ${ }^{2}$ The same is written in [2, p. 2]; see Sect. 5below (in particular, Prop. 5.2] and Lemma 5.3) for relations between the notions "split" and "leak" here and in [2.
    ${ }^{3}$ It is convenient to formulate relations in terms of (generally nonexistent) random variables $X_{t}$ when it is immediate to rewrite these relations in terms of LFSBMs.
    ${ }^{4}$ Typically, $Y_{t_{1}, \ldots, t_{d}}$ decays for large $\left|t_{1}\right|$.
    ${ }^{5}$ In [2] p. 2] the leak is taken along a coordinate hyperplane $\left\{\left(t_{1}, \ldots, t_{d}\right): t_{k}=r\right\}$; in contrast, here we restrict ourselves to $k=1$ and $r=0$, which simplifies Def. 1.2 but complicates Def. 1.3(c).
    ${ }^{6}$ That is, $Y$ and this leak are identically distributed.

[^1]:    ${ }^{1}$ See Corollary 2.3.
    ${ }^{2}$ See Corollary 2.9.
    ${ }^{3}$ See Corollary 2.10
    ${ }^{4}$ Follows from Def. $\quad$ 1.3(a), since $\mathbb{E} \exp \varepsilon \int_{A \cup B}\left|X_{t}\right| \mathrm{d} t \quad \leq$ $\mathbb{E}\left(\exp \varepsilon \int_{A}\left|X_{t}\right| \mathrm{d} t\right)\left(\exp \varepsilon \int_{B}\left|X_{t}\right| \mathrm{d} t\right) \leq\left(\mathbb{E} \exp 2 \varepsilon \int_{A}\left|X_{t}\right| \mathrm{d} t\right)^{1 / 2}\left(\mathbb{E} \exp 2 \varepsilon \int_{B}\left|X_{t}\right| \mathrm{d} t\right)^{1 / 2}$.
    ${ }^{5}$ See Def. 1.3(b).
    ${ }^{6}$ See Prop. 2.19

[^2]:    ${ }^{1}$ Of course, $[0,1)^{k}+s$ stands for the unit cube shifted by $s$. Typically, $X_{t_{1}, \ldots, t_{d}}$ decays for large $t_{k+1}^{2}+\cdots+t_{d}^{2}$.
    ${ }^{2}$ A leak $\tilde{Y}$ for $\tilde{X}$ (along $\left\{\left(t_{1}, \ldots, t_{d}\right): t_{1}=0\right\}$ ) could be thought of as a leak for $X$ along $\left\{\left(t_{1}, \ldots, t_{d}\right): t_{i}=r\right\}$ (recall the last footnote to Def. (1.2) taken at $\left(t_{2}, \ldots, t_{i}, t_{1}+\right.$ $\left.r, t_{i+1}, \ldots, t_{d}\right)$. Note that $Y_{\left(t_{1}, \ldots, t_{d}\right)}$ switches at $t_{1}=0$; accordingly, $Y$ switches at $t_{k}=0$. Typically, $Y_{\left(t_{1}, \ldots, t_{d}\right)}$ decays for large $t_{k}^{2}+\cdots+t_{d}^{2}$.

[^3]:    ${ }^{1}$ Or rather, $Y$ is distributed like this.

[^4]:    ${ }^{1} \mathbb{1}_{A}$ stands for the indicator function of a set $A$; it equals 1 within $A$ and 0 outside $A$.
    ${ }^{2}$ To be used in Sect. 5

[^5]:    ${ }^{1}$ The sets $\mathbb{R} \times(0,+\infty)^{d}$ are pairwise disjoint, of course.
    ${ }^{2} \log ^{-d}(\ldots)$ means $1 /(\log (\ldots))^{d}$, of course.

[^6]:    ${ }^{1}$ The lower bound will be used in Sect. 5.

[^7]:    ${ }^{1}$ The proof is straightforward and boring, but written out anyway.

[^8]:    ${ }^{1}$ According to Def. 1.4(c).
    ${ }^{2}$ According to Def. 1.4 (c).
