QUOTIENT ALGEBRA OF COMPACT-BY-APPROXIMABLE OPERATORS ON BANACH SPACES FAILING THE APPROXIMATION PROPERTY

HANS-OLAV TYLLI AND HENRIK WIRZENIUS

ABSTRACT. We initiate a study of structural properties of the quotient algebra $\mathcal{K}(X)/\mathcal{A}(X)$ of the compact-by-approximable operators on Banach spaces X failing the approximation property. Our main results and examples include the following: (i) there is a linear isomorphic embedding from c_0 into $\mathcal{K}(Z)/\mathcal{A}(Z)$, where Z belongs to the class of Banach spaces constructed by Willis that have the metric compact approximation property but fail the approximation property, (ii) there is a linear isomorphic embedding from a non-separable space $c_0(\Gamma)$ into $\mathcal{K}(Z_{F,I})/\mathcal{A}(Z_{F,I})$, where $Z_{F,I}$ is a universal compact factorisation space arising from the work of Johnson and Figiel.

1. INTRODUCTION

For Banach spaces X and Y let $\mathcal{K}(X, Y)$ be the Banach space of compact operators $X \to Y$ in the uniform operator norm, and denote by $\mathcal{A}(X,Y) = \overline{\mathcal{F}(X,Y)}$ the closed subspace consisting of the approximable operators $X \to Y$. Here $\mathcal{F}(X, Y)$ is the linear subspace consisting of the bounded finite rank operators $X \to Y$. We put $\mathcal{K}(X) = \mathcal{K}(X, X)$ and $\mathcal{A}(X) = \mathcal{A}(X, X)$ for $Y = X$, so that $\mathcal{A}(X) \subset \mathcal{K}(X)$ are closed two-sided ideals of the Banach algebra $\mathcal{L}(X)$ of the bounded operators on X. Consequently the quotient algebra $\mathfrak{A}_X := \mathcal{K}(X)/\mathcal{A}(X)$ is a non-unital Banach algebra equipped with the quotient norm

$$
||T + \mathcal{A}(X)|| = dist(T, \mathcal{A}(X)) = \inf_{S \in \mathcal{A}(X)} ||T - S||.
$$

It is well known that $\mathcal{A}(X) = \mathcal{K}(X)$ whenever X has the approximation property, so that the quotient \mathfrak{A}_X can only be non-zero within the class of Banach spaces X that fail to have the approximation property. It remains a longstanding problem, see [\[LT77,](#page-19-0) Problem 1.e.9] or [\[Cas01,](#page-19-1) Problem 2.7], whether conversely $\mathcal{A}(X) = \mathcal{K}(X)$ will imply that X has the approximation property. Properties of the quotient algebras \mathfrak{A}_X are rather elusive and inaccessible, not least because it is a non-trivial task to construct examples of Banach spaces failing the approximation property, and they have not been much studied. Recently Dales [\[Dal13\]](#page-19-2) revived the interest in various questions about the size and algebraic structure of \mathfrak{A}_X by collecting results and highlighting a number of problems. It is known, see [\[Dal00,](#page-19-3) 2.5.8(iv)], that \mathfrak{A}_X is a radical Banach algebra for any Banach space X, that is,

Key words and phrases. Quotient algebra, compact-by-approximable operators, approximation properties.

any quotient element $S + \mathcal{A}(X)$ is quasi-nilpotent in \mathfrak{A}_X . Consequently, from an algebraic perspective the non-trivial quotient algebras \mathfrak{A}_X are natural (non-commutative) radical Banach algebras whose structure is very poorly understood.

It was shown by Bachelis [\[Bac76\]](#page-19-4) that if E is a Banach space which has the bounded approximation property and E contains a closed linear subspace X which fails the approximation property, then E contains a closed linear subspace Y such that $\mathcal{A}(Y, X) \subset \mathcal{K}(Y, X)$. Moreover, if in addition $E \oplus E$ is isomorphic to E, then E contains the closed linear subspace $Z = Y \oplus X$ for which $\mathcal{A}(Z) \subsetneq \mathcal{K}(Z)$. This extended an earlier result due to Alexander [\[Ale74\]](#page-18-0) for the sequence spaces $E = \ell^p$ with $2 < p < \infty$.

In this paper we show that in fact the quotient algebra \mathfrak{A}_X is infinite-dimensional for many Banach spaces X . Our results mostly draw on techniques from Banach space theory, which provide less information about the algebraic structure of \mathfrak{A}_X . In section [2](#page-1-0) we review for our purposes two general constructions, which yield that the quotient algebra \mathfrak{A}_X is infinite-dimensional for certain classes of Banach spaces. In section [3](#page-7-0) we first observe that \mathfrak{A}_X is infinite-dimensional for the class of Banach spaces X, where X has the bounded compact approximation property but fails the approximation property. The first examples of such Banach spaces were constructed by Willis [\[Wil92\]](#page-20-0), and our main result demonstrates more precisely that \mathfrak{A}_Z always contains a linear isomorphic copy of the sequence space c_0 for the spaces Z from [\[Wil92\]](#page-20-0). However, the linear embedding $c_0 \rightarrow \mathfrak{A}_Z$ does not preserve much of the algebraic structure. In section [4](#page-13-0) we further show that \mathfrak{A}_X is infinitedimensional for two different universal spaces X. In the first example $X = C_1^*$, where C_1 is the complementably universal separable conjugate space constructed by Johnson [\[Joh72\]](#page-19-5). In the second example we show that there is a linear isomorphic embedding of a nonseparable sequence space $c_0(\Gamma)$ into $\mathfrak{A}_{Z_{F,I}}$, where Z_{FJ} is a universal compact factorisation space suggested by results of Johnson [\[Joh71\]](#page-19-6) and Figiel [\[Fig73\]](#page-19-7).

Recently there has been significant advances in the explicit classification of the lattice of closed two-sided ideals $I \subset \mathcal{L}(X)$ for some classical Banach spaces X, see e.g. [\[SZ18\]](#page-19-8), [\[FSZ17\]](#page-19-9) and their references. Moreover, the Calkin algebra $\mathcal{L}(X)/\mathcal{K}(X)$ has been explicitly determined for special Banach spaces X , see [\[AH11\]](#page-18-1), [\[Tar12\]](#page-20-1), [\[MPZ16\]](#page-19-10) and their references. However, the preceding results concern Banach spaces having a Schauder basis, or at least the bounded approximation property, which are disjoint classes of spaces from those relevant for the study of the quotients \mathfrak{A}_X .

2. General constructions

In this section we review for our subsequent use two direct sum constructions (perhaps known in some form) that produce Banach spaces Z for which the quotient algebra \mathfrak{A}_Z is infinite-dimensional, by starting from any Banach space X that fails the approximation property. The drawback is that in general X only embeds as a complemented subspace in Z , where Z is typically quite different from X . We also discuss the algebraic relevance of these constructions.

We first recall the various approximation properties of Banach spaces that will be required. The Banach space X has the approximation property $(A.P.$ in short) if for any compact subset $K \subset X$ and any $\varepsilon > 0$ there is a finite rank operator $T \in \mathcal{F}(X)$ such that

(2.1)
$$
\sup_{x \in K} ||x - Tx|| \le \varepsilon.
$$

If one instead allows approximation by $T \in \mathcal{K}(X)$ in condition [\(2.1\)](#page-2-0), then X is said to have the compact approximation property $(C.A.P.)$. Moreover, X has the bounded approximation property (B.A.P.), respectively the bounded compact approximation property (B.C.A.P.), if there is a uniform constant $M < \infty$ so that the approximating operator T from [\(2.1\)](#page-2-0) can be chosen to satisfy $||T|| \leq M$. Finally, X has the metric C.A.P. if above $M = 1$.

We refer e.g. to [\[LT77,](#page-19-0) 1.e] and the survey [\[Cas01\]](#page-19-1) for useful general information about these approximation properties. Recall that any Banach space with a Schauder basis has the B.A.P., and that the first example of a Banach space without the A.P. was constructed by Enflo [\[Enf73\]](#page-19-11). The references [\[LT77,](#page-19-0) 2.d], [\[LT79,](#page-19-12) 1.g] and [\[Pie80,](#page-19-13) 10.4] contain the detailed constructions of some Banach spaces failing the A.P. Presently the space $\mathcal{L}(\ell^2)$ of the bounded operators on the Hilbert space ℓ^2 is the most explicit space known to fail the A.P. by a result of Szankowski [\[Sza81\]](#page-20-2). Moreover, the Calkin algebra $\mathcal{L}(\ell^2)/\mathcal{K}(\ell^2)$ also fails the A.P. [\[GS89\]](#page-19-14).

To motivate our first construction we recall a classical fact due to Grothendieck. If the Banach space X fails to have the A.P., then there is a linear subspace $Y \subset X$ and a complete norm $|\cdot|$ on Y, such that the inclusion map $J : (Y, |\cdot|) \to X$ is a compact non-approximable operator. For this fact see e.g. the argument for the implication $(v) \Rightarrow$ (i) in [\[LT77,](#page-19-0) Thm. 1.e.4]. It easily follows that $\mathcal{A}(X \oplus Y) \subset \mathcal{K}(X \oplus Y)$, where $Y = (Y, |\cdot|)$.

This fact can be generalised in many ways, and the following construction implies that \mathfrak{A}_Z is infinite-dimensional, where e.g. Z is the countable direct ℓ^p -sum $X \oplus (\bigoplus_{n\in \mathbb{N}} Y)_{\ell^p}$, and X and Y are as above. Here $1 \leq p \leq \infty$, where for notational unity the case $p = \infty$ denotes a direct c_0 -sum equipped with the supremum norm.

Proposition 2.2. *Suppose that* X and Y_n ($n \in \mathbb{N}$) are Banach spaces such that one of the *following conditions holds:*

$$
\mathcal{A}(Y_n, X) \subsetneq \mathcal{K}(Y_n, X), \quad n \in \mathbb{N},
$$

(ii)
$$
\mathcal{A}(X,Y_n) \subsetneq \mathcal{K}(X,Y_n), \quad n \in \mathbb{N}.
$$

Let $Z = X \oplus (\bigoplus_{n \in \mathbb{N}} Y_n)_{\ell^p}$ for $1 \leq p \leq \infty$. Then the quotient \mathfrak{A}_Z is infinite-dimensional.

Proof. Let $P_0: Z \to X$ and $P_n: Z \to Y_n$ be the natural projections, respectively $J_0: X \to Y_n$ Z and $J_n: Y_n \to Z$ the corresponding inclusion maps for $n \in \mathbb{N}$.

Suppose that (i) holds. We may after a normalisation find compact operators $S_n \in$ $\mathcal{K}(Y_n, X)$ so that

$$
dist(S_n, \mathcal{A}(Y_n, X)) = 1, \quad n \in \mathbb{N}.
$$

Consider the compact operators $T_n = J_0 S_n P_n \in \mathcal{K}(Z)$ for $n \in \mathbb{N}$. We claim that

(2.3) dist(Tⁿ − Tm, A(Z)) ≥ 1

for any $n, m \in \mathbb{N}$ with $n \neq m$. In particular, (2.3) says that $(T_n + \mathcal{A}(Z)) \subset \mathfrak{A}_Z$ is a bounded sequence which does not have any convergent subsequences, whence \mathfrak{A}_Z is infinite-dimensional.

Towards the desired estimate suppose that $V \in \mathcal{A}(Z)$ is arbitrary. Then $P_0 V J_n \in$ $\mathcal{A}(Y_n, X)$, so that for $m \neq n$ one gets that

$$
1 = dist(S_n, \mathcal{A}(Y_n, X)) \le ||S_n - P_0 V J_n||
$$

= $||P_0(T_n - T_m - V)J_n|| \le ||T_n - T_m - V||$,

since $T_m J_n = J_0 S_m P_m J_n = 0$ above. This implies that [\(2.3\)](#page-2-1) holds.

If condition (ii) holds, then there are $R_n \in \mathcal{K}(X, Y_n)$ so that $dist(R_n, \mathcal{A}(X, Y_n)) = 1$ for $n \in \mathbb{N}$. Let $U_n = J_n R_n P_0 \in \mathcal{K}(Z)$ for $n \in \mathbb{N}$. A straightforward modification of the estimate for [\(2.3\)](#page-2-1) shows that also in this case $dist(U_n - U_m, \mathcal{A}(Z)) \geq 1$ for $n \neq m$. This completes the argument. \Box

Of course, the argument in Proposition [2.2](#page-2-2) also shows that $\mathcal{K}(Y, X)/\mathcal{A}(Y, X)$, respectively $\mathcal{K}(X,Y)/\mathcal{A}(X,Y)$, are infinite-dimensional quotient spaces for $Y = (\bigoplus_{n\in\mathbb{N}} Y_n)_{\ell^p}$. However, our focus is on the quotient algebras \mathfrak{A}_X , and it must be kept in mind that it is much more difficult to study \mathfrak{A}_X for a *given* Banach space X. Recently Kürsten and Pietsch [\[KP14\]](#page-19-15) produced various examples of compact non-approximable operators as the central part of the canonical factorisation $\ell^1 \to \ell^1/Ker(T) \to \overline{T(\ell^1)} \to c_0$ for certain operators $T \in \mathcal{L}(\ell^1, c_0)$, but such methods are less adapted to specific quotient algebras.

We will later apply the following variant of Proposition [2.2,](#page-2-2) which contains more precise information. In conditions (iii) and (iv) below the ℓ^p -sum is replaced by the supremum norm and a c_0 -condition for $p = \infty$.

Proposition 2.4. *Suppose that* X *is a Banach space having the following properties: (i) There is a uniformly bounded sequence* $(P_n) \subset \mathcal{L}(X)$ *of projections on* X *so that* $P_nP_m = 0$ whenever $n \neq m$,

(ii) $\mathfrak{A}_{X_n} \neq \{0\}$ *for every* $n \in \mathbb{N}$ *, where* $X_n = P_n X$ *.*

Then \mathfrak{A}_X *is infinite-dimensional.*

Suppose in addition that there is $1 \leq p \leq \infty$ *and constants* $C, D < \infty$ *so that*

 (iii) $\|\sum_{n=1}^{\infty} x_n\| \leq C \cdot \left(\sum_{n=1}^{\infty} \|x_n\|^p\right)^{1/p}$ *whenever* $x_n \in P_n X$ *for* $n \in \mathbb{N}$ *and* $\sum_{n=1}^{\infty} ||x_n||^p < \infty$ *,* (iv) $\left(\sum_{n=1}^{\infty} ||P_n x||^p\right)^{1/p} \le D ||x||$ *for* $x \in X$ *.*

Then there is a linear embedding $c_0 \to \mathfrak{A}_X$ *, that is,* \mathfrak{A}_X *contains a closed subspace which is linearly isomorphic to the sequence space* c_0 *.*

Note that in (iii) the condition implies that the series $\sum_{n=1}^{\infty} x_n$ converges in X. Moreover, (iii) is always valid with $C = 1$ for $p = 1$, and (iv) follows from (i) for $p = \infty$. The typical application of Proposition [2.4](#page-3-0) is to direct ℓ^p -sums $X = (\bigoplus_{n\in\mathbb{N}} X_n)_{\ell^p}$, where $\mathfrak{A}_{X_n} \neq \{0\}$ for every $n \in \mathbb{N}$, see Corollary [2.6](#page-5-0) below. However, it is not assumed here that the linear span of $\cup_{n\in\mathbb{N}}P_nX$ is dense in X, which will be relevant in Section [3.](#page-7-0)

Proof. Suppose first that X satisfies conditions (i) and (ii), and put $M = \sup_n ||P_n||$. From (i) we find, after a normalisation and possibly by passing to $S_n - V_n$ for some $V_n \in \mathcal{A}(X_n)$, compact operators $S_n \in \mathcal{K}(X_n)$ so that

(2.5)
$$
dist(S_n, \mathcal{A}(X_n)) = 1 \text{ and } ||S_n|| \le 2
$$

for $n \in \mathbb{N}$.

Let $J_n: X_n \to X$ be the inclusion map for $X_n = P_n X$ and $n \in \mathbb{N}$. Consider the compact operators $U_n = J_n S_n P_n \in \mathcal{K}(X)$ for $n \in \mathbb{N}$. By a straightforward modification of the estimates in Proposition [2.2](#page-2-2) one obtains that

$$
dist(U_n - U_m, \mathcal{A}(Z)) \ge 1/M
$$

for any $n, m \in \mathbb{N}$ with $n \neq m$. For this estimate one uses the fact that $P_nP_m = 0$ implies that $P_n J_m = 0$, for $m \neq n$. Thus \mathfrak{A}_X is infinite-dimensional.

Suppose next that X also satisfies conditions (iii) and (iv) for $1 \leq p < \infty$. Let $(a_k) \in c_0$ be arbitrary. Observe that for any $m > n$ and $x \in X$ we get from (iii) and (iv) that

$$
\|\sum_{k=1}^{m} a_k U_k x - \sum_{k=1}^{n} a_k U_k x\| = \|\sum_{k=n+1}^{m} a_k J_k S_k P_k x\| \le C \cdot \left(\sum_{k=n+1}^{m} |a_k|^p \cdot \|S_k P_k x\|^p\right)^{1/p}
$$

$$
\le 2C \cdot \sup_{n+1 \le k \le m} |a_k| \cdot \left(\sum_{k=n+1}^{m} \|P_k x\|^p\right)^{1/p}
$$

$$
\le 2CD \cdot \sup_{n+1 \le k \le m} |a_k| \cdot \|x\|,
$$

which converges uniformly to 0 as $n \to \infty$. We conclude that $(\sum_{k=1}^n a_k U_k)_{n \in \mathbb{N}}$ is a Cauchysequence in $\mathcal{K}(X)$, so that $\sum_{k=1}^{\infty} a_k U_k \in \mathcal{K}(X)$ defines a compact operator for any $(a_k) \in c_0$. Moreover, for $x \in X$ and $(a_k) \in c_0$ we obtain similarly as above from (iii) and (iv) that

$$
\|\sum_{k=1}^{\infty} a_k U_k x\| \le 2CD \cdot \sup_{k \in \mathbb{N}} |a_k| \cdot \|x\|,
$$

so that

$$
dist(\sum_{k=1}^{\infty} a_k U_k, \mathcal{A}(X)) \le ||\sum_{k=1}^{\infty} a_k U_k|| \le 2CD \cdot ||(a_k)||_{\infty}.
$$

This means that $(a_k) \mapsto (\sum_{k=1}^{\infty} a_k U_k) + \mathcal{A}(X)$ defines a bounded linear map $\psi : c_0 \to \mathfrak{A}_X$. The argument for $p = \infty$ is similar.

We claim that ψ is bounded from below for $1 \leq p \leq \infty$, so that ψ defines a linear embedding of c_0 into \mathfrak{A}_X . Towards this, let $(a_k) \in c_0$ be arbitrary and pick $r \in \mathbb{N}$ such that $||(a_k)||_{\infty} = |a_r|$. Then for any $U \in \mathcal{A}(X)$ we get from $P_r J_k = 0$ for $r \neq k$, that

$$
M \cdot ||\sum_{k=1}^{\infty} a_k U_k - U|| \ge ||P_r(\sum_{k=1}^{\infty} a_k U_k - U)J_r|| = ||P_r(\sum_{k=1}^{\infty} a_k J_k S_k P_k - U)J_r||
$$

= $||a_r S_r - P_r U J_r|| \ge ||a_r S_r + \mathcal{A}(X_r)|| = |a_r|$.

It follows that $||\psi(a_k)|| = dist(\sum_{k=1}^{\infty} a_k U_k, A(X)) \ge (1/M)||(a_k)||_{\infty}$ for $(a_k) \in c_0$, which concludes the argument. \Box

Note that in the above argument the series $\sum_{k=1}^{\infty} a_k U_k$ defines a bounded operator on X for any $(a_k) \in \ell^{\infty}$, but this operator will usually not be compact.

In the sequel we will use the notation $Y \approx Z$ for linearly isomorphic spaces Y and Z.

Corollary 2.6. *Suppose that there is* $1 \leq p \leq \infty$ *such that one of the following conditions holds (where the case* $p = \infty$ *refers below to a direct* c_0 *-sum):*

 (i) $X = (\bigoplus_{n \in \mathbb{N}} X_n)_{\ell^p}$, where $\mathfrak{A}_{X_n} \neq \{0\}$ for every $n \in \mathbb{N}$, or

(ii) X is a Banach space so that $\mathfrak{A}_X \neq \{0\}$ and $(\bigoplus_{\mathbb{N}} X)_{\ell^p} \approx X$.

Then \mathfrak{A}_X *contains a linear isomorphic copy of* c_0 *.*

The basic examples are found in the following application.

Corollary 2.7. Let $1 \leq p < \infty$ and $p \neq 2$. Then there is a closed linear subspace $X \subset \ell^p$ so that \mathfrak{A}_X *contains a linear isomorphic copy of* c_0 *. Moreover, there is a closed linear subspace* $X \subset c_0$ *, so that* \mathfrak{A}_X *contains a copy of* c_0 *.*

Proof. There is a closed linear subspace $Z \subset \ell^p$ that fails the A.P. for any $1 \leq p < \infty$ and $p \neq 2$. This follows from the work of Enflo and Davie for $2 < p < \infty$, see [\[LT77,](#page-19-0) 2.d], and Szankowski [\[Sza78\]](#page-20-3) for $1 \leq p < 2$. By [\[Bac76,](#page-19-4) Thm. 1] there is a closed linear subspace $Y \subset \ell^p$ such that $\mathcal{A}(Y \oplus Z) \subsetneq \mathcal{K}(Y \oplus Z)$. Let

$$
X = \left(\bigoplus_{\mathbb{N}} (Y \oplus Z)\right)_{\ell^p} \subset \left(\bigoplus_{\mathbb{N}} \ell^p\right)_{\ell^p} \approx \ell^p.
$$

Then Corollary [2.6](#page-5-0) yields a linear embedding $c_0 \to \mathfrak{A}_X$. The argument for c_0 is similar. \square

Remark 2.8. Suppose that E has the B.A.P., $E \oplus E \approx E$ and E contains a closed subspace X which fails the A.P. By [\[Bac76,](#page-19-4) Thm. 1] there is a closed linear subspace $Y \subset E$ such that $\mathcal{A}(Y, X) \subsetneq \mathcal{K}(Y, X)$. Fix $n \in \mathbb{N}$ and consider

$$
Z_n=X\oplus (Y\oplus \ldots \oplus Y),
$$

with n copies of Y in the direct sum. Then Z_n is a closed subspace of E, up to linear isomorphism, since $E \oplus E \approx E$. It is not difficult to modify the argument in Propositions [2.2](#page-2-2) and [2.4](#page-3-0) to find a linearly independent family $\{T_j + \mathcal{A}(Z_n) : j = 1, \ldots, n\}$ in \mathfrak{A}_{Z_n} , whence $dim(\mathfrak{A}_{Z_n}) \geq n$.

However, we note that it is not clear whether in this setting from [\[Bac76,](#page-19-4) Thm. 1] there always is a closed linear subspace $Z \subset E$ such that \mathfrak{A}_Z is infinite-dimensional.

The algebraic differences between c_0 and radical Banach algebras readily imply that the linear embedding ψ : $c_0 \rightarrow \mathfrak{A}_X$ in Proposition [2.4,](#page-3-0) or its applications, is not an algebra homomorphism. In fact, ψ cannot preserve much of the multiplicative structure.

Proposition 2.9. Suppose that ψ is any linear embedding $c_0 \to \mathfrak{A}_X$, where X is a Banach *space. Then for every non-zero* $a \in c_0$ *there is* $b \in c_0$ *such that* $\psi(ab) \neq \psi(a)\psi(b)$ *.*

Proof. It is straightforward to check that

$$
\mathcal{A} = \{a \in c_0 : \psi(ax) = \psi(a)\psi(x) = \psi(x)\psi(a) \text{ for all } x \in c_0\}
$$

is a closed subalgebra of c_0 . If $A \neq \{0\}$, then the restriction $\psi_{|A}$ defines an algebra isomorphism $A \to B$, where $B = \psi(A)$ is a non-trivial closed subalgebra of \mathfrak{A}_X . In particular,

$$
\sigma_{\mathcal{A}}(a) = \sigma_{\mathcal{B}}(\psi(a)), \quad a \in \mathcal{A},
$$

where $\sigma_{\mathcal{A}}(a)$ denotes the spectrum of $a \in \mathcal{A}$ computed in the subalgebra \mathcal{A} (and analogously for $\sigma_B(\psi(a))$. However, this is known to be impossible. In fact, β is a radical algebra as a subalgebra of the radical algebra \mathfrak{A}_X . On the other hand, non-zero elements $a \in \mathcal{A}$ are never quasi-nilpotent in A, as $\sigma_{\mathcal{A}}(a)$ contains the spectrum $\sigma(a)$ of a in c_0 . Thus $\mathcal{A} = \{0\},\$ and the above claim follows.

For similar reasons the restriction of ψ to the closed ideal

$$
\mathcal{A}_D = \{(x_n) \in c_0 : x_n = 0 \text{ for } n \notin D\}
$$

of c_0 is not an algebra homomorphism for any subset $D \subset \mathbb{N}$. Nevertheless, we point out that the linear embedding ψ from Proposition [2.4](#page-3-0) generates a commutative subalgebra in the quotient algebra.

Proposition 2.10. Let ψ : $c_0 \rightarrow \mathfrak{A}_X$ be the linear embedding constructed in Proposition [2.4,](#page-3-0) and let **B** be the closed subalgebra of \mathfrak{A}_X generated by the image $\psi(c_0)$. Then **B** is a *commutative algebra.*

Proof. Note first that

(2.11)
$$
\psi(a)\psi(b) = \psi(b)\psi(a) \text{ for } a, b \in c_0,
$$

so that $\psi(c_0)$ is a commuting subset of \mathfrak{A}_X . Namely, if $a = (a_k)$, $b = (b_k) \in c_0$, then

$$
\left(\sum_{k=1}^{m} a_k U_k\right) \left(\sum_{r=1}^{n} b_r U_r\right) = \sum_{k=1}^{m \wedge n} a_k b_k U_k^2 = \left(\sum_{r=1}^{n} b_r U_r\right) \left(\sum_{k=1}^{m} a_k U_k\right),
$$

since by the construction in Proposition [2.4](#page-3-0) one has $U_kU_r = 0$ for $k \neq r$. Above $m \wedge n$ denotes the smaller of m and n. Hence (2.11) follows by passing to the limit in the quotient norm of \mathfrak{A}_X .

Recall next that the finite linear combinations of the products $\psi(x_{k_1})^{m_1} \cdot \ldots \cdot \psi(x_{k_s})^{m_s}$, where $x_{k_1}, \ldots, x_{k_s} \in c_0$ and $m_1, \ldots, m_s \ge 1$, form a dense subset of \mathcal{B} . Since any two such finite linear combinations commute by [\(2.11\)](#page-6-0), it follows by the standard approximation argument that $\mathcal{B} \subset \mathfrak{A}_X$ is a closed commutative subalgebra.

It should be kept in mind that the quotient algebras \mathfrak{A}_X are usually non-commutative. For completeness we next recall two simple conditions towards this.

Example 2.12. Let X and Y be Banach spaces. (i) Suppose that $X \oplus X \approx X$ and that there are $A, B \in \mathcal{K}(X)$ so that $AB \notin \mathcal{A}(X)$ or $BA \notin \mathcal{A}(X)$. Then the compact operators \widehat{A} and \widehat{B} on $X \oplus X$ do not commute modulo $\mathcal{A}(X \oplus X)$, where

$$
\widehat{A}(x,y) = (Ay,0), \ \widehat{B}(x,y) = (0,Bx), \quad (x,y) \in X \oplus X.
$$

(ii) Suppose that there are $U \in \mathcal{K}(Y, X)$ and $V \in \mathcal{K}(Y)$ so that $UV \notin \mathcal{K}(Y, X)$. Then the operators $\widehat{U}, \widehat{V} \in \mathcal{K}(X \oplus Y)$ do not commute modulo $\mathcal{A}(X \oplus Y)$, where

$$
\hat{U}(x, y) = (Uy, 0), \ \hat{V}(x, y) = (0, Vy), \quad (x, y) \in X \oplus Y.
$$

3. \mathfrak{A}_Z for the Willis spaces Z

The main result of this section demonstrates that c_0 embeds isomorphically into the quotient algebra $\mathfrak{A}_Z = \mathcal{K}(Z)/\mathcal{A}(Z)$, whenever Z belongs to a class of Banach spaces constructed by Willis [\[Wil92\]](#page-20-0).

Our starting point is the following observation, which points out classes of Banach spaces X for which \mathfrak{A}_X is always non-trivial. Part (ii) of the following proposition confirms the expectation from [\[Dal13\]](#page-19-2) that \mathfrak{A}_Z is infinite-dimensional for the spaces Z from [\[Wil92\]](#page-20-0). Remark [3.2.](#page-8-0)(ii) below indicates a different proof of this result suggested by Dales [\[Dal13\]](#page-19-2). Recall that the Banach algebra A is nilpotent, if there is $m \in \mathbb{N}$ such that the product $x_1 \cdot \ldots \cdot x_m = 0$ for any $x_1, \ldots, x_m \in \mathcal{A}$.

Proposition 3.1. *(i) If the Banach space* X *has the C.A.P., but fails to have the A.P., then* $\mathfrak{A}_X \neq \{0\}$.

(ii) If the Banach space X has the B.C.A.P., but fails to have the A.P., then \mathfrak{A}_X *is infinite-dimensional.* More precisely, there is $V \in \mathcal{K}(X)$ such that $V^n \notin \mathcal{A}(X)$ for every $n \in \mathbb{N}$, and the closed commutative subalgebra B generated by $V + \mathcal{A}(X)$ in \mathfrak{A}_X is infinite*dimensional.*

Proof. The proof of (i) is the case $n = 1$ of the first part of the argument for part (ii), so we will only verify (ii).

Let $n \in \mathbb{N}$ be arbitrary and fix $M \geq 1$ such that X has the B.C.A.P. with constant M. Since X does not have the A.P. by assumption, there is a compact subset $K \subset X$ and a constant $c > 0$ so that

$$
\sup_{x \in K} ||x - Vx|| \ge c
$$

for every $V \in \mathcal{F}(X)$. On the other hand, since X has the B.C.A.P. with constant M, there is a compact operator $U \in \mathcal{K}(X)$, so that $||U|| \leq M$ and

$$
\sup_{x \in K} ||x - Ux|| < \frac{c}{2M_0},
$$

where $M_0 = \sum_{k=0}^{n-1} M^k$. Hence we get that

$$
||x - U^n x|| = ||(I_X + U + \dots + U^{n-1})(x - Ux)|| \le \left(\sum_{k=0}^{n-1} ||U||^k\right) \cdot ||x - Ux||
$$

$$
\le \left(\sum_{k=0}^{n-1} M^k\right) \cdot \frac{c}{2M_0} = c/2
$$

for every $x \in K$. It follows that $U^n \in \mathcal{K}(X) \setminus \mathcal{A}(X)$. Note that here the operator U depends on n.

The preceding fact means that \mathfrak{A}_X is radical Banach algebra which is not nilpotent. It follows from general results about the Jacobson radical, see [\[Dal00,](#page-19-3) Prop. 1.5.6.(iv)], that \mathfrak{A}_X is infinite-dimensional. Moreover, by an application of the Baire theorem, see [\[Gra69\]](#page-19-16) or [\[Pal94,](#page-19-17) Prop. 4.4.11.(b)], there is a compact operator $V \in \mathcal{K}(X)$ such that $V^n \notin \mathcal{A}(X)$ for every $n \in \mathbb{N}$. It follows as above that the closed commutative subalgebra \mathcal{B} generated by $V + \mathcal{A}(X)$ in \mathfrak{A}_X is infinite-dimensional.

Remark 3.2. (i) The first examples of Banach spaces, which have the metric C.A.P. but fail the A.P., were found by Willis [\[Wil92\]](#page-20-0). In Proposition [3.1](#page-7-1) the classes of Banach spaces satisfying condition (i), respectively (ii), are really different. This fact is based on the spaces from [\[Wil92\]](#page-20-0) in combination with known constructions and an observation from [\[Cas01,](#page-19-1) Prop. 8.2] or [\[Oja06,](#page-19-18) Cor. 2.4].

For this let Y be a Banach space with the A.P. which fails to have the B.A.P., see e.g. [\[LT77,](#page-19-0) 1.e.18-1.e.20]. Observe that Y also fails the B.C.A.P., since $\mathcal{K}(Y) = \mathcal{A}(Y)$. Consider $X = Y \oplus Z$, where Z is a Banach space which has the metric C.A.P. but fails to have the A.P., as given by [\[Wil92\]](#page-20-0). In this event $X = Y \oplus Z$ has the C.A.P., while X fails both the A.P. and the B.C.A.P., as such properties are inherited by complemented subspaces.

(ii) Suppose that X has the B.C.A.P. It is known as a consequence of the Cohen-Hewitt factorisation theorem, see e.g. [\[Dal00,](#page-19-3) 2.9.26 and 2.9.37], that any operator $S \in \mathcal{K}(X)$ factors as $S = UV$ for suitable $U, V \in \mathcal{K}(X)$. Clearly this property passes to the quotient algebra \mathfrak{A}_X , so that \mathfrak{A}_X cannot be a nilpotent algebra if $\mathfrak{A}_X \neq \{0\}$. This also implies that \mathfrak{A}_X is infinite-dimensional in part (ii) of Proposition [3.1,](#page-7-1) as pointed out by Dales [\[Dal13\]](#page-19-2), but the argument included above uses only elementary facts.

The argument for Proposition [3.1.](#page-7-1)(ii) is algebraic in nature, and does not provide explicit information about \mathfrak{A}_X . The main purpose of this section is to sharpen the result for the class of Banach spaces found by Willis [\[Wil92\]](#page-20-0). More precisely, for any Banach space X that fails the A.P., Willis obtains a Banach space Z_X that has the metric C.A.P., but fails to have the A.P. We begin by recalling the relevant details of the construction for our purposes.

Suppose that the Banach space X fails to have the A.P., and fix a compact subset $K \subset X$ and a constant $c > 0$ so that

$$
\sup_{x \in K} \|x - Vx\| \ge c
$$

for any finite rank operator $V \in \mathcal{F}(X)$. By a classical fact [\[LT77,](#page-19-0) Prop. 1.e.2] one may assume that $K = \overline{conv} \{\pm x_n : n \in \mathbb{N}\}\,$, where $0 < ||x_n|| \leq 1$ for all $n \in \mathbb{N}$ and $||x_n|| \to 0$ as $n \to \infty$. For any $0 < t < 1$ consider the closed compact symmetric subset

$$
U_t = \overline{conv}\{\pm \frac{x_n}{\|x_n\|^t} : n \in \mathbb{N}\}
$$

of X and let $Y_t \subset X$ be the linear span of U_t normed by the Minkowski functional

$$
|x|_t = \inf\{\lambda > 0 : x \in \lambda U_t\}, \quad x \in Y_t.
$$

We will require the following facts: $(Y_t, |\cdot|_t)$ is a Banach space for any $0 < t < 1$, U_t is the closed unit ball of Y_t and

$$
(3.4) \t\t\t |x_n|_t \leq ||x_n||^t, \quad n \in \mathbb{N}.
$$

Moreover, for any $0 < s < t < 1$ one has $U_s \subset U_t \subset B_X$ and $Y_s \subset Y_t \subset X$, so that

(3.5)
$$
||x|| \le |x|_t \le |x|_s, \quad x \in Y_s.
$$

In particular, the inclusions $Y_s \to Y_t$ and $Y_t \to X$ are bounded whenever $0 < s < t < 1$.

Let Z be the linear span of the simple functions $\{y\chi_{(s,t)}: 0 < s < t < 1, y \in Y_s\}$ on $(0, 1)$ equipped with the norm

$$
||f|| = \int_0^1 |f(r)|_r dr = \sum_{k=1}^n \int_{u_k}^{v_k} |y_k|_r dr,
$$

for $f = \sum_{k=1}^n y_k \chi_{(u_k, v_k)} \in \mathcal{Z}$, where $0 < u_1 < v_1 \le u_2 < \ldots \le u_k < v_k < 1$ and $y_k \in Y_{u_k}$ for $k = 1, \ldots, n$. Note that $f(r) \in Y_r$ for $f \in \mathcal{Z}$ and $0 < r < 1$, and that the above integral exists in the Riemann sense by the monotonicity of the map $r \mapsto |y_k|_r$ for each k. Finally, let $Z = Z_X$ be the completion of $(Z, \|\cdot\|)$.

Willis showed [\[Wil92,](#page-20-0) Prop. 1 and 2] that Z has the metric C.A.P., but fails the A.P. Note that Z is non-reflexive and Z^* is non-separable, since the closed subspace $L^1(0,1)x_1 \subset Z$ is isomorphic to $L^1(0,1)$, whence $\mathcal{A}(Z)$ is also non-separable. The following result is the main one of this paper.

Theorem 3.6. Suppose that X fails to have the A.P. and let $Z = Z_X$ be the above Willis *space associated to X. Then there is a linear isomorphic embedding* ψ : $c_0 \rightarrow \mathfrak{A}_Z$.

Recall from Proposition [2.9](#page-5-1) that the linear embedding $\psi : c_0 \to \mathfrak{A}_Z$ is not an algebra homomorphism.

Proof. In the argument we will verify in the following steps that the conditions (i)-(iv) of Proposition [2.4](#page-3-0) are satisfied with $p = 1$.

Step 1. Let $0 < s < t < 1$. We claim that the set U_s is compact in Y_t , so that the inclusion operator $J_{s,t}: Y_s \to Y_t$ is compact.

Indeed, towards this note that

$$
|\frac{x_n}{\|x_n\|^s}|_t \le \|x_n\|^{t-s} \to 0
$$

as $n \to \infty$. This yields that the $|\cdot|_t$ -closure $\overline{conv}^{|\cdot|_t} {\{\pm x_n}/{||x_n||^s : n \in \mathbb{N}\}}$ is compact in Y_t by Mazur's theorem, so that $J_{s,t}: Y_s \to Y_t$ is a compact inclusion operator, because the unit ball $B_{Y_s} = U_s = \overline{conv} \{\pm x_n/||x_n||^s : n \in \mathbb{N}\}.$

Step 2. Claim: the inclusion map $R_s: Y_s \to X$ is not an approximable operator for any $0 < s < 1$, and $\mathcal{A}(Y_s, Y_t) \subsetneq \mathcal{K}(Y_s, Y_t)$ whenever $0 < s < t < 1$. In particular, Y_t does not have the A.P. for any $0 < t < 1$.

In fact, suppose to the contrary that $R_s \in \mathcal{A}(Y_s, X)$ and let $\varepsilon > 0$ be given. In view of the counter assumption there exists a finite rank operator

$$
R = \sum_{k=1}^{n} f_k \otimes y_k \in Y_s^* \otimes X
$$

such that $||R_s - R|| < \varepsilon/2$, where $f_1, \ldots, f_n \in Y_s^*$ and $y_1, \ldots, y_n \in X$. In particular, note that $\|Rx - x\| < \varepsilon/2$ for $x \in K$, since $K \subset U_s$. Note further that $K \subset Y_s$ is a relatively compact subset, since [\(3.4\)](#page-9-0) implies that $|x_n|_{s} \leq ||x_n||^s \to 0$ as $n \to \infty$.

Put $\delta = \varepsilon/(2\sum_{k=1}^n ||y_k||) > 0$. According to the argument in [\[LT77,](#page-19-0) p. 33] one knows that the range $R_s^*(X^*)$ is dense in Y_s^* with respect to the topology of uniform convergence on the compact subsets of Y_s . Hence we may pick functionals $g_1, g_2, \ldots, g_n \in X^*$ such that

$$
\sup_{x \in K} |\langle R_s x, g_k \rangle - \langle x, f_k \rangle| = \sup_{x \in K} |\langle x, R_s^* g_k \rangle - \langle x, f_k \rangle| < \delta
$$

for all $k = 1, 2, ..., n$. Then the finite rank operator $S = \sum_{k=1}^{n} g_k \otimes y_k \in \mathcal{F}(X)$ satisfies

$$
||Sx - x|| \le ||Sx - Rx|| + ||Rx - x||
$$

\n
$$
\le \sum_{k=1}^{n} |\langle R_s x, g_k \rangle - \langle x, f_k \rangle| \cdot ||y_k|| + ||Rx - x|| < \varepsilon/2 + \varepsilon/2 = \varepsilon
$$

for $x \in K$. This contradicts property [\(3.3\)](#page-8-1) of the compact set $K \subset X$ once $0 < \varepsilon < c$.

Moreover, since $R_s = R_t \circ J_{s,t}$, where $R_s \notin \mathcal{A}(Y_s, X)$, it follows from the result in Step 1 that $J_{s,t} \in \mathcal{K}(Y_s, Y_t) \setminus \mathcal{A}(Y_s, Y_t)$.

Step 3. For any fixed $s \in (0,1)$ define the linear map $T_s: Y_s \to Z$ by

$$
T_s(y) = \frac{1}{1-s}y\chi_{(s,1)}, \quad y \in Y_s.
$$

We claim that T_s is a compact operator. (This fact was used in [\[Wil92\]](#page-20-0) for $s = 1/2$.)

To verify the claim, note that for any $n \in \mathbb{N}$ one has

$$
||T_s(x_n)|| = \frac{1}{1-s} \int_0^1 |x_n \chi_{(s,1)}(r)|_r dr = \frac{1}{1-s} \int_s^1 |x_n|_r dr
$$

\n
$$
\leq \frac{1}{1-s} \int_s^1 ||x_n||^r dr = \frac{1}{(1-s)} \frac{(||x_n|| - ||x_n||^s)}{\ln ||x_n||}
$$

\n
$$
\leq \frac{1}{(1-s)} \frac{||x_n||^s}{|\ln ||x_n|||},
$$

so that

$$
||T_s(x_n/||x_n||^s)|| \le \frac{1}{(1-s)} \frac{1}{||\ln ||x_n|||}.
$$

Since $x_n \to 0$ in X as $n \to \infty$, we conclude that $||T_s(x_n/||x_n||^s)|| \to 0$ as $n \to \infty$. By Mazur's theorem the set

$$
\overline{conv} \{ \pm T_s(x_n/\|x_n\|^s) : n \in \mathbb{N} \}
$$

is compact in Z, and since $T_sU_s \subset \overline{conv} \{\pm T_s(x_n/\|x_n\|^s) : n \in \mathbb{N}\}\,$, we get that T_s is a compact operator $Y_s \to Z$.

For the remainder of the argument we next fix intertwining sequences (s_n) and (t_n) such that $0 < s_1 < t_1 < s_2 < t_2 < \ldots < 1$, where $s_n \to 1$ as $n \to \infty$. Then $f \mapsto P_n f = f \chi_{(s_n,t_n)}$ is a well-defined norm-1 projection of Z onto the closed subspace $Z_n = P_n Z \subset Z$ for any $n \in \mathbb{N}$, since

$$
||P_nf|| = \int_{s_n}^{t_n} |f(r)|_r dr \le \int_0^1 |f(r)|_r dr = ||f||
$$

for any $f \in Z$. Moreover, we may define a bounded linear operator $J: Z \to X$ by

(3.7)
$$
J(f) = \int_0^1 f(r) dr, \quad f \in Z.
$$

In fact, for a simple function $f = \sum_{k=1}^n y_k \chi_{(u_k,v_k)} \in \mathcal{Z}$, where $0 < u_1 < v_1 \le u_2 < \ldots \le u_k$ $u_k < v_k < 1$ and $y_k \in Y_{u_k}$ for each $k = 1, \ldots, n$, put

$$
J(f) = \sum_{k=1}^{n} (v_k - u_k) y_k = \int_0^1 f(r) dr.
$$

Observe that by [\(3.5\)](#page-9-1) one has

$$
||J(f)|| \le \sum_{k=1}^{n} (v_k - u_k) ||y_k|| \le \sum_{k=1}^{n} \int_{u_k}^{v_k} |y_k|_r dr = ||f||
$$

for such simple functions $f \in \mathcal{Z}$, so that the above map admits by density a bounded linear extension J to Z that satisfies (3.7) .

The following step verifies the crucial condition (ii) from Proposition [2.4.](#page-3-0)

Step 4. Claim: $\mathfrak{A}_{Z_n} \neq \{0\}$ for all $n \in \mathbb{N}$.

Towards this claim let $J_n: Z_n \to Z$ denote the inclusion map for $n \in \mathbb{N}$. It is easy to check that the inclusion $R_{s_n}: Y_{s_n} \to X$ factors as

$$
(3.8) \t\t R_{s_n} = c_n J J_n P_n T_{s_n},
$$

where $c_n = \frac{1-s_n}{t_n-s_n}$ $\frac{1-s_n}{t_n-s_n}$ and the operators $T_{s_n}: Y_{s_n}$ → Z and $J: Z \to X$ are defined in Step 3, respectively in [\(3.7\)](#page-11-0). Since R_{s_n} is not an approximable operator by Step 2, it follows from [\(3.8\)](#page-11-1) that $P_nT_{s_n}$ is not approximable $Y_{s_n} \to Z_n$. Recall from Step 3 that T_{s_n} is a compact operator, whence

$$
P_nT_{s_n} \in \mathcal{K}(Y_{s_n}, Z_n) \setminus \mathcal{A}(Y_{s_n}, Z_n).
$$

This means that Z_n does not have the A.P. On the other hand, Z_n is a 1-complemented subspace of Z, where Z has the metric C.A.P. by [\[Wil92,](#page-20-0) Prop. 2], so Z_n also has the metric C.A.P. Consequently $\mathfrak{A}_{Z_n} \neq \{0\}$ in view of Proposition [3.1.](#page-7-1)

We finally check the remaining conditions of Proposition [2.4](#page-3-0) with $p = 1$ for Z and the sequence $(P_n) \subset \mathcal{L}(Z)$ of norm-1 projections onto the subspaces Z_n . Condition (iii) is obvious for $p = 1$. Moreover, in view of the disjoint supports on $(0, 1)$ of the functions in the subspaces Z_n , the integration norm in Z satisfies

(3.9)
$$
\sum_{k=1}^{\infty} ||P_k f|| = \sum_{k=1}^{\infty} \int_{s_k}^{t_k} |f(r)|_r dr \le \int_0^1 |f(r)|_r dr = ||f||
$$

for any $f \in \mathbb{Z}$. Hence condition (iv) is also satisfied, and the proof of the theorem is completed by an application of Proposition [2.4.](#page-3-0)

Remark 3.10. The proof in [\[Wil92,](#page-20-0) Prop. 2] that Z has the metric C.A.P. uses a sequence $(T_n) \subset \mathcal{K}(Z)$ of vector-valued convolution operators on Z. It is conceivable that basic subsequence techniques applied to $(T_n + A(Z))$ in \mathfrak{A}_Z might produce isomorphic copies of c_0 , or even of other spaces. However, for this approach to be feasible one is likely to need descriptions of the dual spaces Z^*, Z^{**} and $\mathcal{K}(Z)^*$.

Recall from the proof of Corollary [2.7](#page-5-2) that there are closed linear subspaces $X \subset \ell^p$ that fail the A.P. for any $1 < p < \infty$ and $p \neq 2$. Willis [\[Wil92,](#page-20-0) Prop. 3 and 4] includes a modified construction, where these subspaces X lead to a separable reflexive space Z_p^{\sharp} , so that again Z_p^{\sharp} has the metric C.A.P. but fails to have the A.P. The space Z_p^{\sharp} is a quotient of a closed subspace of $L^p(0,1)$, see [\[Wil92,](#page-20-0) Prop. 3]. We observe next for completeness that Theorem [3.6](#page-9-2) remains valid for Z_p^{\sharp} , but we will not reproduce all the technical details.

Example 3.11. There is a linear isomorphic embedding $\psi: c_0 \to \mathfrak{A}_{Z_p^{\sharp}}$ for $1 < p < \infty$ and $p \neq 2$.

Proof. The construction in [\[Wil92,](#page-20-0) p. 103] is based on certain modified compact convex symmetric sets $V_t \subset X$ for $0 < t < 1$ that also depend on p. As before one introduces associated Banach spaces $(W_t, |\cdot|_t)$ such that $W_s \subset W_t \subset X$ for $0 < s < t < 1$, where W_t is the linear span of V_t in X. The space Z_p^{\sharp} is the completion of the linear span of the simple functions $\{y\chi_{(s,t)}: 0 < s < t < 1, y \in W_s\}$ on $(0, 1)$ equipped with the norm

$$
||f||_p = \left(\int_0^1 |f(r)|_r^p dr\right)^{1/p}.
$$

Fix once more sequences (s_n) and (t_n) such that $0 < s_1 < t_1 < s_2 < t_2 < \ldots < 1$, where $s_n \to 1$ as $n \to \infty$, and let P_n be the norm-1 projection of Z_p^{\sharp} onto the closed subspace $U_n := P_n(Z_p^{\sharp}) \subset Z_p^{\sharp}$ consisting of the functions supported on (s_n, t_n) for each n.

Let $R_s: Y_s \to X$ be the inclusion map from Theorem [3.6,](#page-9-2) and let $T_{s_n}^{\sharp}: Y_{s_n} \to Z_p^{\sharp}$ and $J^{\sharp}: Z_p^{\sharp} \to X$ be analogous operators to those of Step 3 of that argument. One verifies as in Step 3 that $T_{s_n}^{\sharp} \in \mathcal{K}(Y_{s_n}, \mathbb{Z}_p^{\sharp})$ for each *n*. Moreover,

$$
R_{s_n} = c_n J^{\sharp} J_n P_n T_{s_n}^{\sharp},
$$

where $c_n = \frac{1-s_n}{t_n-s_n}$ $\frac{1-s_n}{t_n-s_n}$. Thus $P_nT_{s_n}^{\sharp}$ is a compact non-approximable operator $Y_{s_n} \to U_n$, since R_{s_n} is non-approximable by Step 2 of Theorem [3.6.](#page-9-2) Hence U_n has the metric C.A.P. but fails the A.P. for all $n \in \mathbb{N}$, so that $\mathfrak{A}_{U_n} \neq \{0\}$ by Proposition [3.1.](#page-7-1)

The rest of the argument is similar to that of Theorem [3.6,](#page-9-2) since conditions (iii) and (iv) from Proposition [2.4](#page-3-0) are satisfied for Z_p^{\sharp} with the exponent $p \in (1, \infty)$. Namely, by the disjointness of the supports one gets that

$$
\|\sum_{n=1}^{\infty} f_n\|_p = \left(\sum_{n=1}^{\infty} \|f_n\|_p^p\right)^{1/p}
$$

whenever $f_n \in P_n(\mathbb{Z}_p^{\sharp})$ for $n \in \mathbb{N}$ and $\sum_{n=1}^{\infty} ||f_n||^p$ is finite.

We note for completeness that various other results and applications which involve the Willis spaces Z_X can be found e.g. in [\[Tyl95\]](#page-20-4), [\[CJ96\]](#page-19-19), [\[LO04\]](#page-19-20) and [\[OZ09\]](#page-19-21).

4. Further examples on universal spaces

In this section we discuss explicit examples of universal Banach spaces X , where the quotient algebra \mathfrak{A}_X is large. The examples include the complementably universal conjugate space C_1^* of Johnson, and some universal compact factorisation spaces that originate in the work of Johnson and Figiel.

We first recall from [\[LT77,](#page-19-0) 1.e.7] that X has the A.P. whenever the dual space X^* has the A.P., and that the converse fails in general. We next show that analogous facts hold for the respective quotient algebras.

Proposition 4.1. *Let* X *be any Banach space and define* $\theta : \mathfrak{A}_X \to \mathfrak{A}_{X^*}$ *by*

$$
\theta(S + \mathcal{A}(X)) = S^* + \mathcal{A}(X^*), \quad S \in \mathcal{K}(X).
$$

Then θ *is an isometric linear embedding* $\mathfrak{A}_X \to \mathfrak{A}_{X^*}$ *, which is an anti-homomorphism.*

The fact that θ is an anti-homomorphism means that θ reverses products, that is,

$$
\theta(ST + \mathcal{A}(X)) = \theta(T + \mathcal{A}(X)) \cdot \theta(S + \mathcal{A}(X))
$$

for $S, T \in \mathcal{K}(X)$. This property is obvious from $(ST)^* = T^*S^*$.

Proof. Note first that $U \in \mathcal{A}(X)$ implies that $U^* \in \mathcal{A}(X^*)$, so θ is a well-defined map. Moreover, θ is an isometry since the principle of local reflexivity implies that

$$
dist(S^*, \mathcal{A}(X^*)) = dist(S, \mathcal{A}(X))
$$

for any X and any compact operator $S \in \mathcal{K}(X)$, see e.g. [\[CS90,](#page-19-22) Prop. 2.5.2].

Remark 4.2. Let X be any Banach space. The map $S \mapsto S^*$ also induces well-defined quotient maps $\psi: \mathcal{L}(X)/\mathcal{A}(X) \to \mathcal{L}(X^*)/\mathcal{A}(X^*)$ and $\chi: \mathcal{L}(X)/\mathcal{K}(X) \to \mathcal{L}(X^*)/\mathcal{K}(X^*)$ as above, but ψ and χ behave differently from θ .

Namely, by the principle of local reflexivity one also has

$$
dist(S, \mathcal{A}(X)) \le 5 \cdot dist(S^*, \mathcal{A}(X^*)) = 5 \cdot \|\psi(S + \mathcal{A}(X))\|
$$

for any bounded operator $S \in \mathcal{L}(X)$ and any Banach space X, see e.g. [\[CS90,](#page-19-22) Prop. 2.5.4]. Moreover, ψ is not always an isometry, see (2.5.7) and (2.5.9) in [\[CS90\]](#page-19-22).

Finally, by [\[Tyl95,](#page-20-4) Example 2.5] there is a Banach space X such that χ is not even bounded from below $\mathcal{L}(X)/\mathcal{K}(X) \to \mathcal{L}(X^*)/\mathcal{K}(X^*)$ in the respective quotient norms. Above X does not have the B.C.A.P. by [\[Tyl95,](#page-20-4) Thm. 2.4].

We next include examples where the difference between \mathfrak{A}_X and \mathfrak{A}_{X^*} is large. Towards this fix $1 \le p \le \infty$ and let $C_p = (\bigoplus_{m \in \mathbb{N}} G_m)_{\ell^p}$ be the class of universal spaces constructed by Johnson [\[Joh71\]](#page-19-6). For the definition fix a sequence $(E_n)_{n\in\mathbb{N}}$ of finite-dimensional spaces which is dense in the Banach-Mazur distance d_{BM} in the class of all finite-dimensional spaces, and repeat each E_n infinitely often to obtain the listing $(G_m)_{m\in\mathbb{N}}$. Above

$$
d_{BM}(E, F) = \inf \{ ||T|| \cdot ||T^{-1}|| : T \text{ linear isomorphism } E \to F \}.
$$

For unity of notation $p = \infty$ corresponds again to a direct c_0 -sum. Note that with this convention C_p has the A.P. for any $1 \leq p \leq \infty$.

Example 4.3. The quotient $\mathfrak{A}_{C_1^*}$ contains a linear isomorphic copy of c_0 , but $\mathfrak{A}_{C_1} = \{0\}$.

Proof. By Corollary [2.7](#page-5-2) there is a separable reflexive subspace $X \subset \ell^p$ such that \mathfrak{A}_X contains a linear isomorphic copy of c_0 . Proposition [4.1](#page-13-1) implies that \mathfrak{A}_{X^*} contains an isomorphic copy of c_0 . (Since X is reflexive, the latter conclusion is also seen directly by passing to adjoints. Obviously $X = Z_p^{\sharp}$ from Example [3.11](#page-12-0) can also be used for the above purpose, but Theorem [3.6](#page-9-2) and Example [3.11](#page-12-0) depend on longer arguments.)

Johnson [\[Joh72,](#page-19-5) Thm. 1] showed that C_1^* is complementably universal for separable spaces. This result says that X^* is isometric to a 1-complemented subspace of C_1^* , that is,

$$
C_1^*=W\oplus M,
$$

where W is isometric to X^* and W is complemented in C_1^* by a norm-1 projection. Finally, by applying the subsequent Proposition [4.4](#page-14-0) to the direct sum $C_1^* = W \oplus M$, we obtain that $\mathfrak{A}_{C_1^*}$ contains a linear isomorphic copy of c_0 .

The following observation can be viewed as a more precise version of Proposition [2.4](#page-3-0) for finite direct sums, and this fact will also be used later on. It will be convenient to denote operators $S \in \mathcal{L}(X \oplus Y)$ on the direct sum $X \oplus Y$ as 2×2 -operator matrices

$$
S = \begin{pmatrix} S_{11} & S_{12} \\ S_{21} & S_{22} \end{pmatrix}
$$

in the canonical way. This means that $S_{11} = P_1SJ_1$, $S_{12} = P_1SJ_2$, $S_{21} = P_2SJ_1$ and $S_{22} = P_2SJ_2$, where P_1 is the projection $X \oplus Y \to X$, J_1 is the inclusion $X \to X \oplus Y$, and P_2 and J_2 are the analogous operators for the summand Y.

Proposition 4.4. Let X and Y be Banach spaces, where $\mathfrak{A}_X \neq \{0\}$. Then \mathfrak{A}_X is algebra *isomorphic to the complemented subalgebra*

$$
\mathcal{M} = \left\{ \begin{pmatrix} S_{11} & 0 \\ 0 & 0 \end{pmatrix} + \mathcal{A}(X \oplus Y) : S_{11} \in \mathcal{K}(X) \right\}
$$

of $\mathfrak{A}_{X \oplus Y}$ *.*

Proof. We first verify that the map Φ given by

$$
\Phi(S + \mathcal{A}(X \oplus Y)) = \begin{pmatrix} S_{11} & 0 \\ 0 & 0 \end{pmatrix} + \mathcal{A}(X \oplus Y), \quad S \in \mathcal{K}(X \oplus Y),
$$

defines a bounded linear projection $\mathfrak{A}_{X\oplus Y} \to \mathcal{M}$. Towards this fact we consider the map $\Psi : \mathcal{K}(X \oplus Y) \to \mathcal{K}(X \oplus Y)$ defined by

$$
\Psi(S) = \begin{pmatrix} S_{11} & 0 \\ 0 & 0 \end{pmatrix}, \quad S = \begin{pmatrix} S_{11} & S_{12} \\ S_{21} & S_{22} \end{pmatrix} \in \mathcal{K}(X \oplus Y).
$$

Observe that Ψ is a bounded linear operator, $\|\Psi\|=1$, since we may write

$$
\Psi(S) = J_1(P_1 S J_1) P_1, \quad S \in \mathcal{K}(X \oplus Y).
$$

Clearly $\Psi(\mathcal{A}(X \oplus Y)) \subset \mathcal{A}(X \oplus Y)$, so that Ψ induces the above map Φ on the quotient space $\mathfrak{A}_{X \oplus Y}$, whence $\|\Phi\| \le \|\Psi\| = 1$.

Next define $\alpha : \mathfrak{A}_X \to \mathfrak{A}_{X \oplus Y}$ by

$$
\alpha(U + \mathcal{A}(X)) = \begin{pmatrix} U & 0 \\ 0 & 0 \end{pmatrix} + \mathcal{A}(X \oplus Y), \quad U \in \mathcal{K}(X).
$$

It is not difficult to check that α is a well-defined algebra homomorphism, and by arguing as above, one gets that $||\alpha|| = 1$. Moreover, if $U \in \mathcal{K}(X)$ and $A \in \mathcal{A}(X \oplus Y)$, then

$$
\|\begin{pmatrix}U&0\\0&0\end{pmatrix}-A\|\geq \|P_1\left(\begin{pmatrix}U&0\\0&0\end{pmatrix}-A\right)J_1\|=\|U-A_{11}\|\geq dist(U,\mathcal{A}(X)).
$$

We conclude that $\|\alpha(U + A(X))\| = \|U + A(X)\|$ holds for all $U \in \mathcal{K}(X)$, so that α defines an algebra isomorphism $\mathfrak{A}_X \to \mathcal{M}$.

The universal conjugate space C_1^* is not separable, but there are spaces Y with Y^* separable, which display the same duality behaviour as $X = C_1$ in Example [4.3.](#page-14-1) For this we use another known construction.

Example 4.5. Let X be a separable reflexive Banach space for which \mathfrak{A}_{X^*} contains a linear isomorphic copy of c_0 , as in Example [4.3.](#page-14-1) A construction due to James and Lindenstrauss, see [\[LT77,](#page-19-0) 1.d.3], provides a Banach space Z (which depends on X) such that Z^{**} has a Schauder basis and $Z^{**}/Z \approx X$. It follows that

$$
Z^{***} \approx Z^* \oplus X^*,
$$

so that Z^{***} is separable. Proposition [4.4](#page-14-0) implies that $\mathfrak{A}_{Z^{***}}$ contains a linear isomorphic copy of c_0 , while $\mathfrak{A}_{Z^{**}} = \{0\}.$

Actually, in this example one may explicitly identify $\mathfrak{A}_{Z^{***}}$ with \mathfrak{A}_{X^*} , since the component operators with respect to the decomposition $Z^{***} \approx Z^* \oplus X^*$ satisfy $\mathcal{K}(Z^*) = \mathcal{A}(Z^*),$ $\mathcal{K}(X^*, Z^*) = \mathcal{A}(X^*, Z^*)$ and $\mathcal{K}(Z^*, X^*) = \mathcal{A}(Z^*, X^*)$. Here one uses the fact that Z^{**} as well as Z^* have the A.P.

Johnson [\[Joh71,](#page-19-6) Thm. 1] and Figiel [\[Fig73,](#page-19-7) Prop. 3.1] showed that for any $1 \le p \le \infty$ the spaces C_p have the following compact factorisation property: given any Banach spaces X, Y and compact operator $T \in \mathcal{K}(X, Y)$, there is a closed infinite-dimensional subspace $W \subset C_p$ as well as compact operators $A_0 \in \mathcal{K}(X, W)$, $B_0 \in \mathcal{K}(W, Y)$ so that $T = B_0 A_0$. Following Aron et al. [\[ALRR99\]](#page-19-23) and [\[MO06\]](#page-19-24) we consider the direct sum

$$
Z_{FJ}^p = (\bigoplus_W W)_{\ell^p},
$$

where W runs through all the closed infinite-dimensional subspaces of C_p in the summation. The case $p = \infty$ is interpreted as a vector-valued c_0 -type direct sum (see below).

The space Z_{FJ}^p is a Figiel-Johnson universal compact factorisation space for $1 \le p \le \infty$, since $Z_{FJ}^{\bar{p}}$ has the following universal property: for any Banach spaces X, Y and $T \in$ $\mathcal{K}(X,Y)$ there is $A \in \mathcal{K}(X,Z_{FJ}^p)$ and $B \in \mathcal{K}(Z_{FJ}^p,Y)$ so that $T = BA$. In fact, if $T = B_0A_0$ factors compactly through some $W \subset C_p$ as above, put $A = J_W A_0$ and $B = B_0 P_W$, where $J_W: W \to \mathbb{Z}_{FJ}^p$ is the inclusion map from the W:th component, and $P_W: \mathbb{Z}_{FJ}^p \to W$ is the corresponding canonical projection. Recall further, see [\[Joh71,](#page-19-6) p. 341], that C_p and C_q are totally incomparable spaces for $p \neq q$, that is, C_p and C_q do not contain any isomorphic infinite-dimensional closed subspaces. Hence Z_{FJ}^p and Z_{FJ}^q are not isomorphic for $p \neq q$.

Let Γ be an uncountable set. Recall that $(x_{\gamma}) \in c_0(\Gamma)$ if the set $\{\gamma \in \Gamma : |x_{\gamma}| > \alpha\}$ is finite for all $\alpha > 0$. It is well known that $c_0(\Gamma)$ is a non-separable Banach space equipped with the supremum norm $\|\cdot\|_{\infty}$. We next show that the universal factorisation spaces Z_{F}^{p} F J have a non-separable quotient algebra $\mathfrak{A}_{Z_{FJ}^p}$ for all $1 \leq p \leq \infty$.

Theorem 4.6. *There is an uncountable set* Γ *so that* $c_0(\Gamma)$ *embeds as a linear isomorphic* $subspace into \mathfrak{A}_{Z_{FJ}^p}$ for any $1 \leq p \leq \infty$ *.*

Proof. We fix $p \in [1,\infty]$ for the duration of the argument. The main novelty of the argument is contained in the following claim.

Claim. There is an uncountable family $\{Z_\gamma : \gamma \in \Gamma\}$ of distinct closed subspaces of C_p such that $\mathfrak{A}_{Z_{\gamma}} \neq \{0\}$ for all $\gamma \in \Gamma$.

Observe first that there is a closed subspace $Z \subset C_p$ such that $\mathfrak{A}_Z \neq \{0\}$. In fact, consider Banach spaces X and Y such that $\mathcal{A}(X, Y) \subsetneq \mathcal{K}(X, Y)$. The preceding Johnson-Figiel factorisation applied to $A \in \mathcal{K}(X, Y) \setminus \mathcal{A}(X, Y)$ gives a closed subspace $W \subset C_p$, as well as $B \in K(W, Y)$ and $C \in K(X, W)$, so that $A = BC$. Here B cannot be an approximable operator, since A is not approximable. Thus we may also factor $B \in K(W, Y)$ compactly through a closed subspace $V \subset C_p$. This produces a compact non-approximable operator $(0 \ 0)$ \bigwedge^r

 $S: W \to V$, so that $U =$ $S_{\perp} 0$ $\notin \mathcal{A}(Z)$, where $Z := W ⊕ V ⊂ C_p ⊕ C_p ≅ C_p$. Here $U(x, y) = (0, Sx)$ for $(x, y) \in Z$. Consequently $\mathfrak{A}_Z \neq \{0\}$.

We may thus fix $T \in \mathcal{K}(Z) \setminus \mathcal{A}(Z)$. Next we find a sequence of distinct closed subspaces Z_n , where $Z \subset Z_n \subset C_p$, as well as operators $T_n \in \mathcal{K}(Z_n) \setminus \mathcal{A}(Z_n)$ for $n \in \mathbb{N}$. In fact, since the subspace $Z \subset C_p$ does not have the A.P., the quotient space C_p/Z is infinitedimensional, and we may pick a normalised basic sequence $(x_n + Z)_{n \in \mathbb{N}}$ in C_p/Z , see e.g.

[\[LT77,](#page-19-0) Thm. 1.a.5]. Consider the closed linear subspace

$$
Z_n = Z + [x_k : 1 \le k \le n] \subset C_p, \quad n \in \mathbb{N},
$$

where we use [D] to denote the closed linear span in C_p of any subset $D \subset C_p$. It is clear that $Z_n \neq Z_m$ whenever $n \neq m$, since the sequence (x_k) is independent modulo Z. Moreover, vectors $x \in Z_n$ have a unique representation $x = z + \sum_{k=1}^n c_k x_k$, where $z \in Z$. Hence there is for any $n \in \mathbb{N}$ a bounded projection $P_n : Z_n \to \overline{Z}$, which is defined by $P_n x = z$ for $x = z + \sum_{k=1}^n c_k x_k \in Z_n$. We next define the linear map T_n in Z_n by

$$
T_n x = Tz + \sum_{k=1}^n c_k x_k, \quad x = z + \sum_{k=1}^n c_k x_k \in Z_n,
$$

for $n \in \mathbb{N}$. One may identify $T_n =$ $\begin{pmatrix} T & 0 \end{pmatrix}$ $0 \quad I_n$ $\overline{ }$ with respect to the direct sum decomposition $Z_n = Z \oplus [x_k : 1 \leq k \leq n]$, where I_n is the associated identity map. It follows that $T_n: Z_n \to Z_n$ is a compact non-approximable operator, since $T \in \mathcal{K}(Z) \setminus \mathcal{A}(Z)$. Hence $\mathfrak{A}_{Z_n} \neq \{0\}$ for each $n \in \mathbb{N}$.

Recall from [\[Joh71,](#page-19-6) p. 341] that $C_p \cong (\bigoplus_{k=1}^{\infty} C_p)_{\ell^p}$, so that the above construction can be applied coordinatewise in each summand. This gives an uncountable family $\{Z_\gamma : \gamma \in \Gamma\}$ of closed subspaces of C_p , where

$$
Z_{\gamma} = (\bigoplus_{j \in \mathbb{N}} (Z^{(j)})_{n_j})_{\ell^p} \subset (\bigoplus_{k=1}^{\infty} C_p)_{\ell^p} \cong C_p
$$

and $\gamma = (n_j)_{j \in \mathbb{N}} \in \Gamma := \prod_{j \in \mathbb{N}} \mathbb{N}$. Here $Z^{(j)}$ denotes an isomorphic copy of Z in the j:th summand C_p in the above direct sum. To check that $Z_\gamma \neq Z_{\gamma'}$ whenever $\gamma \neq \gamma'$, note that if $\gamma \neq \gamma'$, where $\gamma = (n_j)$ and $\gamma' = (m_j)$, then $n_j \neq m_j$ for some $j \in \mathbb{N}$. Thus the respective j:th component spaces satisfy $(Z^{(j)})_{n_j} \neq (Z^{(j)})_{m_j}$, whence $Z_{\gamma} \neq Z_{\gamma'}$. Moreover, $(Z^{(1)})_{n_1} \subset Z_{\gamma}$ is a complemented subspace, so it follows from Proposition [4.4](#page-14-0) that $\mathfrak{A}_{Z_{\gamma}} \neq \{0\}$ for any $\gamma \in \Gamma$. This finishes the verification of the Claim.

To complete the argument we consider the complemented subspace $Y = (\bigoplus_{\gamma \in \Gamma} Z_{\gamma})_{\ell^p}$ of Z_{FJ}^p . By Proposition [4.4](#page-14-0) it suffices to find a linear isomorphic embedding $c_0(\Gamma) \to \mathfrak{A}_Y$. This step is a modification of the corresponding argument in Proposition [2.4.](#page-3-0) Firstly, for each $\gamma \in \Gamma$ pick a compact operator $T_{\gamma} \in \mathcal{K}(Z_{\gamma})$ so that

$$
dist(T_{\gamma}, \mathcal{A}(Z_{\gamma})) = 1, \quad ||T_{\gamma}|| < 2.
$$

Let $U_{\gamma} = J_{\gamma}T_{\gamma}P_{\gamma}$, where $J_{\gamma}: Z_{\gamma} \to Y$ is the natural inclusion map and $P_{\gamma}: Y \to Z_{\gamma}$ the natural projection for $\gamma \in \Gamma$. Then the series $\sum_{\gamma \in \Gamma} a_{\gamma} U_{\gamma}$ defines a compact operator $Y \to Y$, and

(4.7)
$$
\|\sum_{\gamma \in \Gamma} a_{\gamma} U_{\gamma}\| \leq 2 \cdot \sup_{\gamma} |a_{\gamma}|,
$$

for any $(a_{\gamma}) \in c_0(\Gamma)$. In fact, consider the finite sets $\Gamma_r = {\gamma \in \Gamma : |a_{\gamma}| > 1/r}$ and the associated compact operator $V_r = \sum_{\gamma \in \Gamma_r} a_{\gamma} U_{\gamma}$ on Y for $r \in \mathbb{N}$. It follows that $(V_r) \subset \mathcal{K}(Y)$

is a Cauchy-sequence, since

$$
||V_{r+s} - V_r|| = ||\sum_{\gamma \in \Gamma_{r+s} \backslash \Gamma_r} a_{\gamma} U_{\gamma}|| \leq 2/r
$$

for each $r, s \in \mathbb{N}$. Thus $\sum_{\gamma \in \Gamma} a_{\gamma} U_{\gamma} = \lim_{r \to \infty} V_r$ defines a compact operator on Y. To check [\(4.7\)](#page-17-0), put $\Gamma_0 = \bigcup_{r \in \mathbb{N}} \Gamma_r$ and let $x = (x_\gamma) \in Y$. It follows that

$$
\|\sum_{\gamma \in \Gamma} a_{\gamma} U_{\gamma} x\|_{\ell^{p}} = \|\sum_{\gamma \in \Gamma_{0}} a_{\gamma} J_{\gamma} T_{\gamma} x_{\gamma}\|_{\ell^{p}} \leq 2 \cdot \sup_{\gamma} |a_{\gamma}| \cdot \|x\|_{\ell^{p}}.
$$

Finally, suppose that $(a_{\gamma}) \in c_0(\Gamma)$ and $|a_{\beta}| = ||(a_{\gamma})||_{\infty}$ for some $\beta \in \Gamma$. If $V \in \mathcal{A}(Y)$ is arbitrary, then

$$
\|\sum_{\gamma \in \Gamma} a_{\gamma} U_{\gamma} - V\| \ge \|P_{\beta}\left(\sum_{\gamma \in \Gamma} a_{\gamma} U_{\gamma} - V\right)J_{\beta}\| = \|a_{\beta} T_{\beta} - P_{\beta} V J_{\beta}\| \ge |a_{\beta}|,
$$

since $U_{\gamma}J_{\beta}=0$ for $\gamma\neq\beta$ by construction.

This completes the proof that $c_0(\Gamma)$ embeds into \mathfrak{A}_Y , and consequently of the theorem, after an application of Proposition [4.4.](#page-14-0)

5. Concluding remarks

We remind that it seems to be unknown whether $\mathfrak{A}_P \neq \{0\}$, where P belongs to the family of spaces constructed by Pisier [\[Pis83\]](#page-19-25), [\[Pis86,](#page-19-26) section 10]. The spaces P fail the A.P. and $\mathcal{A}(P) = \mathcal{N}(P)$, where $\mathcal{N}(P)$ denotes the space of nuclear operators $P \to P$. Moreover, $\mathcal{K}(P, P^*) = \mathcal{A}(P, P^*) = \mathcal{N}(P, P^*)$ by [\[Joh90\]](#page-19-27).

Argyros and Haydon [\[AH11\]](#page-18-1) constructed Banach spaces X_{AH} having a Schauder basis such that the Calkin algebra $\mathcal{L}(X_{AH})/\mathcal{K}(X_{AH})$ is one-dimensional. Their construction was subsequently modified by Tarbard [\[Tar12\]](#page-20-1) to obtain certain finite-dimensional Calkin algebras. Dales [\[Dal13\]](#page-19-2) noted that it remains unclear whether there is a similar phenomenon for the compact-by-approximable algebras, that is, whether there are Banach spaces X failing the A.P., such that $\mathfrak{A}_X \neq \{0\}$ is a finite-dimensional (radical) algebra. Note that if such a space X exists, then X cannot have the B.C.A.P. by Proposition [3.1.](#page-7-1)(ii).

It also appears unknown whether there is a Banach space X such that $\mathcal{A}(X)$ is separable (that is, X^* is separable), but $\mathcal{K}(X)$ is non-separable.

Acknowledgements: We are grateful to Garth Dales for communicating [\[Dal13\]](#page-19-2) and for some subsequent discussions. This paper is part of the Ph.D.-thesis of Henrik Wirzenius under the supervision of the first author.
