Abstract. We summarize the main results of our investigation of B-type topological Landau-Ginzburg models whose target is an arbitrary open Riemann surface. Such a Riemann surface need not be affine algebraic and in particular it may have infinite genus or an infinite number of Freudenthal ends. Under mild conditions on the Landau-Ginzburg superpotential, we give a complete description of the triangulated structure of the category of topological D-branes in such models as well as counting formulas for the number of topological D-branes considered up to relevant equivalence relations.

## 1. Introduction

It is well-known [\[1,](#page-8-0) [2\]](#page-8-1) that classical B-type topological Landau-Ginzburg (LG) models with Dbranes can be associated to any pair  $(X, W)$ , where X is a non-compact Kähler manifold and  $W: X \to \mathbb{C}$  is a non-constant holomorphic function defined on X. When the canonical line bundle of X is holomorphically trivial and the critical set of  $W$  is compact, it is expected that the quantization of such models produces a non-anomalous two-dimensional topological field theory (2d TFT) which obeys the general axioms introduced in [\[3\]](#page-8-2) and hence is characterized entirely by an open-closed TFT datum, an algebraic structure subject to certain axioms which encode the sewing constraints of the TFT. As shown in [\[2\]](#page-8-1), path integral arguments lead to a proposal for the open-closed TFT datum of the quantum B-type LG model defined by such a pair  $(X, W)$ , a proposal which was clarified and analyzed mathematically in [\[4,](#page-8-3) [5\]](#page-9-0) (see [\[6\]](#page-9-1) for a brief summary). When X is Stein and Calabi-Yau, this proposal simplifies as explained in [\[7\]](#page-9-2) and summarized in [\[8\]](#page-9-3).

As already pointed out in  $[4]$ , an interesting particular case arises when X is complex onedimensional, i.e. an open Riemann surface (a non-compact Riemann surface without boundary, which we assume to be connected). Since any open Riemann surface is Stein and holomorphically parallelizable (hence Calabi-Yau), this fits into the class of models considered in [\[7\]](#page-9-2), whose TFT datum admits the simplified description discussed in loc. cit. and summarized in [\[8\]](#page-9-3).

In this contribution, we outline our investigation of B-type LG models with open Riemann surface target [\[9\]](#page-9-4), which in turn relies on algebraic results derived for a large class of rings in references [\[10,](#page-9-5) [11\]](#page-9-6). We make free use of certain concepts and terminology which were introduced in  $[3]$  and  $[1, 2, 4, 7]$  $[1, 2, 4, 7]$  $[1, 2, 4, 7]$  $[1, 2, 4, 7]$  and which are summarized in  $[6]$  and  $[8]$ .

The open Riemann surfaces considered in this contribution are fully general. In particular, they can have infinite genus and an infinite number of Freudenthal ends<sup>[1](#page-1-0)</sup>. As such, the topological LG models discussed herein are the most general non-anomalous B-type LG models with non-singular complex one-dimensional target.

#### 2. Open Riemann surfaces

In this section, we recall some well-known facts regarding open Riemann surfaces.

**Definition 2.1.** A Riemann surface *(in the sense of Weyl-Radó) is a Hausdorff, borderless and* connected complex manifold  $\Sigma$  such that dim<sub>C</sub>  $\Sigma = 1$ .

Theorem 2.2 (Radó). The following mutually-equivalent statements hold for any Riemann surface Σ:

- (a)  $\Sigma$  is paracompact.
- (b)  $\Sigma$  has a countable basis.
- $(c) \Sigma$  is countable at infinity.

Definition 2.3. A Riemann surface is called open if it is non-compact.

## 2.1. The topological type of open Riemann surfaces

Unlike the compact case, the topological classification of open Riemann surfaces is quite involved, since such a surface can have infinite genus as well as an infinity of Freudenthal ends (a.k.a. "ideal points"). The ends of Riemann surfaces were studied in the classical work of Kerékjártó [\[12\]](#page-9-7) and Stoilow [\[13\]](#page-9-8) (see [\[14\]](#page-9-9) for a summary in modern mathematical language).

# Definition 2.4.

• The transfinite genus of  $\Sigma$  is the cardinal number:

$$
g(\Sigma) = \frac{1}{2} \text{rk}_{\mathbb{Z}} H^1(\Sigma, \mathbb{Z}) .
$$

• The ideal boundary  $\partial_{\infty} \Sigma$  of  $\Sigma$  is the set of Freudenthal ends of  $\Sigma$ , endowed with its natural topology.

**Proposition 2.5** (Kerékjártó). The following statements hold for any open Riemann surface  $\Sigma$ :

- 1.  $q(\Sigma)$  is finite or countable.
- 2.  $\partial_{\infty}\Sigma$  is a finite or countable compact Hausdorff topological space which is totally disconnected.

# Remarks.

- 1.  $\partial_{\infty} \Sigma$  can be a Cantor space.
- 2. Adjoining  $\partial_{\infty} \Sigma$  to  $\Sigma$  produces the so-called Kerékjártó-Stoilow compactification  $\hat{\Sigma}$  of  $\Sigma$  (see  $[12, 13, 14]$  $[12, 13, 14]$  $[12, 13, 14]$ .

There exists a natural disjoint union decomposition  $\partial_{\infty} \Sigma = \partial_{\infty}^1 \Sigma \cup \partial_{\infty}^2 \Sigma$  where the ends belonging to  $\partial_{\infty}^1 \Sigma$  and  $\partial_{\infty}^2 \Sigma$  are called of *first* and *second* kind.

<span id="page-1-0"></span> $<sup>1</sup>$  An open Riemann surface coincides with the analyticization of a complex affine curve iff it has finite genus</sup> and a finite number of ends, in which case it can be obtained by removing a finite set of points from a compact Riemann surface.

#### <span id="page-2-0"></span>2.2. The complex geometry of open Riemann surfaces

The following statements summarize classical results due to Kerékjártó and Stoilow:

**Theorem 2.6** (Kerékjártó). Let  $\Sigma$  and  $\Sigma'$  be two open Riemann surfaces. Then the following statements are equivalent:

(a)  $\Sigma$  and  $\Sigma'$  are unoriented-homeomorphic.

(b)  $g(\Sigma) = g(\Sigma')$  and there exists a homeomorphism  $\psi : \partial_{\infty} \Sigma \to \partial_{\infty} \Sigma'$  such that  $\psi(\partial_{\infty}^1 \Sigma) = \partial_{\infty}^1 \Sigma'$ .

Theorem 2.7 (Richards-Stoilow). The following statements hold:

- (i) The unoriented homeomorphism type of an open Riemann surface  $\Sigma$  is entirely determined by the triplet  $(g(\Sigma), \partial_{\infty}^1 \Sigma, \partial_{\infty} \Sigma)$ .
- (ii) Consider any triplet  $(g, F^1, F)$  with  $g \in \mathbb{Z}_{\geq 0} \sqcup \{\aleph_0\}$ , F a non-empty compact, Hausdorff and totally disconnected countable topological space and  $F^1 \subset F$  a (possibly empty) subset of F, endowed with the topology induced from F. Then there exists an open Riemann surface  $\Sigma$ with  $g(\Sigma) = g$ ,  $\partial_{\infty} \Sigma \simeq_{\text{homeo}} F$  and  $\partial_{\infty}^1 \Sigma \simeq_{\text{homeo}} F^1$ .

The following results are crucial in the context of B-type LG models:

Theorem 2.8 (Behnke-Stein). Every open Riemann surface is Stein.

Theorem 2.9 (Grauert-Röhrl). Any holomorphic vector bundle on an open Riemann surface  $\Sigma$  is holomorphically trivial. In particular, the analytic Picard group Pic( $\Sigma$ ) vanishes and the canonical line bundle  $K_{\Sigma}$  is holomorphically trivial.

It follows that any open Riemann surface is Stein (and hence Kählerian) and holomorphically Calabi-Yau. Hence any open Riemann surface can be used as the target space of a B-type LG model whose TFT datum admits the simplified description discussed in [\[7\]](#page-9-2) and summarized in [\[8\]](#page-9-3). Since the holomorphic tangent bundle  $T\Sigma$  is trivial by Grauert-Röhrl theorem, any open Riemann surface is holomorphically parallelizable.

**Proposition 2.10** (various authors). Every non-compact Riemann surface  $\Sigma$  admits a holomorphic embedding in  $\mathbb{C}^3$  and a holomorphic immersion in  $\mathbb{C}^2$ .

Remark. It is not known if any open Riemann surface admits a proper holomorphic embedding in  $\mathbb{C}^2$ .

2.3. The ring  $\mathcal{O}(\Sigma)$ 

Let  $\Sigma$  be an open Riemann surface. This subsection recalls certain results regarding the ring  $\mathcal{O}(\Sigma)$  of complex-valued holomorphic functions defined on  $\Sigma$ .

**Theorem 2.11** (Bers). Let  $\Sigma_1$  and  $\Sigma_2$  be two connected non-compact Riemann surfaces. Then  $\Sigma_1$  and  $\Sigma_2$  are biholomorphic iff their rings of holomorphic functions  $\mathcal{O}(\Sigma_1)$  and  $\mathcal{O}(\Sigma_2)$  are isomorphic as unital C-algebras.

**Theorem 2.12** (Iss'sa). Let  $\Sigma_1$  and  $\Sigma_2$  be two connected non-compact Riemann surfaces. Then  $\Sigma_1$  and  $\Sigma_2$  are biholomorphic iff their fields of meromorphic functions  $\mathcal{M}(\Sigma_1)$  and  $\mathcal{M}(\Sigma_2)$  are isomorphic as unital C-algebras.

Proposition 2.13 (Henriksen-Alling). The following statements hold:

- 1. The cardinal Krull dimensions of all open Riemann surfaces are equal to each other (denote this cardinal number by  $\mathbf{k}$ ).
- 2. We have  $\mathbf{k} \geq 2^{\aleph_1}$ .

**Definition 2.14.** An elementary divisor domain *(EDD)* is an integral domain R such that any matrix with coefficients from R admits a Smith normal form.

**Theorem 2.15** (Helmer-Henriksen-Alling). For any open Riemann surface  $\Sigma$ , the ring  $\mathcal{O}(\Sigma)$  is an elementary divisor domain.

## 2.4. Special uniformizers

Let  $\Sigma$  be an open Riemann surface and  $\text{ord}_x : \mathcal{M}(\Sigma) \to \mathbb{Z}$  be the map which assigns to a meromorphic function  $f \in \mathcal{M}(\Sigma)$  its order at the point  $x \in \Sigma$ .

**Definition 2.16.** A special local uniformizer for  $\Sigma$  at the point  $x \in \Sigma$  is a meromorphic function  $t_x \in \mathcal{M}(\Sigma)$  such that  $\text{ord}_x(t_x) = 1$  and  $\text{ord}_y(t_x) = 0$  for all  $y \in \Sigma \setminus \{x\}$ . Notice that  $t_x \in \mathcal{O}(\Sigma)$ .

**Proposition 2.17.** The special local uniformizers of  $\Sigma$  coincide with the prime elements of  $\mathcal{O}(\Sigma)$ . In particular, a special local uniformizer at x is determined up to multiplication by a unit of  $\mathcal{O}(\Sigma)$  (i.e. a nowhere-vanishing element of  $\mathcal{O}(\Sigma)$ ).

## 2.5. Critically-finite elements of  $\mathcal{O}(\Sigma)$

Most of our results for B-type Landau-Ginzburg models with open Riemann surface target depend on the assumption that the Landau-Ginzburg superpotential is critically finite in the sense discussed below. The notion of critically finite element was introduced in [\[10,](#page-9-5) [11\]](#page-9-6), which studied categories of finite rank matrix factorizations for Bézout and elementary divisor domains.

**Definition 2.18.** A divisor  $r \in \mathcal{O}(\Sigma)$  of  $f \in \mathcal{O}(\Sigma)$  is called critical if  $r^2 | f$ .

**Definition 2.19.** A non-zero non-unit  $f \in \mathcal{O}(\Sigma)$  is called:

- non-critical, if f has no critical divisors;
- critically-finite, if f has a factorization of the form:

$$
f = f_0 f_c \quad \text{with} \quad f_c = p_1^{n_1} \dots p_N^{n_N} \quad ,
$$

where  $N \geq 1$ ,  $n_i \geq 2$ ,  $p_1, \ldots, p_N \in \mathcal{O}(\Sigma)$  are critical prime divisors of f with  $(p_i) \neq (p_j)$ for  $i \neq j$  and  $f_0 \in \mathcal{O}(\Sigma)$  is non-critical and coprime with  $f_c$ .

**Lemma 2.20.** Let  $f \in \mathcal{O}(\Sigma)$  be a non-zero element and  $D(f)$  be the analytic divisor of f. Then the following statements hold:

- 1. f is a unit of  $\emptyset(\Sigma)$  iff  $D(f) = 0$ .
- 2. f is a prime element of  $\mathcal{O}(\Sigma)$  (i.e. a special local uniformizer of  $\Sigma$ ) iff  $D(f) = x$  for some  $x \in \Sigma$ .
- 3. f is non-critical iff  $D(f)$  is multiplicity-free at any point in its support, i.e. iff it has the form:

$$
D(f) = \sum_{x \in \mathcal{Z}(f)} x ,
$$

where  $\mathcal{Z}(f)$  denotes the zero set of f (which is at most countable).

- 4. If  $g \in \mathcal{O}(\Sigma)$  is another holomorphic function, then  $f|g$  iff  $D(f) \leq D(g)$ .
- 5. f is critically-finite iff  $f = gh$ , where  $g \in \mathcal{O}(\Sigma)$  is non-critical and  $h \in \mathcal{O}(\Sigma)$  satisfies:

$$
D(h) = \sum_{x \in \mathcal{Z}(h)} n_x \cdot x ,
$$

with  $\mathcal{Z}(h)$  a non-empty finite set and  $n_x > 1$  for every  $x \in \mathcal{Z}(h)$ .

## 3. B-type Landau-Ginzburg models with one-dimensional target

**Definition 3.1.** A Landau-Ginzburg (LG) pair is a pair  $(X, W)$  such that:

- 1. X is a non-compact complex and Kählerian connected manifold of dimension  $d > 0$ , which is holomorphically Calabi-Yau in the sense that its holomorphic canonical line bundle  $K_X$  is holomorphically trivial.
- 2.  $W \in \mathcal{O}(X)$  is a non-constant holomorphic complex-valued function defined on X, which is called the Landau-Ginzburg superpotential.

Given an LG pair  $(X, W)$ , let  $Z_W \stackrel{\text{def.}}{=} \{x \in X | (\partial W)(x) = 0\}$  be the critical set of W. Since any Stein manifold is Kählerian, a particular case of LG pair is obtained by taking  $X$  to be Stein. This situation was studied in [\[7\]](#page-9-2) (see [\[8\]](#page-9-3) for a summary).

**Definition 3.2.** A one-dimensional LG pair is an LG pair  $(X, W)$  such that dim<sub>C</sub>  $X = 1$ .

Since any open Riemann surface is Stein and holomorphically Calabi-Yau (see Subsection [2.2\)](#page-2-0), we have:

**Proposition 3.3.** An LG pair is one-dimensional iff  $X$  coincides with an open Riemann surface  $\Sigma$ .

Since any compact analytic subset of a Stein manifold is finite, the critical set of  $W \in \mathcal{O}(\Sigma)$ is compact iff it is finite. Let  $(\Sigma, W)$  be a one-dimensional LG pair with compact (and hence finite) critical set  $Z_W$ . For any  $p \in Z_W$ , let:

$$
\mathbf{M}(\hat{W}_p) \stackrel{\text{def.}}{=} \frac{\mathcal{O}_{\Sigma, p}}{\langle \hat{W}'_p \rangle}
$$

denote the **analytic** Milnor algebra of the analytic function germ  $\hat{W}_p$  of W at p and  $\nu_p \stackrel{\text{def.}}{=}$  $\dim_{\mathbb{C}} M(\hat{W}_p)$  denote the analytic Milnor number of W at p. Here  $\langle W'_p \rangle$  is the ideal of  $\mathcal{O}(\Sigma)$ generated by  $\frac{dW(p)}{dz}$ , where z is any local holomorphic coordinate of  $\Sigma$  centered at p (this ideal is independent of the choice of such a local coordinate). Let  $t_p \in \mathcal{M}(\Sigma)$  be a special local uniformizer of  $\Sigma$  at p.

**Proposition 3.4.** [\[9\]](#page-9-4) We have  $\text{M}(\hat{W}_p) \simeq_{\text{\O}(\Sigma)} \bigoplus_{i=1}^N \mathcal{O}_{\Sigma, p} / \langle \hat{t}_p^{\nu_p} \rangle$  .

**Proposition 3.5.** [\[9\]](#page-9-4) The bulk state space of the open-closed TFT defined by  $(\Sigma, W)$  can be identified with the direct sum of analytic Milnor algebras:

$$
\mathcal{H} \simeq_{\mathcal{O}(X)} \oplus_{p \in Z_W} \mathcal{M}(\hat{W}_p) .
$$

In particular, we have:

$$
\dim_{\mathbb{C}} \mathcal{H} = \sum_{p \in Z_W} \nu_p \quad .
$$

#### 3.1. The topological D-brane category

For any unital commutative ring R, let  $MF(R, W)$  denote the category of finite rank matrix factorizations of W over R and  $HMF(R, W)$  denote its total cohomology category (which is  $\mathbb{Z}_2$ -graded and R-linear). Let  $\text{hmf}(R, W) \stackrel{\text{def.}}{=} \text{HMF}^{\hat{0}}(R, W)$  denote the sub-category obtained from  $HMF(R, W)$  by keeping only the even morphisms. It is well-known that  $hmf(R, W)$  has a natural structure of triangulated category with involutive shift functor.

**Proposition 3.6.** [\[9\]](#page-9-4) Let  $(\Sigma, W)$  be a one-dimensional LG pair. Then the D-brane category  $\mathcal{T}$ of the associated 2d TFT (i.e. of the quantum LG model with target  $(X, W)$ ) can be identified with:

$$
\mathcal{T} \simeq_{\mathcal{O}(\Sigma)} \text{HMF}(\mathcal{O}(\Sigma), W) .
$$

**Definition 3.7.** A matrix factorization  $(M, D)$  of W over  $\mathcal{O}(\Sigma)$  is called elementary if  $\text{rk} M^{\hat{0}} = \text{rk} M^{\hat{1}} = 1.$ 

In the limit  $W \to 0$ , the B-type LG model parameterized by  $(X, W)$  reduces to a B-type nonlinear sigma model with non-compact target  $X$ . Intuitively, elementary factorizations correspond to 'elementary D-branes', i.e. those topological D-branes which are obtained by 'topological tachyon condensation' in a pair formed of a single brane and a single anti-brane of this nonlinear sigma model, where tachyon condensation is driven by turning on the Landau-Ginzburg superpotential W. See  $[15, 16, 17, 18]$  $[15, 16, 17, 18]$  $[15, 16, 17, 18]$  $[15, 16, 17, 18]$  for the origin of this interpretation in open topological string field theory.

**Definition 3.8.** The  $\mathbb{Z}_2$ -graded cocycle category  $\text{ZMF}(\mathcal{O}(\Sigma), W)$  has the same objects as  $MF(\Sigma, W)$  but its morphisms are the closed morphisms of  $MF(\mathcal{O}(\Sigma), W)$ .

Let  $\text{zmf}(\mathcal{O}(\Sigma), W)$  be the even subcategory of  $\text{ZMF}(\mathcal{O}(\Sigma), W)$ . We say that two matrix factorizations of W are *strongly isomorphic* if they are isomorphic in  $\text{zmf}(\mathcal{O}(\Sigma), W)$ . Notice that an elementary factorization of W is indecomposable in the additive category  $\text{zmf}(\mathcal{O}(\Sigma), W)$ , but it need not be indecomposable in  $\mathcal{T}^{\hat{0}} = \text{hmf}(\mathcal{O}(\Sigma), W)$ .

## 3.2. Critically-finite superpotentials

The following result characterizes critically-finite superpotentials:

**Proposition 3.9.** [\[9\]](#page-9-4) Let  $(\Sigma, W)$  be a one-dimensional LG pair. Then the following statements are equivalent:

- (a) W is a critically-finite element of  $\mathcal{O}(\Sigma)$ .
- (b) The intersection  $\mathcal{Z}(W) \cap Z_W$  is finite.
- $(c)$  The divisor of W has the form:

$$
D(W) = D_0 + \sum_{i=1}^{N} n_i x_i ,
$$

where  $D_0$  is either the trivial divisor or an effective divisor whose multiplicity at every point of its support is one, the symbols  $x_1, \ldots, x_N$  (with  $N \geq 1$ ) denote a finite collection of points of  $\Sigma$  which do not belong to the support of  $D_0$  and  $n_i \geq 2$  for all  $i = 1, \ldots, N$ .

(d) We have  $W = W_0 W_c$ , where  $W_0$  has no zeros or only simple zeros,  $W_c$  has a finite number of zeros, each of which has multiplicity at least two and  $W_0$ ,  $W_c$  have no common zero.

In particular, any holomorphic function W with finite critical set is a critically-finite element of  $\emptyset(\Sigma)$ .

**Remark.** Any critically-finite superpotential  $W \in \mathcal{O}(\Sigma)$  can be written as:

<span id="page-5-0"></span>
$$
W = W_0 W_c \text{ , with } W_c = \prod_{i=1}^{N} t_{x_i}^{n_i} \text{ ,}
$$
 (1)

where:

- (i)  $W_0 \in \mathcal{O}(\Sigma)$  has a finite or countable number of zeros, all of which are simple.
- (ii)  $x_1, \ldots, x_N$  (with  $N \geq 1$ ) are distinct points of  $\Sigma$  and  $t_{x_i}$  are special uniformizers at these points.
- (iii) None of the points  $x_i$  is a zero of  $W_0$ .

In this case, we have  $D_0 = D(W_0)$  and we set  $D_c \stackrel{\text{def.}}{=} \sum_{i=1}^{N} n_i x_i$ .

3.3. Primary factorizations and the Krull-Schmidt property of hmf( $\mathcal{O}(\Sigma), W$ )

Recall that an additive category  $A$  is called Krull-Schmidt if any object of  $A$  decomposes as a finite sum of indecomposable objects with quasi-local endomorphism rings. We say that a matrix factorization of W is *trivial* if it is a zero object in  $hmf(\Sigma, W)$ .

**Proposition 3.10.** [\[9\]](#page-9-4) Any elementary factorization of W over  $\mathcal{O}(\Sigma)$  is strongly isomorphic to an elementary factorization of the form  $e_v \stackrel{\text{def.}}{=} (\mathcal{O}(\Sigma)^{1|1}, D_v)$ , where  $v \in \mathcal{O}(\Sigma)$  is a divisor of W and  $D_v \stackrel{\text{def.}}{=} \left[ \begin{array}{cc} 0 & v \\ v & 0 \end{array} \right]$  $u \quad 0$ , with  $u \stackrel{\text{def.}}{=} W/v \in \mathcal{O}(\Sigma)$ .

**Definition 3.11.** An element  $f \in \mathcal{O}(\Sigma)$  is called primary if it is a power of a prime element of  $\mathcal{O}(\Sigma)$ . An elementary factorization  $e_v$  of W is called primary if v is a primary divisor of W.

If  $e_v$  is a primary factorization of W over  $\mathcal{O}(\Sigma)$ , then we have  $v = at_x^k$  for some  $a \in \mathcal{O}(\Sigma)^\times$ , some  $k \in \mathbb{Z}_{>0}$  and some  $x \in \Sigma$ . In this case, W has a zero of order at least k at the point  $x \in \Sigma$ .

**Theorem 3.12.** [\[9\]](#page-9-4) Suppose that  $W$  is critically-finite. Then the additive category hmf( $\mathcal{O}(\Sigma), W$ ) is a Krull-Schmidt category whose non-zero indecomposables are the nontrivial primary matrix factorizations of W.

Hence any finite rank matrix factorization (in particular, any non-primary elementary factorization) of W decomposes into primary factorizations in the category hmf( $\mathcal{O}(\Sigma)$ , W). The primary factorizations of W play the role of 'simple' (a.k.a 'irreducible') topological D-branes of the B-type LG model.

# 3.4. The triangulated structure of hmf( $\mathcal{O}(\Sigma)$ , W)

Let R be a unital commutative ring. Let  $\text{mod}_R$  be the Abelian category of finitely-generated R-modules.

## Definition 3.13.

(i) The projectively stable category  $\overline{mod}_R$  has the same objects as  $\overline{mod}_R$  and modules of morphisms given by:

 $\underline{\mathrm{Hom}}_R(M, N) \stackrel{\text{def.}}{=} \mathrm{Hom}_R(M, N) / \mathcal{P}_R(M, N) \quad \forall M, N \in \mathrm{Ob}(\mathrm{mod}_R)$ ,

where  $P_R(M, N) \subset \text{Hom}_R(M, N)$  consists of those morphisms of mod<sub>R</sub> which factor through a projective module of finite rank.

(ii) The injectively stable category  $\overline{mod}_R$  has the same objects as  $mod_R$  and modules of morphisms given by:

 $\overline{\text{Hom}}_R(M,N) \stackrel{\text{def.}}{=} \text{Hom}_R(M,N)/\mathcal{I}_R(M,N) \quad \forall M,N \in \text{Ob}(\text{mod}_R)$ ,

where  $\mathcal{I}_R(M, N) \subset \text{Hom}_R(M, N)$  consists of those morphisms of mod<sub>R</sub> which factor through an injective module of finite rank.

**Remark.** When R is a self-injective ring, the categories  $\text{mod}_R$  and  $\text{mod}_R$  are equivalent to each other and the category  $\text{mod}_R$  is naturally triangulated since in this case  $\text{mod}_R$  is a Frobenius category (i.e. an exact category whose projective and injective objects coincide).

The following result gives a complete description of the triangulated structure of the category  $\mathcal{T}^{\hat{0}} = \text{hmf}(\mathcal{O}(\Sigma), W)$  for the case when W is critically finite:

**Theorem 3.14.** [\[9\]](#page-9-4) Let  $W \in \mathcal{O}(\Sigma)$  be a critically-finite superpotential of the form [\(1\)](#page-5-0). Then the following statements hold:

- 1. The ring  $A_i \stackrel{\text{def.}}{=} \mathcal{O}(\Sigma)/\langle t_{x_i}^{n_i} \rangle$  is Artinian and Frobenius (hence also self-injective) for all  $i=1,\ldots,N$ .
- 2. For each  $i = 1, \ldots, N$ , there exist equivalences of triangulated categories:

$$
D_{\text{Sing}}(A_i) \simeq \underline{\text{mod}}_{A_i} ,
$$

where  $\underline{\text{mod}}_{A_i}$  denotes the projectively stable category of finitely-generated  $A_i$ -modules.

3. The triangulated category  $\underline{\text{mod}}_{A_i}$  is Krull-Schmidt with non-zero indecomposable objects given by the  $A_i$ -modules:

$$
V_i^{(k)} \stackrel{\text{def.}}{=} \mathcal{O}(\Sigma)/\langle t_{x_i}^k \rangle \simeq \langle t_{x_i}^{n_i-k} \rangle / \langle t_{x_i}^{n_i} \rangle \text{ where } k = 1, \dots, n_i - 1.
$$

This category admits Auslander-Reiten triangles, having the Auslander-Reiten quiver shown in Figure [1.](#page-7-0) Moreover, it is classically generated by the residue field  $V_i^{(1)} = \mathcal{O}(\Sigma)/\langle t_{x_i} \rangle$  of  $A_i$ .

4. The triangulated category  $D_{\text{Sing}}(A_i) \simeq \underline{\text{mod}}_{A_i}$  is 1-Calabi-Yau for all i, with involutive shift functor:  $\lambda$ 

$$
\Omega(V_i^{(k)}) = V_i^{(n_i - k)} \quad \forall k = 1, ..., n_i - 1
$$
.

5. There exists an equivalences of triangulated categories:

$$
\operatorname{hmf}(\mathcal{O}(\Sigma), W) \simeq \vee_{i=1}^{N} \operatorname{D}_{\operatorname{Sing}}(A_i) \simeq \vee_{i=1}^{N} \underline{\operatorname{mod}}_{A_i}
$$

.

6. The triangulated category  $hmf(\mathcal{O}(\Sigma), W)$  is 1-Calabi-Yau, Krull-Schmidt and admits Auslander-Reiten triangles. Its Auslander-Reiten quiver is disconnected, with connected components given by the Auslander-Reiten quivers of the categories  $\underline{\text{mod}}_{A_i}$ .

<span id="page-7-0"></span>**Figure 1.** Auslander-Reiten quiver for  $\underline{mod}_{A_i}$  when  $n_i = 5$ . The Auslander-Reiten translation fixes all vertices and the multiplicities of all arrows are trivial.

## 3.5. Counting indecomposables in hmf( $\mathcal{O}(\Sigma), W$ )

The following result gives the count of simple topological D-branes of the LG model:

**Proposition 3.15.** [\[9\]](#page-9-4) Suppose that W is critically finite of the form given in eq. (1). Then the number of isomorphism classes of indecomposable non-zero objects of the category hmf $(\mathcal{O}(\Sigma), W)$  $equals \sum_{i=1}^{N} (n_i - 1) = -N + \sum_{i=1}^{N} n_i.$ 

The degrees  $n_i$  of the prime factors  $t_{x_i}$  arising in the decomposition of  $W_c$  define a  $\mathbb{Z}_2$ -grading on the set  $I_N \stackrel{\text{def.}}{=} \{1, \ldots, N\}$  whose components are given by:

$$
I_N^{\hat{0}} \stackrel{\text{def.}}{=} \{ i \in I_N \mid n_i \text{ is even} \}, \ I_N^{\hat{1}} \stackrel{\text{def.}}{=} \{ i \in I_N \mid n_i \text{ is odd} \}.
$$

Let:

$$
N^{\hat{0}} \stackrel{\text{def.}}{=} |I_N^{\hat{0}}| \text{ and } N^{\hat{1}} \stackrel{\text{def.}}{=} |I_N^{\hat{1}}|
$$

denote the cardinalities of these subsets of I, which satisfy  $N^{\hat{0}} + N^{\hat{1}} = N$ . Any non-empty subset  $K \subset I_N$  is endowed with the Z<sub>2</sub>-grading induced from  $I_N$ , which has components:

$$
K^{\hat{0}} \stackrel{\text{def.}}{=} K \cap I_N^{\hat{0}} \ , \ K^{\hat{1}} \stackrel{\text{def.}}{=} K \cap I_N^{\hat{1}} \ .
$$

3.6. Counting elementary factorizations in hmf( $\mathcal{O}(\Sigma), W$ ) and HMF( $\mathcal{O}(\Sigma), W$ )

The following result allows one to count elementary topological D-branes as well as elementary brane-antibrane pairs:

**Theorem 3.16.** [\[9\]](#page-9-4) Suppose that W is a critically-finite element of  $\mathcal{O}(\Sigma)$  with the decomposition given in eq.  $(1)$ . Then:

1. The number of isomorphism classes of elementary factorizations in the category hmf $(\emptyset(\Sigma), W)$  is given by:

$$
\widehat{\mathcal{N}}_W = \sum_{k=0}^{N^{\hat{1}}} \sum_{\substack{K \subsetneq I_N, \\ |K^{\hat{1}}|=k}} 2^{N^{\hat{0}}+k} \prod_{i \in K} \left\lfloor \frac{n_i-1}{2} \right\rfloor .
$$

2. The number of isomorphism classes of elementary matrix factorizations in the category  $HMF(\emptyset(\Sigma), W)$  is given by:

$$
\mathcal{N}_W = 2^{r^{\hat{0}}} + \sum_{k=0}^{N^{\hat{1}}} 2^{N^{\hat{0}}+k-1} \sum_{\substack{K \subsetneq I_N \\ |K^{\hat{1}}|=k}} \prod_{i \in K} \lfloor \frac{n_i-1}{2} \rfloor \quad .
$$
