# EULER MATRICES AND THEIR ALGEBRAIC PROPERTIES REVISITED 

YAMILET QUINTANA ${ }^{(1)}$, WILLIAM RAMÍREZ ${ }^{(2)}$, AND ALEJANDRO URIELES ${ }^{(2)}$

#### Abstract

This paper is concerned with the generalized Euler polynomial matrix $\mathscr{E}^{(\alpha)}(x)$ and the Euler matrix $\mathscr{E}$. Taking into account some properties of Euler polynomials and numbers, we deduce product formulae for $\mathscr{E}^{(\alpha)}(x)$ and determine the inverse matrix of $\mathscr{E}$. We establish some explicit expressions for the Euler polynomial matrix $\mathscr{E}(x)$, which involving the generalized Pascal, Fibonacci and Lucas matrices, respectively. From these formulae we get some new interesting identities involving Fibonacci and Lucas numbers. Also, we provide some factorizations of the Euler polynomial matrix in terms of Stirling matrices, as well as, a connection between the shifted Euler matrices and Vandermonde matrices.

## 1. Introduction

The classical Euler polynomials $E_{n}(x)$ and the generalized Euler polynomials $E_{n}^{(\alpha)}(x)$ of (real or complex) order $\alpha$, are usually defined as follows (see, for details, [1, 15, 20, 22]):

$$
\begin{equation*}
\left(\frac{2}{e^{z}+1}\right)^{\alpha} e^{x z}=\sum_{n=0}^{\infty} E_{n}^{(\alpha)}(x) \frac{z^{n}}{n!}, \quad|z|<\pi, \quad 1^{\alpha}:=1, \tag{1.1}
\end{equation*}
$$

and

$$
\begin{equation*}
E_{n}(x):=E_{n}^{(1)}(x), \quad n \in \mathbb{N}_{0}, \tag{1.2}
\end{equation*}
$$

where $\mathbb{N}_{0}:=\mathbb{N} \cup\{0\}$ and $\mathbb{N}=\{1,2,3, \ldots\}$.
The numbers $E_{n}^{(\alpha)}:=E_{n}^{(\alpha)}(0)$ are called generalized Euler numbers of order $\alpha, n \in \mathbb{N}_{0}$. It is well-known that the classical Euler numbers are defined by the generating function

$$
\begin{equation*}
\frac{2}{e^{z}+e^{-z}}=\sum_{n=0}^{\infty} \varepsilon_{n} \frac{z^{n}}{n!} \tag{1.3}
\end{equation*}
$$

The sequence $\left\{\varepsilon_{n}\right\}_{n \geq 0}$ counts the numbers of alternating $n$-permutations. Let recall us that a permutation $\sigma$ of a set of $n$ elements (or $n$-permutation), is said alternating if and only if the $n-1$ differences $\sigma(i+1)-\sigma(i)$ for $i=1,2, \ldots, n-1$ have alternating signs (cf. [5, p. 258]). From (1.2)

[^0]and (1.3) it is easy to check that the connection between the classical Euler numbers and the Euler polynomials is given by the formula
\[

$$
\begin{equation*}
\varepsilon_{n}=2^{n} E_{n}\left(\frac{1}{2}\right), \quad n \in \mathbb{N}_{0} \tag{1.4}
\end{equation*}
$$

\]

So, the numbers $E_{n}:=E_{n}(0)$ also are known in the literature as Euler numbers (cf., e.g., 14, 20]). The first six generalized Euler polynomials are

$$
\begin{aligned}
E_{0}^{(\alpha)}(x)= & 1, \quad E_{1}^{(\alpha)}(x)=x-\frac{\alpha}{2}, \quad E_{2}^{(\alpha)}(x)=x^{2}-\alpha x+\frac{\alpha(\alpha-1)}{4} \\
E_{3}^{(\alpha)}(x)= & x^{3}-\frac{3 \alpha}{2} x^{2}+\frac{3 \alpha(\alpha-1)}{4} x-\frac{3 \alpha^{2}(\alpha-1)}{8}, \\
E_{4}^{(\alpha)}(x)= & x^{4}-2 \alpha x^{3}+\frac{3 \alpha(\alpha-1)}{2} x^{2}-\frac{\alpha^{2}(\alpha-3)}{2} x+\frac{\alpha\left(\alpha^{3}-6 \alpha^{2}+3 \alpha-26\right)}{16} \\
E_{5}^{(\alpha)}(x)= & x^{5}-\frac{5 \alpha}{2} x^{4}+\frac{5 \alpha(\alpha-1)}{2} x^{3}-\frac{5 \alpha^{2}(\alpha-3)}{4} x^{2}+\frac{5 \alpha(\alpha-1)\left(\alpha^{2}-5 \alpha-2\right)}{16} x \\
& -\frac{\alpha^{2}\left(\alpha^{3}-10 \alpha^{2}+15 \alpha+10\right)}{32}
\end{aligned}
$$

Recent and interesting works dealing with these polynomials, Appell and Apostol type polynomials, their properties and applications in several areas as such as combinatorics, number theory, numerical analysis and partial differential equations, can be found by reviewing the current literature on this subject. For a broad information on old literature and new research trends about these classes of polynomials we strongly recommend to the interested reader see [5, 8 $, 10,14,21,23-26]$.

From the generating relation (1.1), it is fairly straightforward to deduce the addition formula:

$$
\begin{equation*}
E_{n}^{(\alpha+\beta)}(x+y)=\sum_{k=0}^{n}\binom{n}{k} E_{k}^{(\alpha)}(x) E_{n-k}^{(\beta)}(y) \tag{1.5}
\end{equation*}
$$

And, it follows also that

$$
\begin{equation*}
E_{n}^{(\alpha)}(x+1)+E_{n}^{(\alpha)}(x)=2 E_{n}^{(\alpha-1)}(x) \tag{1.6}
\end{equation*}
$$

Since $E_{n}^{(0)}(x)=x^{n}$, making the substitution $\beta=0$ into (1.5) and interchanging $x$ and $y$, we get

$$
\begin{equation*}
E_{n}^{(\alpha)}(x+y)=\sum_{k=0}^{n}\binom{n}{k} E_{k}^{(\alpha)}(y) x^{n-k} \tag{1.7}
\end{equation*}
$$

And, as an immediate consequence, we have

$$
\begin{align*}
E_{n}(x+y) & =\sum_{k=0}^{n}\binom{n}{k} E_{k}(y) x^{n-k}  \tag{1.8}\\
E_{n}(x) & =\sum_{k=0}^{n}\binom{n}{k} E_{k} x^{n-k} \tag{1.9}
\end{align*}
$$

Using (1.4), (1.8) and the well-known relation $E_{n}(1-x)=(-1)^{n} E_{n}(x)$, it is possible to deduce the following connection formula between $E_{n}$ and the classical Euler numbers $\varepsilon_{n}$ :

$$
E_{n}=\left\{\begin{array}{l}
-\frac{1}{2^{n}} \sum_{k=0}^{n}\binom{n}{k} \varepsilon_{n-k}, \quad \text { if } n \text { is odd },  \tag{1.10}\\
0, \quad \text { if } n \text { is even. }
\end{array}\right.
$$

Inspired by the article [30] in which the authors introduce the generalized Bernoulli matrix and establish some algebraic properties of the Bernoulli polynomial and Bernoulli matrices, in the present article we focus our attention on the algebraic and differential properties of the generalized Euler matrix. It is worthwhile to mention that the authors of [30] to point out that their proposed methodology can be used for obtaining similar properties in the setting of the generalized Euler matrix. However, the authors of [30] do not actually write out any proof about this statement.

The outline of the paper is as follows. Section 2 has an auxiliary character and provides some background as well as some results which will be used throughout the paper. Making use of the some identities above, we introduce the generalized Euler matrix in Section 3. Then, we study some interesting particular cases of this matrix, namely, the Euler polynomial matrix, the Euler matrix and the specialized Euler matrix. The main results of this section are Theorems [3.1, 3.2, 3.3 and 3.4. because these theorems contain the information concerning the product formula for the Euler matrix, an explicit expression for the inverse matrix of the specialized Euler matrix, the factorization of the Euler matrix via the generalized Pascal matrix of first kind, and a useful factorization for the inverse matrix of a particular "horizontal sliding" of the Euler polynomial matrix, respectively. Also, some consequences of these results are showed (see for instance, Corollaries 3.1, 3.2, 3.3 and 3.4). Section 4 shows several factorizations of the generalized Euler matrix in terms the Fibonacci and Lucas matrices, respectively (cf. Theorems 4.1 and 4.1). Also, some new identities involving Fibonacci and Lucas numbers are given in this section. Finally, in Section 5 we provide some factorizations of the Euler polynomial matrix in terms of Stirling matrices, and the shifted Euler matrices and their connection with Vandermonde matrices are given.

## 2. Background and previous results

Throughout this paper, all matrices are in $M_{n+1}(\mathbb{R})$, the set of all $(n+1)$-square matrices over the real field. Also, for $i, j$ any nonnegative integers we adopt the following convention

$$
\binom{i}{j}=0, \text { whenever } j>i .
$$

In this section we recall the definitions of the generalized Pascal matrix, the Fibonacci matrix and the Lucas matrix, as well as, some properties of these matrices.
Definition 2.1. Let $x$ be any nonzero real number. The generalized Pascal matrix of first kind $P[x]$ is an $(n+1) \times(n+1)$ matrix whose entries are given by (see [2, 28]):

$$
p_{i, j}(x)=\left\{\begin{array}{l}
\binom{i}{j} x^{i-j}, \quad i \geq j,  \tag{2.11}\\
0, \quad \text { otherwise } .
\end{array}\right.
$$

In [2, 28, 29] some properties of the generalized Pascal matrix of first kind are showed, for example, its matrix factorization by special summation matrices, its associated differential equation and its
bivariate extensions. The following proposition summarizes some algebraic and differential properties of $P[x]$.

Proposition 2.1. Let $P[x]$ be the generalized Pascal matrix of first kind and order $n+1$. Then the following statements hold.
(a) Special value. If the convention $0^{0}=1$ is adopted, then it is possible to define

$$
\begin{equation*}
P[0]:=I_{n+1}=\operatorname{diag}(1,1, \ldots, 1), \tag{2.12}
\end{equation*}
$$

where $I_{n+1}$ denotes the identity matrix of order $n+1$.
(b) $P[x]$ is an invertible matrix and its inverse is given by

$$
\begin{equation*}
P^{-1}[x]:=(P[x])^{-1}=P[-x] . \tag{2.13}
\end{equation*}
$$

(c) [2, Theorem 2] Addition theorem of the argument. For $x, y \in \mathbb{R}$ we have

$$
\begin{equation*}
P[x+y]=P[x] P[y] . \tag{2.14}
\end{equation*}
$$

(d) [2, Theorem 5] Differential relation (Appell type polynomial entries). $P[x]$ satisfies the following differential equation

$$
\begin{equation*}
D_{x} P[x]=\mathfrak{L} P[x]=P[x] \mathfrak{L}, \tag{2.15}
\end{equation*}
$$

where $D_{x} P[x]$ is the matrix resulting from taking the derivative with respect to $x$ of each entry of $P[x]$ and the entries of the $(n+1) \times(n+1)$ matrix $\mathfrak{L}$ are given by

$$
\begin{aligned}
l_{i, j} & =\left\{\begin{array}{l}
p_{i, j}^{\prime}(0), \quad i \geq j, \\
0, \quad \text { otherwise },
\end{array}\right. \\
& =\left\{\begin{array}{l}
j+1, \quad i=j+1, \\
0, \quad \text { otherwise } .
\end{array}\right.
\end{aligned}
$$

(e) ([288, Theorem 1]) The matrix $P[x]$ can be factorized as follows.

$$
\begin{equation*}
P[x]=G_{n}[x] G_{n-1}[x] \cdots G_{1}[x], \tag{2.16}
\end{equation*}
$$

where $G_{k}[x]$ is the $(n+1) \times(n+1)$ summation matrix given by

$$
G_{k}[x]= \begin{cases}{\left[\begin{array}{cc}
I_{n-k} & 0 \\
0 & S_{k}[x]
\end{array}\right], \quad k=1, \ldots, n-1,} \\
S_{n}[x], & k=n,\end{cases}
$$

being $S_{k}[x]$ the $(k+1) \times(k+1)$ matrix whose entries $S_{k}(x ; i, j)$ are given by

$$
S_{k}(x ; i, j)=\left\{\begin{array}{l}
x^{i-j}, \quad j \leq i, \\
0, \quad j>i,
\end{array} \quad(0 \leq i, j \leq k) .\right.
$$

Another necessary structured matrices in what follows, are the Fibonacci and Lucas matrices. Below, we recall the definitions of each one of them.

DEFINITION 2.2. Let $\left\{F_{n}\right\}_{n \geq 1}$ be the Fibonacci sequence, i.e., $F_{n}=F_{n-1}+F_{n-2}$ for $n \geq 2$ with initial conditions $F_{0}=0$ and $F_{1}=1$. The Fibonacci matrix $\mathscr{F}$ is an $(n+1) \times(n+1)$ matrix whose entries are given by [12]:

$$
f_{i, j}=\left\{\begin{array}{l}
F_{i-j+1}, \quad i-j+1 \geq 0  \tag{2.17}\\
0, \quad i-j+1<0
\end{array}\right.
$$

Let $\mathscr{F}^{-1}$ be the inverse of $\mathscr{F}$ and denote by $\tilde{f}_{i, j}$ the entries of $\mathscr{F}^{-1}$. In [12] the authors obtained the following explicit expression for $\mathscr{F}^{-1}$.

$$
\tilde{f}_{i, j}=\left\{\begin{array}{l}
1, \quad i=j  \tag{2.18}\\
-1, \quad i=j+1, j+2 \\
0, \quad \text { otherwise }
\end{array}\right.
$$

DEFINITION 2.3. Let $\left\{L_{n}\right\}_{n \geq 1}$ be the Lucas sequence, i.e., $L_{n+2}=L_{n+1}+L_{n}$ for $n \geq 1$ with initial conditions $L_{1}=1$ and $L_{2}=3$. The Lucas matrix $\mathscr{L}$ is an $(n+1) \times(n+1)$ matrix whose entries are given by [31]:

$$
l_{i, j}=\left\{\begin{array}{l}
L_{i-j+1}, \quad i-j \geq 0  \tag{2.19}\\
0, \quad \text { otherwise }
\end{array}\right.
$$

Let $\mathscr{L}^{-1}$ be the inverse of $\mathscr{L}$ and denote by $\tilde{l}_{i, j}$ the entries of $\mathscr{L}^{-1}$. In 31, Theorem 2.2] the authors obtained the following explicit expression for $\mathscr{L}^{-1}$.

$$
\tilde{u}_{i, j}=\left\{\begin{array}{l}
1, \quad i=j,  \tag{2.20}\\
-3, \quad i=j+1, \\
5(-1)^{i-j} 2^{i-j-2}, \quad i \geq j+2, \\
0, \quad \text { otherwise } .
\end{array}\right.
$$

For $x$ any nonzero real number, the following relation between the matrices $P[x]$ and $\mathscr{L}$ was stated and proved in [31, Theorem 3.1].

$$
\begin{equation*}
P[x]=\mathscr{L} \mathscr{G}[x]=\mathscr{H}[x] \mathscr{L} \tag{2.21}
\end{equation*}
$$

where the entries of the $(n+1) \times(n+1)$ matrices $\mathscr{G}[x]$ and $\mathscr{H}[x]$ are given by

$$
\begin{aligned}
& g_{i, j}(x)=x^{-j-1}\left[x^{i+1}\binom{i}{j}-3 x^{i}\binom{i-1}{j}+5(-1)^{i+1} 2^{i-1} m_{i-1, j+1}\left(\frac{x}{2}\right)\right], \\
& h_{i, j}(x)=x^{-j-1}\left[x^{i+1}\binom{i}{j}-3 x^{i}\binom{i}{j+1}+(-1)^{j+1} \frac{5 x^{i+j+2}}{2^{j+3}} n_{i+1, j+3}\left(\frac{2}{x}\right)\right],
\end{aligned}
$$

respectively, with

$$
m_{i, j}(x):=\left\{\begin{array}{l}
\sum_{k=j}^{i}(-1)^{k}\binom{k}{j} x^{k}, \quad i \geq j, \\
0, \quad i<j,
\end{array} \quad \text { and } \quad n_{i, j}(x):= \begin{cases}\sum_{k=j}^{i}(-1)^{k}\binom{i}{k} x^{k}, & i \geq j, \\
0, & i<j .\end{cases}\right.
$$

## 3. The generalized Euler matrix

Definition 3.1. The generalized $(n+1) \times(n+1)$ Euler matrix $\mathscr{E}^{(\alpha)}(x)$ is defined by

$$
E_{i, j}^{(\alpha)}(x)=\left\{\begin{array}{l}
\binom{i}{j} E_{i-j}^{(\alpha)}(x), \quad i \geq j  \tag{3.22}\\
0, \quad \text { otherwise }
\end{array}\right.
$$

While, $\mathscr{E}(x):=\mathscr{E}^{(1)}(x)$ and $\mathscr{E}:=\mathscr{E}(0)$ are called the Euler polynomial matrix and the Euler matrix, respectively. In the particular case $x=\frac{1}{2}$, we call the matrix $\mathbb{E}:=\mathscr{E}\left(\frac{1}{2}\right)$ specialized Euler matrix.

It is clear that (1.6) yields the following matrix identity:

$$
\begin{equation*}
\mathscr{E}^{(\alpha)}(x+1)+\mathscr{E}^{(\alpha)}(x)=2 \mathscr{E}^{(\alpha-1)}(x) . \tag{3.23}
\end{equation*}
$$

Since $\mathscr{E}^{(0)}(x)=P[x]$, replacing $\alpha$ by 1 in (3.23) we have

$$
\begin{equation*}
\mathscr{E}(x+1)+\mathscr{E}(x)=2 P[x] . \tag{3.24}
\end{equation*}
$$

Then, putting $x=0$ in (3.24) and taking into account (2.12), we get

$$
\mathscr{E}(1)+\mathscr{E}=2 I_{n+1} .
$$

Analogously,

$$
\mathscr{E}+\mathscr{E}(-1)=2 P\left[-\frac{1}{2}\right] .
$$

From (1.4) it follows that the entries of the specialized Euler matrix $\mathbb{E}$ are given by

$$
e_{i, j}=\left\{\begin{array}{l}
\binom{i}{j} 2^{j-i} \varepsilon_{i-j}, \quad i \geq j,  \tag{3.25}\\
0, \quad \text { otherwise }
\end{array}\right.
$$

From (1.10) it follows that the entries of the Euler matrix $\mathscr{E}$ are given by

$$
E_{i, j}=\left\{\begin{array}{l}
\binom{i}{j} E_{i-j}, \quad i>j \text { and } i-j \text { odd }  \tag{3.26}\\
1, \quad i=j, \\
0, \quad \text { otherwise }
\end{array}\right.
$$

The next result is an immediate consequence of Definition 3.1 and the addition formula (1.5).
Theorem 3.1. The generalized Euler matrix $\mathscr{E}^{(\alpha)}(x)$ satisfies the following product formula.

$$
\begin{equation*}
\mathscr{E}^{(\alpha+\beta)}(x+y)=\mathscr{E}^{(\alpha)}(x) \mathscr{E}^{(\beta)}(y)=\mathscr{E}^{(\beta)}(x) \mathscr{E}^{(\alpha)}(y)=\mathscr{E}^{(\alpha)}(y) \mathscr{E}^{(\beta)}(x) . \tag{3.27}
\end{equation*}
$$

Proof. We proceed as in the proof of [30, Theorem 2.1], making the corresponding modifications. Let $A_{i, j}^{(\alpha, \beta)}(x, y)$ be the $(i, j)$-th entry of the matrix product $\mathscr{E}^{(\alpha)}(x) \mathscr{E}^{(\beta)}(y)$, then by the addition formula (1.5) we have

$$
\begin{aligned}
A_{i, j}^{(\alpha, \beta)}(x, y) & =\sum_{k=0}^{n}\binom{i}{k} E_{i-k}^{(\alpha)}(x)\binom{k}{j} E_{k-j}^{(\beta)}(y) \\
& =\sum_{k=j}^{i}\binom{i}{k} E_{i-k}^{(\alpha)}(x)\binom{k}{j} E_{k-j}^{(\beta)}(y) \\
& =\sum_{k=j}^{i}\binom{i}{j}\binom{i-j}{i-k} E_{i-k}^{(\alpha)}(x) E_{k-j}^{(\beta)}(y) \\
& =\binom{i}{j} \sum_{k=0}^{i-j}\binom{i-j}{k} E_{i-j-k}^{(\alpha)}(x) E_{k}^{(\beta)}(y) \\
& =\binom{i}{j} E_{i-j}^{(\alpha)}(x+y),
\end{aligned}
$$

which implies the first equality of (3.27). The second and third equalities of (3.27) can be derived in a similar way.
Corollary 3.1. Let $\left(x_{1}, \ldots, x_{k}\right) \in \mathbb{R}^{k}$. For $\alpha_{j}$ real or complex parameters, the Euler matrices $\mathscr{E}^{\left(\alpha_{j}\right)}(x)$ satisfies the following product formula, $j=1, \ldots, k$.

$$
\begin{equation*}
\mathscr{E}^{\left(\alpha_{1}+\alpha_{2}+\cdots+\alpha_{k}\right)}\left(x_{1}+x_{2}+\cdots+x_{k}\right)=\mathscr{E}^{\left(\alpha_{1}\right)}\left(x_{1}\right) \mathscr{E}^{\left(\alpha_{2}\right)}\left(x_{2}\right) \cdots \mathscr{E}^{\left(\alpha_{k}\right)}\left(x_{k}\right) . \tag{3.28}
\end{equation*}
$$

Proof. The application of induction on $k$ gives the desired result.
If we take $x=x_{1}=x_{2}=\cdots=x_{k}$ and $\alpha=\alpha_{1}=\alpha_{2}=\cdots=\alpha_{k}$, then we obtain the following simple formula for the powers of the generalized Euler matrix, and consequently, for the powers of the Euler polynomial and Euler matrices.
Corollary 3.2. The generalized Euler matrix $\mathscr{E}^{(\alpha)}(x)$ satisfies the following identity.

$$
\begin{equation*}
\left(\mathscr{E}^{(\alpha)}(x)\right)^{k}=\mathscr{E}^{(k \alpha)}(k x) \tag{3.29}
\end{equation*}
$$

In particular,

$$
\begin{align*}
(\mathscr{E}(x))^{k} & =\mathscr{E}^{(k)}(k x), \\
\mathscr{E}^{k} & =\mathscr{E}^{(k)} . \tag{3.30}
\end{align*}
$$

Remark 3.1 Note that Theorem 3.1 and Corollaries 3.1 and 3.2 are respectively, the analogous of Theorem 2.1 and Corollaries 2.2 and 2.3 of [30] in the setting of Euler matrices.

Let $\mathscr{D}$ be the $(n+1) \times(n+1)$ matrix whose entries are defined by

$$
d_{i, j}=\left\{\begin{array}{l}
\left(1+(-1)^{i-j}\right)\binom{i}{j} 2^{j-i-1}, \quad i \geq j,  \tag{3.31}\\
0, \quad \text { otherwise } .
\end{array}\right.
$$

Theorem 3.2. The inverse matrix of the specialized Euler matrix $\mathbb{E}$ is given by

$$
\mathbb{E}^{-1}=\mathscr{D}
$$

Furthermore,

$$
\left[\mathscr{E}^{(k)}\left(\frac{k}{2}\right)\right]^{-1}=\mathscr{D}^{k}
$$

Proof. Taking into account (1.4) and (3.25), it is possible to deduce

$$
\sum_{k=0}^{n} \frac{\left(1+(-1)^{k}\right)}{2}\binom{n}{k} 2^{n-k} E_{n-k}\left(\frac{1}{2}\right)=\sum_{k=0}^{n} \frac{\left(1+(-1)^{k}\right)}{2}\binom{n}{k} \varepsilon_{n-k}=\delta_{n, 0}
$$

where $\delta_{n, 0}$ is the Kronecker delta (cf., e.g., [18, pp. 107-109]). So, we obtain that the ( $i, j$ )-th entry of the matrix product $\mathscr{D E}$ may be written as

$$
\begin{gathered}
\sum_{k=j}^{i}\binom{i}{k} \frac{\left(1+(-1)^{i-k}\right)}{2} 2^{k-i}\binom{k}{j} E_{k-j}\left(\frac{1}{2}\right) \\
=\binom{i}{j} 2^{j-i} \sum_{k=j}^{i}\binom{i-j}{k-j} \frac{\left(1+(-1)^{i-k}\right)}{2} 2^{k-j} E_{k-j}\left(\frac{1}{2}\right) \\
=\binom{i}{j} 2^{j-i} \sum_{k=0}^{i-j}\binom{i-j}{k} \frac{\left(1+(-1)^{i-j-k}\right)}{2} 2^{k} E_{k}\left(\frac{1}{2}\right)=\binom{i}{j} 2^{j-i} \delta_{i-j, 0},
\end{gathered}
$$

and consequently, $\mathscr{D} \mathbb{E}=I_{n+1}$. Similar arguments allow to show that $\mathbb{E} \mathscr{D}=I_{n+1}$, and hence $\mathbb{E}^{-1}=\mathscr{D}$.
Finally, from the identity $\mathbb{E}^{-1}=\mathscr{D}$ and (3.30) we see that

$$
\left[\mathscr{E}^{(k)}\left(\frac{k}{2}\right)\right]^{-1}=\left(\mathbb{E}^{k}\right)^{-1}=\left(\mathbb{E}^{-1}\right)^{k}=\mathscr{D}^{k} .
$$

This last chain of equalities finishes the proof.

It is worthwhile to mention that the calculation of $\mathbb{E}^{-1}$ strongly depends on the use of inverse relations derived from exponential generating functions (cf. [18, Chap. 3, Sec. 3.4]). This tool can be applied in order to determine $\mathbb{E}^{-1}$, but it not works for determining of $\mathscr{E}^{-1}$. This fact and (1.10) suggest that methodology proposed in [30] does not suffice to finding an explicit formula for $\mathscr{E}^{-1}$.

The next result establishes the relation between the generalized Euler matrix and the generalized Pascal matrix of first kind.

Theorem 3.3. The generalized Euler matrix $\mathscr{E}^{(\alpha)}(x)$ satisfies the following relation.

$$
\begin{equation*}
\mathscr{E}^{(\alpha)}(x+y)=\mathscr{E}^{(\alpha)}(x) P[y]=P[x] \mathscr{E}^{(\alpha)}(y)=\mathscr{E}^{(\alpha)}(y) P[x] . \tag{3.32}
\end{equation*}
$$

In particular,

$$
\begin{gather*}
\mathscr{E}(x+y)=P[x] \mathscr{E}(y)=P[y] \mathscr{E}(x),  \tag{3.33}\\
\mathscr{E}(x)=P[x] \mathscr{E},  \tag{3.34}\\
\mathscr{E}\left(x+\frac{1}{2}\right)=P[x] \mathbb{E}, \tag{3.35}
\end{gather*}
$$

and

$$
\begin{equation*}
\mathscr{E}=P\left[-\frac{1}{2}\right] \mathbb{E} . \tag{3.36}
\end{equation*}
$$

Proof. The substitution $\beta=0$ into (3.27) yields

$$
\mathscr{E}^{(\alpha)}(x+y)=\mathscr{E}^{(\alpha)}(x) \mathscr{E}^{(0)}(y)=\mathscr{E}^{(0)}(x) \mathscr{E}^{(\alpha)}(y)=\mathscr{E}^{(\alpha)}(y) \mathscr{E}^{(0)}(x) .
$$

Since $\mathscr{E}^{(0)}(x)=P[x]$, we obtain

$$
\mathscr{E}^{(\alpha)}(x+y)=P[x] \mathscr{E}^{(\alpha)}(y) .
$$

A similar argument allows to show that $\mathscr{E}^{(\alpha)}(x+y)=\mathscr{E}^{(\alpha)}(x) P[y]$ and $\mathscr{E}^{(\alpha)}(x+y)=\mathscr{E}^{(\alpha)}(y) P[x]$.

Next, the substitution $\alpha=1$ into (3.32) yields (3.33). From the substitutions $y=0$ and $y=\frac{1}{2}$ into (3.33), we obtain the relations (3.34) and (3.35), respectively.

Finally, the substitution $x=-\frac{1}{2}$ into (3.35) completes the proof.

Remark 3.2 Note that the relation (3.33) is the analogous of [30, Eq. (13)] in the context of Euler polynomial matrices and, the counterpart of (3.34) is [30, Eq. (14)]. However, the relation (3.35) is slightly different from [30, Eq. (14)], since it involves an Euler polynomial matrix with "shifted argument" and the specialized Euler matrix. More precisely, the relation [30, Eq. (14)] reads as

$$
\mathscr{B}(x)=P[x] \mathscr{B},
$$

consequently, this relation expresses to the Bernoulli polynomial matrix $\mathscr{B}(x)$ in terms of the matrix product between the generalized Pascal matrix of first kind $P[x]$ and the Bernoulli matrix $\mathscr{B}$. While, on the left hand side of (3.35) appears an Euler polynomial matrix with "shifted argument", and the matrix product on the right hand side of (3.35) contains to the specialized Euler matrix $\mathbb{E}$.

The following example shows the validity of Theorem 3.3,

Example 3.1. Let us consider $n=3$. It follows from the definition 3.1 that

$$
\mathbb{E}=\left[\begin{array}{cccc}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
-\frac{1}{4} & 0 & 1 & 0 \\
0 & -\frac{3}{4} & 0 & 1
\end{array}\right] \quad \text { and } \quad \mathscr{E}\left(x+\frac{1}{2}\right)=\left[\begin{array}{cccc}
1 & 0 & 0 & 0 \\
x & 1 & 0 & 0 \\
x^{2}-\frac{1}{4} & 2 x & 1 & 0 \\
x^{3}-\frac{3}{4} x & 3 x^{2}-\frac{3}{4} & 3 x & 1
\end{array}\right] .
$$

On the other hand, from (3.35) and a simple computation we have

$$
\mathscr{E}\left(x+\frac{1}{2}\right)=\underbrace{\left[\begin{array}{cccc}
1 & 0 & 0 & 0 \\
x & 1 & 0 & 0 \\
x^{2} & 2 x & 1 & 0 \\
x^{3} & 3 x^{2} & 3 x & 1
\end{array}\right]}_{P[x]} \underbrace{\left[\begin{array}{cccc}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
-\frac{1}{4} & 0 & 1 & 0 \\
0 & -\frac{3}{4} & 0 & 1
\end{array}\right]}_{\mathbb{E}}=\left[\begin{array}{cccc}
1 & 0 & 0 & 0 \\
x & 1 & 0 & 0 \\
x^{2}-\frac{1}{4} & 2 x & 1 & 0 \\
x^{3}-\frac{3}{4} x & 3 x^{2}-\frac{3}{4} & 3 x & 1
\end{array}\right] .
$$

The next theorem follows by a simple computation.
Theorem 3.4. The inverse of the Euler polynomial matrix $\mathscr{E}\left(x+\frac{1}{2}\right)$ can be expressed as

$$
\begin{equation*}
\left[\mathscr{E}\left(x+\frac{1}{2}\right)\right]^{-1}=\mathbb{E}^{-1} P[-x]=\mathscr{D} P[-x] . \tag{3.37}
\end{equation*}
$$

In particular,

$$
\begin{equation*}
\mathscr{E}^{-1}=\mathscr{D} P\left[\frac{1}{2}\right] . \tag{3.38}
\end{equation*}
$$

Proof. Using (2.13), (3.35) and Theorem 3.2 the relation (3.37) is deduced. The substitution $x=-\frac{1}{2}$ into (3.37) yields (3.38).

Example 3.2. Let us consider $n=3$. From the definition 3.1 and a standard computation we obtain

$$
\left[\mathscr{E}\left(x+\frac{1}{2}\right)\right]^{-1}=\left[\begin{array}{cccc}
1 & 0 & 0 & 0 \\
x & 1 & 0 & 0 \\
x^{2}-\frac{1}{4} & 2 x & 1 & 0 \\
x^{3}-\frac{3}{4} x & 3 x^{2}-\frac{3}{4} & 3 x & 1
\end{array}\right]^{-1}=\left[\begin{array}{cccc}
1 & 0 & 0 & 0 \\
-x & 1 & 0 & 0 \\
x^{2}+\frac{1}{4} & -2 x & 1 & 0 \\
-x^{3}-\frac{3}{4} x & 3 x^{2}+\frac{3}{4} & -3 x & 1
\end{array}\right] .
$$

On the other hand, from (3.37) we have

$$
\left[\mathscr{E}\left(x+\frac{1}{2}\right)\right]^{-1}=\underbrace{\left[\begin{array}{cccc}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
\frac{1}{4} & 0 & 1 & 0 \\
0 & \frac{3}{4} & 0 & 1
\end{array}\right]}_{\mathscr{D}} \underbrace{\left[\begin{array}{cccc}
1 & 0 & 0 & 0 \\
-x & 1 & 0 & 0 \\
x^{2} & -2 x & 1 & 0 \\
-x^{3} & 3 x^{2} & -3 x & 1
\end{array}\right]}_{P[-x]}=\left[\begin{array}{cccc}
1 & 0 & 0 & 0 \\
-x & 1 & 0 & 0 \\
x^{2}+\frac{1}{4} & -2 x & 1 & 0 \\
-x^{3}-\frac{3}{4} x & 3 x^{2}+\frac{3}{4} & -3 x & 1
\end{array}\right]
$$

Hence, when $x=-\frac{1}{2}$, we get

$$
\mathscr{E}^{-1}=\underbrace{\left[\begin{array}{cccc}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
\frac{1}{4} & 0 & 1 & 0 \\
0 & \frac{3}{4} & 0 & 1
\end{array}\right]}_{\mathscr{D}} \underbrace{\left[\begin{array}{cccc}
1 & 0 & 0 & 0 \\
\frac{1}{2} & 1 & 0 & 0 \\
\frac{1}{4} & 1 & 1 & 0 \\
\frac{1}{8} & \frac{3}{4} & \frac{3}{2} & 1
\end{array}\right]}_{P\left[\frac{1}{2}\right]}=\left[\begin{array}{llll}
1 & 0 & 0 & 0 \\
\frac{1}{2} & 1 & 0 & 0 \\
\frac{1}{2} & 1 & 1 & 0 \\
\frac{1}{2} & \frac{3}{2} & \frac{3}{2} & 1
\end{array}\right] .
$$

At this point, an apart mention deserves the recent work [11] since it states an explicit formula to the inverse matrix of the $q$-Pascal matrix plus one in terms of the $q$-analogue of the Euler matrix $\mathscr{E}$.

As a consequence of the relations (2.16), (2.21), and Theorems 3.3 and 3.4 we obtain the following corollaries.

Corollary 3.3. The Euler polynomial matrix $\mathscr{E}\left(x+\frac{1}{2}\right)$ and its inverse can be factorized by summation matrices as follows.

$$
\begin{gathered}
\mathscr{E}\left(x+\frac{1}{2}\right)=G_{n}[x] G_{n-1}[x] \cdots G_{1}[x] \mathbb{E}, \\
{\left[\mathscr{E}\left(x+\frac{1}{2}\right)\right]^{-1}=\mathscr{D} G_{n}[-x] G_{n-1}[-x] \cdots G_{1}[-x] .}
\end{gathered}
$$

In particular,

$$
\begin{aligned}
\mathscr{E} & =G_{n}\left[-\frac{1}{2}\right] G_{n-1}\left[-\frac{1}{2}\right] \cdots G_{1}\left[-\frac{1}{2}\right] \mathbb{E}, \\
\mathscr{E}^{-1} & =\mathscr{D} G_{n}\left[\frac{1}{2}\right] G_{n-1}\left[\frac{1}{2}\right] \cdots G_{1}\left[\frac{1}{2}\right] .
\end{aligned}
$$

Corollary 3.4. For $x$ any nonzero real number, the Euler polynomial matrix $\mathscr{E}\left(x+\frac{1}{2}\right)$ and its inverse can be factorized, respectively, in terms of the Lucas matrix $\mathscr{L}$ and its inverse as follows.

$$
\begin{gathered}
\mathscr{E}\left(x+\frac{1}{2}\right)=\mathscr{L} \mathscr{G}[x] \mathbb{E}=\mathscr{H}[x] \mathscr{L} \mathbb{E}, \\
{\left[\mathscr{E}\left(x+\frac{1}{2}\right)\right]^{-1}=\mathscr{D}(\mathscr{G}[x])^{-1} \mathscr{L}^{-1}=\mathscr{D} \mathscr{L}^{-1}(\mathscr{H}[x])^{-1} .}
\end{gathered}
$$

In particular,

$$
\begin{aligned}
\mathscr{E} & =\mathscr{L} \mathscr{G}\left[-\frac{1}{2}\right] \mathbb{E}=\mathscr{H}\left[-\frac{1}{2}\right] \mathscr{L} \mathbb{E}, \\
\mathscr{E}^{-1} & =\mathscr{D}\left(\mathscr{G}\left[-\frac{1}{2}\right]\right)^{-1} \mathscr{L}^{-1}=\mathscr{D} \mathscr{L}^{-1}\left(\mathscr{H}\left[-\frac{1}{2}\right]\right)^{-1} .
\end{aligned}
$$

We end this section showing others identities, which can be easily deduced from the content of this paper. So, we will omit the details of their proofs.

$$
\begin{aligned}
D_{x} \mathscr{E}(x+y) & =\mathfrak{L} P[x] \mathscr{E}(y), \\
D_{x} \mathscr{E}(x) & =\mathfrak{L} P[x] \mathscr{E}, \\
D_{x} \mathscr{E}\left(x+\frac{1}{2}\right) & =\mathfrak{L} P[x] \mathbb{E}, \\
D_{x}\left[\mathscr{E}\left(x+\frac{1}{2}\right)\right]^{-1} & =\mathscr{D} \mathfrak{L} P[-x] .
\end{aligned}
$$

## 4. Generalized Euler polynomial matrices via Fibonacci and Lucas matrices

For $0 \leq i, j \leq n$ and $\alpha$ a real or complex number, let $\mathscr{M}^{(\alpha)}(x)$ be the $(n+1) \times(n+1)$ matrix whose entries are given by (cf. 30, Eq. (18)]):

$$
\begin{equation*}
\tilde{m}_{i, j}^{(\alpha)}(x)=\binom{i}{j} E_{i-j}^{(\alpha)}(x)-\binom{i-1}{j} E_{i-j-1}^{(\alpha)}(x)-\binom{i-2}{j} E_{i-j-2}^{(\alpha)}(x) . \tag{4.39}
\end{equation*}
$$

We denote $\mathscr{M}(x)=\mathscr{M}^{(1)}(x)$ and $\mathscr{M}=\mathscr{M}(0)$.
Similarly, let $\mathscr{N}^{(\alpha)}(x)$ be the $(n+1) \times(n+1)$ matrix whose entries are given by (cf. [30, Eq. (32)]):

$$
\begin{equation*}
\tilde{n}_{i, j}^{(\alpha)}(x)=\binom{i}{j} E_{i-j}^{(\alpha)}(x)-\binom{i}{j+1} E_{i-j-1}^{(\alpha)}(x)-\binom{i}{j+2} E_{i-j-2}^{(\alpha)}(x) . \tag{4.40}
\end{equation*}
$$

We denote $\mathscr{N}(x)=\mathscr{N}^{(1)}(x)$ and $\mathscr{N}=\mathscr{N}(0)$.
From the definitions of $\mathscr{M}^{(\alpha)}(x)$ and $\mathscr{N}^{(\alpha)}(x)$, we see that

$$
\begin{aligned}
& \tilde{m}_{0,0}^{(\alpha)}(x)=\tilde{m}_{1,1}^{(\alpha)}(x)=\tilde{n}_{0,0}^{(\alpha)}(x)=\tilde{n}_{1,1}^{(\alpha)}(x)=E_{0}^{(\alpha)}(x)=1, \\
& \tilde{m}_{0, j}^{(\alpha)}(x)=\tilde{n}_{0, j}^{(\alpha)}(x)=0, \quad j \geq 1, \\
& \tilde{m}_{1,0}^{(\alpha)}(x)=\tilde{n}_{1,0}^{(\alpha)}(x)=E_{1}^{(\alpha)}(x)-E_{0}^{(\alpha)}(x)=x-\frac{\alpha}{2}-1, \\
& \tilde{m}_{1, j}^{(\alpha)}(x)=\tilde{n}_{1, j}^{(\alpha)}(x)=0, \quad j \geq 2, \\
& \tilde{m}_{i, 0}^{(\alpha)}(x)=\tilde{n}_{i, 0}^{(\alpha)}(x)=E_{i}^{(\alpha)}(x)-E_{i-1}^{(\alpha)}(x)-E_{i-2}^{(\alpha)}(x), \quad i \geq 2 .
\end{aligned}
$$

For $0 \leq i, j \leq n$ and $\alpha$ a real or complex number, let $\mathscr{L}_{1}^{(\alpha)}(x)$ be the $(n+1) \times(n+1)$ matrix whose entries are given by

$$
\begin{equation*}
\hat{l}_{i, j}^{(\alpha, 1)}(x)=\binom{i}{j} E_{i-j}^{(\alpha)}(x)-3\binom{i-j}{j} E_{i-j-1}^{(\alpha)}(x)+5 \sum_{k=j}^{i-2}(-1)^{i-k} 2^{i-k-2}\binom{k}{j} E_{k-j}^{(\alpha)}(x) . \tag{4.41}
\end{equation*}
$$

We denote $\mathscr{L}_{1}(x)=\mathscr{L}_{1}^{(1)}(x)$ and $\mathscr{L}_{1}=\mathscr{L}_{1}(0)$.
Similarly, let $\mathscr{L}_{2}^{(\alpha)}(x)$ be the $(n+1) \times(n+1)$ matrix whose entries are given by

$$
\begin{equation*}
\hat{l}_{i, j}^{(\alpha, 2)}(x)=\binom{i}{j} E_{i-j}^{(\alpha)}(x)-3\binom{i}{j+1} E_{i-j-1}^{(\alpha)}(x)+5 \sum_{k=j+1}^{i}(-1)^{k-j} 2^{k-j-2}\binom{i}{k} E_{i-k}^{(\alpha)}(x) . \tag{4.42}
\end{equation*}
$$

We denote $\mathscr{L}_{2}(x)=\mathscr{L}_{2}^{(1)}(x)$ and $\mathscr{L}_{2}=\mathscr{L}_{2}(0)$.
From the definitions of $\mathscr{L}_{1}^{(\alpha)}(x)$ and $\mathscr{L}_{2}^{(\alpha)}(x)$, we see that

$$
\begin{aligned}
& \hat{l}_{i, i}^{(\alpha, 1)}(x)=\hat{l}_{i, i}^{(\alpha, 2)}(x)=1, \quad i \geq 0, \\
& \hat{l}_{0, j}^{(\alpha, 1)}(x)=\hat{l}_{0, j}^{(\alpha, 2)}(x)=0, \quad j \geq 1, \\
& \hat{l}_{1,0}^{(\alpha, 1)}(x)=\hat{l}_{1,0}^{(\alpha, 2)}(x)=E_{1}^{(\alpha)}(x)-3 E_{0}^{(\alpha)}(x)=x-\frac{\alpha}{2}-3, \\
& \hat{l}_{1, j}^{(\alpha, 1)}(x)=\hat{l}_{1, j}^{(\alpha, 2)}(x)=0, \quad j \geq 2, \\
& \hat{l}_{i, 0}^{(\alpha, 1)}(x)=E_{i}^{(\alpha)}(x)-3 E_{i-1}^{(\alpha)}(x)+5 \sum_{k=0}^{i-2}(-1)^{i-k} 2^{i-k-2} E_{k}^{(\alpha)}(x), \quad i \geq 2, \\
& \hat{l}_{i, 0}^{(\alpha, 2)}(x)=E_{i}^{(\alpha)}(x)-3 i E_{i-1}^{(\alpha)}(x)+5 \sum_{k=1}^{i}(-1)^{k} 2^{k-2}\binom{i}{k} E_{i-k}^{(\alpha)}(x), \quad i \geq 2, \\
& \hat{l}_{i, 1}^{(\alpha, 1)}(x)=i E_{i-1}^{(\alpha)}(x)-\frac{7(i-1)}{2} E_{i-2}^{(\alpha)}(x)+5 \sum_{k=1}^{i-2}(-1)^{i-k} 2^{i-k-2} k E_{k-1}^{(\alpha)}(x), \quad i \geq 3 .
\end{aligned}
$$

The following results show several factorizations of $\mathscr{E}(\alpha)(x)$ in terms of Fibonacci and Lucas matrices, respectively.
ThEOREM 4.1. The generalized Euler polynomial matrix $\mathscr{E}^{(\alpha)}(x)$ can be factorized in terms of the Fibonacci matrix $\mathscr{F}$ as follows.

$$
\begin{equation*}
\mathscr{E}^{(\alpha)}(x)=\mathscr{F} \mathscr{M}^{(\alpha)}(x) \tag{4.43}
\end{equation*}
$$

or,

$$
\begin{equation*}
\mathscr{E}^{(\alpha)}(x)=\mathscr{N}^{(\alpha)}(x) \mathscr{F} . \tag{4.44}
\end{equation*}
$$

In particular,

$$
\begin{gather*}
\mathscr{F} \mathscr{M}(x)=\mathscr{E}(x)=\mathscr{N}(x) \mathscr{F},  \tag{4.45}\\
\mathscr{F} \mathscr{M}=\mathscr{E}=\mathscr{N} \mathscr{F}, \tag{4.46}
\end{gather*}
$$

and

$$
\begin{equation*}
\mathscr{F} \mathscr{M}\left(\frac{1}{2}\right)=\mathbb{E}=\mathscr{N}\left(\frac{1}{2}\right) \mathscr{F} . \tag{4.47}
\end{equation*}
$$

Proof. Since the relation (4.43) is equivalent to $\mathscr{F}^{-1} \mathscr{E}^{(\alpha)}(x)=\mathscr{M}^{(\alpha)}(x)$, it is possible to follow the proof given in [30, Theorem 4.1], making the corresponding modifications, for obtaining (4.43). The relation (4.44) can be obtained using a similar procedure. The relations (4.45), (4.46) and (4.47) are straightforward consequences of (4.43) and (4.44).

Also, the relations (4.43) and (4.44) allow us to deduce the following identity:

$$
\mathscr{M}^{(\alpha)}(x)=\mathscr{F}^{-1} \mathscr{N}^{(\alpha)}(x) \mathscr{F} .
$$

As a consequence of Theorems 3.4 and 4.1, we can derive simple factorizations for the inverses of the polynomial matrices $\mathscr{M}\left(x+\frac{1}{2}\right)$ and $\mathscr{N}\left(x+\frac{1}{2}\right)$ :
Corollary 4.1. The inverses of the polynomial matrices $\mathscr{M}\left(x+\frac{1}{2}\right)$ and $\mathscr{N}\left(x+\frac{1}{2}\right)$ can be factorized as follows.

$$
\begin{align*}
& {\left[\mathscr{M}\left(x+\frac{1}{2}\right)\right]^{-1}=\mathscr{D} P[-x] \mathscr{F},}  \tag{4.48}\\
& {\left[\mathscr{N}\left(x+\frac{1}{2}\right)\right]^{-1}=\mathscr{F} \mathscr{D} P[-x] .} \tag{4.49}
\end{align*}
$$

In particular,

$$
\begin{align*}
& \mathscr{M}^{-1}=\mathscr{D} P\left[\frac{1}{2}\right] \mathscr{F}, \quad \text { and } \quad \mathscr{N}^{-1}=\mathscr{F} \mathscr{D} P\left[\frac{1}{2}\right],  \tag{4.50}\\
& {\left[\mathscr{M}\left(\frac{1}{2}\right)\right]^{-1}=\mathscr{D} \mathscr{F}, \quad \text { and } \quad\left[\mathscr{N}\left(\frac{1}{2}\right)\right]^{-1}=\mathscr{F} \mathscr{D} .} \tag{4.51}
\end{align*}
$$

An analogous reasoning as used in the proof of Theorem 4.1 allows us to prove the results below.
ThEOREM 4.2. The generalized Euler polynomial matrix $\mathscr{E}^{(\alpha)}(x)$ can be factorized in terms of the Lucas matrix $\mathscr{L}$ as follows.

$$
\begin{equation*}
\mathscr{E}^{(\alpha)}(x)=\mathscr{L}_{1}^{(\alpha)}(x), \tag{4.52}
\end{equation*}
$$

or,

$$
\begin{equation*}
\mathscr{E}^{(\alpha)}(x)=\mathscr{L}_{2}^{(\alpha)}(x) \mathscr{L} \tag{4.53}
\end{equation*}
$$

In particular,

$$
\begin{gather*}
\mathscr{L} \mathscr{L}_{1}(x)=\mathscr{E}(x)=\mathscr{L}_{2}(x) \mathscr{L}  \tag{4.54}\\
\mathscr{L} \mathscr{L}_{1}=\mathscr{E}=\mathscr{L}_{2} \mathscr{L} \tag{4.55}
\end{gather*}
$$

and

$$
\begin{equation*}
\mathscr{L}_{\mathscr{L}_{1}^{\left(\frac{1}{2}\right)}}(x)=\mathbb{E}=\mathscr{L}_{2}^{\left(\frac{1}{2}\right)}(x) \mathscr{L} \tag{4.56}
\end{equation*}
$$

Also, the relations (4.52) and (4.53) allow us to deduce the following identity:

$$
\mathscr{L}_{1}^{(\alpha)}(x)=\mathscr{L}^{-1} \mathscr{L}_{2}^{(\alpha)}(x) \mathscr{L}
$$

Corollary 4.2. The inverses of the polynomial matrices $\mathscr{L}_{1}\left(x+\frac{1}{2}\right)$ and $\mathscr{L}_{2}\left(x+\frac{1}{2}\right)$ can be factorized as follows.

$$
\begin{align*}
& {\left[\mathscr{L}_{1}\left(x+\frac{1}{2}\right)\right]^{-1}=\mathscr{D} P[-x] \mathscr{L}}  \tag{4.57}\\
& {\left[\mathscr{L}_{2}\left(x+\frac{1}{2}\right)\right]^{-1}=\mathscr{L} \mathscr{D} P[-x]} \tag{4.58}
\end{align*}
$$

In particular,

$$
\begin{gather*}
\mathscr{L}_{1}^{-1}=\mathscr{D} P\left[\frac{1}{2}\right] \mathscr{L}, \quad \text { and } \quad \mathscr{L}_{2}^{-1}=\mathscr{L} \mathscr{D} P\left[\frac{1}{2}\right]  \tag{4.59}\\
{\left[\mathscr{L}_{1}\left(\frac{1}{2}\right)\right]^{-1}=\mathscr{D} \mathscr{L}, \quad \text { and } \quad\left[\mathscr{L}_{2}\left(\frac{1}{2}\right)\right]^{-1}=\mathscr{L} \mathscr{D} .} \tag{4.60}
\end{gather*}
$$

Remark 4.1 It is worthwhile to mention that if we consider $a \in \mathbb{C}, b \in \mathbb{C} \backslash\{0\}$ and $s=0,1$, then Theorems 4.1 and 4.2, as well as, their corollaries have corresponding analogous forms for generalized Fibonacci matrices of type $s, \mathscr{F}^{(a, b, s)}$, and for generalized Fibonacci matrices $\mathscr{U}^{(a, b, 0)}$ with second order recurrent sequence $U_{n}^{(a, b)}$ subordinated to certain constraints. The reader may consult [27] in order to complete the details of this assertion.

We finish this section with some new identities involving the Fibonacci numbers, the Lucas numbers and the generalized Euler polynomials and numbers.

Theorem 4.3. For $0 \leq r \leq n$ and $\alpha$ any real or complex number, we have

$$
\begin{aligned}
\binom{n}{r} E_{n-r}^{(\alpha)}(x)= & F_{n-r+1}+\left[(r+1) x-\frac{(r+1) \alpha+2}{2}\right] F_{n-r} \\
& +\sum_{k=r+2}^{n}\binom{k}{r}\left\{E_{k-r}^{(\alpha)}(x)-\frac{k-r}{k}\left[E_{k-r-1}^{(\alpha)}(x)+\frac{k-r-1}{k-1} E_{k-r-2}^{(\alpha)}(x)\right]\right\} F_{n-k+1} \\
= & F_{n-r+1}+\left[n\left(x-\frac{\alpha}{2}\right)-1\right] F_{n-r} \\
& +\sum_{k=0}^{n-2}\binom{n}{k}\left\{E_{n-k}^{(\alpha)}(x)-\frac{n-k}{k+1}\left[E_{n-k-1}^{(\alpha)}(x)+\frac{n-k-1}{k+2} E_{n-k-2}^{(\alpha)}(x)\right]\right\} F_{k-r+1} .
\end{aligned}
$$

Proof. We proceed as in the proof of 30, Theorem 4.2], making the corresponding modifications. From (4.39), it is clear that

$$
\tilde{m}_{r, r}^{(\alpha)}(x)=1, \quad \tilde{m}_{r+1, r}^{(\alpha)}(x)=(r+1) x-\frac{(r+1) \alpha+2}{2},
$$

and, for $k \geq 2$ :

$$
\tilde{m}_{k, r}^{(\alpha)}(x)=\binom{k}{r}\left\{E_{k-r}^{(\alpha)}(x)-\frac{k-r}{k}\left[E_{k-r-1}^{(\alpha)}(x)+\frac{k-r-1}{k-1} E_{k-r-2}^{(\alpha)}(x)\right]\right\} .
$$

Next, it follows from (4.43) that

$$
\begin{aligned}
\binom{n}{r} E_{n-r}^{(\alpha)}(x)= & E_{n, r}^{(\alpha)}(x) \\
= & \sum_{k=r}^{n} F_{n-k+1} \tilde{m}_{k, r}^{(\alpha)}(x) \\
= & F_{n-r+1}+F_{n-r} \tilde{m}_{r+1, r}^{(\alpha)}(x)+\sum_{k=r+2}^{n} F_{n-k+1} \tilde{m}_{k, r}^{(\alpha)}(x) \\
= & F_{n-r+1}+\left[(r+1) x-\frac{(r+1) \alpha+2}{2}\right] F_{n-r} \\
& +\sum_{k=r+2}^{n}\binom{k}{r}\left\{E_{k-r}^{(\alpha)}(x)-\frac{k-r}{k}\left[E_{k-r-1}^{(\alpha)}(x)+\frac{k-r-1}{k-1} E_{k-r-2}^{(\alpha)}(x)\right]\right\} F_{n-k+1} .
\end{aligned}
$$

This chain of equalities completes the first part of the proof. The second one is obtained in a similar way, taking into account the following identities:

$$
\tilde{n}_{n, n}^{(\alpha)}(x)=1, \quad \tilde{n}_{n, n-1}^{(\alpha)}(x)=n\left(x-\frac{\alpha}{2}\right)-1,
$$

and, for $0 \leq k \leq n-2$ :

$$
\tilde{n}_{n, k}^{(\alpha)}(x)=\binom{n}{k}\left\{E_{n-k}^{(\alpha)}(x)-\frac{n-k}{k+1}\left[E_{n-k-1}^{(\alpha)}(x)+\frac{n-k-1}{k+2} E_{n-k-2}^{(\alpha)}(x)\right]\right\} .
$$

Corollary 4.3. For $0 \leq r \leq n$ and $\alpha$ any real number, we have

$$
\begin{aligned}
& (-1)^{n}\binom{n}{r} E_{n-r}^{(\alpha)}(x)=(-1)^{r} F_{n-r+1}+(-1)^{r+1}\left[\frac{(r+1)(2 x-\alpha)+2}{2}\right] F_{n-r} \\
& +\sum_{k=r+2}^{n}(-1)^{k}\binom{k}{r}\left\{E_{k-r}^{(\alpha)}(x)+\frac{k-r}{k}\left[E_{k-r-1}^{(\alpha)}(x)-\frac{k-r-1}{k-1} E_{k-r-2}^{(\alpha)}(x)\right]\right\} F_{n-k+1} \\
& \quad=(-1)^{r} F_{n-r+1}+(-1)^{r+1}\left[n\left(x-\frac{\alpha}{2}\right)-1\right] F_{n-r} \\
& +\sum_{k=0}^{n-2}(-1)^{n-k+r}\binom{n}{k}\left\{E_{n-k}^{(\alpha)}(x)+\frac{n-k}{k+1}\left[E_{n-k-1}^{(\alpha)}(x)+\frac{n-k-1}{k+2} E_{n-k-2}^{(\alpha)}(x)\right]\right\} F_{k-r+1} .
\end{aligned}
$$

Proof. Replacing $x$ by $\alpha-x$ in (4.61) and applying the formula

$$
E_{n}^{(\alpha)}(x)=(-1)^{n} E_{n}^{(\alpha)}(\alpha-x)
$$

to the resulting identity, we obtain the first identity of Corollary 4.3. An analogous reasoning yields the second identity.

Analogous reasonings to those used in the proofs of Theorem 4.3 and Corollary 4.3 allow us to prove the following results.

ThEOREM 4.4. For any real or complex number $\alpha$, we have the following identities

$$
\begin{align*}
E_{n}^{(\alpha)}(x)= & L_{n+1}+\left(x-\frac{\alpha}{2}-3\right) L_{n}+\sum_{k=2}^{n}\left(E_{k}^{(\alpha)}(x)-3 E_{k-1}^{(\alpha)}(x)\right) L_{n-k+1} \\
& +5 \sum_{k=2}^{n} \sum_{s=0}^{k-2}(-1)^{k-s} 2^{k-s-2} L_{n-k+1} E_{s}^{(\alpha)}(x) \tag{4.61}
\end{align*}
$$

whenever $n \geq 2$.

$$
\begin{align*}
n E_{n-1}^{(\alpha)}(x)= & L_{n}+(2 x-\alpha-3) L_{n-1}+\sum_{k=3}^{n}\left(k E_{k-1}^{(\alpha)}(x)-3(k-1) E_{k-2}^{(\alpha)}(x)\right) L_{n-k+1} \\
& +5 \sum_{k=3}^{n} \sum_{s=1}^{k-2}(-1)^{k-s} 2^{k-s-2} s L_{n-k+1} E_{s-1}^{(\alpha)}(x) \tag{4.62}
\end{align*}
$$

whenever $n \geq 3$.
Corollary 4.4. The following identities hold.

$$
\begin{align*}
(-1)^{n} E_{n}^{(\alpha)}(x)= & L_{n+1}-\left(x-\frac{\alpha}{2}+3\right) L_{n}+\sum_{k=2}^{n}(-1)^{k}\left(E_{k}^{(\alpha)}(x)+3 E_{k-1}^{(\alpha)}(x)\right) L_{n-k+1} \\
& +5 \sum_{k=2}^{n} \sum_{s=0}^{k-2}(-1)^{k-s} 2^{k-s-2} L_{n-k+1} E_{s}^{(\alpha)}(x) \tag{4.63}
\end{align*}
$$

whenever $n \geq 2$.

$$
\begin{align*}
(-1)^{n-1} n E_{n-1}^{(\alpha)}(x)= & L_{n}+(\alpha-2 x-3) L_{n-1} \\
& +\sum_{k=3}^{n}(-1)^{k-1}\left(k E_{k-1}^{(\alpha)}(x)+3(k-1) E_{k-2}^{(\alpha)}(x)\right) L_{n-k+1} \\
& +5 \sum_{k=3}^{n} \sum_{s=1}^{k-2}(-1)^{k-1} 2^{k-s-2} s L_{n-k+1} E_{s-1}^{(\alpha)}(x) \tag{4.64}
\end{align*}
$$

whenever $n \geq 3$.
By (4.61), (4.62), (4.63) and (4.64) we obtain the following interesting identities involving Lucas and Euler numbers.

- For $n \geq 2$ :

$$
E_{n}-\left(L_{n+1}-\frac{7}{2} L_{n}\right)=\sum_{k=2}^{n}\left(E_{k}-3 E_{k-1}+5 \sum_{s=0}^{k-2}(-1)^{k-s} 2^{k-s-2} E_{s}\right) L_{n-k+1}
$$

$$
(-1)^{n} E_{n}=L_{n+1}-\frac{5}{2} L_{n}+\sum_{k=2}^{n}(-1)^{k}\left(E_{k}+3 E_{k-1}\right) L_{n-k+1}+5 \sum_{k=2}^{n} \sum_{s=0}^{k-2}(-1)^{k-s} 2^{k-s-2} L_{n-k+1} E_{s}
$$

- For $n \geq 3$ :

$$
\begin{aligned}
n E_{n-1}-\left(L_{n}-4 L_{n-1}\right)= & \sum_{k=3}^{n}\left(k E_{k-1}-3(k-1) E_{k-2}\right) L_{n-k+1} \\
& +5 \sum_{k=3}^{n} \sum_{s=1}^{k-2}(-1)^{k-s} 2^{k-s-2} s E_{s-1} L_{n-k+1} \\
(-1)^{n-1} n E_{n-1}-L_{n}-(\alpha-2 x-3) L_{n-1}= & \sum_{k=3}^{n}(-1)^{k-1}\left(k E_{k-1}+3(k-1) E_{k-2}\right) L_{n-k+1} \\
& +5 \sum_{k=3}^{n} \sum_{s=1}^{k-2}(-1)^{k-1} 2^{k-s-2} s L_{n-k+1} E_{s-1}
\end{aligned}
$$

Another similar combinatorial identities may be obtained using the results of [13]. We leave to the interested reader the formulation of them.

## 5. Euler matrices and their relation with Stirling and Vandermonde matrices

Let $s(n, k)$ and $S(n, k)$ be the Stirling numbers of the first and second kind, which are respectively defined by the generating functions [20, Chapther 1, Section 1.6]:

$$
\begin{align*}
\sum_{k=0}^{n} s(n, k) z^{k} & =z(z-1) \cdots(z-n+1)  \tag{5.65}\\
(\log (1+z))^{k} & =k!\sum_{n=k}^{\infty} s(n, k) \frac{z^{n}}{n!}, \quad|z|<1 \\
z^{n} & =\sum_{k=0}^{n} S(n, k) z(z-1) \cdots(z-k+1) \\
\left(e^{z}-1\right)^{k} & =k!\sum_{n=k}^{\infty} S(n, k) \frac{z^{n}}{n!}
\end{align*}
$$

In combinatorics, it is well-known that the value $|s(n, k)|$ represents the number of permutations of $n$ elements with $k$ disjoint cycles. While, the Stirling numbers of the second kind $S(n, k)$ give the number of partitions of $n$ objects into $k$ non-empty subsets. Another way to compute these numbers is by means of the formula (see [6, Eq. (5.1)] or [18, p. 226]:

$$
S(n, k)=\frac{1}{k!} \sum_{l=0}^{k}(-1)^{k-l}\binom{k}{l} l^{n}, \quad 1 \leq k \leq n
$$

A recent connection between the Stirling numbers of the second kind and the Euler polynomials is given by the formula (see [7, Theorem 3.1, Eq. (3.3)]):

$$
\begin{equation*}
E_{n}(x)=\sum_{k=0}^{n}(-1)^{n-k}\binom{n}{k}\left[\sum_{l=1}^{n-k+1} \frac{(-1)^{l-1}(l-1)!}{2^{l-1}} S(n-k+1, l)\right] x^{k} \tag{5.66}
\end{equation*}
$$

Proceeding as in the proof of [7, Theorem 3.1], one can find a similar relation to the previous one but connecting Stirling numbers of the first kind and a particular class of generalized Euler polynomials.

THEOREM 5.1. Let us assume that $\alpha=m \in \mathbb{N}$. Then, the connection between the Stirling numbers of the first kind and the generalized Euler polynomial $E_{n}^{(m)}(x)$ is given by the formula:

$$
\begin{equation*}
E_{n}^{(m)}(x)=\frac{1}{2^{n}} \sum_{k=0}^{n}\binom{n}{k}\left[\sum_{j=0}^{n-k} s(n-k, j)(-m)^{j}\right](2 x)^{k} \tag{5.67}
\end{equation*}
$$

Proof. By Leibniz's theorem for differentiation we have

$$
\begin{aligned}
\frac{\partial^{r}}{\partial z^{r}}\left[\left(\frac{2}{e^{z}+1}\right)^{m} e^{x z}\right] & =\sum_{k=0}^{r}\binom{r}{k}\left[\left(\frac{2}{e^{z}+1}\right)^{m}\right]^{(k)} \frac{\partial^{r-k}}{\partial z^{r-k}}\left(e^{x z}\right) \\
& =\sum_{k=0}^{r}\binom{r}{k}\left[\left(\frac{2}{e^{z}+1}\right)^{m}\right]^{(k)} x^{r-k} e^{x z} \\
& =\left(\frac{2}{e^{z}+1}\right)^{m} e^{(x+1) z} \sum_{k=0}^{r}\binom{r}{k} \frac{(-m)_{k} x^{r-k}}{\left(e^{z}+1\right)^{k}}
\end{aligned}
$$

where in the last expression $(-m)_{k}$ denotes the falling factorial with opposite argument $-m$.
Combining this with the $r$-th differentiation on both sides of the generating function in (1.1) reveals that

$$
\sum_{n=r}^{\infty} E_{n}^{(m)}(x) \frac{z^{n-r}}{(n-r)!}=\left(\frac{2}{e^{z}+1}\right)^{m} e^{(x+1) z} \sum_{k=0}^{r}\binom{r}{k} \frac{(-m)_{k} x^{r-k}}{\left(e^{z}+1\right)^{k}}
$$

Further taking $z \rightarrow 0$ and employing (5.65) give

$$
\begin{aligned}
E_{r}^{(m)}(x) & =\sum_{k=0}^{r}\binom{r}{k}(-m)_{k} \frac{x^{r-k}}{2^{k}}=\frac{1}{2^{r}} \sum_{k=0}^{r}\binom{r}{k}(-m)_{r-k}(2 x)^{k} \\
& =\frac{1}{2^{r}} \sum_{k=0}^{r}\binom{r}{k}\left[\sum_{j=0}^{r-k} s(r-k, j)(-m)^{j}\right](2 x)^{k}
\end{aligned}
$$

Finally, changing $r$ by $n$ the proof of the formula (5.66) is complete.
DEfinition 5.1. For the Stirling numbers $s(i, j)$ and $S(i, j)$ of the first kind and of the second kind respectively, define $\mathfrak{S}$ and $\mathscr{S}$ to be the $(n+1) \times(n+1)$ matrices by

$$
\mathfrak{S}_{i, j}=\left\{\begin{array}{l}
s(i, j), \quad i \geq j,  \tag{5.68}\\
0, \quad \text { otherwise },
\end{array} \quad \text { and } \quad \mathscr{S}_{i, j}=\left\{\begin{array}{l}
S(i, j), \quad i \geq j \\
0, \quad \text { otherwise }
\end{array}\right.\right.
$$

The matrices $\mathfrak{S}$ and $\mathscr{S}$ are called Stirling matrix of the first kind and of the second kind, respectively (see [通).

In order to obtain factorizations for Euler matrices via Stirling matrices we will need the following matrices:

Let $\tilde{S}_{n}$ be the factorial Stirling matrix, i.e., the $n \times n$ matrix whose $(i, j)$-th entry is given by $\tilde{S}_{i, j, n}:=j!\mathscr{S}_{i, j}, i \geq j$ and otherwise 0 .

For $m \in \mathbb{N}$, let $\mathfrak{S}^{(m)}$ be the $(n+1) \times(n+1)$ matrix whose $(i, j)$-entries are defined by

$$
\mathfrak{S}_{i, j}^{(m)}=\left\{\begin{array}{l}
\binom{i}{j} \sum_{k=0}^{i-j} s(i-j, k)(-m)^{k}, \quad i \geq j,  \tag{5.69}\\
0, \quad \text { otherwise. }
\end{array}\right.
$$

Let $\tilde{C}$ and $\tilde{D}$ be the $(n+1) \times(n+1)$ matrices whose $(i, j)$-entries are defined by

$$
\tilde{C}_{i, j}=\left\{\begin{array}{l}
\binom{i}{j}(-1)^{i-j} \sum_{k=0}^{i-j}\left(-\frac{1}{2}\right)^{k} \tilde{S}_{i-j-k, k, i-j}, \quad i \geq j,  \tag{5.70}\\
0, \quad \text { otherwise. }
\end{array}\right.
$$

$$
\tilde{D}_{i, j}=\left\{\begin{array}{l}
\binom{i}{j}(-1)^{i-j} \sum_{k=0}^{i-j}\left(-\frac{1}{2}\right)^{k} \tilde{S}_{i-j-k, k+1, i-j}, \quad i \geq j  \tag{5.71}\\
0, \quad \text { otherwise }
\end{array}\right.
$$

The next theorem shows the corresponding factorizations of the generalized Euler matrix $\mathscr{E}^{(m)}$, $m \in \mathbb{N}$, in terms of the Stirling matrices, when the expressions (5.66) and (5.67) are incorporated.
Theorem 5.2. For $m \in \mathbb{N}$, the generalized Euler matrix $\mathscr{E}^{(m)}(x)$ can be factorized as follows.

$$
\begin{equation*}
\mathscr{E}^{(m)}(x)=\mathfrak{S}^{(m)} P[x] . \tag{5.72}
\end{equation*}
$$

In the case of the Stirling matrix of the second kind, we have

$$
\begin{equation*}
\mathscr{E}(x)=(\tilde{C}+\tilde{D}) P[x] . \tag{5.73}
\end{equation*}
$$

Furthermore,

$$
\begin{equation*}
\mathfrak{S}^{(1)}=\tilde{C}+\tilde{D} \tag{5.74}
\end{equation*}
$$

Proof. For $m \in \mathbb{N}$ and $i \geq j$, let $A_{i, j}^{(m)}(x)$ be the $(i, j)$-th entry of the matrix product $\mathfrak{S}^{(m)} P[x]$, then

$$
\begin{aligned}
A_{i, j}^{(m)}(x) & =\sum_{k=j}^{i} \mathfrak{S}_{i, k}^{(m)} p_{k, j}(x)=\sum_{k=j}^{i}\binom{i}{k}\binom{k}{j}\left[\sum_{r=0}^{i-k} s(i-k, r)(-m)^{r}\right] x^{k-j} \\
& =\sum_{k=j}^{i}\binom{i}{j}\binom{i-j}{k-j} 2^{j-i}\left[\sum_{r=0}^{i-k} s(i-k, r)(-m)^{r}\right](2 x)^{k-j} \\
& =\frac{\binom{i}{j}}{2^{i-j}} \sum_{k=0}^{i-j}\binom{i-j}{k}\left[\sum_{r=0}^{i-j-k} s(i-j-k, r)(-m)^{r}\right](2 x)^{k}=\binom{i}{j} E_{i-j}^{(m)}(x),
\end{aligned}
$$

The last equality is an immediate consequence of (5.67), and (5.72) follows from the previous chain of equalities.

In order to prove (5.73), we proceed in a similar way to the previous one, tanking into account (5.66), (5.70), (5.71), and making the corresponding modifications. Finally, the substitution $m=1$ into (5.72) yields (5.74).

DEFINITION 5.2. The $(n+1) \times(n+1)$ shifted Euler polynomial matrix $\tilde{\mathscr{E}}(x)$ are given by

$$
\begin{equation*}
\tilde{\mathscr{E}}_{i, j}(x)=\mathscr{E}_{i}(j+x), \quad 0 \leq i, j \leq n . \tag{5.75}
\end{equation*}
$$

Let us consider the Vandermonde matrix:

$$
\mathscr{V}(x):=\left[\begin{array}{ccccc}
1 & 1 & 1 & \cdots & 1 \\
x & 1+x & 2+x & \cdots & n+x \\
x^{2} & (1+x)^{2} & (2+x)^{2} & \cdots & (n+x)^{2} \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
x^{n} & (1+x)^{n} & (2+x)^{n} & \cdots & (n+x)^{n}
\end{array}\right] .
$$

In [4, Theorem 2.1], the following factorization for the Vandermonde matrix $\mathscr{V}(x)$ was stated.

$$
\begin{equation*}
\mathscr{V}(x)=\left([1] \oplus \tilde{S}_{n}\right) \Delta_{n+1}(x) P^{T}:=\left([1] \oplus \tilde{S}_{n}\right) \Delta_{n+1}(x)(P[1])^{T}, \tag{5.76}
\end{equation*}
$$

where $\Delta_{n+1}(x)(P[1])^{T}$ represents the LU-factorization of a lower triangular matrix whose $(i, j)$-th entry is $\binom{x}{i-j}$, if $i \geq j$ and otherwise 0 .

The relation between the shifted Euler polynomial matrix $\tilde{\mathscr{E}}(x)$ and the matrices $\mathscr{V}(x)$ and $\tilde{S}_{n}$ is contained in the following result.
Theorem 5.3. The shifted Euler polynomial matrix $\tilde{\mathscr{E}}(x)$ can be factorized in terms of the Vandermonde matrix $\mathscr{V}(x)$ and consequently, in terms of the factorial Stirling matrix $\tilde{S}_{n}$ as follows:

$$
\begin{gather*}
\tilde{\mathscr{E}}(x)=\mathscr{E} \mathscr{V}(x),  \tag{5.77}\\
\tilde{\mathscr{E}}(x)=\mathscr{E}\left([1] \oplus \tilde{S}_{n}\right) \Delta_{n+1}(x) P^{T} . \tag{5.78}
\end{gather*}
$$

Proof. Let $\tilde{\mathscr{E}}_{i, j}(x)$ be the $(i, j)$-th entry of the shifted Euler polynomial matrix $\tilde{\mathscr{E}}(x)$. Then, using (1.9) we get

$$
\tilde{\mathscr{E}}_{i, j}(x)=\mathscr{E}_{i}(j+x)=\sum_{k=0}^{i}\binom{i}{k} E_{i-k}(j+x)^{k}=\sum_{k=0}^{i} E_{i, k} \mathscr{V}_{k, j}(x) \text {. }
$$

Hence, (5.77) follows from this chain of equalities. The relation (5.78) is a straightforward consequence of (5.76).

Remark 5.1 Note that the relations (5.77) and (5.78) are the analogous of [30, Eqs. (37), (38)], respectively, in the context of Euler polynomial matrices.

Finally, in the present paper, all matrix identities have been expressed using finite matrices. Since such matrix identities involve lower triangular matrices, they have a resemblance for infinite matrices. We state this property briefly as follows.

Let $\mathscr{E}_{\infty}^{(\alpha)}(x), \mathscr{E}_{\infty}\left(x+\frac{1}{2}\right), \mathscr{E}_{\infty}(x), \mathscr{E}_{\infty}, \mathbb{E}_{\infty}, \mathscr{D}_{\infty}, \tilde{E}_{\infty}(x), P_{\infty}[x], \mathscr{F}_{\infty}, \mathscr{F}_{\infty}^{-1}, \mathscr{L}_{\infty}, \mathscr{G}_{\infty}[x], \mathscr{H}_{\infty}[x]$, $\mathscr{M}_{\infty}^{(\alpha)}(x), \mathscr{M}_{\infty}\left(x+\frac{1}{2}\right), \mathscr{N}_{\infty}^{(\alpha)}(x), \mathscr{N}_{\infty}\left(x+\frac{1}{2}\right), \mathscr{V}_{\infty}$ and $\mathfrak{S}_{\infty}^{(m)}$, be the infinite cases of the matrices $\mathscr{E}^{(\alpha)}(x), \mathscr{E}\left(x+\frac{1}{2}\right), \mathscr{E}(x), \mathscr{E}, \mathbb{E}, \mathscr{D}, \tilde{\mathscr{E}}(x), P[x], \mathscr{F}, \mathscr{F}^{-1}, \mathscr{L}, \mathscr{G}[x], \mathscr{H}[x], \mathscr{M}^{(\alpha)}(x), \mathscr{M}\left(x+\frac{1}{2}\right)$, $\mathscr{N}^{(\alpha)}(x), \mathscr{N}\left(x+\frac{1}{2}\right), \mathscr{V}$ and $\mathfrak{S}^{(m)}$ respectively. Then the following identities hold.

$$
\begin{aligned}
2 \mathscr{E}_{\infty}^{(\alpha-1)}(x) & =\mathscr{E}_{\infty}^{(\alpha)}(x+1)+\mathscr{E}_{\infty}^{(\alpha)}(x), \\
\mathscr{E}_{\infty}^{(\alpha)}(x+y) & =\mathscr{E}_{\infty}^{(\alpha)}(x) P_{\infty}[y]=P_{\infty}[x] \mathscr{E}_{\infty}^{(\alpha)}(y)=\mathscr{E}_{\infty}^{(\alpha)}(y) P_{\infty}[x], \\
\mathscr{E}_{\infty}(x+y) & =P_{\infty}[x] \mathscr{E}_{\infty}(y)=P_{\infty}[y] \mathscr{E}_{\infty}(x), \\
\mathscr{E}_{\infty}(x) & =P_{\infty}[x] \mathscr{E}_{\infty}, \\
\mathscr{E}_{\infty}\left(x+\frac{1}{2}\right) & =P_{\infty}[x] \mathbb{E}_{\infty}, \\
{\left[\mathscr{E}_{\infty}\left(x+\frac{1}{2}\right)\right]^{-1} } & =\mathscr{D}_{\infty} P_{\infty}[-x], \\
\mathscr{E}_{\infty}\left(x+\frac{1}{2}\right) & =\mathscr{L}_{\infty} \mathscr{G}_{\infty}[x] \mathbb{E}_{\infty}=\mathscr{H}_{\infty}[x] \mathscr{L}_{\infty} \mathbb{E}_{\infty}, \\
\mathscr{E}_{\infty}^{(\alpha)}(x) & =\mathscr{F}_{\infty} \mathscr{M}_{\infty}^{(\alpha)}(x)=\mathscr{N}_{\infty}^{(\alpha)}(x) \mathscr{F}_{\infty}, \\
\mathscr{M}_{\infty}^{(\alpha)}(x) & =\mathscr{F}_{\infty}^{-1} \mathscr{N}_{\infty}^{(\alpha)}(x) \mathscr{F}_{\infty}, \\
{\left[\mathscr{M}_{\infty}\left(x+\frac{1}{2}\right)\right]^{-1} } & =\mathscr{D}_{\infty} P_{\infty}[-x] \mathscr{F}_{\infty}, \\
{\left[\mathscr{N}_{\infty}\left(x+\frac{1}{2}\right)\right]^{-1} } & =\mathscr{F}_{\infty} \mathscr{D}_{\infty} P_{\infty}[-x], \\
\mathscr{E}_{\infty}^{(m)}(x) & =\mathscr{S}_{\infty} P_{\infty}[x], \\
\tilde{E}_{\infty}(x) & =\mathscr{E}_{\infty} \mathscr{V}_{\infty}(x) .
\end{aligned}
$$
