#### Abstract

In multi-scalar field cosmologies new dynamical degrees of freedom are introduced which can explain the observational phenomena. Unlike the usual scalar field theory where a single scalar field is considered, the multi-scalar field cosmologies allow more than one scalar field and exhibits interetsing consequences, such as quintom, hybrid inflation etc. The current work study the existence of exact solutions and integrable dynamical systems in multi-scalar field cosmology and more specifically in the so-called Chiral cosmology where nonlinear terms exists in the kinetic term of the scalar fields. We present the exact analytic solutions for a system of $N$-scalar fields. In particular, we consider a multi scalar field cosmological scenario comprised of $N$-scalar fields that are minimally coupled to the Einstein gravity. The geometry of the universe is described by the spatially flat homogeneous and isotropic line element and the scalar fields may interact in their kinetic or/and potential terms. Within this set up, we show that for a specific geometry in the kinetic part of the scalar fields and specific potential form, the gravitational field equations for the class of $N$-scalar field models can be exactly solved. More specifically, we show that the Einstein field equations in $N$-scalar field cosmology can be reduced to that of a $(N+1)$-linear system.

## 1. INTRODUCTION

Scalar fields play a significant role in cosmological studies because they can describe various phenomena of our universe such as the inflationary era (inflaton), the late time acceleration (dark energy), the dark matter component in the universe, unification of early inflation to late acceleration [14]. Scalar fields are defined to be either minimally or non-minimally coupled to the gravity [15-19] while they also can attribute, in a dynamical way, the higher-order derivatives of modified theories of gravity, the later is achieved with the use of Lagrange multipliers 20-24]. Moreover, scalar fields also play an essential role in the conformal transformation which relates the Einstein and the Jordan frames [25]; hence their study is important in order to understand the physical properties of conformal transformations and relation of solutions between the different frames [26 28$]$.

In the present work we concentrate on a specific cosmological scenario which has drawn a remarkable attention to the scientific society in last several years, is the multi-scalar field theory. In particular, two or more scalar fields which in general interact in the potential or/and in the kinetic terms, have been considered earlier to describe the evolution of the universe. The multi-scalar field models provide new degrees of freedom which can be used to connect with the phenomena described in string theory to cosmology and phenomenology [29, 30]. Furthermore, the multi-scalar fields can also be defined in the Einstein and in the Jordan frames. In the later scenario, they describe tensor multi-scalar field models [31]. An interesting connection of the tensor multi-scalar field models is that they are related with multidimensional cosmologies (32].

The simplest multi-scalar field theory is the quintom theory in which the two scalar fields, namely a quintessence scalar field and a phantom field contribute to the dark sector, specifically the dark energy, of the universe 33 37. One of the main properties of such quintom models is that the equation-of-state parameter for the dark energy fluid is able to evolve across the cosmological constant boundary ' -1 ' 33, 38]. Moreover, multi-scalar field models are considered for the description of inflation [39-41], such as hybrid inflation, double inflation, $\alpha$-attractors etc., as these models can provide a different exit from the standard inflationary era 42 47]. Hybrid inflation is [39] described by a two-scalar fields model where the one field describes the inflaton and the second field is an auxiliary Higgs-type field. In such

[^0]a inflationary model the exit from the inflation is described by a waterfall regime where the second field is rapid rolling when inflaton reaches a specific value [48]. Other cosmological applications of multi-scalar field models with or without interaction can be found in [50 58] and references therein. The multi-scalar fields can describe different states for the matter source of the universe; for instance, the multi-scalar fields can describe the dark sector, i.e., dark energy and dark matter, while the interaction terms between the scalar fields provide an interaction between the different fluid terms. In terms of the phenomenology, this kind of interactions provide viable cosmological parameters [59 61].

Concerning analytic solutions of the gravitational field equations, there are various analytic and exact solutions in the literature on scalar field cosmology in homogeneous spacetimes. Most of the solutions correspond to a Friedmann-Lemaître-Robertson-Walker (FLRW) geometry [62-70] while only a few analytic solutions are known for anisotropic Bianchi spacetimes [71, 72]. In the case of multi-scalar field scenarios, there are a small number of exact and analytic solutions known in the literature with or without the interaction between the scalar fields [73-82].

In this work we discuss a family of exact solutions for $N$-scalar field cosmologies where the scalar fields interact in the kinetic and in the potential terms, the so-called Chiral cosmological model. In particular, we have seen that the scalar fields are defined in a hyperbolic geometry, i.e., in a space of negative constant curvature, and when $N=2$ they reduce to the sigma models [83], which have various applications in inflation 79] as well as in the late-time accelerating phase of the universe 84]. The plan of the paper is the following.

In Section 2, we present the gravitational field equations of multi scalar field models in a flat FLRW geometry. In Section 3 we describe the exact analytical solutions for such multi scalar field cosmologies. Finally, in Section 4 we conclude the present work with a brief summary.

## 2. CHIRAL COSMOLOGY

The recent observations support the cosmological principle that means in large scales our universe is isotropic and homogeneous [85]. Thus, in the context of General Relativity the natural spacetime is described by the FLRW geometry. Moreover, the FLRW universe with zero spatial curvature is preferable by the recent observational evidences [86], which leads the spacetime to be described by the following line element

$$
\begin{equation*}
d s^{2}=-d t^{2}+a^{2}(t)\left(d x^{2}+d y^{2}+d z^{2}\right) \tag{1}
\end{equation*}
$$

where $a(t)$ is the expansion scale factor of the universe.
We consider the Action Integral

$$
\begin{equation*}
S=\int \sqrt{-g} d x^{4} R+\int \sqrt{-g} d x^{4} L_{\Phi}\left(\Phi^{C}, \nabla_{\mu} \Phi^{C}\right) \tag{2}
\end{equation*}
$$

where $L_{\Phi}\left(\Phi^{B}, \nabla \Phi^{B}\right)$ describes the Lagrangian of the $N$-scalar fields given by the following expression 8789 .

$$
\begin{equation*}
L_{\Phi}\left(\Phi^{C}, \nabla_{\mu} \Phi^{C}\right)=-\frac{1}{2} g^{\mu \nu} J_{A B}\left(\Phi^{C}\right) \nabla_{\mu} \Phi^{A} \nabla_{\nu} \Phi^{B}-V\left(\Phi^{C}\right) \tag{3}
\end{equation*}
$$

where $\mu, \nu=1,2,3,4$ and $A, B=1,2 \ldots N$. The tensor $g_{\mu \nu}$ denotes the natural spacetime and $J_{A B}\left(\Phi^{C}\right)$ describes the space in which the $N$-fields are defined. For instance, for $N=2$, quintom model is recovered when $J_{A B}\left(\Phi^{C}\right)=$ $(1,-1)$, while the $\sigma$-model is recovered when $J_{A B}\left(\Phi^{C}\right)=\left(1, e^{2 \Phi_{1}}\right)$.

At this point we would like to remark that these are not the only choices where the quintom model or the (special case of) $\sigma$-model are recovered. In particular, for every second rank tensor $J_{A B}\left(\Phi^{C}\right)$ which defines the $M^{2}$ space, quintom model is recovered, but for different functional forms of the potential function $V\left(\Phi^{C}\right)$. On the other hand, when $J_{A B}\left(\Phi^{C}\right)$ describes a maximally symmetric space with negative curvature, the $\sigma$-model is recovered.

Now, the variation of the Action Integral (2) with respect to the metric tensor provides the Einstein field equations

$$
\begin{equation*}
G_{\mu \nu}=T_{\mu \nu}\left(\Phi^{C}, \nabla_{\mu} \Phi^{C}\right) \tag{4}
\end{equation*}
$$

in which the energy-momentum tensor assumes the following expression

$$
\begin{equation*}
T_{\mu \nu}\left(\Phi^{C}, \nabla_{\mu} \Phi^{C}\right)=J_{A B}\left(\Phi^{C}\right) \nabla_{\mu} \Phi^{A} \nabla_{\nu} \Phi^{B}-g_{\mu \nu}\left(-\frac{1}{2} g^{\mu \nu} J_{A B}\left(\Phi^{C}\right) \nabla_{\mu} \Phi^{A} \nabla_{\nu} \Phi^{B}-V\left(\Phi^{C}\right)\right) \tag{5}
\end{equation*}
$$

while the variation of the Action Integral (22) with respect to $\Phi^{A}$ gives

$$
\begin{equation*}
g^{\mu \nu}\left(\nabla_{\mu} J_{B}^{A}\left(\Phi^{C}\right) \nabla_{\nu} \Phi^{B}\right)+J_{B}^{A}\left(\Phi^{C}\right) \frac{\partial V\left(\Phi^{C}\right)}{\partial \Phi^{B}}=0 \tag{6}
\end{equation*}
$$

For the line element (11) and by assuming that the $N$-fields inherits the isometries of the FLRW space the field equations (4), (6) are simplified as follows

$$
\begin{gather*}
-3 H^{2}+\frac{1}{2} J_{A B}\left(\Phi^{C}\right) \dot{\Phi}^{A} \dot{\Phi}^{B}+V\left(\Phi^{C}\right)=0  \tag{7}\\
-2 \dot{H}-3 H^{2}+\frac{1}{2} J_{A B}\left(\Phi^{C}\right) \dot{\Phi}^{A} \dot{\Phi}^{B}-V\left(\Phi^{C}\right)=0 \tag{8}
\end{gather*}
$$

and

$$
\begin{equation*}
\ddot{\Phi}^{A}+\tilde{\Gamma}_{B C}^{A}\left(\Phi^{D}\right) \dot{\Phi}^{B} \dot{\Phi}^{C}+3 H \dot{\Phi}^{A}+J^{A B}\left(\Phi^{C}\right) V_{, B}\left(\Phi^{C}\right)=0 \tag{9}
\end{equation*}
$$

where an overhead dot means the derivative with respect the variable " $t$ "; $H \equiv \dot{a} / a$ is the Hubble function and $\tilde{\Gamma}_{B C}^{A}\left(\Phi^{D}\right)$ denotes the symmetric connection coefficients of $J_{A B}\left(\Phi^{C}\right)$, defined as

$$
\begin{equation*}
\tilde{\Gamma}_{B C}^{A}\left(\Phi^{D}\right)=\frac{1}{2} J^{A D}\left(J_{A D, C}+J_{D B, C}-J_{A B, D}\right) \tag{10}
\end{equation*}
$$

The field equations can be written, in an equivalent way, in terms of the energy density $\rho_{\Phi}$ and pressure $p_{\Phi}$ as

$$
\begin{gather*}
-3 H^{2}+\rho_{\Phi}=0,  \tag{11}\\
-2 \dot{H}-3 H^{2}+p_{\Phi}=0, \tag{12}
\end{gather*}
$$

and

$$
\begin{equation*}
\dot{\rho}_{\Phi}+3 H\left(\rho_{\Phi}+p_{\Phi}\right)=0, \tag{13}
\end{equation*}
$$

in which the energy density and the pressure of the scalar field, respectively given by

$$
\begin{align*}
& \rho_{\Phi}=\frac{1}{2} J_{A B}\left(\Phi^{C}\right) \dot{\Phi}^{A} \dot{\Phi}^{B}+V\left(\Phi^{C}\right)  \tag{14}\\
& p_{\Phi}=\frac{1}{2} J_{A B}\left(\Phi^{C}\right) \dot{\Phi}^{A} \dot{\Phi}^{B}-V\left(\Phi^{C}\right), \tag{15}
\end{align*}
$$

describe the components of the total fluid source, that is

$$
\begin{equation*}
\rho_{\Phi}=\sum_{A=1}^{N} \rho_{A}\left(\Phi^{C}, \nabla_{\mu} \Phi^{C}\right), p_{\Phi}=\sum_{A=1}^{N} p_{A}\left(\Phi^{C}, \nabla_{\mu} \Phi^{C}\right) \tag{16}
\end{equation*}
$$

where the definitions of $\rho_{A}\left(\Phi^{C}, \nabla_{\mu} \Phi^{C}\right), p_{A}\left(\Phi^{C}, \nabla_{\mu} \Phi^{C}\right)$ depend on the assumptions for the model of study every time. However, the time evolution of the total fluid source and of the scalar factor is independently from the definition of the energy density for the individual fields.

The field equations (7)-(9) are not independent. The first-order equation (17) can be seen as a conservation law for the second-order equations (8)-(9). That means, the integration constants of a solution of (8)-(9) are constrained by eq. (7). Moreover, the degrees of freedom of the field equations (8)-(9) is $(N+1)$, and because equation (77) is a conservation law, thus, one needs to find the $N$-linear independent integrals of motion, which are in involution, in order to determine (Liouville-Arnold) integrability. Consequently, to write the solutions in closed-form expressions.

Thereafter, in order to determine the exact and analytic solutions for the model of our consideration we should determine the conservation laws. That can be achieved by many ways, however, two of the most systematic ways are the Lie theory and the singularity analysis. These two theories provide new constraints for the determination of the unknown functions of the our model, namely, $J_{A B}\left(\Phi^{C}\right)$ and $V\left(\Phi^{C}\right)$, which lead to integrable systems 77,90 92].

In contrast to that approaches, in this work we follow the inverse steps. Specifically, we consider "classical" wellknown integrable systems and then we determine the equivalent multi-scalar field models.

## 3. EXACT SOLUTIONS

Cosmological constant $\Lambda$ is the simplest candidate for the dark energy fluid which drives the accelerating phase of the universe, and it has been found to be in well agreement with a series of astronomical observations. While it is well known that $\Lambda$ suffers from two major problems, namely, the fine-tuning and the coincidence problems 93, 94, but it is the dark energy model with a minimal degrees of freedom. Moreover, in this context, the evolution of the scale factor is given by an exact expression, and in particular by an exponential function.

In $\Lambda$-cosmology, assuming the absence of any matter source, the field equations are

$$
\begin{equation*}
-3 a \dot{a}^{2}+2 a^{3} \Lambda=0 \tag{17}
\end{equation*}
$$

and

$$
\begin{equation*}
\ddot{a}+\frac{1}{2 a} \dot{a}^{2}-a \Lambda=0 . \tag{18}
\end{equation*}
$$

The latter system describes the de Sitter universe where $a(t)=a_{0} \exp \left(\sqrt{\frac{2 \Lambda}{3}} t\right)$. While expression (17)-(18) is a set of nonlinear differential equations that can be linearized under the change of variables $a(t)=r(t)^{\frac{2}{3}}$. Indeed they can be written in the equivalent form as follows [95]

$$
\begin{equation*}
-\frac{1}{2} \dot{r}^{2}+\frac{\omega^{2}}{2} r^{2}=0, \quad \ddot{r}-\omega^{2} r=0 \quad \text { with } \quad \omega^{2}=\frac{3}{2} \Lambda . \tag{19}
\end{equation*}
$$

These linear equations form a maximally symmetric system 96] which is nothing else than the one-dimensional "oscillator" (hyperbolic for $\Lambda>0$, harmonic for $\Lambda<0$ ).

## 3.1. $1+1$ degrees of freedom

The quintessence UDM (unified dark matter) cosmological models $97-100$ provide a de Sitter point in the evolution of the universe as a late-time attractor while they can also provide a component in the Hubble function similar to that of the pressureless fluid term. In Ref. [100], it has been shown that the UDM scalar field model is in a fair agreement with that of the $\Lambda$-cosmology at the background and perturbation levels, while some recent cosmological constraints show that the UDM model as the dark energy candidate is observational supported [66].

Except from the above physical properties, the UDM scalar field model has an important mathematical property - it is integrable as is described by the Liouville-Arnold theorem. The potential function of the UDM model is given by the expression

$$
\begin{equation*}
V(\phi)=\left(V_{0}+V_{1} \cosh ^{2}\left(\sqrt{\frac{3}{8}} \phi\right)\right) \tag{20}
\end{equation*}
$$

while the field equations can be written in a linear form under the point transformation 66]

$$
\begin{equation*}
a^{3}=\frac{3}{8}\left(x^{2}-y^{2}\right), \phi=\sqrt{\frac{8}{3}} \arctan h\left(\frac{y}{x}\right) \tag{21}
\end{equation*}
$$

as follows

$$
\begin{gather*}
-\frac{1}{2} \dot{x}^{2}+\frac{1}{2} \dot{y}^{2}+\frac{\omega_{1}^{2}}{2} x^{2}-\frac{\omega_{2}^{2}}{2} y^{2}=0  \tag{22}\\
\ddot{x}-\omega_{1}^{2} x=0, \ddot{y}-\omega_{2}^{2} y=0 \tag{23}
\end{gather*}
$$

in which $\omega_{1}^{2}=\omega_{1}^{2}\left(V_{0}, V_{1}\right)$ and $\omega_{2}^{2}=\omega_{1}^{2}\left(V_{0}, V_{1}\right)$. At this point it is important to remark that the same property holds either when $\phi$ is a phantom scalar field ${ }^{1}$.

[^1]However, the most generic $1+1$ dimensional Lagrangian which describes a linear system is

$$
\begin{equation*}
L(x, \dot{x}, y, \dot{y})=-\frac{1}{2} \dot{x}^{2}+\frac{1}{2} \dot{y}^{2}-\frac{\omega_{1}^{2}}{2} x^{2}+\frac{\omega_{2}^{2}}{2} y^{2}-\mu^{2} x y \tag{24}
\end{equation*}
$$

with Euler-Lagrange equations

$$
\begin{equation*}
\ddot{x}-\omega_{1}^{2} x-\mu^{2} y=0, \ddot{y}-\omega_{2}^{2} y+\mu^{2} x=0 \tag{25}
\end{equation*}
$$

where also we consider the constraint

$$
\begin{equation*}
-\frac{1}{2} \dot{x}^{2}+\frac{1}{2} \dot{y}^{2}+\frac{\omega_{1}^{2}}{2} x^{2}-\frac{\omega_{2}^{2}}{2} y^{2}+\mu^{2} x y=0 \tag{26}
\end{equation*}
$$

Under the inverse point transformation (21), the Lagrangian (24) becomes

$$
\begin{equation*}
L(a, \dot{a}, \phi, \dot{\phi})=-3 a \dot{a}^{2}+\frac{1}{2} a^{3} \dot{\phi}^{2}-\frac{4}{3} a^{3}\left[\omega_{2}^{2}+\left(\omega_{1}^{2}-\omega_{2}^{2}\right) \cosh ^{2}\left(\sqrt{\frac{3}{8}} \phi\right)+\mu^{2} \sinh \left(2 \sqrt{\frac{3}{8}} \phi\right)\right] \tag{27}
\end{equation*}
$$

The latter potential reduces to the UDM model when $\mu=0$. Hence, we can see that by considering the Lagrangian which defines the most general linear system of second-order differential equations, we are able to construct a new integrable scalar field model.

As far as concerns the generic solution of (25) that is given with the use of the exponential matrix. Indeed system (25) can be written as

$$
\left(\begin{array}{c}
\dot{x}  \tag{28}\\
\dot{y} \\
\dot{p}_{x} \\
\dot{p}_{y}
\end{array}\right)=\left(\begin{array}{cccc}
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 \\
\omega_{1}^{2} & \mu^{2} & 0 & 0 \\
-\mu^{2} & \omega_{2}^{2} & 0 & 0
\end{array}\right)\left(\begin{array}{c}
x \\
y \\
p_{x} \\
p_{y}
\end{array}\right)
$$

whose general solution is, $\mathbf{x}=\mathbf{x}_{0} e^{\mathbf{A} t}$, where $\mathbf{A}$ is the $4 \times 4$ matrix of the latter system and $\mathbf{x}_{0}$ is the matrix $\mathbf{x}$ at $t=0$. Hence, the Jordan representation of matrix $\mathbf{A}$ defines the generic solution of the field equations, recall that the Jordan representation depends on the free parameters $\omega_{1}, \omega_{2}$ and $\mu^{2}$.

Now in the simplest case where $\omega_{1}=\omega_{2}=0$, the generic solution of system (25) is

$$
\begin{align*}
& x(t)=\left(c_{1} \cos (\omega t)+c_{2} \sin (\omega t)\right) \cosh (\omega t)+\left(c_{3} \cos (\omega t)+c_{4} \sin (\omega t)\right) \sinh (\omega t),  \tag{29}\\
& y(t)=\left(c_{4} \cos (\omega t)-c_{3} \sin (\omega t)\right) \cosh (\omega t)+\left(c_{2} \cos (\omega t)-c_{1} \sin (\omega t)\right) \sinh (\omega t) . \tag{30}
\end{align*}
$$

where the constraint equation (27) provides the algebraic equation $c_{1} c_{4}-c_{2} c_{3}=0$ and $\omega=\sqrt{2} \mu^{2}$. Consequently, the latter solution can provide a bouncing universe. For instance, when all the coefficient constants are equal the scale factor becomes

$$
\begin{equation*}
a^{3}(t)=\frac{3}{4} c_{1}^{2} e^{2 \omega t} \sin (2 \omega t) \tag{31}
\end{equation*}
$$

which provides a periodic universe. Moreover, when $c_{1}=c_{2}$ then the scale factor becomes

$$
\begin{equation*}
a^{3}(t)=\frac{3}{8}\left(c_{2}^{2}-c_{3}^{2}\right)+\frac{3}{8} \sin (2 \omega t)\left(\left(c_{2}^{2}+c_{3}^{2}\right) \cosh (2 \omega t)+2 c_{2} c_{3} \sinh (2 \omega t)\right) \tag{32}
\end{equation*}
$$

which is a periodic solution around a constant scale factor, the latter solution is physically accepted when $c_{2}^{2}-c_{3}^{2}>0$.

## 3.2. $2+1$ degrees of freedom

Let us consider the Lagrangian function

$$
\begin{equation*}
L(x, \dot{x}, y, \dot{y}, z, \dot{z})=-\frac{1}{2} \dot{x}^{2}+\frac{1}{2} \dot{y}^{2}-\frac{\omega_{1}^{2}}{2} x^{2}+\frac{\omega_{2}^{2}}{2} y^{2}+\frac{\omega_{3}^{2}}{2} z^{2}-\mu_{1}^{2} x y-\mu_{2}^{2} x z+\mu_{3}^{2} y z \tag{33}
\end{equation*}
$$

which describes the linear system

$$
\begin{align*}
& \ddot{x}-\omega_{1}^{2} x-\mu_{1}^{2} y-\mu_{2}^{2} z=0  \tag{34}\\
& \ddot{y}+\mu_{1}^{2} x-\omega_{2}^{2} y-\mu_{3}^{2} z=0  \tag{35}\\
& \ddot{z}+\mu_{2}^{2} x-\omega_{3}^{2} z-\mu_{3}^{2} y=0 \tag{36}
\end{align*}
$$

with constraint equation the conservation law of "energy" for the latter system to be zero.
The generic solution of the latter system is given with the us of the exponential matrix, $\mathbf{x}=\mathbf{x}_{0} e^{\mathbf{A} t}$, in which $\mathbf{x}=\left(x, y, z, p_{x}, p_{y}, p_{z}\right)^{T}$ and

$$
A=\left(\begin{array}{cccccc}
0 & 0 & 0 & 1 & 0 & 0  \tag{37}\\
0 & 0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 \\
\omega_{1}^{2} & \mu_{1}^{2} & \mu_{2}^{2} & 0 & 0 & 0 \\
-\mu_{1}^{2} & \omega_{2}^{2} & \mu_{3}^{2} & 0 & 0 & 0 \\
-\mu_{2}^{2} & \mu_{3}^{2} & \omega_{3}^{3} & 0 & 0 & 0
\end{array}\right)
$$

Under the point transformation

$$
\begin{aligned}
& x=\sqrt{\frac{8}{3}} a^{\frac{3}{2}} \cosh \left(\sqrt{\frac{3}{8}} \phi\right) \\
& y=\sqrt{\frac{8}{3}} a^{\frac{3}{2}} \sinh \left(\sqrt{\frac{3}{8}} \phi\right) \cos \left(\sqrt{\frac{3}{8}} \psi\right) \\
& z=\sqrt{\frac{8}{3}} a^{\frac{3}{2}} \sinh \left(\sqrt{\frac{3}{8}} \phi\right) \sin \left(\sqrt{\frac{3}{8}} \psi\right)
\end{aligned}
$$

Lagrangian (33) takes the following form

$$
\begin{align*}
L(a, \dot{a}, \phi, \dot{\phi}, \psi, \dot{\psi})= & -3 a \dot{a}^{2}+\frac{1}{2} a^{3}\left(\dot{\phi}^{2}+\sinh ^{2}\left(\sqrt{\frac{3}{8}} \phi\right) \dot{\psi}^{2}\right)+ \\
& -\frac{4}{3} a^{3}\left[\omega_{1}^{2}+\left(\left(\omega_{1}^{2}-\omega_{2}^{2}\right)+\left(\omega_{2}^{2}-\omega_{3}^{2}\right) \sin ^{2}\left(\sqrt{\frac{3}{8}} \psi\right)-\mu_{3} \sin \left(2 \sqrt{\frac{3}{8}} \psi\right)\right) \sinh ^{2} \phi\right]+ \\
& -\frac{4}{3} a^{3}\left[\left(\mu_{1} \cos \left(\sqrt{\frac{3}{8}} \psi\right)+\mu_{2} \sin \left(\sqrt{\frac{3}{8}} \psi\right)\right) \sinh \left(2 \sqrt{\frac{3}{8}} \phi\right)\right] \tag{38}
\end{align*}
$$

The latter Lagrangian describes the field equations for a two-scalar fields model where the two scalar fields interact in the kinetic terms and in the potential terms as well. In particular, the scalar fields are defining in the hyperbolic case. The latter model for $\mu_{1}=\mu_{2}=\mu_{3}=0$, has been found and studied before in 77 and it is an extension of the UDM model in the case of two scalar fields.

In a similar fashion we continue with the extension of the exact solutions in higher-degrees of freedom.

## 3.3. $\quad N+1$ degrees of freedom

In order to generalize our results in case of $N$-scalar fields we assume the Lagrangian

$$
\begin{equation*}
L\left(x, \dot{x}, y_{\beta}, \dot{y}_{\beta}\right)=-\frac{1}{2} \dot{x}^{2}+\frac{1}{2} \sum_{\beta=1}^{N}\left(\dot{y}_{\beta}\right)^{2}-\frac{\omega_{0}^{2}}{2} x^{2}+\frac{1}{2} \sum_{\beta=1}^{N}\left(\omega_{\beta} y_{\beta}\right)^{2}-\sum_{\beta=1}^{N}\left(\mu_{\beta}^{2} x y_{\beta}\right)+\sum_{(\beta \neq \gamma) \beta, \gamma=1}^{N}\left(\mu_{\beta \gamma}^{2} y_{\beta} y_{\gamma}\right) \tag{39}
\end{equation*}
$$

which describes the following system of linear equations

$$
\begin{equation*}
\ddot{x}-\omega_{0}^{2} x-\sum_{\beta=1}^{N}\left(\mu_{\beta}^{2} y_{\beta}\right)=0 \tag{40}
\end{equation*}
$$

$$
\begin{equation*}
\ddot{y}_{\beta}+\mu_{\beta}^{2} x-\omega_{\beta}^{2} y_{\beta}-\sum_{(\beta \neq \gamma) \gamma=1}^{N}\left(\mu_{\beta \gamma}^{2} y_{\gamma}\right)=0 . \tag{41}
\end{equation*}
$$

Moreover, we consider the constraint condition

$$
\begin{equation*}
-\frac{1}{2} \dot{x}^{2}+\frac{1}{2} \sum_{\beta=1}^{N}\left(\dot{y}_{\beta}\right)^{2}+\frac{\omega_{0}^{2}}{2} x^{2}-\frac{1}{2} \sum_{\beta=1}^{N}\left(\omega_{\beta} y_{\beta}\right)^{2}+\sum_{\beta=1}^{N}\left(\mu_{\beta}^{2} x y_{\beta}\right)-\sum_{(\beta \neq \gamma) \beta, \gamma=1}^{N}\left(\mu_{\beta \gamma}^{2} y_{\beta} y_{\gamma}\right)=0 \tag{42}
\end{equation*}
$$

The latter condition is important in order the generic solution of (40)-(41) to be valid for the case of multi-scalar fields model.

Hence, system (40)-(41) can be written in the equivalent form

$$
\begin{equation*}
\dot{\mathbf{X}}=\mathbf{A} \mathbf{X} \tag{43}
\end{equation*}
$$

with $X=\left(x, y_{\beta}, p_{x}, p_{\beta}\right)^{T}$, and

$$
\mathbf{A}=\left(\begin{array}{cc}
0 & \mathbf{I}  \tag{44}\\
\mathbf{B} & 0
\end{array}\right)
$$

in which $\mathbf{I}$ is the unitary matrix of dimension $(N+1)$ and $B$ is an $(N+1) \times(N+1)$ matrix defined as

$$
\mathbf{B}=\left(\begin{array}{ccccc}
\omega_{0}^{2} & \mu_{1} & \mu_{2} & \ldots & \mu_{N}  \tag{45}\\
-\mu_{1} & \omega_{1}^{2} & \mu_{12} & \ldots & \mu_{1 N} \\
-\mu_{2} & \mu_{21} & \omega_{2}^{2} & \ldots & \mu_{2 N} \\
\ldots & \ldots & \ldots & \ldots & \ldots \\
-\mu_{N} & \mu_{N 1} & \ldots & \mu_{N 2} & \omega_{N}^{2}
\end{array}\right)
$$

Thus, the functional form of the solution of system (43) depends on the eigenvalues of the matrix $\mathbf{B}$, and consequently on the values of the free parameters $\omega$ and $\mu$.

We consider the point transformation

$$
\begin{aligned}
& x=\sqrt{\frac{8}{3}} a^{\frac{3}{2}} \cosh \left(\sqrt{\frac{3}{8}} \phi_{1}\right) \\
& y_{1}=\sqrt{\frac{8}{3}} a^{\frac{3}{2}} \sinh \left(\sqrt{\frac{3}{8}} \phi_{1}\right) \cos \left(\sqrt{\frac{3}{8}} \phi_{2}\right) \\
& y_{2}=\sqrt{\frac{8}{3}} a^{\frac{3}{2}} \sinh \left(\sqrt{\frac{3}{8}} \phi_{1}\right) \sin \left(\sqrt{\frac{3}{8}} \phi_{2}\right) \cos \left(\sqrt{\frac{3}{8}} \phi_{3}\right) \\
& \ldots \\
& y_{N-1}=\sqrt{\frac{8}{3}} a^{\frac{3}{2}} \sinh \left(\sqrt{\frac{3}{8}} \phi_{1}\right) \prod_{\beta=2}^{N-1} \sin \left(\sqrt{\frac{3}{8}} \phi_{\beta}\right) \cos \left(\sqrt{\frac{3}{8}} \phi_{N}\right) \\
& y_{N}=\sqrt{\frac{8}{3}} a^{\frac{3}{2}} \sinh \left(\sqrt{\frac{3}{8}} \phi_{1}\right) \prod_{\beta=2}^{N} \sin \left(\sqrt{\frac{3}{8}} \phi_{\beta}\right)
\end{aligned}
$$

where the Lagrangian (39) takes the following form

$$
\begin{align*}
L\left(a, \dot{a}, \phi_{\beta}, \dot{\phi}_{\beta}\right)= & -3 a a^{2}+\frac{1}{2} a^{3}\left[\left(\dot{\phi}_{1}\right)^{2}+\sinh ^{2}\left(\sqrt{\frac{3}{8}} \phi_{1}\right)\left(\dot{\phi}_{2}\right)^{2}+\sin ^{2}\left(\sqrt{\frac{3}{8}} \phi_{2}\right)\left(\dot{\phi}_{3}\right)^{2}+\sum_{\beta=3}^{N}\left(\left(\dot{\phi}_{\beta}\right)^{2} \prod_{\gamma=2}^{\beta-1} \sin ^{2}\left(\sqrt{\frac{3}{8}} \phi_{\gamma}\right)\right)\right]+ \\
& -\frac{4}{3} a^{3}\left(\omega_{0}^{2}+\left(\omega_{0}^{2}-\omega_{1}^{2}\right) \sinh ^{2}\left(\sqrt{\frac{3}{8}} \phi_{1}\right)\right) \\
& -\frac{4}{3} a^{3}\left[\left(\left(\omega_{1}^{2}-\omega_{2}^{2}\right)-\left(\left(\omega_{2}^{2}+\omega_{3}^{2}\right)+\left(\omega_{3}^{2}+\ldots\right)\right) \sin ^{2}\left(\sqrt{\frac{3}{8}} \phi_{4}\right)\right) \sin ^{2}\left(\sqrt{\frac{3}{8}} \phi_{2}\right)\right] \\
& -\frac{4}{3} a^{3} \sinh \left(2 \sqrt{\frac{3}{8}} \phi_{1}\right)\left(\sum_{\gamma=2}^{N-1}\left(\prod_{\beta=2}^{\gamma} \sin \left(\sqrt{\frac{3}{8}} \phi_{\beta}\right) \cos \left(\sqrt{\frac{3}{8}} \phi_{N}\right)\right)+\sinh \left(\sqrt{\frac{3}{8}} \phi_{1}\right) \prod_{\beta=2}^{N} \sin \left(\sqrt{\frac{3}{8}} \phi_{\beta}\right)\right) \\
& -\frac{4}{3} a^{3} \sinh \left(2 \sqrt{\frac{3}{8}} \phi_{1}\right)\left(\sum_{(\beta \neq \gamma) \beta, \gamma=2}^{N} \mu_{\beta}\left(y_{\beta} y_{\gamma}\right)\right) . \tag{46}
\end{align*}
$$

The above Lagrangian stands for the multi-scalar fields cosmology which is equivalent to the linear system (43). According to our knowledge, probably this is the first analytic solution for $n$ - interacting scalar field cosmologies presented in the literature.

## 4. CONCLUSIONS

The theory of scalar fields has enriched the understanding of the universe evolution in various ways. From early evolution of the universe to its current state, scalar field theory has played an essential role [1-14]. In particular, the early inflationary scenario, the intermediate matter dominated era, late time accelerating phase as well as the unification of these two accelerating eras have been widely framed into this picture. Usually, in scalar field theory, we consider a single field with a potential, however, the scalar field theory consisting of multiple scalar fields are equally welcome and have been found to offer some exciting results in the context of universe evolution. It has been found that a system of two scalar fields can describe some interesting cosmological consequences, such as the crossing of the cosmological constant boundary ' -1 ' (known as quintom models [33-36]) which for a single scalar field model is impossible since the single scalar field models can only describe either the quintessence or the phantom regime. Moreover, these multi-fluid models are also able to explain the early inflationary universe (known as hybrid inflation) [39 41] with a different graceful exit compared to the standard inflationary paradigm [42 44]. Thus, in many ways, multi-scalar field models are potentially enriched.

In the present work, we have investigated the exact solutions for minimally coupled multi-scalar field models. So far we are concerned with the literature, this is the first time we have presented the exact solutions for the multi-scalar field models. Assuming a spatially flat FLRW geometry of the universe with $N$-number of minimally coupled scalar fields in the context of Einstein gravity, we show that the gravitational field equations can be exactly solved where the component scalar fields may interact with one another via their kinetic and/or potential terms.

The study of the integrability of that cosmological models it is important when we would like to study them either numerical. We can easily infer that the solutions are not sensitive on the initial conditions which means the conclusions which can be made are valid for different initial conditions. On the other hand, these exact solutions can be used as toy models for the general study of some families of multi-scalar field cosmologies.

The cosmological evolution of these models, and the application of the exact solutions for the study of various phases of the universe is a subject of special study, but exceeds the scopus of this work. Such an analysis will be published in a forthcoming work.
