Characterizations of indicator functions and contrast representations of fractional factorial designs with multi-level factors

Satoshi Aoki[∗]

Abstract

A polynomial indicator function of designs is first introduced by Fontana, Pistone and Rogantin (2000) for two-level designs. They give the structure of the indicator function of two-level designs, especially from the viewpoints of the orthogonality of the designs. Based on the structure, they use the indicator functions to classify all the orthogonal fractional factorial designs with given sizes using computational algebraic software. In this paper, generalizing the results on two-level designs, the structure of the indicator functions for multi-level designs is derived. We give a system of algebraic equations for the coefficients of indicator functions of fractional factorial designs with given orthogonality. We also give another representation of the indicator function, a contrast representation, which reflects the size and the orthogonality of the corresponding design directly. The contrast representation is determined by a contrast matrix, and does not depend on the level-coding, which is one of the advantages of it. We use these results to classify orthogonal $2^3 \times 3$ designs with strength 2 and orthogonal $2^4 \times 3$ designs with strength 3 by a computational algebraic software.

Keywords: Computational algebraic statistics, Fractional factorial designs, Gröbner bases, Indicator functions, Orthogonal designs.

1 Introduction

Applications of Gröbner basis theory to various problems of statistics arises in early 1990s. One of the first works in this developing field, a computational algebraic statistics, is given by Pistone and Wynn (12) , where the Gröbner basis theory is applied to the identifiability problem in the design of experiments. After this work, various algebraic approaches to the problems in the design of experiments are presented by researchers both in the fields of algebra and statistics. A theory of the indicator function of fractional factorial designs is one of the early results in this branch.

[∗]Graduate School of Science, Faculty of Science, Kobe University.

The indicator function is first introduced by Fontana, Pistone and Rogantin ([\[6\]](#page-23-1)) for two-level fractional factorial designs. In [\[6\]](#page-23-1), based on the results of [\[12\]](#page-23-0), one-to-one correspondence between the design and its indicator function is shown. This correspondence enables us to translate various statistical concepts to algebraic concepts, i.e., various results on the fractional factorial designs can be interpreted to the structure of their indicator functions. For example, abberation and resolution are important concepts in design of experiments, and there is a well-established history starting with [\[2\]](#page-23-2) for two-level fractional factorial designs. An important contribution of [\[6\]](#page-23-1) is to characterize these concepts as the structure of the indicator functions.

To illustrate the motivation of this paper, we glance at the arguments of [\[6\]](#page-23-1) by examples. Note that the necessary definitions on the designs and indicator functions will be given in Section [2.](#page-4-0) Figure [1](#page-1-0) shows examples of two-level fractional factorial designs. We

Figure 1: Examples of fractional factorial designs for two-level factors. Left(F_1): a regular fractional factorial design with the defining relation $x_1x_2x_4 = x_1x_3x_5 = 1$. Right(F_2): an example of nonregular designs.

code the levels of each factor as $\{-1, 1\}$ according to [\[6\]](#page-23-1). For each design, each row of the table shows the combination of the levels of the factors x_i 's for each experimental run, and each column corresponds to each factor. For example, the design F_1 is a fractional factorial design for 5 two-level factors x_1, \ldots, x_5 , composed of 8 points in $\{-1, 1\}^5$,

$$
\{(1,1,1,1,1),(1,1,-1,1,-1),\ldots,(-1,-1,-1,1,1)\}.
$$

In the field of design of experiments, F_1 is known as a regular fractional factorial design with the defining relation $x_1x_2x_4 = x_1x_3x_5 = 1$. On the other hand, the design F_2 is an example of nonregular designs. For details on the regularity of designs, see [\[13\]](#page-24-0) for example.

The indicator functions of F_1 and F_2 are given as follows, respectively.

$$
F_1: f_1(x_1, x_2, x_3, x_4, x_5) = \frac{1}{4} + \frac{1}{4} (x_1 x_2 x_4 + x_1 x_3 x_5 + x_2 x_3 x_4 x_5)
$$

\n
$$
F_2: f_2(x_1, x_2, x_3, x_4) = \frac{3}{8} - \frac{1}{8} x_4 + \frac{1}{8} (x_1 x_2 + x_1 x_3 - x_2 x_3) + \frac{1}{8} (x_1 x_3 x_4 + x_2 x_3 x_4) + \frac{3}{8} x_2 x_3 x_4
$$

We see, for example, $f_1(x_1, \ldots, x_5) = 1$ for 8 points in F_1 , and $f_1(x_1, \ldots, x_5) = 0$ for the other 24 points not in F_1 . The indicator function of the design of n two-level factors,

 x_1, x_2, \ldots, x_n has a unique polynomial representation of the form

$$
f(x_1,\ldots,x_n)=\sum_{\mathbf{a}\in\{0,1\}^n}\theta_{\mathbf{a}}\mathbf{x}^{\mathbf{a}},\qquad(1)
$$

where $\mathbf{x}^a = \prod^n x_i^{a_i}$ and $\mathbf{a} = (a_1, \ldots, a_n) \in \{0,1\}^n$. As is shown in [\[6\]](#page-23-1), the set of the $i=1$ coefficients $\{\theta_a\}_{a\in\{0,1\}^n}$ has all the information of the corresponding design. For example, we see the following facts from the coefficients of the indicator functions f_1 and f_2 for F_1 and F_2 .

- The constant term $\theta_{(0,\ldots,0)}$ shows the ratio between the size of the design to the size of the full factorial design. In fact, F_1 is a $1/4$ fraction of the full factorial 2^5 design, and F_2 is a 3/8 fraction of the full factorial 2^4 design.
- The coefficient of the main effect term θ_a , $\sum_j a_j = 1$, i.e., the coefficient of the monomial x^a with the degree 1, shows the "balance" of two levels for this factor. In fact, for F_1 , $\theta_{(1,0,0,0,0)} = \cdots = \theta_{(0,0,0,0,1)} = 0$ shows F_1 is an equireplicated design, i.e., two levels appear equally often for each factor. On the other hand, for F_2 , $\theta_{(1,0,0,0)} = \theta_{(0,1,0,0)} = \theta_{(0,0,1,0)} = 0$ and $\theta_{(0,0,0,1)} \neq 0$ show F_2 is equireplicated for factors x_1, x_2, x_3 but not for x_4 .
- The coefficient of the two-factor interaction term θ_a , $\sum_j a_j = 2$, i.e., the coefficient of the monomial x^a with the degree 2, shows the "orthogonality" of the design. In fact, for F_1 , $\theta_{(1,1,0,0,0)} = \cdots = \theta_{(0,0,0,1,1)} = 0$ shows F_1 is an orthogonal design, i.e., possible combinations of levels, $(-1, -1)$, $(-1, 1)$, $(1, -1)$, $(1, 1)$, appear equally often for each pair of the factors. On the other hand, for F_2 , $\theta_{(1,0,0,1)} = \theta_{(0,1,0,1)} =$ $\theta_{(0,0,1,1)} = 0$ shows that the factor x_4 is orthogonal to each of the other factors, whereas $\theta_{(1,1,0,0)}, \theta_{(1,0,1,0)}, \theta_{(0,1,1,0)} \neq 0$ shows that x_1, x_2, x_3 are not orthogonal in each other.

In other words, statistical concepts such as aberration and resolution can be related to the structure of the corresponding indicator functions directly for two-level designs. In particular, the structure of the indicator function of regular two-level designs can be characterized by their defining relations, and are fully revealed. See [\[14\]](#page-24-1) for detail. Another characterization of the indicator function of two-level designs relating the Doptimality of the design is given by the author in [\[1\]](#page-23-3).

In [\[6\]](#page-23-1), these structures of the indicator function are applied to the classification of the design, which is also the object of this paper. The argument of [\[6\]](#page-23-1) is as follows. For the indicator function [\(1\)](#page-2-0) of two-level designs, the set of the coefficients $\{\theta_a\}_{a\in\{0,1\}^n}$ satisfies a system of algebraic equations

$$
\theta_{\mathbf{a}} = \sum_{\mathbf{a}' \in \{0,1\}^n} \theta_{\mathbf{a}'} \theta_{\mathbf{a} + \mathbf{a}'}, \quad \mathbf{a} \in \{0,1\}^n,
$$
\n⁽²⁾

where the sum $a + a'$ is considered under "mod 2" (Proposition 3.7 of [\[6\]](#page-23-1)). Therefore, adding constraints for some orthogonality of the designs to [\(2\)](#page-2-1), we have a system of algebraic equations having the designs with these orthogonality as the solutions. For example, for the case of $n = 5$, additional constraints

$$
\theta_{(0,0,0,0,0)} = \frac{1}{4}, \quad \theta_{\mathbf{a}} = 0 \text{ for } \sum_{j} a_j = 1, 2 \tag{3}
$$

to [\(2\)](#page-2-1) yields a system of algebraic equations having all the orthogonal designs with the size 8 as the solution (and F_1 corresponds to one of the solutions). In this way, the complete lists of the orthogonal designs for $n = 4, 5$ are computed by a computational algebraic software in [\[6\]](#page-23-1). Recall that solving a system of algebraic equations is a fundamental problem where the theory of Gröbner basis is used.

In this paper, we consider generalization of the above argument on two-level designs to general fractional factorial designs. Note that the direct relations between the size and orthogonality of designs and their indicator functions are obtained only for twolevel designs. To see this, consider a fractional factorial design of three-level factors F_3 displayed in Figure [2.](#page-3-0) F_3 is a regular fractional factorial design with the defining relation $x_1 + x_2 + x_3 = x_1 + 2x_2 + x_4 = 0 \pmod{3}$. Though F_3 is a regular design (and therefore

F_{3}

the resolution of F_3 is seen in its defining relation), the structure of its indicator function seems complicated as follows.

$$
f(x_1, x_2, x_3, x_4)
$$

= $1 - x_1^2 - x_2^2 - x_3^2 - x_4^2 + x_1^2 x_2^2 + x_1^2 x_3^2 + x_1^2 x_4^2 + x_2^2 x_3^2 + x_2^2 x_4^2 + x_3^2 x_4^2$
+ $\frac{1}{4} (x_1^2 x_2 x_3 - x_1^2 x_2 x_4 + x_1^2 x_3 x_4 + x_1 x_2^2 x_3 + x_1 x_2^2 x_4 - x_2^2 x_3 x_4$
+ $x_1 x_2 x_3^2 - x_1 x_3^2 x_4 + x_2 x_3^2 x_4 - x_1 x_2 x_4^2 - x_1 x_3 x_4^2 - x_2 x_3 x_4^2)$
- $\frac{3}{4} (x_1^2 x_2^2 x_3^2 + x_1^2 x_2^2 x_4^2 + x_1^2 x_3^2 x_4^2 + x_2^2 x_3^2 x_4^2)$ (4)

There are several approaches to consider the indicator functions of multi-level designs. In [\[11\]](#page-23-4), a complex coding is proposed to generalize the arguments on two-level cases to multi-level cases. For example, instead of $\{-1, 0, 1\}$ above, the three-level factor is coded as $\{1, w, w^2\}$, where $w = \exp(2\pi\sqrt{-1/3})$ in [\[11\]](#page-23-4). The idea of the complex coding is based on a theory of a harmonic analysis, where the indicator function is viewed as a discrete Fourier transform. Other approach is presented in $[4]$ for the real coefficients field. However, it is better if we can consider $\mathbb Q$, the field of rational numbers, as the coefficients field, because algebraic computations are conducted in \mathbb{Q} (or finite fields $\mathbb{Z}/p\mathbb{Z}$) for standard computational algebraic software. Another approach is a concept of Hilbert basis presented in [\[3\]](#page-23-6), where the case of repeated treatments are considered by considering counting functions instead of indicator functions. In this paper, we give generalization of the relations for two-level designs such as [\(2\)](#page-2-1) and [\(3\)](#page-3-1) to general multi-level designs for the rational coefficients field \mathbb{Q} , and show how to relate the structure of the designs to the structure of their indicator functions.

The construction of this paper is as follows. In Section [2,](#page-4-0) we give necessary definitions and theorems on the indicator functions. In Section 3, we give the structure of the indicator functions for general fractional factorial designs. We also derive another representation of the indicator functions, namely, contrast representation, to reflect the orthogonality of the designs directly. In Section 4, we use these results to classify $2^3 \times 3$ and $2⁴ \times 3$ designs with given orthogonalities by a computational algebraic software.

2 The indicator functions of fractional factorial designs

In this section, we give necessary materials on the indicator functions of fractional factorial designs. The arguments are based on the theory of interpolatory polynomial functions on designs, which is one of the first applications of Gröbner basis theory to statistics introduced by [\[12\]](#page-23-0). See [\[10\]](#page-23-7) or Chapter 5 of [\[5\]](#page-23-8) for detail.

Let x_1, \ldots, x_n be n factors. Let $A_j \subset \mathbb{Q}$ be a level set of a factor x_j for $j = 1, \ldots, n$, where Q denotes the field of rational numbers. We denote by $r_j = #A_j$ the cardinality of A_j and assume $r_j \geq 2$ for $j = 1, \ldots, n$. A full factorial design of the factors x_1, \ldots, x_n is $D = A_1 \times \cdots \times A_n$. For later use, we introduce an *index set*

$$
\mathcal{I} = \{(i_1, \ldots, i_n) \in [r_1] \times \cdots \times [r_n]\},\
$$

where $[k] = \{1, 2, ..., k\}$ for a positive integer k. We specify each point of D as $D =$ ${d_i \in \mathbb{Q}^n : i \in \mathcal{I}}$. When we code $A_j = [r_j]$ for $j = 1, \ldots, n, \mathcal{I}$ coincides with D itself.

A subset of D is called a fractional factorial design. A fractional factorial design $F \subset D$ can be written as $F = \{d_i \in D : i \in \mathcal{I}'\}$ where \mathcal{I}' is a subset of \mathcal{I} . Each design can be viewed as a finite subset of \mathbb{Q}^n , i.e., as an algebraic variety, because each design can be characterized as the set of the solutions of a system of polynomial equations with rational coefficients. The size of a design is the cardinality of the design. We write the size of a full factorial design D as $m = \prod_{j=1}^n r_j$ for later use.

Let $\mathbb{Q}[x_1,\ldots,x_n]$ be the polynomial ring with coefficients in \mathbb{Q} . For a design $F \subset \mathbb{Q}^n$, we denote by $I(F)$ the set of polynomials in $\mathbb{Q}[x_1, \ldots, x_n]$ which are 0 at every point of F, i.e.,

$$
I(F) = \{f \in \mathbb{Q}[x_1,\ldots,x_n] : f(\boldsymbol{d}) = 0, \ \forall \boldsymbol{d} \in F\}.
$$

It is easy to prove that the set $I(F)$ is an ideal of $\mathbb{Q}[x_1, \ldots, x_n]$. $I(F)$ is called the design *ideal* of F. The design ideal introduced by $[12]$ is a fundamental tool to consider designs algebraically. The design ideal is a radical ideal (Theorem 20 of [\[10\]](#page-23-7)). The set of points $\mathbf{d} \in \mathbb{Q}^n$ satisfying $f(\mathbf{d}) = 0$ for all $f \in I(F)$ is F itself.

For a full factorial design D , the design ideal $I(D)$ can be written as

$$
I(D) = \langle x_j^{r_j} - g_j, \ j = 1, \ldots, n \rangle,
$$

where g_j is a polynomial in $\mathbb{Q}[x_j]$ with the degree less than r_j , $j = 1, \ldots, n$. Here $\langle \{f_i\} \rangle$ means "the ideal generated by $\{f_i\}$ ". In other words, the set

$$
G = \{x_j^{r_j} - g_j, \ j = 1, \dots, n\}
$$
 (5)

is a generator of $I(D)$. In addition, G is a reduced Gröbner basis of $I(D)$ for any monomial order. Note that the term $x_i^{r_j}$ $j_j^{r_j}$ is greater than the leading term of g_j with respect to any monomial order. We write the set of the monomials that are not divisible by the initial monomials of $G, \{x_j^{r_j}\}$ $j^{r_j}, \; j = 1, \ldots, n\}, \;$ as

$$
Est(D) = \left\{ \boldsymbol{x}^{\boldsymbol{a}} = \prod_{j=1}^{n} x_j^{a_j} : \boldsymbol{a} \in L \right\},\
$$

where

$$
L = \{ \mathbf{a} = (a_1, \dots, a_n) \in \mathbb{Z}_{\geq 0}^n : 0 \leq a_j \leq r_j - 1, j = 1, \dots, n \}
$$

and $\mathbb{Z}_{\geq 0}$ is the set of nonnegative integers. Note that the cardinality of L is m. From $D = \{d_i \in \mathbb{Q}^n : i \in \mathcal{I}\}\$ and L, we define a model matrix by

$$
X=[\boldsymbol{d}_{\boldsymbol{i}}^{\boldsymbol{a}}]_{\boldsymbol{i}\in\mathcal{I};\boldsymbol{a}\in L},
$$

where $\boldsymbol{d_i^a} = \prod_{j=1}^n d_{ij}^{a_j}$ i_j and d_{ij} is the level of the factor j in the experimental run indexed by $i \in \mathcal{I}$. Note that X is called a design matrix in Definition 26 of [\[10\]](#page-23-7). By ordering the elements of Z and L, X is an $m \times m$ matrix, and is nonsingular (Theorem 26 of [\[10\]](#page-23-7)).

The quotient of $\mathbb{Q}[x_1,\ldots,x_n]$ modulo the design ideal $I(D) \in \mathbb{Q}[x_1,\ldots,x_n]$ is defined by

$$
\mathbb{Q}[x_1,\ldots,x_n]/I(D)=\{[f] : f \in \mathbb{Q}[x_1,\ldots,x_n]\},\
$$

where we define $[f] = \{g \in \mathbb{Q}[x_1,\ldots,x_n] \text{ such that } f - g \in I(D)\}.$ In the terminology of the designs of experiments, two polynomial models f and g are *confounded* on D if and only if $f - g \in I(D)$. Therefore each element $[f] \in \mathbb{Q}[x_1, \ldots, x_n]/I(D)$ is the set of the polynomials $g \in \mathbb{Q}[x_1,\ldots,x_n]$ that is confounded to f on D. An important fact is that Est(D) is a basis of $\mathbb{Q}[x_1,\ldots,x_n]/I(D)$ as a \mathbb{Q} -vector space. See Theorem 15 of [\[10\]](#page-23-7) for detail.

Suppose we have a Q-valued response (or, observations) $y = (y(i))_{i \in \mathcal{I}}$ on $D = \{d_i \in \mathcal{I}\}$ $\mathbb{Q}^n : \boldsymbol{i} \in \mathcal{I}$. Note that each polynomial $f \in \mathbb{Q}[x_1, \ldots, x_n]$ can be viewed as a response function on D, i.e., $f \in \mathbb{Q}^D$ where we denote \mathbb{Q}^D by the vector space of functions from D to Q. The *interpolatory polynomial function* for **y** is a polynomial $f \in \mathbb{Q}[x_1, \ldots, x_n]$

satisfying $f(\mathbf{d_i}) = y(\mathbf{i}), \mathbf{i} \in \mathcal{I}$. From the fact that $\text{Est}(D)$ is a basis of $\mathbb{Q}[x_1, \ldots, x_n]/I(D)$, the interpolatory polynomial function for y is written uniquely as

$$
f(x_1,\ldots,x_n)=\sum_{\mathbf{a}\in L}\theta_{\mathbf{a}}\mathbf{x}^{\mathbf{a}},\qquad(6)
$$

where an $m \times 1$ column vector $\theta = (\theta_a)_{a \in L}$ is given by $\theta = X^{-1}y$ for an $m \times 1$ column vector \boldsymbol{y} . See Theorem 26 of [\[10\]](#page-23-7) for detail.

Now we introduce an indicator function.

Definition 2.1 ([\[6\]](#page-23-1)). Let $F \subset D$ be a fractional factorial design. The indicator function of F is a response function f on D satisfying

$$
f(\boldsymbol{d}) = \begin{cases} 1, & \text{if } \boldsymbol{d} \in F, \\ 0, & \text{if } \boldsymbol{d} \in D \setminus F. \end{cases}
$$

By the definition, the indicator function is constructed as follows. Write a fractional factorial design $F \subset D$ as $F = \{d_i \in D : i \in \mathcal{I}'\}$ for a subset $\mathcal{I}' \subset \mathcal{I}$. Then the indicator function of F is the interpolatory polynomial function for a response $y = (y(i))_{i \in \mathcal{I}}$, where

$$
y(\boldsymbol{i}) = \begin{cases} 1, & \text{if } \boldsymbol{i} \in \mathcal{I}' \\ 0, & \text{if } \boldsymbol{i} \in \mathcal{I} \setminus \mathcal{I}'. \end{cases} (7)
$$

From the uniqueness of the interpolarory polynomial function mentioned above, the representation of the indicator function is unique.

Example 2.2. Consider designs of 3 factors x_1, x_2, x_3 , where x_1, x_2 are two-level factors and x_3 is a three-level factor. We code the levels of each factor as

$$
A_1 = A_2 = \{-1, 1\}, \ A_3 = \{-1, 0, 1\}.
$$

Therefore $r_1 = r_2 = 2, r_3 = 3$, and the full factorial design $D = A_1 \times A_2 \times A_3$ has $m = 12$ points. The index set is $\mathcal{I} = \{1,2\} \times \{1,2\} \times \{1,2,3\}$. The full factorial design D is written as $D = \{d_i : i \in \mathcal{I}\}\text{, where}$

$$
\begin{array}{llll}\n\mathbf{d}_{(1,1,1)} = (-1,-1,-1), & \mathbf{d}_{(1,1,2)} = (-1,-1,0), & \mathbf{d}_{(1,1,3)} = (-1,-1,1), \\
\mathbf{d}_{(1,2,1)} = (-1,1,-1), & \mathbf{d}_{(1,2,2)} = (-1,1,0), & \mathbf{d}_{(1,2,3)} = (-1,1,1), \\
\mathbf{d}_{(2,1,1)} = (1,-1,-1), & \mathbf{d}_{(2,1,2)} = (1,-1,0), & \mathbf{d}_{(2,1,3)} = (1,-1,1), \\
\mathbf{d}_{(2,2,1)} = (1,1,-1), & \mathbf{d}_{(2,2,2)} = (1,1,0), & \mathbf{d}_{(2,2,3)} = (1,1,1).\n\end{array}
$$

The design ideal of D is written as

$$
I(D) = \langle x_1^2 - 1, x_2^2 - 1, x_3^3 - x_3 \rangle \subset \mathbb{Q}[x_1, x_2, x_3],
$$

and $G = \{x_1^2 - 1, x_2^2 - 1, x_3^3 - x_3\}$ is a reduced Gröbner basis of $I(D)$ for any monomial order. Therefore we have

$$
Est(D) = \{1, x_1, x_2, x_3, x_3^2, x_1x_2, x_1x_3, x_2x_3, x_1x_2x_3, x_1x_3^2, x_2x_3^2, x_1x_2x_3^2\}.
$$

Note that there are m monomials in $Est(D)$. Corresponding L is given by

$$
L = \{ (0,0,0), (1,0,0), (0,1,0), (0,0,1), (0,0,2), (1,1,0), (1,0,1), (0,1,1), (1,1,1), (1,0,2), (0,1,2), (1,1,2) \}.
$$

The model matrix X is given in Figure [3.](#page-7-0) Note that, differently than in the usual ANOVA decomposition, the columns corresponding to the interactions are not orthogonal to the columns corresponding to the simple factors. Here, and hereafter, we write each element of L and I by omitting commas as $(a_1 \cdots a_n)$ or $(i_1 \cdots i_n)$ instead of (a_1, \cdots, a_n) or (i_1, \dots, i_n) for simplicity.

Figure 3: The model matrix of a full factorial design $D = \{-1, 1\}^2 \times \{-1, 0, 1\}$.

Now consider a fractional factorial design $F = \{d_i : i \in \mathcal{I}'\} \subset D$, where $\mathcal{I}' =$ $\{(111), (122), (213), (223)\}.$ The indicator function of F is constructed as the interpolatory polynomial function [\(6\)](#page-6-0) for a response $y = (y(i))_{i \in \mathcal{I}}$ satisfying [\(7\)](#page-6-1). For this $\mathcal{I}', y =$ $(1, 0, 0, 0, 1, 0, 0, 0, 1, 0, 0, 1)^T$ and we have

$$
\boldsymbol{\theta} = X^{-1} \mathbf{y} = \frac{1}{8} (2, -2, 2, 1, 1, -2, 3, 1, -1, 3, -3, 3)^T,
$$

where T is a transpose. Therefore the indicator function of F is</sup>

$$
f(x_1, x_2, x_3) = \frac{1}{4} - \frac{1}{4}(x_1 - x_2) + \frac{1}{8}(x_3 + x_3^2) - \frac{1}{4}x_1x_2 + \frac{3}{8}x_1x_3 + \frac{1}{8}x_2x_3 - \frac{1}{8}x_1x_2x_3 + \frac{3}{8}(x_1x_3^2 - x_2x_3^2 + x_1x_2x_3^2).
$$

3 Characterization of orthogonal fractional factorial designs by indicator functions

Now we consider relations between the design and its indicator function. We start with the generalization of the relation [\(2\)](#page-2-1) for two-level designs to multi-level designs.

A polynomial $f \in \mathbb{Q}[x_1,\ldots,x_n]$ is an indicator function of some fractional factorial design $F \subset D = \{d_i \in \mathbb{Q}^n : i \in \mathcal{I}\}\$ if and only if $f^2 - f \in I(D)$, i.e., f and f^2 are in the same equivalence class of $\mathbb{Q}[x_1, \ldots, x_n]/I(D)$. Therefore, suppose f represented as [\(6\)](#page-6-0) is an indicator function of some fractional factorial design, we have

$$
\sum_{a \in L} \theta_a x^a = \left(\sum_{a \in L} \theta_a x^a \right)^2 \mod I(D)
$$

=
$$
\sum_{a_1 \in L} \sum_{a_2 \in L} \theta_{a_1} \theta_{a_2} x^{a_1 + a_2} \mod I(D).
$$

Here, write the standard form of \sum $a_1 \in L$ \sum $a_2 \in L$ $\theta_{a_1}\theta_{a_2}x^{a_1+a_2}$ with respect to G as

$$
r = \sum_{a \in L} \mu_a x^a. \tag{8}
$$

In other words, r is a unique remainder when we divide \sum $a_1 \in L$ \sum $a_2 \in L$ $\theta_{a_1}\theta_{a_2}x^{a_1+a_2}$ by G, the reduced Gröber basis of $I(D)$. Then we have the following result.

Proposition 3.1 (Generalization of Proposition 3.7 of [\[6\]](#page-23-1)). A polynomial f represented as [\(6\)](#page-6-0) is an indicator function of some fractional factorial design if and only if a system of algebraic equations

$$
\theta_a = \mu_a, \quad a \in L \tag{9}
$$

holds, where μ_a is given by [\(8\)](#page-8-0).

Proof. From the division algorithm and the property of the Gröbner basis. See Chapter 2 of [\[5\]](#page-23-8).

The meaning of the relation [\(9\)](#page-8-1) is explained as follows. From the theory of the interpolatory polynomial function on D , each \mathbb{Q} -valued function on D is represented (on D) by a polynomial with the monomials in $Est(D)$. This applies to the indicator function f of a fraction $F \subset D$. In this case, the reduced Gröbner basis of $I(D)$ is simply the list of the univariate monic polynomials [\(5\)](#page-5-0) defining the levels of each factor, and the remainder r is derived by substitution as it is.

Example 3.2 (Continuation of Example [2.2\)](#page-6-2). Consider $2 \times 2 \times 3$ designs. When we code

the levels as $A_1 = A_2 = \{-1, 1\}, A_3 = \{-1, 0, 1\}$, the relation [\(9\)](#page-8-1) is as follows.

$$
\begin{array}{rcl}\n\theta_{000} &=& \theta_{100}^{2} + \theta_{010}^{2} + \theta_{000}^{2} + \theta_{110}^{2} \\
\theta_{100} &=& 2\theta_{100}\theta_{000} + 2\theta_{010}\theta_{110} \\
\theta_{001} &=& 2\theta_{100}\theta_{101} + 2\theta_{010}\theta_{000} \\
\theta_{001} &=& 2\theta_{100}\theta_{101} + 2\theta_{010}\theta_{001} + 2\theta_{001}\theta_{002} + 2\theta_{001}\theta_{000} + 2\theta_{110}\theta_{111} + 2\theta_{101}\theta_{102} + 2\theta_{011}\theta_{012} + 2\theta_{111}\theta_{112} \\
\theta_{002} &=& 2\theta_{100}\theta_{102} + 2\theta_{010}\theta_{012} + \theta_{001}^{2} + \theta_{002}^{2} + 2\theta_{002}\theta_{000} + 2\theta_{110}\theta_{112} + \theta_{101}^{2} + \theta_{111}^{2} + \theta_{102}^{2} + \theta_{012}^{2} \\
&+ \theta_{112}^{2} \\
\theta_{110} &=& 2\theta_{100}\theta_{010} + 2\theta_{000}\theta_{110} \\
\theta_{101} &=& 2\theta_{100}\theta_{001} + 2\theta_{001}\theta_{111} + 2\theta_{001}\theta_{102} + 2\theta_{002}\theta_{101} + 2\theta_{000}\theta_{101} + 2\theta_{110}\theta_{011} + 2\theta_{011}\theta_{112} + 2\theta_{111}\theta_{012} \\
\theta_{011} &=& 2\theta_{100}\theta_{011} + 2\theta_{010}\theta_{011} + 2\theta_{001}\theta_{112} + 2\theta_{002}\theta_{011} + 2\theta_{000}\theta_{011} + 2\theta_{110}\theta_{101} + 2\theta_{101}\theta_{
$$

These results are easily obtained by standard algebraic softwares, such as Macaulay2 ([\[8\]](#page-23-9)). Each solution of the above system of polynomial equations corresponds to the coefficients of the indicator function for each fractional factorial designs.

If we change the level codings, the relation [\(9\)](#page-8-1) changes. For example, when we code the levels as $A_1 = A_2 = \{0, 1\}, A_3 = \{0, 1, 2\},\$ the relation [\(9\)](#page-8-1) is as follows.

θ⁰⁰⁰ = θ 2 000 θ¹⁰⁰ = θ 2 ¹⁰⁰ + 2θ100θ⁰⁰⁰ θ⁰¹⁰ = θ 2 ⁰¹⁰ + 2θ010θ⁰⁰⁰ θ⁰⁰¹ = −4θ001θ⁰⁰² − 6θ 2 ⁰⁰² + 2θ001θ⁰⁰⁰ θ⁰⁰² = θ 2 ⁰⁰¹ + 6θ001θ⁰⁰² + 7θ 2 ⁰⁰² + 2θ002θ⁰⁰⁰ θ¹¹⁰ = 2θ100θ⁰¹⁰ + 2θ100θ¹¹⁰ + 2θ010θ¹¹⁰ + 2θ000θ¹¹⁰ + θ 2 110 θ¹⁰¹ = 2θ100θ⁰⁰¹ + 2θ100θ¹⁰¹ − 4θ002θ¹⁰¹ + 2θ000θ¹⁰¹ − 4θ001θ¹⁰² − 12θ002θ¹⁰² − 4θ101θ¹⁰² − 6θ 2 102 θ⁰¹¹ = 2θ010θ⁰⁰¹ + 2θ010θ⁰¹¹ − 4θ002θ⁰¹¹ + 2θ000θ⁰¹¹ − 4θ001θ⁰¹² − 12θ002θ⁰¹² − 4θ011θ⁰¹² − 6θ 2 012 θ¹¹¹ = 2θ001θ¹¹⁰ + 2θ010θ¹⁰¹ + 2θ110θ¹⁰¹ + 2θ100θ⁰¹¹ + 2θ110θ⁰¹¹ + 2θ100θ¹¹¹ + 2θ010θ¹¹¹ − 4θ002θ¹¹¹ + 2θ000θ¹¹¹ + 2θ110θ¹¹¹ − 4θ011θ¹⁰² − 4θ111θ¹⁰² − 4θ101θ⁰¹² − 4θ111θ⁰¹² − 12θ102θ⁰¹² − 4θ001θ¹¹² − 12θ002θ¹¹² − 4θ101θ¹¹² − 4θ011θ¹¹² − 4θ111θ¹¹² − 12θ102θ¹¹² − 12θ012θ¹¹² − 6θ 2 112 θ¹⁰² = 2θ100θ⁰⁰² + 2θ001θ¹⁰¹ + 6θ002θ¹⁰¹ + θ 2 ¹⁰¹ + 2θ100θ¹⁰² + 6θ001θ¹⁰² + 14θ002θ¹⁰² + 2θ000θ¹⁰² +6θ101θ¹⁰² + 7θ 2 102 θ⁰¹² = 2θ010θ⁰⁰² + 2θ001θ⁰¹¹ + 6θ002θ⁰¹¹ + θ 2 ⁰¹¹ + 2θ010θ⁰¹² + 6θ001θ⁰¹² + 14θ002θ⁰¹² + 2θ000θ⁰¹² + 6θ011θ⁰¹² + 7θ 2 012 θ¹¹² = 2θ002θ¹¹⁰ + 2θ101θ⁰¹¹ + 2θ001θ¹¹¹ + 6θ002θ¹¹¹ + 2θ101θ¹¹¹ + 2θ011θ¹¹¹ + θ 2 ¹¹¹ + 2θ010θ¹⁰² +2θ110θ¹⁰² + 6θ011θ¹⁰² + 6θ111θ¹⁰² + 2θ100θ⁰¹² + 2θ110θ⁰¹² + 6θ101θ⁰¹² + 6θ111θ⁰¹² + 14θ102θ⁰¹² + 2θ100θ¹¹² + 2θ010θ¹¹² + 6θ001θ¹¹² + 14θ002θ¹¹² + 2θ000θ¹¹² + 2θ110θ¹¹²

In actual applications, there are cases where the level coding has not essential meaning, such as for the designs of qualitative factors. However, for our purpose of solving a system of polynomial equations using computational algebraic software, an appropriate level coding is important in view of computational time. In the author's experiences, it is

 $+ 6\theta_{101}\theta_{112} + 6\theta_{011}\theta_{112} + 6\theta_{111}\theta_{112} + 14\theta_{102}\theta_{112} + 14\theta_{012}\theta_{112} + 7\theta_{112}^2$

better to code $\{-1, 1\}$ rather than $\{0, 1\}$ for two-level factor, and $\{-1, 0, 1\}$ rather than $\{0, 1, 2\}$ for three-level factor. We consider this point in Section 4. $\{0, 1, 2\}$ for three-level factor. We consider this point in Section [4.](#page-17-0)

As we see in Example [3.2,](#page-8-2) the relation [\(9\)](#page-8-1) is very complicated compared to the relation for two-level cases [\(2\)](#page-2-1). Among the various characterizations of the coefficients of the indicator functions of two-level designs given in [\[6\]](#page-23-1), the relation of the indicator functions of complementary designs can be generalized to multi-level cases as follows.

Proposition 3.3 (Generalization of Corollary 3.5 of [\[6\]](#page-23-1)). If F and \overline{F} are complementary fractions and $\theta = (\theta_a)_{a \in L}$ and $\bar{\theta} = (\bar{\theta}_a)_{a \in L}$ are the coefficients of the corresponding indicator functions given by (6) respectively, then

$$
\theta_{0\cdots 0} = 1 - \bar{\theta}_{0\cdots 0}
$$
 and $\theta_{\boldsymbol{a}} = -\bar{\theta}_{\boldsymbol{a}}, \ \forall \ \boldsymbol{a} \neq (0,\ldots,0).$

Proof. Write the model matrix X as

$$
X = \left[\mathbf{1}_m \mid \mathbf{s}_2 \mid \cdots \mid \mathbf{s}_m\right]
$$

and write $X^{-1}\mathbf{1}_m = (c_1, \ldots, c_m)^T$. Then we have $c_1 = 1, c_2 = \cdots = c_m = 0$ from the non-singularity of X in the relation

$$
\mathbf{1}_m=c_1\mathbf{1}_m+c_2\mathbf{s}_2+\cdots+c_m\mathbf{s}_m.
$$

Therefore for the responses $y, \bar{y} \in \{0, 1\}^m$ such that $y + \bar{y} = 1_m$, we have

$$
\boldsymbol{\theta} + \bar{\boldsymbol{\theta}} = X^{-1}(\boldsymbol{y} + \bar{\boldsymbol{y}}) = (1, 0, \dots, 0)^T.
$$

Next consider structure of the indicator functions of designs with given characteristic. The idea is to express the structure of the indicator functions as additional constraints to the system of polynomial equations [\(9\)](#page-8-1) to classify designs with given characteristic. The additional constraints are derived as follows. Recall that the coefficients vector $\boldsymbol{\theta}$ is given by $\boldsymbol{\theta} = X^{-1} \boldsymbol{y}$ in [\(6\)](#page-6-0). Here, treat $\boldsymbol{y} = (y(\boldsymbol{i}))_{\boldsymbol{i} \in \mathcal{I}}$ as a vector of $\{0,1\}^m$ in [\(7\)](#page-6-1) and express the characteristic of designs as

$$
\mathbf{c}^T \mathbf{y} = s, \ s \in \mathbb{Q} \tag{10}
$$

for a constant column vector $\boldsymbol{c} \in \mathbb{Q}^m$. For example, $\boldsymbol{y} \in \{0,1\}^m$ corresponding to designs with the size s satisfies the constraint

$$
\mathbf{1}_m^T \boldsymbol{y} = s,
$$

where $\mathbf{1}_m = (1, \ldots, 1)^T$ is an $m \times 1$ column vector of the elements 1's. Equireplicated designs or orthogonal designs can be expressed by

$$
\boldsymbol{c}^T\boldsymbol{y}=0
$$

for some contrast vectors c .

Based on the above idea, we define a contrast matrix. For each subset $J \subset [n]$, we define $\mathcal{I}_J = \prod_{j \in J} [r_j] \subset \mathcal{I}$ and its cardinality by $m_J = \prod_{j \in J} r_j$. We also define i_J by the restriction of $\mathbf{i} = (i_1, \ldots, i_n) \in \mathcal{I}$ to the index of \mathcal{I}_J . For example of $n = 4$ and $J = \{1, 2, 4\}$, we have $i_J = (i_1, i_2, i_4)$.

Definition 3.4. The contrast matrix C is an $m \times m$ matrix of the form

$$
C^T = \begin{bmatrix} \mathbf{1}_m & C_1^T & C_2^T & \cdots & C_n^T \end{bmatrix},
$$

where C_k is a $v_k \times m$ matrix where

$$
v_k = \sum_{J \subset [n], \#J = k} \left(\prod_{j \in J} (r_j - 1) \right).
$$

The set of $m \times 1$ column vectors of C_k^T is

$$
\left\{ \boldsymbol{c}_{J(\tilde{\boldsymbol{i}})} = \{c_{J(\tilde{\boldsymbol{i}})}(\boldsymbol{i})\}_{\boldsymbol{i}\in\mathcal{I}} \; : \; J\subset[n], \#J = k, \tilde{\boldsymbol{i}} \in \prod_{j\in J}[r_j-1] \right\},\
$$

where

$$
c_{J(\tilde{i})}(\boldsymbol{i}) = \begin{cases} 1, & \boldsymbol{i}_J = 1, \\ -1, & \boldsymbol{i}_J = \tilde{i} + 1, \\ 0, & \text{otherwise} \end{cases}
$$

for $\#J=1$, and

$$
c_{J(\tilde{\boldsymbol{i}})}(\boldsymbol{i}) = \begin{cases} 1, & \boldsymbol{i}_J = (\tilde{i}_1, \ldots, \tilde{i}_{k-1}, 1), \\ -1, & \boldsymbol{i}_J = (\tilde{i}_1, \ldots, \tilde{i}_{k-1}, \tilde{i}_k + 1), \\ 0, & \text{otherwise} \end{cases}
$$

for $\#J \geq 2$.

Note that the contrast matrix C is constructed only from \mathcal{I} . In other words, C is uniquely determined from r_1, \ldots, r_n . Especially, C does not depend on the level coding.

Example 3.5 (Continuation of Example [3.2\)](#page-8-2). For $2 \times 2 \times 3$ designs, the contrast matrix C is given in Figure 4. C is given in Figure [4.](#page-12-0)

The contrast matrix C given in Definition [3.4](#page-11-0) relates to the theory of contingency tables. Suppose the response y is a vector of nonnegative integers, then we can treat y as a frequency of contingency table $y = \{y_i : i \in \mathcal{I}\}\$ with the set of cells \mathcal{I} . In this case, we see that the condition

$$
\mathbf{1}_m^T \mathbf{y} = s, \ C_\ell \mathbf{y} = \mathbf{0}_{v_\ell}, \ \ell = 1, \ldots, t,
$$

means equal ℓ -dimensional marginal totals for $\ell = 1, \ldots, t$. The definition of the contrast matrix and the following theorem (Theorem [3.6\)](#page-12-1) are based on this connection. As another relation, C is a configuration matrix in the theory of toric ideals. See Section1.5.3 of $[9]$.

By the contrast matrix, we specify the size and the orthogonality of the designs as follows. We call a design $F \subset D$ is *orthogonal of strength t* $(t \leq n)$, if for any t factors, all possible combinations of levels appear equally often in F . This definition is from the theory of orthogonal arrays. See Chapter 7 of [\[13\]](#page-24-0), for example. In particular, an orthogonal design of strength n is a full factorial design.

Theorem 3.6. If $y \in \{0,1\}^m$ is a response on D given by [\(7\)](#page-6-1), the fractional factorial design $F = \{d_i \in D : i \in \mathcal{I}'\}$ is size s and orthogonal of strength t if and only if

$$
\begin{cases}\n\mathbf{1}_m^T \mathbf{y} = s, \\
C_k \mathbf{y} = \mathbf{0}_{v_k}, \quad k = 1, \dots, t,\n\end{cases} \tag{11}
$$

where $\mathbf{0}_{\ell} = (0, \ldots, 0)^T$ is an $\ell \times 1$ column vector of the elements 0's, and s is a common multiple of $\left\{\prod\right.$ j∈J r_j : $\#J=t$ \mathcal{L} .

To prove Theorem [3.6,](#page-12-1) we define J-marginal vector of $\bm{y}=(y(\bm{i}))_{\bm{i}\in\mathcal{I}}$ by $\bm{y}_J=(y_J(\bm{i}_J))_{\bm{i}_J\in\mathcal{I}_J},$ where

$$
y_J(\boldsymbol{i}_J) = \sum_{\boldsymbol{i}_{J^c} \in \mathcal{I}_{J^c}} y(\boldsymbol{i}_J, \boldsymbol{i}_{J^c}).
$$

Note that J^c denotes the complement of J , and in $y(i_J, i_{J^c})$, for notational simplicity, the indices in \mathcal{I}_J are collected to the left. Also we are writing $y(i_J, i_{J^c})$ instead of $y((i_J, i_{J^c}))$. For example of $n=3$, we have $\mathbf{y}_{\{2\}}=(y_{\{2\}(i_{\{2\}})})_{i_{\{2\}}\in\mathcal{I}_{\{2\}}}= (y_{\{2\}}(i_2))_{i_2\in[r_2]}$, where

$$
y_{\{2\}}(i_2) = \sum_{i_1 \in [r_1]} \sum_{i_3 \in [r_3]} y(i_1, i_2, i_3),
$$

and $\mathbf{y}_{\{1,3\}} = (y_{\{1,3\}}(\boldsymbol{i}_{\{1,3\}}))_{\boldsymbol{i}_{\{1,3\}} \in \mathcal{I}_{\{1,3\}}} = (y_{\{1,3\}}(i_1, i_3))_{(i_1, i_3) \in [r_1] \times [r_3]},$ where

$$
y_{\{1,3\}}(i_1, i_3) = \sum_{i_2 \in [r_2]} y(i_1, i_2, i_3),
$$

and so on. The concept of the J-marginal vector is from the theory of contingency tables. For detail, see Chapter 4.2 of [\[7\]](#page-23-11), "Basic facts and concepts" of Contingency tables, for example.

Proof of Theorem [3.6.](#page-12-1) Suppose that the size s is a common multiple of $\Big\{ \prod_{i=1}^N X_i \Big\}$ j∈J r_j : $\#J=t$ \mathcal{L} . Using the J-marginal vector y_{J} , F is size s and orthogonal of strength t if and only if

$$
\begin{cases}\n\mathbf{1}_m^T \mathbf{y} = s, \\
y_J(\mathbf{i}_J) = \frac{s}{m_J}, \ \forall \ \mathbf{i}_J \in \mathcal{I}_J \ \text{ for all } J \subset [n] \text{ with } \#J \le t.\n\end{cases} \tag{12}
$$

The relation $(12) \Rightarrow (11)$ $(12) \Rightarrow (11)$ is straightforward, because the relation $C_k \mathbf{y} = \mathbf{0}_{v_k}$ is equivalent to

$$
y_J(i_1, \ldots, i_{k-1}, 1) = y_J(i_1, \ldots, i_{k-1}, 2) = \cdots = y_J(i_1, \ldots, i_{k-1}, r_k), \ \forall (i_1, \ldots, i_{k-1}) \in \prod_{j=1}^{k-1} [r_j - 1]
$$
\n(13)

for $J = \{1, 2, \ldots, k\}$ from Definition [3.4.](#page-11-0)

To show $(11) \Rightarrow (12)$ $(11) \Rightarrow (12)$, we use an induction for t. For the case of $t = 1$, we have

$$
y_{\{j\}}(1) = y_{\{j\}}(2) = \cdots = y_{\{j\}}(r_j), \ \ j = 1, \ldots, n
$$

from C_1 **y** = **0**_{v₁}. From $s = \sum^{r_j}$ $i_j=1$ $y_{\{j\}}(i_j)$, we have

$$
y_{\{j\}}(i_j) = \frac{s}{r_j} = \frac{s}{m_{\{j\}}}
$$

for $j = 1, \ldots, n$. Next consider the case of t under the assumption that the theorem holds for the case of $t-1$. We write $J = \{1, 2, \ldots, t\}$ for a J with $\#J = t$ without loss of generality. Our purpose is to show that

$$
\boldsymbol{y}_{J}(\boldsymbol{i}_{J})=\frac{s}{m_{J}},\ \ \forall \boldsymbol{i}_{J}\in\mathcal{I}_{J}
$$

for $J = \{1, 2, \ldots, t\}$. Similarly to the relation [\(13\)](#page-13-1), for $\boldsymbol{i}_J = (i_1, \ldots, i_{t-1}, i_t) \in \left(\prod^{t-1}$ $j=1$ $[r_j-1]\bigg\rangle \times$

 $[r_t]$ we have

$$
\frac{s}{m_{J\setminus\{t\}}}=y_{J\setminus\{t\}}(i_1,\ldots,i_{t-1})=\sum_{i_t=1}^{r_t}y_J(i_1,\ldots,i_{t-1},i_t)
$$

and therefore

$$
y_J(i_1, ..., i_{t-1}, i_t) = \frac{1}{r_t} \cdot \frac{s}{m_{J \setminus \{t\}}} = \frac{s}{m_J}
$$

holds for $i_t = 1, \ldots, r_t$. To show the relation for other i_j 's, suppose p elements of $\{i_1, \ldots, i_{t-1}\}$ equal to $\{r_1, \ldots, r_{t-1}\}$, i.e.,

$$
p = \#\{i_j : i_j = r_j, j = 1, \dots, t-1\}.
$$

Again we use an induction for p here. For the case of $p = 1$, suppose $i_1 = r_1$ without loss of generality. We have

$$
y_J(r_1,i_2,\ldots,i_t) = y_{J\setminus\{1\}}(i_2,\ldots,i_t) - \sum_{i_1=1}^{r_1-1} y_J(i_1,i_2,\ldots,i_t).
$$

From the assumption of the induction for t, we have $y_{J\setminus\{1\}}(i_2,\ldots,i_t) = \frac{s}{\sqrt{1-s}}$ $m_{J\setminus\{1\}}$. Also from the assumption of the induction for p, we have $y_J(i_1, i_2, \ldots, i_t) = \frac{s}{m_J}$ for $i_1 = 1, \ldots, r_1 - 1$. Therefore we have

$$
y_J(r_1, i_2, \dots, i_t) = \frac{s}{m_{J \setminus \{1\}}} - (r_1 - 1) \cdot \frac{s}{m_J} = \frac{s}{m_J}
$$

.

The case of p under the assumption that the relation holds for the case of $p - 1$ can be shown similarly. shown similarly.

From Theorem [3.6](#page-12-1) and the relation $\theta = X^{-1}y$, the constraints to be added to the relation [\(9\)](#page-8-1) for the orthogonal designs of strength t ($t \leq n$) becomes

$$
\mathbf{1}_m^T X \boldsymbol{\theta} = s, \ C_{\ell} X \boldsymbol{\theta} = \mathbf{0}_{v_{\ell}}, \ \ \ell = 1, \ldots, t.
$$

This is a generalization of relation for two-level case such as [\(3\)](#page-3-1).

Example 3.7 (Continuation of Example [3.5\)](#page-11-1). Consider $\{-1,1\} \times \{-1,1\} \times \{-1,0,1\}$ designs. In addition to the polynomial equations derived in Example [3.5,](#page-11-1) the coefficients of the indicator functions of designs with size s satisfy the relation

$$
12\theta_{000} + 8\theta_{002} = s.
$$

The constraints for the equireplicated designs, i.e., orthogonal designs of strength 1, are

$$
-12\theta_{100} - 8\theta_{102} = 0,
$$

$$
-12\theta_{010} - 8\theta_{012} = 0,
$$

$$
-4\theta_{001} + 4\theta_{002} = 0,
$$

$$
-8\theta_{001} = 0.
$$

Therefore for a given s that is a common multiple of $\{2, 2, 3\}$, i.e., only $s = 6$ is the compatible size of the fractional factorial designs in this case, we can enumerate all the equireplicated designs as the solutions of a system of these polynomial equations. \Box

Considering Theorem [3.6](#page-12-1) for the case of $t = n$, we have the following.

Corollary 3.8. The contrast matrix C is a non-singular $m \times m$ matrix.

Now we give another representation of the indicator function reflecting the orthogonality. For the indicator function [\(6\)](#page-6-0), consider a non-singular linear transformation $\theta \mapsto \mu = CX\theta$. New variables z is also defined by $z = ((CX)^{-1})^T x$, where $x = (x^a)_{a \in L}$ is an $m \times 1$ column vector of variables, and $\boldsymbol{z} = \{z_{J(\tilde{\boldsymbol{i}})} : J \subset [n], \tilde{\boldsymbol{i}} \in \prod_{j \in J} [r_j - 1]\}$ is also an $m \times 1$ column vector of variables. Then we have a representation of the indicator function for z ,

$$
f(\boldsymbol{z}) = \sum_{J \subset [n], \tilde{\boldsymbol{i}} \in \prod_{j \in J} [r_j - 1]} \mu_{J(\tilde{\boldsymbol{i}})} z_{J(\tilde{\boldsymbol{i}})}.
$$
(14)

We call (14) the contrast representation of the indicator function.

From the contrast representation, we see the size and the orthogonality of the designs directly, which is the advantage of the contrast representation. For example, the constant term μ_{\emptyset} is the size of the design, and

$$
\mu_{J(\tilde{\mathbf{i}})} = 0 \text{ for } \#J = 1, \tilde{\mathbf{i}} \in \prod_{j \in J} [r_j - 1]
$$

corresponds to equireplicated designs, and so on.

Example 3.9. In Section [1,](#page-0-0) we see the indicator function of 3^{4-2} regular fractional factorial design F_3 in Figure [2](#page-3-0) is [\(4\)](#page-3-2). The contrast representation of F_3 is

$$
f(z) = 9 + z_{123(111)} + z_{123(112)} - z_{123(122)} - z_{123(212)} - z_{123(221)} - z_{124(111)} - z_{124(122)} + z_{124(211)} + z_{124(212)} - z_{124(221)} - z_{134(111)} + z_{134(121)} + z_{134(122)} - z_{134(212)} - z_{134(221)} - z_{234(111)} - z_{234(122)} + z_{234(211)} + z_{234(212)} - z_{234(221)} - z_{1234(1111)} - z_{1234(2221)}.
$$

From this representation, we see that the size of F_3 is 9, and F_3 is an orthogonal design of strength 2.

Another example is a $1/2$ fraction of $2 \times 2 \times 3$ design F_4 displayed in Figure [5.](#page-15-1) The

$$
F_4
$$

 x_1 x_2 x_3
 x_1 -1 -1
 x_2 x_3
 x_1 -1 -1
 x_1 -1 0
 x_1 -1 0
 x_1 -1 1
 x_1 -1 -1
 x_1 -1

Figure 5: An example of $1/2$ fraction of $\{-1, 1\}^2 \times \{-1, 0, 1\}$ design.

indicator function and the contrast representation of F_4 are

.

$$
f(x_1, x_2, x_3) = \frac{1}{2} - \frac{1}{2}x_1x_2 - \frac{1}{4}x_2x_3 - \frac{1}{4}x_1x_2x_3 - \frac{1}{4}x_2x_3^2 + \frac{3}{4}x_1x_2x_3^2 \tag{15}
$$

and

$$
f(z) = 6 + 2z_{2(1)} + z_{12(11)} - z_{23(12)} + z_{123(111)},
$$
\n(16)

respectively. From the contrast representation, we see that the size of F_4 is 6. We also see that x_1 and x_3 are orthogonal from

$$
\mu_{1(1)} = \mu_{3(1)} = \mu_{3(2)} = \mu_{13(11)} = \mu_{13(12)} = 0.
$$

On the other hand, $\mu_{2(1)} \neq 0$ implies that F_3 is not equireplicated for x_2 .

In addition, the contrast representation does not depend on the level coding, whereas the indicator function depends on the level coding. This is another advantage of the contrast representation.

Proposition 3.10. In the contrast representation [\(14\)](#page-15-0), μ is determined only from the contrast matrix C . It does not depend on the model matrix X , especially on the levelcoding.

Proof. From
$$
\boldsymbol{\theta} = X^{-1} \boldsymbol{y}
$$
, we have $\boldsymbol{\mu} = CX \boldsymbol{\theta} = Cy$.

In other words, the influence of the level-coding on the contrast representation is involved in the variables z. For the same contrast matrix C and the response $y \in \{0, 1\}^m$ given by [\(7\)](#page-6-1), the contrast representation of the design $F = \{d_i \in D : i \in \mathcal{I}'\}$ has the same coefficient vector $\mu = Cy$ regardless of the level-coding. On the other hand, the variable z depends on the level-coding and is defined by $\mathbf{z} = ((CX)^{-1})^T \mathbf{x}$.

Solving a system of polynomial equations for the coefficients of the indicator function or the contrast representation by computational algebraic softwares, we can obtain the complete list of fractional factorial designs with given orthogonality in theory. It is true that the computational feasibility is an important issue, which we see in Section 4. Another important point arises in classifying the solutions to the equivalence classes for permutations of levels or factors. For two-level cases, as we see in [\[6\]](#page-23-1), the equivalence classes for permutations of levels and factors are simply obtained by sign changes or permutation of indices for the coefficients of the indicator functions. To consider multi-level cases, we give the description of the equivalence classes as follows. Suppose $S_{\mathcal{I}}$ is a group of permutations of \mathcal{I} , and $G \subset S_{\mathcal{I}}$ is a group we consider, i.e., a group of permutations of levels for each factor and permutations of factors if possible. For each $g \in G$, let P_g be an $m \times m$ permutation matrix. Then we have the following.

Proposition 3.11. Let $G \subset S_{\mathcal{I}}$ is a group. Then the equivalence classes for θ and μ with respect to G are

$$
[\boldsymbol{\theta}] = \{X^{-1}P_gX\boldsymbol{\theta} \; : \; g \in G\}
$$

and

$$
[\boldsymbol{\mu}] = \{ CP_g C^{-1} \boldsymbol{\mu} \; : \; g \in G \},
$$

respectively.

Proof. Let $\tilde{\mathbf{y}} = P_g \mathbf{y}$. Let the corresponding indicator functions be $f(\mathbf{x}) = \boldsymbol{\theta}^T \mathbf{x}$ and $\tilde{f}(\boldsymbol{x}) = \tilde{\boldsymbol{\theta}}^T \boldsymbol{x}$, where $\boldsymbol{\theta} = X^{-1} \boldsymbol{y}$ and $\tilde{\boldsymbol{\theta}} = X^{-1} \tilde{\boldsymbol{y}}$, respectively. Then we have the relation

$$
\tilde{\boldsymbol{\theta}} = X^{-1}\tilde{\boldsymbol{y}} = X^{-1}P_g\boldsymbol{y} = X^{-1}P_gX\boldsymbol{\theta}.
$$

Similarly, for the constant representations $f(z) = \mu^T z$ and $\tilde{f}(z) = \tilde{\mu}^T z$ where $\mu = C y$ and $\tilde{\mu} = C\tilde{y}$, respectively, we have

$$
\tilde{\mu} = C\tilde{\mathbf{y}} = C P_g \mathbf{y} = C P_g C^{-1} \boldsymbol{\mu}.
$$

Proposition [3.11](#page-16-0) shows that neither the indicator function nor the contrast representation has the invariance property for multi-level cases. We will see it in the computations in Section [4.](#page-17-0)

4 Classifications of orthogonal $2^3 \times 3$ and $2^4 \times 3$ designs

In this section, we consider $2^3 \times 3$ and $2^4 \times 3$ designs. Using a computational algebraic software, we solve systems of the polynomial equations and derive a classification of designs with given characteristic. All the computations are done by Macaulay 2(8) installed in a virtual machine (vmware) on a laptop with 2.80 GHz CPU and 8 GB memory. The memory allocated to the virtual machine is 512 MB.

4.1 Full enumeration of the orthogonal fractions of the $2^3 \times 3$ designs of strength 2

First we consider the orthogonal fractions of the $2³ \times 3$ designs of strength 2. Corresponding system of algebraic equations includes a set of $m = 2^3 \times 3 = 24$ general relations, 1 relation for the size, 5 relations for the balance for each factor and 9 relations for the orthogonality of strength 2, for 25 variables. Note that there are $m+1$ variables, where $+1$ corresponds to the variable for the size s . To obtain a compatible size s , first we calculate the Gröbner basis of the ideal I generated by the 39 polynomials corresponding to the above 39 relations for the elimination ordering where the variable s is the lowest. For the level-coding $\{-1, 1\}^3 \times \{-1, 0, 1\}$, the Gröbner basis is calculated within 0.1 seconds, and the elimination ideal is

$$
I \cap \mathbb{Q}[s] = \langle s^3 - 36s^2 + 288s \rangle = \langle s(s - 12)(s - 24) \rangle,
$$

i.e., only the size $s = 12$ is compatible. This result is also obvious because the size of the orthogonal designs must be the multiple of 2×2 and 2×3 . Note that the Grönber basis calculations heavily depend on the level-coding. To see this, the author also try the same computation under the level-coding $\{0, 1\}^3 \times \{0, 1, 2\}$, and find that the computation does not finish in one week.

Now we fix $s = 12$ and calculate all the solutions. We find that there are 44 solutions, classified into 3 equivalence classes as follows.

• Type (a): 2 relations. The indicator function and the contrast representation of the representative fraction displayed in Figure [6\(](#page-19-0)a) are

$$
\frac{1}{2} + \frac{1}{2}x_1x_2x_3
$$

and

$$
12 - 3z_{123(111)},
$$

respectively. This is a class of the regular fractional factorial designs with the defining relation $x_1x_2x_3 = 1$.

• Type (b): 6 relations. The indicator function and the contrast representation of the representative fraction displayed in Figure [6\(](#page-19-0)b) are

$$
\frac{1}{2} + \frac{1}{2}x_1x_2x_3 - \frac{1}{2}x_1x_2x_3x_4 - \frac{1}{2}x_1x_2x_3x_4^2
$$

and

$$
12 - z_{123(111)} - z_{1234(1112)},
$$

respectively, each with 4 relations. The indicator function and the contrast representation of another fraction in the same equivalence class are

$$
\frac{1}{2} - \frac{1}{2}x_1x_2x_3 + x_1x_2x_3x_4^2
$$

and

$$
12 - z_{123(111)} - z_{1234(1111)},
$$

respectively, each with 2 relations.

• Type (c): 36 relations. The indicator function and the contrast representation of the representative fraction displayed in Figure [6\(](#page-19-0)c) are

$$
\frac{1}{2} + \frac{1}{2}x_1x_2x_3 - \frac{1}{2}x_1x_3x_4 - \frac{1}{2}x_1x_2x_3x_4^2
$$

and

 $12 - z_{123(111)} + z_{134(111)} + 2z_{134(112)} + z_{1234(1111)} + z_{1234(1112)}$

respectively, each with 12 relations. The indicator function and the contrast representation of another fraction in the same equivalence class are

$$
\frac{1}{2} - \frac{1}{2}x_1x_2 - \frac{1}{4}x_1x_2x_4 + \frac{1}{4}x_1x_2x_3x_4 + \frac{3}{4}x_1x_2x_4^2 + \frac{1}{4}x_1x_2x_3x_4^2
$$

and

 $12 - z_{123(111)} + 2z_{124(111)} + z_{124(112)} + z_{1234(1111)} + z_{1234(1112)}$

respectively, each with 24 relations.

	Type(a)				Type(b)			Type(c)

-1			1				1				

Figure 6: Orthogonal fractions of the $2^3 \times 3$ designs of strength 2

In the above list, Type (a) is the class of the regular fractions, whereas Type (b) and Type (c) are classes of the non-regular fractions. Note that Type (b) and Type (c) differ only in the last columns (the levels of x_4) in Figure [6.](#page-19-0) For each row where the levels of (x_1, x_2, x_3) is unique, there are 4 such rows, the levels of x_4 are fixed $(x_4 = 1)$ in Type (b), whereas the levels of x_4 are 1 or -1 in Type (c). Type (b) and (c) can also be characterized considering the designs obtained from a traditional $OA(12, 3¹2⁴)$ orthogonal array as follows. The orthogonal array $OA(12, 3¹2⁴)$ in Appendix 8C of [\[13\]](#page-24-0) is displayed in Figure [7.](#page-20-0) From $OA(12, 3^12^4)$, we can obtain $1/2$ fractions of $2^3 \times 3$ designs by selecting 3 columns from the columns {2, 3, 4, 5}. We see that all the designs constructed in this way are included in the equivalence class of Type (c). Therefore Type (c) is regarded as the class of $OA(12, 3^12^4)$ designs.

4.2 Full enumeration of the orthogonal fractions of the $2^4 \times 3$ designs of strength 3

Next we consider the fractions of the $2^4 \times 3$ designs. For this case, enumeration of the orthogonal fractions of strength 2 may be difficult to compute for standard PC. In fact, the Gröbner basis of the elimination ideal for the compatible size does not obtained after 1 week calculation under the level-coding $\{-1,1\}^4 \times \{-1,0,1\}$. Therefore we enumerate the orthogonal fractions of strength 3 instead. Note that, for fixed size s, there are $m = 48$ variables with constraints $1 + 6 + 14 = 21$ relations for strength 2, and with constraints $1+6+14+16=37$ relations for strength 3. Therefore, by eliminating variables, the number of variables reduces 11 for strength 3, whereas to 27 for strength 2. The compatible size must be $s = 24$ for strength 3, that is only the multiple of $2 \times 2 \times 2$ and $2 \times 2 \times 3$ less than $m = 48$. This fact is also checked by the Gröbner basis calculation. After calculation within 0.1 seconds, we see that the elimination ideal is

$$
I \cap \mathbb{Q}[s] = \langle s^3 - 72s^2 + 1152s \rangle = \langle s(s - 24)(s - 48) \rangle.
$$

1	2	3	4	5
$\overline{0}$	0	0	0	0
$\overline{0}$	$\overline{0}$	1	0	1
$\overline{0}$	1	$\overline{0}$	1	1
$\overline{0}$	1	1	1	$\overline{0}$
$\overline{1}$	$\overline{0}$	$\overline{0}$	1	1
$\overline{1}$	0	1	1	0
1	1	$\overline{0}$	$\overline{0}$	1
1	1	1	$\overline{0}$	$\overline{0}$
$\overline{2}$	$\overline{0}$	$\overline{0}$	1	$\overline{0}$
$\overline{2}$	0	1	$\overline{0}$	1
$\overline{2}$	1	0	0	0
$\overline{2}$	1	1	1	1

Figure 7: Orthogonal array $OA(12, 3^12^4)$ (Appendix 8C of [\[13\]](#page-24-0)).

Therefore we fix $s = 24$ and calculate all the solutions. We find there are 56 solutions, classified into 3 equivalence classes as follows.

• Type (a): 2 relations. The indicator function and the contrast representation of the representative fraction displayed in Figure [8\(](#page-22-0)a) are

$$
\frac{1}{2} + \frac{1}{2}x_1x_2x_3x_4
$$

and

$$
24 + 3z_{1234(1111)},
$$

respectively. This is a class of the regular fractional factorial designs with the defining relation $x_1x_2x_3x_4 = 1$.

• Type (b): 6 relations. The indicator function and the contrast representation of the representative fraction displayed in Figure [8\(](#page-22-0)b) are

$$
\frac{1}{2} - \frac{1}{2}x_1x_2x_3x_4 - \frac{1}{2}x_1x_2x_3x_4x_5 + \frac{1}{2}x_1x_2x_3x_4x_5^2
$$

and

$$
24 - z_{1234(1111)} + z_{12345(11111)} + z_{12345(11112)},
$$

respectively, each with 4 relations. The indicator function and the contrast representation of another fraction in the same equivalence class are

$$
\frac{1}{2} + \frac{1}{2}x_1x_2x_3x_4 - x_1x_2x_3x_4x_5^2
$$

and

 $24 - z_{1234(1111)} - z_{12345(11111)},$

respectively, each with 2 relations.

• Type (c): 48 relations. The indicator function and the contrast representation of the representative fraction displayed in Figure [8\(](#page-22-0)c) are

$$
\frac{1}{2} - \frac{1}{2}x_1x_2x_3x_4 - \frac{1}{2}x_1x_2x_4x_5 + \frac{1}{2}x_1x_2x_3x_4x_5^2
$$

and

$$
24 - z_{1234(1111)} - z_{1245(1111)} - 2z_{1245(1112)} - z_{12345(11112)},
$$

respectively, each with 16 relations. The indicator function and the contrast representation of another fraction in the same equivalence class are

$$
\frac{1}{2} + \frac{1}{2}x_1x_2x_3 + \frac{1}{4}x_1x_2x_3x_5 + \frac{1}{4}x_1x_2x_3x_4x_5 - \frac{3}{4}x_1x_2x_3x_5^2 + \frac{1}{4}x_1x_2x_3x_4x_5^2
$$

and

 $24 + z_{1234(1111)} + 2z_{1235(1111)} + z_{1235(1112)} + z_{12345(11111)}$

respectively, each with 32 relations.

An interpretation of this list is similar to the $2^3 \times 3$ case. In Figure [8,](#page-22-0) Type (b) and Type (c) differ only in the last column (the levels of x_5). For each row where the levels of (x_1, x_2, x_3, x_4) is unique, there are 8 such rows, the levels of x_5 are fixed $(x_5 = -1)$ in Type (b), whereas the levels of x_5 are 1 or -1 in Type (c).

5 Discussion

In this paper, we give how to construct a system of polynomial equations for the coefficients of the indicator functions of multi-level fractional factorial designs with given orthogonality. We also define the contrast representation of the indicator function, which reflects the orthogonality of the design directly. The contrast representation has an advantage that it does not depends on the level-coding. Using these results, we show the classifications of the orthogonal fractions of the $2^3 \times 3$ designs with strength 2 and $2^4 \times 3$ designs with strength 3.

In theory, we can obtain classifications of fractional factorial designs for any size by our method. However, the computational feasibility depends on the size of problems. For the class of $2^m \times 3$ designs, we see that the $2^4 \times 3$ problem for orthogonality with strength 3 is easy to calculate. However, a $2^5 \times 3$ problem of strength 3 orthogonality seems very difficult to compute. As for the class of $2^m \times 3^2$ designs, we find that the $2^3 \times 3^2$ problem of strength 2 orthogonality is hard to compute, i.e., the Gröbner basis calculation for the elimination ideal does not finish in 1 week. In addition, it is obvious that there is no orthogonal fractions $2^3 \times 3^2$ with strength 3 because the size must be a multiple of $2 \times 2 \times 2$ and $2 \times 3 \times 3$. As a consequence, we only have limited computational results in this paper.

In particular, the merit of the contrast representation must be investigated from the computational aspects. It seems that a system of polynomial equations for μ is easy to solve than that for θ . Note that the polynomial relations for μ are obtained by substituting $\theta = (CX)^{-1}\mu$ to the polynomial relations for θ . Therefore, translating the

Figure 8: Orthogonal fractions of the $2^4\times 3$ designs of strength 3

relations for θ to the relations for μ corresponds to the matrix operations of inverse in advance. Unfortunately, for the problems considered in this paper, the systems of the polynomial equations for θ and μ are both quite easy or quite difficult, and the effectiveness of the contrast representation from the computational aspect is not shown. Therefore the quantitative evaluation of the effect of this transformation is one of the open problems. It is also an open problem to compare our method to the brute-force search.
