FILLINGS AND FITTINGS OF UNIT COTANGENT BUNDLES OF ODD-DIMENSIONAL SPHERES

MYEONGGI KWON AND KAI ZEHMISCH

ABSTRACT. We introduce the concept of fittings to symplectic fillings of the unit cotangent bundle of odd-dimensional spheres. Assuming symplectic asphericity we show that all fittings are diffeomorphic to the respective unit co-disc bundle.

1. INTRODUCTION

There is a general question in symplectic geometry: How much does the boundary of a compact symplectic manifold know about its interior? When the boundary is of contact type, the question becomes meaningful. In fact, this question is of high current interest in dimension 4. But much less is known about the topology of the fillings in higher dimensions. By results of Eliashberg–Floer–McDuff, see [6, Theorem 1.5], and Barth–Geiges–Zehmisch [2] the diffeomorphism type of symplectically aspherical fillings is uniquely determined for many subcritically Stein fillable contact manifolds. But almost nothing is known in the *critical* case so far. This paper is about symplectically aspherical fillings of the unit cotangent bundle of odd-dimensional spheres. These are never subcritically Stein by [2, Theorem 1.2] because the unit cotangent bundle is of critical Stein type. For basic notions the reader is referred to Geiges' book [4].

For a given natural number d we consider the cotangent bundle T^*S^{2d+1} of the round (2d+1)-dimensional sphere. Like every cotangent bundle, T^*S^{2d+1} admits the Liouville canonical 1-form λ , which in local coordinates is given by $\mathbf{p} \, \mathrm{d} \mathbf{q}$. The induced contact structure on the unit cotangent bundle

$$M = ST^*S^{2d+1}$$

is denoted by ξ . The resulting contact manifold (M, ξ) admits a natural symplectic filling $(W_{\rm st}, \omega_{\rm st})$ given by the unit disc bundle $(DT^*S^{2d+1}, d\lambda)$. We call $(W_{\rm st}, \omega_{\rm st})$ the standard filling.

We would like to find natural conditions under which a symplectic filling (W, ω) of (M, ξ) is diffeomorphic to W_{st} . Observe that a blow up of (W, ω) at any interior point results in a new symplectic filling of (M, ξ) , which cannot be diffeomorphic to W_{st} . The reason is that diffeomorphically the blow up is a connected sum with $\mathbb{C}P^{4d+2}$ with the opposite orientation and therefore contains a homologically nontrivial symplectic 2-sphere. In order to exclude this ambiguity we require all fillings

This research is part of a project in the SFB/TRR 191 Symplectic Structures in Geometry, Algebra and Dynamics, funded by the DFG.

to be **symplectically aspherical**, that is we require the symplectic form to be zero evaluated on all spherical homology 2-classes.

Unfortunately, symplectic asphericity seems not to be rigid enough to determine the diffeomorphism type of symplectic fillings of the unit cotangent bundle (M, ξ) of S^{2d+1} . That's why we want to search for an additional condition. In dimension 4 holomorphic curves as such are often self-dual in a symplectic way and in terms of Poincaré duality. This is crucial for uniqueness of symplectic fillings in dimension 4. Therefore, we are looking for symplectic hypersurfaces inside a given filling (W, ω) that behave nicely w.r.t. the boundary of (W, ω) and that remember a sufficiently large amount of symplectic informations of $(W_{\rm st}, \omega_{\rm st})$.

In the given situation this means the following: The standard filling (W_{st}, ω_{st}) itself appears as a Weinstein neighbourhood of the graph of the anti-Hopf map inside $\mathbb{C}^{d+1} \times \mathbb{C}P^d$, see Section 3.1, and embeds into the obvious partial compactification $\mathbb{C}P^1 \times \mathbb{C}^d \times \mathbb{C}P^d$. The intersection of W_{st} with $\mathbb{C}P^1 \times \mathbb{C}^d \times \mathbb{C}P^{d-1}$ defines a complex hypersurface in (W_{st}, ω_{st}) relative to the boundary. This complex hypersurface inherits the same homologically trivial intersection behaviour as holomorphic spheres $\mathbb{C}P^1 \times \mathbb{C}^d \times \mathbb{C}P^d$. We call a filling that admits such a complex hypersurface a **fitting**, see Section 4.1. As it will turn out fittings are the right concept to ensure uniqueness:

Theorem 1.1. If (W, ω) is a symplectically aspherical fitting of (M, ξ) , then W and W_{st} are diffeomorphic.

2. FROM HOMOLOGY GROUPS TO DIFFEOMORPHISM TYPE

In Section 3 we will verify the assumptions of the following proposition for fittings. The argumentation will be similar to earlier work which can be found in [2, Section 5] and [3, Section 4].

Proposition 2.1. Let (W, ω) be a symplectically aspherical filling of (M, ξ) . If W is simply connected and has the homology type of W_{st} , i.e. $H_kW = H_kW_{st}$ for all k, then W is diffeomorphic to W_{st} . In other words, the diffeomorphism type of W is unique in this case.

This section is intended to provide evidence for this statement.

2.1. A cobordism. We consider the cotangent disc bundle $D_R T^* S^{2d+1}$ of radius R > 1 so that the unit cotangent disc bundle $W_{\text{st}} = DT^* S^{2d+1}$ appears as a subset of $D_R T^* S^{2d+1}$. Via gluing of smooth manifolds with boundary we define

$$W_1 := \left(D_R T^* S^{2d+1} \setminus \operatorname{Int} W_{\mathrm{st}} \right) \cup_M W$$

by replacing $W_{\rm st}$ with W inside $D_R T^* S^{2d+1}$. For sufficiently large radius R the spherical shell bundle $(D_R T^* S^{2d+1} \setminus \operatorname{Int} W_{\rm st})$ contains a copy W_0 of $W_{\rm st}$. This copy of $W_{\rm st}$ is obtained by first taking a section s of the sphere bundle $ST^*S^{2d+1} \to S^{2d+1}$ and then shifting DT^*S^{2d+1} suitably inside T^*S^{2d+1} in the direction of s. This shifted copy of $W_{\rm st}$ is also considered to be contained in W_1 . We define a cobordism X between $M_0 := \partial W_0$ and $M_1 := \partial W_1$ by

$$X := W_1 \setminus \operatorname{Int} W_0.$$

Remark 2.2. The construction of the cobordism X heavily relies on the existence of a nowhere vanishing vector field on S^{2d+1} . This is the first of two places in our argument that requires the spheres S^{2d+1} to have odd dimensions. The second one is the use of the Hopf fibration in Section 3.1.

2.2. Applying the *h*-cobordism theorem. Under the assumptions of Proposition 2.1 the cobordism X is an *h*-cobordism: The boundary components M_0 and M_1 are both S^{2d} -bundles over S^{2d+1} , $d \ge 1$, and, hence, simply connected thanks to the corresponding homotopy sequence. The cobordism X itself is simply connected too. Indeed, $W_1 \simeq W$ is simply connected by assumption. The contraction $S^{2d+1} \simeq W_{\rm st}$ induces a contraction $S \simeq W_0$ of W_0 onto the shifted copy S of S^{2d+1} under the shift that we used in the construction of X in Section 2.1. This contraction defines a contraction of $W_1 \setminus S$ onto Int X. Simply connectedness of X now follows with the simply connectedness of W_1 together with a general position argument that uses $2 + (2d+1) < 4d + 2 = \dim W_1$. It follows that the inclusions $M_0 \hookrightarrow X$ and $M_1 \hookrightarrow X$ of the boundaries induce isomorphisms of the respective fundamental groups.

Lemma 2.3. $H_*(X, M_0) = 0$.

Proof of Proposition 2.1. With Lemma 2.3, Poincaré–Lefschetz duality and the universal coefficient theorem imply $H_*(X, M_1) = 0$. A combination of Hurewicz' and Whitehead's theorem implies that the inclusions $M_0 \hookrightarrow X$ and $M_1 \hookrightarrow X$ are strong deformation retracts. This uses our preceding considerations on the simply connectedness of M_0, M_1 , and X. In other words $\{M_0, X, M_1\}$ is a simply connected *h*-cobordism of dimension $4d + 2 \ge 6$.

The *h*-cobordism theorem implies that X is diffeomorphic to $[0,1] \times M_0$ via a diffeomorphism that restricts to the identity on $0 \times M_0$, see [8]. Gluing back W_0 to X and extending the diffeomorphism suitably we obtain that W_1 is diffeomorphic to a collar extension of W_0 . It follows that W and $W_{\rm st}$ are diffeomorphic. \Box

2.3. Killing relative homology. It remains to prove Lemma 2.3. By the excision axiom this lemma is equivalent to $H_*(W_1, W_0) = 0$.

To show homology vanishing of the pair (W_1, W_0) we observe that $S^{2d+1} \simeq W_0$, so that, invoking our assumptions, $H_k S^{2d+1} = H_k W_0 = H_k W_1$ for all $k \in \mathbb{Z}$. The long exact sequence of (W_1, W_0) implies $H_k(W_1, W_0) = 0$ for all $k \neq 2d + 1, 2d + 2$ and exactness of

$$0 \to H_{2d+2}(W_1, W_0) \to H_{2d+1}W_0 \to H_{2d+1}W_1 \to H_{2d+1}(W_1, W_0) \to 0$$

Therefore, in order to prove Proposition 2.1 it suffices to show that the map $\iota_* \colon H_{2d+1}W_0 \to H_{2d+1}W_1$ induced by the inclusion $W_0 \subset W_1$ is invertible.

We will use the **cobordism diagram** below. To explain the cobordism diagram we consider the shift map that brings $W_{\rm st}$ to W_0 in the construction we gave in Section 2.1. The image of the section s, which is contained in $\partial W_{\rm st}$, is mapped to $S_0 \subset M_0$ under the shift map. Also, with the construction of X we find a diffeomorphism $M_0 \to M_1$ that maps S_0 onto the section S_1 , say, such that S_0 is isotopic to S_1 inside W_1 . This isotopy extends to an isotopy of W_0 inside W_1 resulting in the following homotopy commutative diagram:

We would like to understand the diagram in homology of degree 2d + 1. Starting with the left triangle we see that the inclusion of the (2d + 1)-sphere S_0 into W_0 is a homotopy equivalence. Using the Gysin sequence of the Euler class zero bundle $ST^*S^{2d+1} \rightarrow S^{2d+1}$ and the universal coefficient theorem we see that the homology of M_0 in degree 2d + 1 equals \mathbb{Z} . Therefore, all morphisms of the left triangle in degree 2d + 1 are multiplication by ± 1 , i.e. the maps (i) are H_{2d+1} -isomorphisms.

Using the outer square we see that the map (ii) is a H_{2d+1} -isomorphism too. We claim that the maps (iii) are H_{2d+1} -isomorphisms. Our assumptions on the homology type of W translate into $H_*W_1 = H_*W_0$. Poincaré–Lefschetz duality and the universal coefficient theorem imply $H_{2d+2}(W_1, M_1) = 0$ and $H_{2d+1}(W_1, M_1) = \mathbb{Z}$. Therefore, the long exact sequence for the pair (W_1, M_1) implies exactness of

$$0 \to H_{2d+1}M_1 \to H_{2d+1}W_1 \to \mathbb{Z} \to \mathbb{Z} \to 0,$$

where we used that $H_{2d}M_1 = \mathbb{Z}$ by the Gysin sequence of the Euler class zero bundle $ST^*S^{2d+1} \to S^{2d+1}$ and the universal coefficient theorem. As any surjection $\mathbb{Z} \to \mathbb{Z}$ is necessarily invertible, $H_{2d+1}M_1 \to H_{2d+1}W_1$ is indeed an isomorphism. Therefore, the maps labeled (iii) are isomorphisms in H_{2d+1} as claimed.

Therefore, all morphisms in the cobordism diagram are H_{2d+1} -isomorphisms. In particular, $\iota_*: H_{2d+1}W_0 \to H_{2d+1}W_1$ is invertible. This completes the proof of Lemma 2.3.

3. HOLOMORPHIC FILLING VIA CAP CONSTRUCTIONS

Cap constructions were used in [5, 9] to verify instances of the Weinstein conjecture, and in [2] for classifications of subcritical fillings. In the critical case too, symplectic caps are essential.

3.1. The anti-Hopf map and capping. The unit sphere $S^{2d+1} \subset \mathbb{C}^{d+1}$, $d \geq 1$, fibres over $\mathbb{C}P^d$ via the Hopf map $S^{2d+1} \to \mathbb{C}P^d$, $z \mapsto [z]$. As observed by Audin–Lalonde–Polterovich ([1]) the graph of the anti-Hopf map

$$S^{2d+1} \longrightarrow \mathbb{C}^{d+1} \times \mathbb{C}P^d, \quad z \longmapsto (z, [\bar{z}]),$$

defines a Lagrangian embedding, which by the Weinstein neighbourhood theorem extends to a symplectic embedding of a neighbourhood of the zero section of the cotangent bundle T^*S^{2d+1} . Rescaling the metric on S^{2d+1} suitably, this defines an embedding of DT^*S^{2d+1} into $\mathbb{C}^{d+1} \times \mathbb{C}P^d$, and we may assume that

$$(M,\xi) = ST^*S^{2d+1} \subset \mathbb{C}^{d+1} \times \mathbb{C}P^d$$

appears as a hypersurface of contact type. The complement of the interior of DT^*S^{2d+1} is a so-called **symplectic cap**

$$\operatorname{Cap} := \mathbb{C}^{d+1} \times \mathbb{C}P^d \setminus \operatorname{Int} \left(DT^* S^{2d+1} \right)$$

and carries the symplectic form

$$\omega_{\operatorname{Cap}} := \mathrm{d}x \wedge \mathrm{d}y \oplus \omega_{\operatorname{FS}}$$

We define a symplectic manifold

$$(Z, \Omega) := (W, \omega) \cup_{(M,\xi)} (\operatorname{Cap}, \omega_{\operatorname{Cap}})$$

via gluing along contact type boundaries. Choose $z_0 \in \mathbb{C}$ such that the complex hypersurface $z_0 \times \mathbb{C}^d \times \mathbb{C}P^d$ is contained in Z.

Lemma 3.1. If the embedding $z_0 \times \mathbb{C}^d \times \mathbb{C}P^d \to Z$ is π_1 -surjective and $H_k(.;\mathbb{F})$ onto for all $k \in \mathbb{Z}$ and all fields \mathbb{F} , then W and W_{st} are diffeomorphic.

Proof. In view of Proposition 2.1 we need to show that $\pi_1 W = 1$ and $H_*W = H_*W_{st}$.

By the π_1 -surjectivity assumption, we have $\pi_1 Z = 1$, since $\mathbb{C}P^d$ is simply connected. As $S^{2d+1} \subset \mathbb{C}^{d+1} \times \mathbb{C}P^d$ has codimension ≥ 3 , we get that Cap is simply connected. By the Seifert–van Kampen theorem, $\pi_1 Z$ is the free product of $\pi_1 W$ and the trivial group, because M is simply connected. It follows that $\pi_1 W = 1$.

By assumption, the induced map $H_*(\mathbb{C}P^d;\mathbb{F}) \to H_*(Z;\mathbb{F})$ is surjective for all fields \mathbb{F} . With the universal coefficient theorem, we find $H_kZ = 0$ for all $k \ge 2d+1$. The Mayer–Vietoris sequence for the decomposition $Z = W \cup \text{Cap}$ along M gives $H_kM = H_kW \oplus H_k(\text{Cap})$ for all $k \ge 2d+1$. Similarly, $H_kM = H_kW_{\text{st}} \oplus H_k(\text{Cap})$ for all $k \ge 2d+1$, so that $H_kW = H_kW_{\text{st}}$ for all $k \ge 2d+1$.

To prove the isomorphism $H_kW = H_kW_{st}$ for all $k \leq 2d$, observe that by excision and Poincaré–Lefschetz duality applied to (Z, W) we have $H^kW = H_{4d+2-k}(Z, \operatorname{Cap})$ for all $k \in \mathbb{Z}$. Note that $k \leq 2d$ translates into $4d + 2 - k \geq 2d + 2$ and that the long exact sequence of the pair (Z, Cap) gives $H_m(Z, \operatorname{Cap}) = H_{m-1}(\operatorname{Cap})$ for all $m \geq 2d + 2$. Hence, $H^kW = H_{4d+1-k}(\operatorname{Cap})$ for all $k \leq 2d$. Similarly, $H^kW_{st} = H_{4d+1-k}(\operatorname{Cap})$ for all $k \leq 2d$ using excision of the pair $(\mathbb{C}^{d+1} \times \mathbb{C}P^d, W_{st})$ and Poincaré–Lefschetz duality. We conclude $H^kW = H^kW_{st}$ for all $k \leq 2d$, which in fact holds true in homology with any field coefficients. The universal coefficient theorem implies $H_kW = H_kW_{st}$ for all $k \leq 2d$, as the reduced homology of S^{2d+1} vanishes in all degrees $\leq 2d$.

3.2. A cap construction. As a first step in defining a moduli space of holomorphic spheres we will partially compactify $\mathbb{C}^{d+1} \times \mathbb{C}P^d$. The subset

$$B_r^2(0) \times \mathbb{C}^d \times \mathbb{C}P^d$$
, $r > 1$,

of $\mathbb{C}^{d+1} \times \mathbb{C}P^d$ completes symplectically to

$$\left(\mathbb{C}P^1 \times \mathbb{C}^d \times \mathbb{C}P^d, r^2\omega_{\mathrm{FS}} \oplus \mathrm{d}x \wedge \mathrm{d}y \oplus \omega_{\mathrm{FS}}\right)$$

where $\omega_{\rm FS}$ stands for the Fubini–Study form of the respective projective space. The Lagrangian image of S^{2d+1} under the anti-Hopf map is contained in $B_r^2(0) \times \mathbb{C}^d \times$

 $\mathbb{C}P^d$. By rescaling the round metric on S^{2d+1} as in Section 3.1, $(M,\xi) = ST^*S^{2d+1}$ also appears as a hypersurface of contact type in $\mathbb{C}P^1 \times \mathbb{C}^d \times \mathbb{C}P^d$ provided with the symplectic form

$$\hat{\omega} := r^2 \omega_{\rm FS} \oplus dx \wedge dy \oplus \omega_{\rm FS} \,.$$

We equip the complement

$$\widehat{\operatorname{Cap}} := \mathbb{C}P^1 \times \mathbb{C}^d \times \mathbb{C}P^d \setminus \operatorname{Int} \left(DT^* S^{2d+1} \right)$$

with the symplectic form induced by $\hat{\omega}$ and obtain a symplectic cap. $\widehat{\text{Cap}}$ contains holomorphic spheres

$$C_1 := \mathbb{C}P^1 \times \mathrm{pt} \times \mathrm{pt}, \qquad C_2 := \mathrm{pt} \times \mathrm{pt} \times \mathbb{C}P^1,$$

where pt stands for a generic choice of a point in the respective factor. In the definition of C_2 , $\mathbb{C}P^1 \subset \mathbb{C}P^d$ denotes a complex line. Dual hypersurfaces are

$$H_1 := \infty \times \mathbb{C}^d \times \mathbb{C}P^d, \qquad H_2 := \mathbb{C}P^1 \times \mathbb{C}^d \times \mathbb{C}P^{d-1}$$

where $\mathbb{C}P^{d-1} \subset \mathbb{C}P^d$ denotes a complex hyperplane. Assuming $\mathbb{C}P^1$ and $\mathbb{C}P^{d-1}$ in general position in $\mathbb{C}P^d$ it follows for the intersection numbers that

$$C_i \cdot H_j = \delta_{ij}$$

for i, j = 1, 2.

3.3. A moduli space. We define a symplectic manifold

$$(\hat{Z}, \hat{\Omega}) := (W, \omega) \cup_{(M,\xi)} \left(\widehat{\operatorname{Cap}}, \hat{\omega}\right).$$

It contains a subset W_{\Box} that by definition is the union of W and all points in $\widehat{\operatorname{Cap}}$ of the form (z_1, \mathbf{z}, w) that satisfy $|z_1| < R$ and $|\mathbf{z}| < R$ for some fixed $R \in (1, r)$. Let J be a tame almost complex structure on $(\hat{Z}, \hat{\Omega})$ that is equal to the standard complex structure J_{st} on $\hat{Z} \setminus W_{\Box}$ induced by $\mathbb{C}P^1 \times \mathbb{C}^d \times \mathbb{C}P^d$.

Lemma 3.2. For all non-constant parametrised holomorphic spheres $C = u(\mathbb{C}P^1)$, $u: \mathbb{C}P^1 \to (\hat{Z}, J)$, the following hold true.

- (i) If $C \subset \hat{Z} \setminus W_{\Box}$, then $u = (u^1, \text{pt}, u^3)$, where $\text{pt} \in \mathbb{C}^d$ and $u^1 \colon \mathbb{C}P^1 \to \mathbb{C}P^1$, $u^3 \colon \mathbb{C}P^1 \to \mathbb{C}P^d$ are holomorphic.
- (ii) If $C \cap (\hat{Z} \setminus \overline{W}_{\Box}) \neq \emptyset$ and $C \cap H_1 = \emptyset$, then $u = (\text{pt}, \text{pt}, u^3)$, where $u^3 : \mathbb{C}P^1 \to \mathbb{C}P^d$ is holomorphic.

Proof. (i) follows with the maximum principle. (ii) holds because the maximum principle in \mathbb{C} - and in \mathbb{C}^d -direction implies that the respective projections of C a posteriori are contained in the level sets of the radial distance functions. Hence, $C \subset \hat{Z} \setminus W_{\Box}$ and the claim follows with (i).

The **moduli space** \mathcal{M} consists of all holomorphic maps $u: \mathbb{C}P^1 \to (\hat{Z}, J)$ such that $u(\mathbb{C}P^1)$ is homologous to C_1 and $u(z) \in z \times \mathbb{C}^d \times \mathbb{C}P^d$ for $z \in \{\pm \varrho, \infty\}$, $\varrho \in (R, r)$.

Remark 3.3. We observe:

- (i) All holomorphic spheres $u \in \mathcal{M}$ are simple because positivity of intersections implies $u \bullet H_1 = C_1 \cdot H_1 = 1$, see [5, 7].
- (ii) The index $2 \dim_{\mathbb{C}}(\hat{Z}) + 2c_1(C_1) 6$ of the underlying Fredholm problem equals 4d, because $T\hat{Z}|_{C_1} = T\mathbb{C}P^1 \oplus \underline{\mathbb{C}}^d \oplus \underline{\mathbb{C}}^d$ and, hence, $c_1(C_1) = 2$.

(iii) If $u(\mathbb{C}P^1) \subset \hat{Z} \setminus W_{\Box}$ for $u \in \mathcal{M}$, then $u = (\mathrm{id}, \mathrm{pt}, \mathrm{pt})$. In particular u is regular. Indeed, with Lemma 3.2 (i) we get $u = (u^1, \mathrm{pt}, u^3)$ for holomorphic spheres u^1 and u^3 in $\mathbb{C}P^1$ and $\mathbb{C}P^d$, resp. Because of $u \bullet H_1 = 1$ the holomorphic map u^1 is an automorphism of $\mathbb{C}P^1$ that fixes 3 points, i.e. $u^1 = \mathrm{id}$. Therefore,

$$r^2\pi = \int_{\mathbb{C}P^1} u^*\hat{\Omega} = r^2\pi + \int_{\mathbb{C}P^1} (u^3)^*\omega_{\mathrm{FS}}.$$

The second integral is the Dirichlet energy of u^3 , which has to vanish by the equation. It follows that u^3 is constant.

- (iv) We choose the almost complex structure J on \hat{Z} such that $u \in \mathcal{M}$ is regular whenever $u(\mathbb{C}P^1) \cap W_{\Box} \neq \emptyset$. This can be done for example by perturbing J on W_{\Box} suitably, see [5, 7]. With these generic choices the moduli space \mathcal{M} is a smooth orientable manifold of dimension 4d.
- (v) By the maximum principle in \mathbb{C}^d -direction as used in Lemma 3.2 (ii) and item (iii) above, the end of \mathcal{M} is naturally diffeomorphic to the model $(\mathbb{C}^d \setminus B_R^{2d}(0)) \times \mathbb{C}P^d$ via the correspondence between

$$\left\{ u \in \mathcal{M} \mid u(\mathbb{C}P^1) \cap \left\{ (z_1, \mathbf{z}, w) \in \widehat{\operatorname{Cap}} \mid |\mathbf{z}| \ge R \right\} \neq \emptyset \right\}$$

and

$$\left\{ u = (\mathrm{id}, \mathbf{z}, w) \mid \mathbf{z} \in \mathbb{C}^d, \ |\mathbf{z}| \ge R, \ w \in \mathbb{C}P^d \right\}.$$

We choose the orientation on \mathcal{M} so that this correspondence preserves the orientations.

Lemma 3.4. If the evaluation map $\widehat{\text{ev}}$: $\mathcal{M} \times \mathbb{C}P^1 \to \hat{Z}$, $(u, z) \mapsto u(z)$ is proper, then W and W_{st} are diffeomorphic.

Proof. By definition of \mathcal{M} , each holomorphic sphere $u(\mathbb{C}P^1)$, $u \in \mathcal{M}$, intersects H_1 at $\infty \in \mathbb{C}P^1$. This intersection is unique by positivity of intersections. Therefore, the evaluation map $\widehat{\text{ev}}$ restricts to an evaluation map on $\mathcal{M} \times \mathbb{C}$ that takes values in $Z = \widehat{Z} \setminus H_1$, i.e. $(u, z) \mapsto u(z)$ is a well-defined map ev: $\mathcal{M} \times \mathbb{C} \to Z$.

As $\widehat{\text{ev}}$ is proper, so is the restricted map ev, hence ev is of mapping degree 1, see Remark 3.3 (v). Using the Umkehr-homomorphism based on Poincaré duality involving compactly supported cohomology, we see that ev is $H_*(.,\mathbb{F})$ -surjective for all fields \mathbb{F} . Surjectivity of ev in π_1 follows with a covering that corresponds to the index of the ev_#-image in $\pi_1(Z)$.

In view of Lemma 3.1 we consider the following commutative diagram:

The induced diagram in π_1 and $H_*(.,\mathbb{F})$ is commutative with upper $ev_{\#}$ and ev_* surjective for all fields \mathbb{F} . Hence, $\iota_{\#}$ and ι_* are surjective.

3.4. **Properness of the evaluation map.** We will investigate properness of the evaluation map. The results of this section are part of the proof of Theorem 1.1. For basics about holomorphic spheres we refer to McDuff–Salamon's book [7].

3.4.1. Gromov convergence. By the description of the end of \mathcal{M} in Remark 3.3 (v) it suffices to consider sequences $\{u^{\nu}\}_{\nu}$ of holomorphic spheres $u^{\nu} \in \mathcal{M}$ whose images $u^{\nu}(\mathbb{C}P^1)$ are contained in

$$W \cup \left\{ (z_1, \mathbf{z}, w) \in \widehat{\operatorname{Cap}} \mid |\mathbf{z}| \le R \right\}.$$

Because the energy

$$E(u^{\nu}) = \int_{\mathbb{C}P^1} (u^{\nu})^* \hat{\Omega} = \pi r^2$$

is uniformly bounded for all $\nu \in \mathbb{N}$, Gromov's compactness theorem applies: u^{ν} converges to a stable holomorphic sphere **u** with three marked points fixed. We denote by $u_1, \ldots, u_N, N \geq 1$, the non-constant components of **u**. The convergence is in C^{∞} precisely if N = 1. Therefore, the evaluation map $\hat{\text{ev}}$ is proper if N = 1.

3.4.2. Intersections. The intersection number of u^{ν} and H_1 is $u^{\nu} \bullet H_1 = 1$ for all $\nu \in \mathbb{N}$. Furthermore a neighbourhood of H_1 is foliated by complex hypersurfaces of the form $z_1 \times \mathbb{C}^d \times \mathbb{C}P^d$ with $|z_1|$ sufficiently large. Hence, we can assume that none of the $u_j(\mathbb{C}P^1)$, $j = 1, \ldots, N$, lies entirely in H_1 , so that the intersection numbers of the bubbles u_j and H_1 are defined, non-negative by positivity of intersections, i.e. $u_j \bullet H_1 \ge 0$ for all $j = 1, \ldots, N$, and sum up to $\sum_{j=1}^N u_j \bullet H_1 = 1$ according to Gromov convergence. Relabelling indices, if necessary, yields

$$u_1 \bullet H_1 = 1$$
 and $u_j \bullet H_1 = 0$

for all $j \geq 2$. By positivity of intersections and the maximum principle this implies that for each $j \geq 2$ we have the following alternative: either $u_j(\mathbb{C}P^1) \subset W_{\Box}$ or $u_j = (\text{pt}, \text{pt}, u_j^3)$ for some holomorphic $u_j^3 : \mathbb{C}P^1 \to \mathbb{C}P^d$, see Lemma 3.2 (ii). In particular,

$$u_j(\mathbb{C}P^1) \subset Z_R$$

for all $j \geq 2$, where

$$Z_R := W \cup \left\{ (z_1, \mathbf{z}, w) \in \operatorname{Cap} \mid |\mathbf{z}| \le R \right\}.$$

This will be used in the following section.

3.4.3. Implementing asphericity. We consider the homology classes $[u_1] \in H_2\hat{Z}$ and $[u_j] \in H_2Z_R$, $j \ge 2$, of the bubble spheres. Because the contact hypersurface $M = ST^*S^{2d+1}$ is simply connected, we can decompose

$$[u_1] = S_1 + A_1 \in H_2W \oplus H_2Cap$$

and

$$[u_i] = S_i + A_i \in H_2 W \oplus H_2(Z_R \setminus \operatorname{Int} W),$$

for all $j \ge 2$, using a general position argument: The bubble spheres intersect M along closed loops. These loops appear as the boundary of disc maps in M for both orientations of the loops. Adding the disc maps to the disc parts of the bubble spheres corresponding to W and its complements – respecting orientations – yields sphere maps that represent the S_i and A_j as desired. Since (W, ω) is symplectically

aspherical, $\hat{\Omega}(S_j) = 0$ for all j = 1, ..., N. Consequently, using Stokes' theorem, we have

$$0 < E(u_j) = \hat{\Omega}(A_j)$$

for all $j = 1, \ldots, N$.

3.4.4. Enumeration. In order to compute the symplectic energy of the holomorphic spheres u_j it suffices to compute $\hat{\Omega}(A_j)$ for the homology 2-classes A_j in Cap, see 3.4.3. Invoking the intersection pattern from 3.4.2 we find integers ℓ_1, \ldots, ℓ_N such that

$$A_1 = [C_1] + \ell_1[C_2]$$
 and $A_j = \ell_j[C_2]$,

for all $j \geq 2$. Indeed, reading this as an equation in H_2Cap this equation holds literally true if $d \geq 2$; if d = 1, the equation holds up to possibly adding a multiple of the fibre class in $M = ST^*S^3 \cong S^3 \times S^2$. However, any representing fibre S^2 is disjoint from the complex hypersurface H_1 and does not contribute to the symplectic energy by local exactness of the symplectic form near M. For that reason we will not spell out the fibre class summands.

Positivity of energy from 3.4.3 yields $r^2 + \ell_1 > 0$ and $\ell_j > 0$ for all $j \ge 2$. Furthermore, using $\hat{\Omega}(A_j) = \hat{\omega}(A_j)$ for all j,

$$\pi r^2 = E(u^{\nu}) = \sum_{j=1}^N \hat{\Omega}(A_j) = \pi r^2 + \ell_1 \pi + \ell_2 \pi + \dots + \ell_N \pi.$$

It follows that $\ell_1 + \cdots + \ell_N = 0$. Therefore,

$$N - 1 \le \ell_2 + \dots + \ell_N = -\ell_1 < r^2$$

Taking $r \in (1, \sqrt{2}]$ in Section 3.2, the cases N = 1 and N = 2 remain. If N = 1, then the evaluation map $\widehat{\text{ev}}$ will be proper. If N = 2, the above inequality turns into $1 = N - 1 \le \ell_2 = -\ell_1 < 2$ so that $\ell_2 = -\ell_1 = 1$, i.e.

 $A_1 = [C_1] - [C_2]$ and $A_2 = [C_2]$.

The symplectic energies of the two bubble spheres satisfy

$$E(u_1) = (r^2 - 1)\pi$$
 and $E(u_2) = \pi$.

4. Fittings

Recall the cap construction from Section 3.1, that

$$(Z, \Omega) = (W, \omega) \cup_{(M,\xi)} (\operatorname{Cap}, \omega_{\operatorname{Cap}}),$$

and consider the complex hypersurface $H := \mathbb{C}^{d+1} \times \mathbb{C}P^{d-1}$ in $\mathbb{C}^{d+1} \times \mathbb{C}P^d$.

4.1. **Definition.** A symplectic filling (W, ω) of $(M, \xi) = ST^*S^{2d+1}$ is called a **fitting** if there exist a closed neighbourhood U of H in $\mathbb{C}^{d+1} \times \mathbb{C}P^d$ and an embedding $\varphi \colon U \to Z$ with $\varphi|_{U \cap \text{Cap}} = \text{id}$ such that $\varphi_* J_{\text{st}}$ is tamed by Ω on $\varphi(U)$ and the homological intersection

$$\varphi_*[H \cap DT^*S^{2d+1}] \cdot S = 0$$

for all spherical classes $S \in H_2W$, i.e. for all classes in the image of the Hurewicz homomorphism.

4.2. **Proof of the Theorem 1.1.** We show that W and W_{st} are diffeomorphic provided that (W, ω) is a symplectically aspherical fitting of (M, ξ) . We consider $(\hat{Z}, \hat{\Omega}, J)$ constructed in Section 3.3 and choose $r \in (1, \sqrt{2})$, see 3.4.4. The embedding φ extends to an embedding (again denoted by φ) of a neighbourhood of $H_2 = \mathbb{C}P^1 \times \mathbb{C}^d \times \mathbb{C}P^{d-1}$ in $\mathbb{C}P^1 \times \mathbb{C}^d \times \mathbb{C}P^d$ into \hat{Z} .

This extended embedding can be assumed to be holomorphic: The almost complex structure J on \hat{Z} equals the standard complex structure J_{st} on $\hat{Z} \setminus W_{\Box}$. We require J to be $\varphi_* J_{\text{st}}$ in $\varphi(U)$ and perturb J on $W_{\Box} \setminus \varphi(U)$ to be generic for all holomorphic spheres that intersect the open set $W_{\Box} \setminus \varphi(U)$ non-trivially.

In order to guarantee transversality of the moduli space \mathcal{M} we need to verify regularity for all $u \in \mathcal{M}$ with $u(\mathbb{C}P^1) \subset \varphi(U)$. For those u, we obtain a holomorphic map

$$\varphi^{-1} \circ u \colon \mathbb{C}P^1 \longrightarrow \mathbb{C}P^1 \times \mathbb{C}^d \times \mathbb{C}P^d$$
,

which by the maximum principle can be written as

$$\varphi^{-1} \circ u = (k, \mathrm{pt}, h)$$

for holomorphic sphere maps k into $\mathbb{C}P^1$ and h into $\mathbb{C}P^d$. It suffices to show that k is an automorphism of $\mathbb{C}P^1$ (and hence k = id by the definition of \mathcal{M}) and that h is constant: We compute symplectic energies of $\varphi^{-1} \circ u$ with respect to the possibly different symplectic forms $\varphi^*\hat{\Omega}$ and $\hat{\omega}$. The symplectic energy of u equals

$$\pi r^2 = \hat{\Omega}([u]) = \hat{\Omega}(A)$$

by asphericity of $(\varphi(U) \cap W, \omega)$ and a splitting $[u] = S + A \in H_2W \oplus H_2\widehat{\operatorname{Cap}}$, see 3.4.3. Because $\hat{\Omega}$ and $\hat{\omega}$ coincide on $\widehat{\operatorname{Cap}}$, this reads as $\pi r^2 = \hat{\omega}(A)$. On the other hand, the symplectic energy of $\varphi^{-1} \circ u$ with respect to $\hat{\omega}$ equals

$$\hat{\omega}([\varphi^{-1} \circ u]) = \hat{\omega}(A),$$

because $[\varphi^{-1} \circ u] = (\varphi^{-1})_*S + A$ in $H_2W_{\mathrm{st}} \oplus H_2\widehat{\operatorname{Cap}}$. This is because $\varphi|_{U \cap \widehat{\operatorname{Cap}}} = \mathrm{id}$ and $W_{\mathrm{st}} = DT^*S^{2d+1}$ has vanishing second homology. We see that

$$\pi r^2 = \hat{\omega}(A) = r^2 \int_{\mathbb{C}P^1} k^* \omega_{\rm FS} + \int_{\mathbb{C}P^1} h^* \omega_{\rm FS} = a\pi r^2 + b\pi$$

for some non-negative integers a, b. It follows that

$$r^2(1-a) = b.$$

Since $1 < r^2 < 2$ is not an integer 1 - a must vanish, so that a = 1 and b = 0. This implies that the energy of k is πr^2 , i.e. k is an automorphism on $(\mathbb{C}P^1, r^2\omega_{\rm FS})$, and that h has zero energy and, hence, must be constant. Therefore, u is of the form $u = (\mathrm{id}, \mathrm{pt}, \mathrm{pt})$ and, in particular, u is regular.

To finish the proof of Theorem 1.1 it remains to show properness of the evaluation map $\widehat{\text{ev}}$, see Lemma 3.4. In view of Section 3.4 we consider the case N = 2 and u_1 as described. Suppose that $u_1(\mathbb{C}P^1)$ is not contained in the complex hypersurface $\varphi(H_2) \subset \widehat{Z}$. By positivity of intersections, the intersection number

$$\varphi(H_2) \bullet u_1 \ge 0$$

is defined and non-negative. On the other hand, $\varphi(H_2) \bullet u_1$ is equal to the homological intersection of $[\varphi(H_2)] = \varphi_*[H_2]$ with $[u_1]$. As in 3.4.4 we use $A_1 = [C_1] - [C_2]$ for the second summand of the decomposition $[u_1] = S_1 + A_1$. If $d \ge 2$ such an equation is literally true; the second homology of $\widehat{\text{Cap}}$ is the one of $\mathbb{C}P^1 \times \mathbb{C}^d \times \mathbb{C}P^d$ by general position. Hence, $[u_1] = S_1 + [C_1] - [C_2]$. The homological intersection condition in the definition of a fitting yields $\varphi_*[H_2] \cdot S_1 = 0$ as S_1 is spherical; the duality relations in Section 3.2 yield

$$\varphi_*[H_2] \cdot [C_1] = 0, \qquad \varphi_*[H_2] \cdot [C_2] = 1.$$

It follows that

$$[\varphi(H_2)] \cdot [u_1] = -1$$

contradicting positivity of intersections. If d = 1, the equation $[u_1] = S_1 + [C_1] - [C_2]$ holds up to adding a multiple of the fibre class in $ST^*S^3 \cong S^3 \times S^2$. Again by the definition of a fitting the fibre class contributes zero to the intersection with $[\varphi(H_2)]$. Therefore, we reach the same contradiction.

Consequently, $u_1(\mathbb{C}P^1) \subset \varphi(H_2)$. Analysing the energy $E(u_1) = (r^2 - 1)\pi$ in terms of $\varphi^{-1} \circ u_1 = (k, \text{pt}, h)$ as before we reach the equality

$$(r^2 - 1)\pi = a'\pi r^2 + b'\pi$$

for non-negative integers a', b'. In other words,

 $r^2(1 - a') = 1 + b'$

with $1 < r^2 < 2$. This is impossible. Therefore, N = 1 and $\widehat{\text{ev}}$ is proper. By Lemma 3.4 W is diffeomorphic to W_{st} . Q.E.D.

Acknowledgement. We thank Hansjörg Geiges for suggesting to use the term *fitting*, and his comments on the first draft of the manuscript.
