Abstract

This review provides an introduction to non-geometric backgrounds in string theory. Starting from a discussion of T-duality, geometric and non-geometric torus-fibrations are reviewed, generalised geometry and its relation to non-geometric backgrounds are explained and compactifications of string theory with geometric and non-geometric fluxes are discussed. Furthermore covered are doubled geometry as well as non-commutative and non-associative structures in the context of non-geometric backgrounds.

1 Introduction

This review is concerned with non-geometric backgrounds in string theory. Such spaces cannot be described in terms of Riemannian geometry and point-particles cannot be placed into them. String theory on the other hand is a theory of strings — one-dimensionally extended objects — and can be well-defined on more general configurations, including non-geometric backgrounds. In this introductory section we briefly review some basic aspects of string theory in view of their application to non-geometric backgrounds. We give a heuristic description of the latter, and we summarise the topics discussed in this work.

1.1 String theory

String theory is in some way the most simple generalisation of a point-particle theory: the one-dimensional world-line is replaced by a two-dimensional world-sheet. At the level of the action this means that the length of the world-line is replaced by the area of the world-sheet

$$\mathcal{S} = -m \int_{\Gamma} ds \quad \longrightarrow \quad \mathcal{S} = -T \int_{\Sigma} dA, \quad (1.1)$$

where ds denotes the line-element on the world-line Γ and dA denotes the area element for the world-sheet Σ . The latter can be an infinite strip corresponding to an open string, or an infinite cylinder corresponding to a closed string. Furthermore, in (1.1) m denotes the mass of the point-particle and correspondingly T is the tension of the string. The action for the string shown in (1.1) is called the Nambu-Goto action. However, for quantising string theory one uses the Polyakov action. The Polyakov action is classically equivalent to the Nambu-Goto action and will be introduced in equation (2.1) below.

Conformal field theory

Even though the replacement (1.1) appears rather simple, it has far-reaching consequences. The world-sheet theory of the string has a conformal symmetry and is therefore a conformal field theory (CFT). Moreover, this CFT is two-dimensional for which the corresponding symmetry algebra is infinite dimensional. (For an introduction to conformal field theory in view of string theory see for instance [1].) Such a large symmetry algebra is an important property of string theory, which is absent for point particles.

It turns out that the conformal symmetry of the two-dimensional theory has an anomaly. More concretely, classically the trace of the energy-momentum tensor

$T_{\alpha\beta}$ with $\alpha, \beta = 1, 2$ vanishes, but in the quantised theory its vacuum expectation value is proportional to the central charge c of the CFT

$$\langle T^\alpha{}_\alpha \rangle = -\frac{c}{12} R. \quad (1.2)$$

Here, R denotes the Ricci scalar on the world-sheet Σ of the string. There are many configurations which lead to a vanishing total central charge and therefore to an anomaly-free theory. The most common ones are the bosonic string in 26-dimensional Minkowski space, the type I and type II superstring theories in ten-dimensional Minkowski space, and two heterotic string theories which are combinations of the bosonic and type II theories.

But also more involved settings are possible. For instance, take the type II superstring in four-dimensional Minkowski space times an abstract CFT with central charge $c = 9$. The latter CFT does not need to have an interpretation in terms of ordinary geometry, in fact, it does not even need to have the notion of a dimension. Nevertheless, string theory is well-defined on such spaces. In a very broad sense, these configurations are non-geometric backgrounds.

Quantum gravity

When quantising the two-dimensional world-sheet theory, one finds that the spectrum of the closed string contains a massless mode corresponding to a symmetric traceless two-tensor. This tensor is subject to equations corresponding to a variant of (1.2), and which are displayed in equation (3.31) below. In particular, this symmetric traceless tensor has to satisfy Einstein's equation – and should therefore be identified with the graviton in a theory of quantum gravity. This observation has been corroborated through computations of scattering amplitudes, which verify that this mode has the couplings expected from a graviton. String theory therefore is a theory of quantum gravity. Furthermore, in string theory – opposed to naive quantum-field theories of point particles – for scattering amplitudes certain divergencies are absent and the theory is expected to be finite.

String theory is not only expected to be a theory of quantum gravity, but it also contains gauge degrees of freedom. In type I theories these can be realised for instance by open strings ending on D-branes. The latter are hyper-surfaces on which open strings can end, and their world-volume supports a gauge theory typically with a $U(N)$ gauge group. String theory therefore is a quantum theory in which gauge (open string) and gravitational (closed string) interactions are unified. As such, it provides a valuable framework for studying the nature of our universe.

Dualities

Let us return to superstring theory in a flat Minkowski background. As mentioned, this configuration is consistent only in ten space-time dimensions and five different (supersymmetric) formulations are known: these are the type I superstring, the type IIA and type IIB superstring theories, and the heterotic string with gauge groups $SO(32)$ and $E_8 \times E_8$. However, it turns out that these five superstring theories are related to each other through a web of dualities. We will give a more precise definition of a duality below, but we consider two different theories to be dual to each other if they “describe the same physics”.

Well-known dualities in string theory are so-called T-duality and S-duality, and the former plays an important role in this work.

- T-duality is a phenomenon already present for the bosonic string. Namely, bosonic string theory compactified on a circle of radius R is completely equivalent to a compactification on a circle of radius $1/R$ (in appropriate units). These two compactifications are two distinct configurations, which however describe the same physics. In the case of the superstring, T-duality interchanges type IIA and type IIB string theory compactified on a circle, and the heterotic $SO(32)$ and $E_8 \times E_8$ theories.
- S-duality is a so-called strong-coupling–weak-coupling duality. Examples for S-duality are type IIB string theory in ten dimensions which is dual to itself, and S-duality between the type I superstring and the heterotic $SO(32)$ string theory.

Furthermore, type IIA string theory has as a strong-coupling limit an eleven-dimensional theory called M-theory. In particular, M-theory compactified on a circle has as a low-energy limit the type IIA superstring. M-theory is related also to the heterotic $E_8 \times E_8$ theory via a compactification on S^1/\mathbb{Z}_2 , where the \mathbb{Z}_2 acts on the circle coordinate ϕ as $\mathbb{Z}_2 : \phi \rightarrow -\phi$. In this way all of the five known superstring theories are related to each other [2]. This web of dualities is summarised in figure 1. But, many more duality relations can be found: for instance, mirror symmetry [3] relates type IIA and type IIB theories compactified on Calabi-Yau manifolds to each other, and the AdS/CFT correspondence [4] relates string theory on an AdS space to a conformal field theory without gravity on its boundary.

The rich structure of dualities is one of the outstanding properties of string theory. They make it possible for instance to relate a difficult-to-solve problem to a much easier setting where a solution can be found. Also, when applying duality transformations to known configurations new ones may be discovered. In fact, this is how the topic of this review has been developed: when applying T-

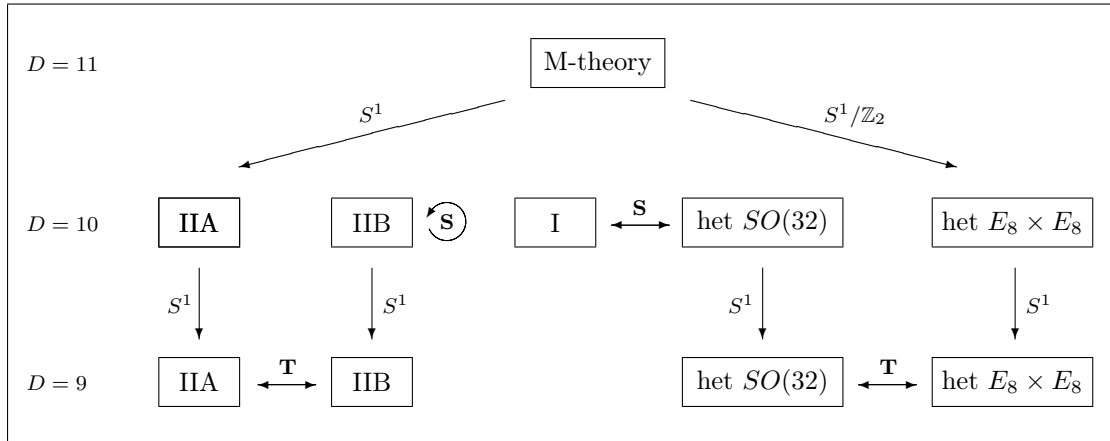

Figure 1: T-duality and S-duality transformations relating the five superstring theories, and their relation to M-theory.

duality transformations to known geometric settings, one can obtain non-geometric backgrounds.

Compactifications

Since string theory is expected to provide a consistent quantum-theory of gravity including gauge interactions, it is natural to try to employ it for the description of our universe. To be able to include ordinary matter we require a supersymmetric world-sheet theory, and for computational convenience such as stability we require the space-time theory to be supersymmetric as well. This leaves us with the five superstring theories mentioned above, realised in ten dimensions.

However, our universe is four-dimensional. To obtain an effectively four-dimensional theory from string theory, one compactifies the latter on a compact six-dimensional space. The choice of this compactification space is restricted by various consistency conditions, but a plethora of discrete and – due to dualities – possibly finite number of choices remains [5]. This abundance of string-theory solutions is called the string-theory landscape [6]. String-theory compactifications can be characterised in different ways, and here we want to briefly mention two approaches:

- Since string theory is a conformal field theory, a compactification can be specified by choosing a particular CFT. We can for instance split the CFT describing string theory into a four-dimensional Minkowski part and a compact part, subject to consistency conditions such as (1.2). Having a CFT description available allows to determine the spectrum to all orders in string-length perturbation theory and to compute for instance scattering amplitudes. How-

ever, for such compactifications it is difficult to study perturbations of the background and it is not always possible to obtain a corresponding geometric interpretation. In a broad sense, the latter cases can therefore be considered to be non-geometric.

- In ten dimensions and at lowest order in string-length perturbation theory, string theory is described by supergravity. Compactifications of string theory in this effective-field-theory description can be characterised by splitting the ten-dimensional Minkowski space into say a four-dimensional part and a compact six-dimensional manifold \mathcal{M} as

$$\mathbb{R}^{1,9} \longrightarrow \mathbb{R}^{1,3} \times \mathcal{M}. \quad (1.3)$$

In order to solve the string-theory equations of motion and preserve supersymmetry in four dimensions, \mathcal{M} is usually required to be a Calabi-Yau three-fold (with all other background fields trivial). However, we can perturb this background by considering non-vanishing vacuum expectation values for instance for p -form field strengths. The latter can be geometric as well as non-geometric fluxes, and we discuss them in detail in this work.

Applications of non-geometric backgrounds

Non-geometric backgrounds are the central theme of this review. We give a more detailed introduction to this topic in section 1.2, but we want to mention already here some of their applications.

- Non-geometric fluxes play a role for string-phenomenology, where they can be used to stabilise moduli. The latter are massless scalar particles usually arising when compactifying a theory, and these particles are incompatible with experimental observations. Non-geometric fluxes can be used to generate a potential for these fields such that they receive a mass and can be integrated out from the low-energy theory.
- In string-cosmology non-geometric fluxes have been used to construct potentials for inflation, with the latter being a period of rapid expansion during the early universe. It has also been argued that non-geometric fluxes can lead to de Sitter vacua with a positive cosmological constant.
- Non-geometric fluxes can furthermore be used to construct non-commutative and non-associative theories of gravity, with the aim to describe the very early universe shortly after the big bang.

- At a more formal level, non-geometric backgrounds can be related to gauged supergravity theories. The latter provide effective four- or higher-dimensional descriptions of string-compactifications with fluxes which preserve some supersymmetry.

1.2 Non-geometric backgrounds

To establish our conventions, let us first note that a transformation which leaves an action functional $\mathcal{S}[\phi]$ invariant (up to boundary terms) will be called a *symmetry*. On the other hand,

The term *duality* will be used for transformations which “leave the physics invariant” – such as a symmetry of the equations of motion or a symmetry of the spectrum – but which is not a symmetry of an action.

We now want to give a more precise definition of non-geometric backgrounds in string theory. The term *non-geometry* is used rather broadly in the literature and does not have a unique meaning. However, let us give the following four characterisations:

- A non-geometric background is a string-theory configuration ...
1. which cannot be described in terms of Riemannian geometry.
 2. in which the left- and right-moving sector of a closed string behave differently.
 3. in which T-duality transformations are needed to make the background well-defined.
 4. in which T-duality transformations are needed to make the background well-defined, but which is *not* T-dual to a background described in terms of Riemannian geometry.

Note that characterisation four is a special case of characterisation three, three is a special case of two, and characterisation two is a special case of characterisation one. Furthermore, the term “string-theory configuration” has been chosen with some care, since not all backgrounds to be considered below are solutions to the equations-of-motion of string theory. In the following we discuss these four characterisations in some more detail.

Characterisation 1

As mentioned before, string theory is a two-dimensional conformal field theory. For a consistent quantum theory the Weyl anomaly (1.2) has to vanish, and one of the simplest examples satisfying this condition is the 26-fold copy of the free boson CFT describing the bosonic string moving in 26-dimensional Minkowski space. However, more complicated CFTs can be used as well to obtain a vanishing Weyl anomaly. Examples are Wess-Zumino-(Novikov-)Witten models (WZW models) [7–9] and Gepner models [10, 11].

For the latter two there are regimes in their parameter space where a geometric description in terms of a metric and other background fields is not possible, even though these backgrounds are well-defined in string-theory. For the $SU(2)$ WZW model at level k this happens for instance at small values of k , and for Gepner models for instance at the Gepner point of the quintic. Hence, according to our characterisation 1, these configurations are non-geometric.

Note furthermore that spaces with singularities, such as orbifolds with fixed points, are not Riemannian either. String theory is well-defined on such backgrounds [12, 13], however, usually these are not considered to be non-geometric.

Characterisation 2

In string theory, the left- and right-moving sector of a closed string are decoupled at tree-level and can be treated independently. At one-loop, modular invariance of the partition function imposes constraints on the coupling between the two sectors, but this still allows for non-trivial solutions. If the left- and right-moving sector are different from each other, it is in general not possible to give a geometric interpretation of the background. The space is therefore called non-geometric. Loosely speaking, the left- and right-moving sectors *see two different geometries* which from a point-particle's point of view cannot be combined into a consistent picture (see figure 2). However, for a string such backgrounds are well-defined. Examples for such constructions are asymmetric orbifolds [14, 15], which we discuss below.

We restrict the difference between the left- and right-moving part of the closed string to the sector describing the metric and Kalb-Ramond B -field. In particular, the heterotic string (for which one sector is the bosonic string and the other is the superstring) has in general a geometric interpretation of the target space and hence is not considered to be a non-geometric configuration.

Characterisation 3

The third characterisation of non-geometric backgrounds employed in the literature is using T-duality: non-geometric spaces are string-theory configurations which can

Figure 2: Illustration of left- and right-moving excitations of the closed string. Each sector “sees” its own geometry A and B, respectively, which do not need to agree. In this case a point-particle interpretation of the background is not possible, and the space is called non-geometric according to characterisation 2.

be made globally well-defined using T-duality transformations as transition maps between local charts [16]. Similarly, monodromies around defects may contain T-duality transformations, leading to a non-geometric background.

Using duality transformations to obtain a global description of a background is not unique to non-geometric backgrounds. Let us discuss this point in some more detail using the illustrations in figure 3.

- In type IIB string theory (p, q) seven-branes are defects which have a two-dimensional transversal space as illustrated in figure 3a. When encircling this defect with the axio-dilaton field τ , the latter undergoes a monodromy transformation which is contained in the S-duality group $SL(2, \mathbb{Z})$. This means that this string-theory configuration is made globally well-defined using a duality transformation.
- A similar mechanism is at work for non-geometric backgrounds (according to the present characterisation). When encircling a non-geometric defect with the metric G and Kalb-Ramond B -field, a T-duality transformation is needed in order to make the background globally well-defined (see figure 3b).

Characterisation 4

Another definition of non-geometric backgrounds which can be found in the literature is as in characterisation 3 above, but which furthermore satisfies that it cannot be T-dualised to a geometric background. More concretely, a subset of T-duality transformation is used to make the background well-defined, and there does not exist another T-duality transformation which maps the configuration to

Figure 3: Illustration of how a field configuration can be made well-defined using a duality transformation. The angular coordinate is denoted by x with identification $x \sim x + 1$. For type IIB string theory shown in figure 3a the singularity is a (p, q) seven-brane, the field τ is the axio-dilaton, and the duality transformation is S-duality. For non-geometric backgrounds illustrated in figure 3b the fields are the metric G and Kalb-Ramond B -field and the duality transformation is T-duality.

a geometric setting. According to this characterisation, the family of backgrounds arising from a three-dimensional toroidal compactification with H -flux (discussed in section 5) does not contain a non-geometric background.

Remark

In this work we are not restricting ourselves to one particular definition of non-geometric backgrounds in string theory, but discuss examples which fit into different characterisations. Nevertheless, the central theme is that of T-duality and therefore our discussion is closely related to T-duality in string theory.

1.3 Structure of this review

In this review we discuss non-geometric backgrounds from various points of view. Since some of these backgrounds can be obtained from T-duality transformations of ordinary geometric configurations, we begin with a brief review of T-duality:

- In section 2 we review T-duality transformations for toroidal compactifications. For these spaces a CFT description is available, and hence the dual backgrounds can be obtained to all orders in string-length perturbation theory. In section 2.2 we first discuss T-duality for the circle, and in section 2.3 we study the generalisation to D -dimensional toroidal backgrounds. The

main result is that such T-duality transformations are realised as $O(D, D, \mathbb{Z})$ transformations.

- In section 3 we turn to T-duality transformations for curved backgrounds. Here a CFT description is usually not available, but the dual configurations can be obtained via the Buscher rules. The latter are valid only at leading order in the string length. We discuss the Buscher rules from different perspectives, using the ordinary sigma-model description as well as a description in terms of WZW-models. We furthermore discuss the equivalence of the original and T-dual backgrounds.
- In section 4 we give a brief introduction to Poisson-Lie duality, which is a framework to study T-duality for backgrounds with non-abelian isometry groups. This type of duality will not play a bigger role in this work, however, we include this topic for completeness.

After having discussed T-duality in string theory, we then turn to non-geometric backgrounds and mostly follow our characterisation three from section 1.2.

- In section 5 we consider the prime example for a non-geometric background and start from a three-torus with H -flux. We show how applying successive T-duality transformations first leads to a twisted torus, and how a second T-duality leads to a non-geometric T-fold. We also associate corresponding geometric and non-geometric fluxes to these backgrounds.
- In section 6 we formalise these findings and consider torus fibrations. For a D -dimensional toroidal fibre the duality group is given by $O(D, D, \mathbb{Z})$ transformations, which can be used as transition functions between local patches. In section 6.1 we revisit the three-torus example and rephrase it using the language of torus fibrations, and in section 6.2 we discuss generalisations thereof. We also construct new examples of non-geometric torus fibrations. In section 6.3 we consider \mathbb{T}^2 -fibrations over a two-sphere, and in section 6.4 we consider the punctured plane as a base-manifold. The latter setting includes the well-known examples of the NS5-brane, Kaluza-Klein monopole and non-geometric 5_2^2 -brane.

Torus fibrations with T-duality transformations as transition functions provide explicit examples for non-geometric backgrounds. Using this knowledge, we then describe such spaces from a more general point of view.

- In section 7 we review the framework of generalised geometry. In this approach one enlarges the tangent-space of a manifold to a generalised tangent-space. This allows for a natural action of the group $O(D, D)$ on the geometry,

which is related to T-duality transformations. After introducing the basic concepts in section 7.1 and giving a more mathematical description in section 7.2, in section 7.3 we discuss the Buscher rules in this framework. In section 7.4 we give a more precise definition of (non-)geometric fluxes using the Courant bracket, and section 7.5 contains a treatment of T-duality transformations in generalised geometry. Finally, in sections 7.6 and 7.7 we consider frame transformations and Bianchi identities.

- In section 8 we discuss non-geometric backgrounds from an effective field-theory point of view. We compactify type II string theory from ten to four dimensions on manifolds with $SU(3) \times SU(3)$ structure, and include geometric as well as non-geometric fluxes. In section 8.2 we give a review of four-dimensional $\mathcal{N} = 2$ and $\mathcal{N} = 1$ supergravity theories, and in sections 8.5 and 8.6 we show how fluxes modify the four-dimensional theory by introducing a gauging of global symmetries. We discuss generalised Scherk-Schwarz reductions in section 8.7, and we comment on the validity of non-geometric solutions and their applications to string phenomenology in sections 8.8 and 8.9.

In the final parts of this review we explain how non-geometric backgrounds can lead to non-commutative and non-associative structures.

- First, in section 9, we review doubled geometry which is a framework where not only the tangent-space of a manifold is doubled but also the space itself. This allows for the construction of a world-sheet theory invariant under T-duality transformations and for a geometric description of non-geometric backgrounds. We also briefly discuss double field theory.
- In section 10 we then explain how non-commutative and non-associative structures can appear in string theory. This includes the derivation of a non-associative tri-product via correlation functions in section 10.1, as well as the derivation of a non-associative phase-space algebra in sections 10.2 and 10.3. We also show how the latter are related to asymmetric orbifolds. In section 10.4 we review topological T-duality and how non-commutativity and non-associativity arises.

A summary of the topics discussed in this review as well as of those omitted can be found in section 11.

2 T-duality in conformal field theory

Non-geometric backgrounds in string theory are closely related to T-duality transformations. In order to prepare for our subsequent discussion, in this section we give a brief introduction to T-duality for toroidal compactifications. For such backgrounds there exists a conformal-field-theory description, which makes it possible to obtain results to all orders in string-length perturbation theory. The standard review on this topic can be found in [17], and we mention that our notation follows in parts [18].

2.1 Prerequisites

We start by fixing our conventions for the world-sheet action of the closed string and by stating some results needed below.

World-sheet action

In the following we consider the closed bosonic string, but most of the results carry over to the superstring. The Polyakov action takes the following general form

$$\mathcal{S} = -\frac{1}{4\pi\alpha'} \int_{\Sigma} \left[G_{\mu\nu} dX^{\mu} \wedge \star dX^{\nu} - B_{\mu\nu} dX^{\mu} \wedge dX^{\nu} + \alpha' \mathbf{R} \phi \star 1 \right], \quad (2.1)$$

where $G_{\mu\nu} = \eta_{\mu\nu}$ with $\mu, \nu = 0, \dots, 25$ is the 26-dimensional Minkowski space metric, $B_{\mu\nu}$ describes a constant B -field and ϕ denotes the dilaton. The two-dimensional world-sheet (without boundary) is denoted by Σ , and the string length ℓ_s is related to the dimension-full constant α' via $\ell_s = 2\pi\sqrt{\alpha'}$. For later convenience we employed a differential-form notation together with the Hodge star-operator as follows

$$\begin{aligned} dX^{\mu} \wedge \star dX^{\nu} &= \sqrt{|h|} d^2\sigma h^{\alpha\beta} \partial_{\alpha} X^{\mu} \partial_{\beta} X^{\nu}, & \star 1 &= \sqrt{|h|} d^2\sigma, \\ dX^{\mu} \wedge dX^{\nu} &= d^2\sigma \epsilon^{\alpha\beta} \partial_{\alpha} X^{\mu} \partial_{\beta} X^{\nu}, \end{aligned} \quad (2.2)$$

where $\{\sigma^0, \sigma^1\}$ are the world-sheet time and space coordinates, $h_{\alpha\beta}$ is the world-sheet metric, h denotes its determinant, and the epsilon-symbol takes values $\epsilon^{\alpha\beta} = \pm 1$. \mathbf{R} denotes the Ricci scalar corresponding to the world-sheet metric $h_{\alpha\beta}$.

In sections 2.2 and 2.3 we will mostly be interested in cylindrical world-sheets Σ of the form $\Sigma = \mathbb{R} \times S^1$, with the non-compact direction corresponding to the world-sheet time coordinate $\sigma^0 \equiv \tau$ and the circle corresponding to the world-sheet space coordinate $\sigma^1 \equiv \sigma$ defined via the identifications $\sigma \sim \sigma + \ell_s$. Accordingly, we impose periodicity conditions for the fields $X^{\mu}(\tau, \sigma)$ along the σ^1 -direction as $X^{\mu}(\tau, \sigma + \ell_s) = X^{\mu}(\tau, \sigma)$. Using then the reparameterisation and Weyl symmetries

of the world-sheet action, we can bring (2.1) into conformal gauge in which the world-sheet metric takes the form $h_{\alpha\beta} = \eta_{\alpha\beta}$. Introducing in addition light-cone coordinates $\sigma^\pm = \sigma^0 \pm \sigma^1$, the above action can be expressed as

$$\mathcal{S} = -\frac{1}{2\pi\alpha'} \int_{\Sigma} d^2\sigma \partial_+ X^\mu (G_{\mu\nu} - B_{\mu\nu}) \partial_- X^\nu, \quad (2.3)$$

and the equations of motion for X^μ are obtained by varying the action (2.3) with respect to X^μ , leading to

$$0 = \partial_+ \partial_- X^\mu. \quad (2.4)$$

2.2 Conformal field theory for S^1

Let us now compactify the closed bosonic string on a circle S^1 and study how T-duality transformations act on this background. Recall also that we consider the world-sheet Σ to be the infinite cylinder $\Sigma = \mathbb{R} \times S^1$.

Compactification

Compactifying the bosonic string on a circle of radius R means that we identify say the 25th target-space coordinate as $X^{25} \sim X^{25} + 2\pi R$. For simplicity we also assume that $B_{\mu 25} = 0$, which means that the B -field has no leg along the circle direction. The mode expansion of $X^{25}(\tau, \sigma)$, solving the equations of motion (2.4) and respecting the periodic identification on the space-time circle, then becomes

$$X^{25}(\tau, \sigma) = X_R^{25}(\tau - \sigma) + X_L^{25}(\tau + \sigma), \quad (2.5)$$

with the right- and left-moving fields

$$\begin{aligned} X_R^{25}(\tau - \sigma) &= x_R^{25} + \frac{2\pi\alpha'}{\ell_s} p_R^{25}(\tau - \sigma) + i\sqrt{\frac{\alpha'}{2}} \sum_{n \neq 0} \frac{1}{n} \alpha_n^{25} e^{-\frac{2\pi i}{\ell_s} n(\tau - \sigma)}, \\ X_L^{25}(\tau + \sigma) &= x_L^{25} + \frac{2\pi\alpha'}{\ell_s} p_L^{25}(\tau + \sigma) + i\sqrt{\frac{\alpha'}{2}} \sum_{n \neq 0} \frac{1}{n} \bar{\alpha}_n^{25} e^{-\frac{2\pi i}{\ell_s} n(\tau + \sigma)}. \end{aligned} \quad (2.6)$$

Here we introduced the centre-of-mass coordinates

$$x_R^{25} = \frac{x_0^{25} - c}{2}, \quad x_L^{25} = \frac{x_0^{25} + c}{2}, \quad (2.7)$$

with c an arbitrary constant, and we have defined the right- and left-moving momenta

$$p_R^{25} = \frac{1}{2} \left(\frac{m}{R} - \frac{nR}{\alpha'} \right), \quad p_L^{25} = \frac{1}{2} \left(\frac{m}{R} + \frac{nR}{\alpha'} \right), \quad (2.8)$$

where $n, m \in \mathbb{Z}$ are the momentum and winding numbers. Having a quantised momentum m along a compact direction follows from requiring single-valuedness of the wave function and is common also for point particles. Having a non-vanishing winding number n is however special to strings. In particular, the closed string can wind n times around the compact direction which is not possible for a point particle. The n th winding sector is described by the relation $X^{25}(\tau, \sigma + \ell_s) = X^{25}(\tau, \sigma) + 2\pi n R$.

Promoting the modes appearing in the expansions (2.6) to operators and replacing Poisson brackets by commutators, we obtain the following non-vanishing commutation relations

$$\begin{aligned} [x_L^{25}, p_L^{25}] &= i, & [\alpha_m^{25}, \alpha_n^{25}] &= m \delta_{m+n}, \\ [x_R^{25}, p_R^{25}] &= i, & [\bar{\alpha}_m^{25}, \bar{\alpha}_n^{25}] &= m \delta_{m+n}. \end{aligned} \tag{2.9}$$

Spectrum

The spectrum of the closed bosonic string is determined by the mass formula together with the level-matching condition. These can be written using the following expressions for the left- and right-moving sector

$$\begin{aligned} \alpha' m_R^2 &= 2\alpha' (p_R^{25})^2 + 2(N_R - 1), \\ \alpha' m_L^2 &= 2\alpha' (p_L^{25})^2 + 2(N_L - 1), \end{aligned} \tag{2.10}$$

where $p_{R,L}^{25}$ have been defined in (2.8) and $N_{R,L} = 0, 1, 2, \dots$ denote the number operators counting string excitations in the corresponding sector (in light-cone quantisation). They are expressed using the oscillators as

$$N_R = \sum_{\mu=2}^{25} \sum_{n=1}^{\infty} \alpha_{-n}^{\mu} \alpha_{+n}^{\mu}, \quad N_L = \sum_{\mu=2}^{25} \sum_{n=1}^{\infty} \bar{\alpha}_{-n}^{\mu} \bar{\alpha}_{+n}^{\mu}. \tag{2.11}$$

The combined spectrum is then described by the mass formula

$$\alpha' m^2 = \alpha' m_R^2 + \alpha' m_L^2, \tag{2.12}$$

and is subject to the level-matching condition

$$\alpha' m_R^2 = \alpha' m_L^2. \tag{2.13}$$

T-duality

Next we note that $(p_R^{25})^2$ and $(p_L^{25})^2$ – both appearing in the mass formula (2.12) and in the level-matching condition (2.13) – are invariant under the following \mathbb{Z}_2

action

$$R \rightarrow \frac{\alpha'}{R}, \quad n \leftrightarrow m. \quad (2.14)$$

This symmetry of the spectrum is called T-duality. Note that under this action the spectrum is invariant [19–22] but the momenta (2.8) are mapped as

$$(p_R^{25}, p_L^{25}) \longrightarrow (-p_R^{25}, +p_L^{25}). \quad (2.15)$$

When requiring the physics to be invariant under the duality transformation, we can deduce from the commutation relations (2.9) that also the centre-of-mass positions should be mapped as $(x_R^{25}, x_L^{25}) \rightarrow (-x_R^{25}, +x_L^{25})$. Since these coordinates and momenta appear in the mode expansions (2.6), it is natural to extend the mapping of the zero modes to the full mode expansion in the following way

$$(X_R^{25}, X_L^{25}) \longrightarrow (-X_R^{25}, +X_L^{25}). \quad (2.16)$$

For the oscillators this implies $(\alpha_n^{25}, \bar{\alpha}_n^{25}) \rightarrow (-\alpha_n^{25}, +\bar{\alpha}_n^{25})$, which leaves the number operators (2.11) as well as the commutation relations (2.9) invariant. The mapping (2.16) is therefore indeed a symmetry of the spectrum. However, under this \mathbb{Z}_2 transformation the action (2.3) is not invariant, in particular, we find

$$\partial_+ X_L^{25} \partial_- X_R^{25} \longrightarrow -\partial_+ X_L^{25} \partial_- X_R^{25}, \quad (2.17)$$

showing that (2.16) is not a symmetry but a duality transformation.

Remarks

Let us close this section with the following remarks:

- For the simple example of the closed bosonic string compactified on a circle of radius R , we have seen that the spectrum is invariant under the mapping $R \rightarrow \alpha'/R$ (together with an exchange of momentum and winding numbers). This means that circle-compactifications with radius R and α'/R are indistinguishable as they lead to the same spectrum.
- In addition to the \mathbb{Z}_2 action shown in (2.14), the right- and left-moving momenta-squared $(p_R^{25})^2$ and $(p_L^{25})^2$ are also invariant under

$$R \rightarrow \frac{\alpha'}{R}, \quad n \leftrightarrow -m. \quad (2.18)$$

The momenta are then mapped as $(p_R^{25}, p_L^{25}) \rightarrow (+p_R^{25}, -p_L^{25})$, which correspondingly extends to the right- and left-moving fields X_R^{25} and X_L^{25} . The full T-duality group for a circle compactification is therefore $\mathbb{Z}_2 \times \mathbb{Z}_2$.

- The \mathbb{Z}_2 transformation (2.14) has a fixed point at $R = \sqrt{\alpha'}$ called the self-dual radius. At this point in moduli space additional massless fields with non-vanishing momentum and winding numbers appear in the spectrum and lead to a symmetry enhancement. (See for instance [18] for a textbook discussion of this mechanism.)
- The self-dual radius is sometimes interpreted as the minimal length scale of the string, since radii $R < \sqrt{\alpha'}$ can be mapped via T-duality to $R > \sqrt{\alpha'}$. However, while this is true for the bosonic string, for the superstring this reasoning fails as T-duality maps for instance the type IIA superstring to the IIB theory or the heterotic $E_8 \times E_8$ theory to the heterotic $SO(32)$ superstring.
- In the case of open strings, the two-dimensional world-sheet Σ has boundaries and hence $\partial\Sigma \neq \emptyset$. The simplest example for such a world-sheet is the infinite strip $\Sigma = \mathbb{R} \times \mathbb{I}$ where $\mathbb{I} = [0, \ell_s]$ is a finite interval, and the fields $X^\mu(\tau, \sigma)$ can then have either Neumann or Dirichlet boundary conditions

$$\begin{array}{ll}
\text{Neumann} & \partial_\sigma X^\mu(\tau, \sigma)|_{\partial\Sigma} = 0, \\
\text{Dirichlet} & X^\mu(\tau, \sigma)|_{\partial\Sigma} = \text{const.}
\end{array} \tag{2.19}$$

The directions with Neumann boundary conditions correspond to the world-volume of a Dp -brane, where p denotes the number of spatial dimensions with Neumann boundary conditions. (The time direction is usually assumed to have Neumann conditions.) Furthermore, in addition to the closed-string background fields $G_{\mu\nu}$, $B_{\mu\nu}$ and ϕ , on a D-brane an open-string gauge field a_μ is present. On a single circle this gauge field may take a constant non-trivial vacuum expectation value, which is called a Wilson loop.

Now, under a T-duality transformation along a circle the Neumann and Dirichlet boundary conditions as well as the momentum and winding numbers are interchanged, and the Wilson loop is interchanged with the position of the boundary on the circle. For more details we refer for instance to the textbook discussions in [23, 18].

2.3 Conformal field theory for \mathbb{T}^D

Let us now generalise the above analysis from circle to toroidal compactifications. We include a constant Kalb-Ramond field B in our analysis, and we will see that the duality group is enlarged.

Compactification

A D -dimensional toroidal compactification can be specified by the identification of D coordinates X^l (in a vielbein basis) as follows

$$X^l \sim X^l + 2\pi L^l, \quad L^l = \sum_{i=1}^D e^l_i n^i, \quad n^i \in \mathbb{Z}, \quad (2.20)$$

where $l = \{25 - D, \dots, 25\}$ labels the compactified directions. The D vectors $e_i = \{e^l_i\}$ are D -dimensional and are required to be linearly-independent, and therefore generate a D -dimensional lattice. Their duals will be denoted by $\bar{e}^i = \{\bar{e}^i_l\}$ which are specified by $\bar{e}^i_l e^l_j = \delta^i_j$. Turning to the fields $X^l(\tau, \sigma)$, similarly as in (2.5) the mode expansions can be split into a left- and right-moving sectors for which we find

$$\begin{aligned} X^l_R(\tau - \sigma) &= x^l_R + \frac{2\pi\alpha'}{\ell_s} p^l_R(\tau - \sigma) + i\sqrt{\frac{\alpha'}{2}} \sum_{n \neq 0} \frac{1}{n} \alpha_n^l e^{-\frac{2\pi i}{\ell_s} n(\tau - \sigma)}, \\ X^l_L(\tau + \sigma) &= x^l_L + \frac{2\pi\alpha'}{\ell_s} p^l_L(\tau + \sigma) + i\sqrt{\frac{\alpha'}{2}} \sum_{n \neq 0} \frac{1}{n} \bar{\alpha}_n^l e^{-\frac{2\pi i}{\ell_s} n(\tau + \sigma)}, \end{aligned} \quad (2.21)$$

where the momenta are expressed in terms of the momentum numbers $m_i \in \mathbb{Z}$ and winding numbers n^i as

$$\begin{aligned} p^l_R &= \frac{1}{2\alpha'} \delta^{lj} \bar{e}_j^i \left(\alpha' m_i - g_{ij} n^j - b_{ij} n^j \right), \\ p^l_L &= \frac{1}{2\alpha'} \delta^{lj} \bar{e}_j^i \left(\alpha' m_i + g_{ij} n^j - b_{ij} n^j \right). \end{aligned} \quad (2.22)$$

The non-trivial information about the metric of the compact space is contained in the lattice vectors e_i . In the vielbein basis employed in (2.20) the corresponding metric is trivial, i.e. $G_{IJ} = \delta_{IJ}$, whereas in the lattice basis the metric and B -field take the form

$$g_{ij} = e_i^l \delta_{lj} e^l_j, \quad b_{ij} = e_i^l B_{lj} e^l_j. \quad (2.23)$$

To make contact with our conventions in section 2.2, let us choose $e^{25}_1 = R$ and $\bar{e}^{1}_{25} = 1/R$ from which we find $g_{11} = R^2$. Since furthermore $b_{11} = 0$ due to the anti-symmetry of the Kalb-Ramond field, we recover the expressions (2.8) from (2.22).

Let us finally note that when promoting the modes appearing in the expansion (2.21) to operators and replacing Poisson brackets by commutators, the corre-

spending non-trivial commutation relations read

$$\begin{aligned} [x_L^I, p_L^J] &= i \delta^{IJ}, & [\alpha_m^I, \alpha_n^J] &= m \delta_{m+n} \delta^{IJ}, \\ [x_R^I, p_R^J] &= i \delta^{IJ}, & [\bar{\alpha}_m^I, \bar{\alpha}_n^J] &= m \delta_{m+n} \delta^{IJ}. \end{aligned} \quad (2.24)$$

Spectrum

The spectrum of the closed bosonic string compactified on a torus can again be expressed using

$$\begin{aligned} \alpha' m_R^2 &= 2\alpha' (p_R)^2 + 2(N_R - 1), \\ \alpha' m_L^2 &= 2\alpha' (p_L)^2 + 2(N_L - 1), \end{aligned} \quad (2.25)$$

where $p_{R,L}^2 = p_{R,L}^I \delta_{IJ} p_{R,L}^J$ and $N_{R,L}$ take a similar form as in (2.11). The right- and left-moving momenta-squared p_R^2 and p_L^2 are now expressed in the following way

$$\begin{aligned} 2\alpha' p_{R,L}^2 &= \frac{\alpha'}{2} m^T g^{-1} m + \frac{1}{2\alpha'} n^T (g - b g^{-1} b) n + n^T b g^{-1} m \mp n^T m \\ &= \frac{1}{2} \begin{pmatrix} n \\ m \end{pmatrix}^T \begin{pmatrix} \frac{1}{\alpha'} (g - b g^{-1} b) & +b g^{-1} \\ -g^{-1} b & \alpha' g^{-1} \end{pmatrix} \begin{pmatrix} n \\ m \end{pmatrix} \\ &\quad \mp \frac{1}{2} \begin{pmatrix} n \\ m \end{pmatrix}^T \begin{pmatrix} 0 & \mathbb{1} \\ \mathbb{1} & 0 \end{pmatrix} \begin{pmatrix} n \\ m \end{pmatrix}, \end{aligned} \quad (2.26)$$

with the upper sign corresponding to p_R^2 and the lower sign to p_L^2 and with matrix multiplication understood. A commonly-used convention is to denote the $2D \times 2D$ dimensional matrices appearing in (2.26) as [24]

$$\mathcal{H} = \begin{pmatrix} \frac{1}{\alpha'} (g - b g^{-1} b) & +b g^{-1} \\ -g^{-1} b & \alpha' g^{-1} \end{pmatrix}, \quad \eta = \begin{pmatrix} 0 & \mathbb{1} \\ \mathbb{1} & 0 \end{pmatrix}, \quad (2.27)$$

where \mathcal{H} is also called the generalised metric. Note that the index structure of the identity matrix $\mathbb{1}$ in η is δ_i^j for the upper-right and δ^i_j for the lower-left part. The combined mass formula and the level-matching condition are again given by

$$\alpha' m^2 = \alpha' m_R^2 + \alpha' m_L^2, \quad \alpha' m_R^2 = \alpha' m_L^2. \quad (2.28)$$

Invariance of the spectrum

Next, we want to determine which transformations leave the spectrum determined by (2.28) invariant. This amounts to requiring (2.26) to be separately invariant

for both sign-choices. Let us first note that under

$$\begin{pmatrix} n \\ m \end{pmatrix} \rightarrow \begin{pmatrix} \tilde{n} \\ \tilde{m} \end{pmatrix} = \mathcal{O} \begin{pmatrix} n \\ m \end{pmatrix} \quad \text{with} \quad \mathcal{O}^T \eta \mathcal{O} = \eta \quad (2.29)$$

the last term in (2.26) stays invariant. The condition $\mathcal{O}^T \eta \mathcal{O} = \eta$ is the defining property of the split orthogonal matrices, and since the transformed \tilde{n}^i and \tilde{m}_i are again required to be integers, we have in particular

$$\mathcal{O} \in O(D, D, \mathbb{Z}). \quad (2.30)$$

From (2.29) we can furthermore infer that $\mathcal{O}^{-1} = \eta \mathcal{O}^T \eta$, and for invariance of the first term in (2.26) we have to demand

$$\mathcal{H} \rightarrow \tilde{\mathcal{H}} = \mathcal{O}^{-T} \mathcal{H} \mathcal{O}^{-1}. \quad (2.31)$$

The relation (2.31) determines how the background fields g_{ij} and b_{ij} contained in the matrix \mathcal{H} transform under $O(D, D, \mathbb{Z})$. We thus see that the generalisation of the T-duality group from circle to toroidal compactifications is $O(D, D, \mathbb{Z})$ [25, 24]. Furthermore, note that $O(1, 1, \mathbb{Z}) = \mathbb{Z}_2 \times \mathbb{Z}_2$ and hence the one-dimensional case is properly included.

Duality transformations

To gain some more insight on how the background fields transform, let us parametrise a general $O(D, D, \mathbb{Z})$ transformation as

$$\mathcal{O} = \begin{pmatrix} A & B \\ C & D \end{pmatrix}, \quad (2.32)$$

where A, B, C, D are $D \times D$ matrices over \mathbb{Z} (with the appropriate index structure). These matrices are subject to the constraint $\mathcal{O}^T \eta \mathcal{O} = \eta$, which reads

$$A^T C + C^T A = 0, \quad A^T D + C^T B = \mathbf{1}, \quad B^T D + D^T B = 0, \quad (2.33)$$

and similar relations follow from $\mathcal{O} \mathcal{O}^{-1} = \mathbf{1}$ as

$$A B^T + B A^T = 0, \quad A D^T + B C^T = \mathbf{1}, \quad C D^T + D C^T = 0. \quad (2.34)$$

From equation (2.31) we can then determine the transformation behaviour of the metric g_{ij} and the B -field b_{ij} . We find in matrix notation

$$\tilde{g} = \Omega_{\pm}^{-T} g \Omega_{\pm}^{-1}, \quad \tilde{g} \pm \tilde{b} = \pm \alpha' \left[C \pm \frac{1}{\alpha'} D (g \pm b) \right] \Omega_{\pm}^{-1}, \quad (2.35)$$

where we defined

$$\Omega_{\pm} = A \pm \frac{1}{\alpha'} B(g \pm b). \quad (2.36)$$

Note that when introducing $E_{\pm} = g \pm b$, the second relation in (2.35) can also be expressed as

$$\tilde{E}_{\pm} = \pm \alpha' \frac{\hat{A} E_{\pm} \pm \alpha' \hat{B}}{\hat{C} E_{\pm} \pm \alpha' \hat{D}} \quad \text{for} \quad \hat{\mathcal{O}} \equiv \mathcal{O}^{-1} = \begin{pmatrix} \hat{A} & \hat{B} \\ \hat{C} & \hat{D} \end{pmatrix}, \quad (2.37)$$

with matrix multiplication understood. For the momenta defined in equation (2.22) we first determine the transformation behaviour of $p_{R/L}^i = \bar{e}^i p_{R/L}^l$ (in the lattice basis) under $O(D, D, \mathbb{Z})$ transformations (2.32) as

$$\tilde{p}_R^i = (\Omega_-)^i{}_j p_R^j, \quad \tilde{p}_L^i = (\Omega_+)^i{}_j p_L^j. \quad (2.38)$$

Similarly as before, we may now extend the duality transformations from the momenta to the full mode expansions of X_R and X_L . In particular, in the lattice basis $X_{R,L}^i = \bar{e}^i X_{R,L}^l$ we have

$$\tilde{X}_R^i = (\Omega_-)^i{}_j X_R^j, \quad \tilde{X}_L^i = (\Omega_+)^i{}_j X_L^j. \quad (2.39)$$

As one can check, this leaves the commutation relations (2.24) as well as the number operators $N_{R,L}$ invariant. The extended transformation (2.39) is therefore also a symmetry of the spectrum and of the commutation relations. Let us now determine how the action (2.3) behaves under such $O(D, D, \mathbb{Z})$ transformations. Using (2.35) together with (2.39), we find

$$\partial_+ X_L^T (g - b) \partial_- X_R \quad \longrightarrow \quad \partial_+ X_L^T \Omega_+^T \left[D(g - b) - \alpha' C \right] \partial_- X_R, \quad (2.40)$$

and thus the action is in general not invariant. The $O(D, D, \mathbb{Z})$ transformations are therefore in general duality transformations.

Next, we discuss how the fields X^l in the vielbein basis transform under the duality group. To do so we need the transformation behaviour of the lattice vectors, which can be inferred from the first relation in (2.35). We find

$$\tilde{e}^l{}_i = \mathcal{O}^l{}_j e^j{}_i (\Omega_{\pm}^{-1})^j{}_i, \quad \mathcal{O} \in O(D), \quad (2.41)$$

where $\mathcal{O}^l{}_j$ is an arbitrary $O(D)$ matrix parametrising changes in the frame bundle and where we can use both sign choices of Ω_{\pm} for the transformed lattice vectors. In order to match with the conventions in section 2.2, for convenience we choose the upper sign in Ω_{\pm} and $\mathcal{O} = \mathbb{1}$, which leads to

$$\tilde{X}_R^l = (e \Omega_+^{-1} \Omega_- \bar{e})^l{}_j X_R^j, \quad \tilde{X}_L^l = X_L^l. \quad (2.42)$$

Examples I – general cases

To illustrate how T-duality transformations act on the background fields, let us discuss some examples. The group $O(D, D, \mathbb{Z})$ is generated by elements denoted here as \mathcal{O}_A , \mathcal{O}_B and $\mathcal{O}_{\pm i}$ [25, 24, 26, 27] and which we specify below. In the following we consider the action of these generators separately, whereas a general $O(D, D, \mathbb{Z})$ is a combination of these.

- We start with transformations parametrised by a $D \times D$ matrix $A \in GL(D, \mathbb{Z})$ in the following way

$$\mathcal{O}_A = \begin{pmatrix} A^{-1} & 0 \\ 0 & A^T \end{pmatrix}. \quad (2.43)$$

Note that \mathcal{O}_A has determinant $+1$. Using (2.31), we can work out the transformed generalised metric to be

$$\tilde{\mathcal{H}}(\tilde{g}, \tilde{b}) = \mathcal{O}_A^{-T} \mathcal{H}(g, b) \mathcal{O}_A^{-1} = \mathcal{H}(A^T g A, A^T b A), \quad (2.44)$$

and hence \mathcal{O}_A describes diffeomorphisms of the background geometry. From the relations in (2.42) we see that the coordinates (in the vielbein basis) are invariant under such transformations,

$$\tilde{X}^I_R = X^I_R, \quad \tilde{X}^I_L = X^I_L, \quad (2.45)$$

and from (2.40) we see that also the action is invariant. Therefore, transformations of the form (2.43) are a symmetry of the theory and belong to the so-called geometric group.

- Next, we consider transformations parametrised by an anti-symmetric $D \times D$ matrix B with integer entries as

$$\mathcal{O}_B = \begin{pmatrix} \mathbb{1} & 0 \\ B & \mathbb{1} \end{pmatrix}, \quad (2.46)$$

where the requirement of anti-symmetry of B is due to (2.33). We also note that \mathcal{O}_B has determinant $+1$, and we find

$$\mathcal{O}_B^{-T} \mathcal{H}(g, b) \mathcal{O}_B^{-1} = \mathcal{H}(g, b + \alpha' B). \quad (2.47)$$

The coordinates in the vielbein basis stay invariant under this transformation,

$$\tilde{X}^I_R = X^I_R, \quad \tilde{X}^I_L = X^I_L, \quad (2.48)$$

but according to (2.40) the action changes as

$$\partial_+ X_L^T (g - b) \partial_- X_R \quad \longrightarrow \quad \partial_+ X_L^T (g - [b + \alpha' \mathbf{B}]) \partial_- X_R. \quad (2.49)$$

In general, these shifts of the B -field are therefore not a symmetry of the action but a duality transformation. However, for the special case of $\mathbf{B} = d\Lambda$ with Λ a well-defined one-form on the world-sheet Σ , such shifts are gauge transformations which after integration by parts leave the action invariant.

- There are furthermore transformations parametrised by matrices of the form $E_i = \text{diag}(0, \dots, 1, \dots, 0)$ with the 1 at the i 'th position. Such a transformation is also called a factorised duality and it takes the form

$$\mathcal{O}_{\pm i} = \begin{pmatrix} \mathbb{1} - E_i & \pm E_i \\ \pm E_i & \mathbb{1} - E_i \end{pmatrix}. \quad (2.50)$$

We note that the determinant of $\mathcal{O}_{\pm i}$ is -1 . The transformation of the background fields can be worked out as follows

$$\begin{aligned} \tilde{g}_{ii} &= \frac{\alpha'^2}{g_{ii}}, \\ \tilde{g}_{mi} &= \pm \alpha' \frac{b_{mi}}{g_{ii}}, & \tilde{b}_{mi} &= \pm \alpha' \frac{g_{mi}}{g_{ii}}, \\ \tilde{g}_{mn} &= g_{mn} - \frac{g_{mi}g_{ni} - b_{mi}b_{ni}}{g_{ii}}, & \tilde{b}_{mn} &= b_{mn} - \frac{b_{mi}g_{ni} - g_{mi}b_{ni}}{g_{ii}}, \end{aligned} \quad (2.51)$$

where $m, n \neq i$ and where the two sign choices correspond to the two possible signs in (2.50). Under this transformation, the coordinates in the vielbein basis behave as

$$\tilde{X}_R^I = (e \Omega_+^{-1} \Omega_- \bar{e}^T)^I{}_J X_R^J, \quad \tilde{X}_L^I = X_L^I, \quad (2.52)$$

with $\Omega_+ = \mathbb{1} - E_i \pm \frac{1}{\alpha'} E_i (g + b)$ and $\Omega_- = \mathbb{1} - E_i \mp \frac{1}{\alpha'} E_i (g - b)$, and the action transforms as

$$\begin{aligned} \partial_+ X_L^T (g - b) \partial_- X_R \\ \longrightarrow \partial_+ X_L^T \left((g - b) - E_i (g - b) - (g - b) E_i \right) \partial_- X_R. \end{aligned} \quad (2.53)$$

Since the action is not invariant, these transformations are not symmetry but duality transformations.

In addition to the generators of the duality group, for later purpose we also consider so-called β -transformations which we denote by \mathcal{O}_β .

- Such transformations are parametrised by an anti-symmetric $D \times D$ matrix β and take the form

$$\mathcal{O}_\beta = \begin{pmatrix} \mathbb{1} & \beta \\ 0 & \mathbb{1} \end{pmatrix}, \quad (2.54)$$

where the anti-symmetry of β is again due to (2.33). Note that \mathcal{O}_β has determinant $+1$, and that it can be expressed using \mathcal{O}_B and the $O(D, D, \mathbb{Z})$ elements

$$\mathcal{O}_\pm = \begin{pmatrix} 0 & \pm\delta^{-1} \\ \pm\delta & 0 \end{pmatrix}, \quad \mathcal{O}_\pm = \prod_{i=1}^D \mathcal{O}_{\pm i}, \quad (2.55)$$

as

$$\mathcal{O}_\beta = \mathcal{O}_\pm \mathcal{O}_B \mathcal{O}_\pm \quad \text{where} \quad \beta^{ij} = \delta^{ip} \mathbf{B}_{pq} \delta^{qj}. \quad (2.56)$$

These transformations can be interpreted as first performing a factorised duality along all directions of the torus, then performing a B -transformation, and finally performing again a factorised duality along all directions.

The coordinates in the vielbein basis transform under a β -transformation in the following way

$$\tilde{X}^I{}_R = (e \Omega_+^{-1} \Omega_- \bar{e}^T)^I{}_J X_R^J, \quad \tilde{X}^I{}_L = X^I{}_L, \quad (2.57)$$

with $\Omega_\pm = \mathbb{1} \pm \frac{1}{\alpha'} \beta (g \pm b)$, and the action transforms as

$$\begin{aligned} & \partial_+ X_L^T (g - b) \partial_- X_R \\ \longrightarrow & \partial_+ X_L^T \left(\left[g + \frac{1}{\alpha'} (g\beta b + b\beta g) \right] - \left[b + \frac{1}{\alpha'} (g\beta g + b\beta b) \right] \right) \partial_- X_R. \end{aligned} \quad (2.58)$$

Such β -transformations are therefore in general not a symmetry of the action but are duality transformations.

Examples II – special cases

After having discussed the action of the generators of $O(D, D, \mathbb{Z})$, let us now turn to three particular situations. For all three examples we consider a rectangular torus with vanishing B -field of the form

$$g_{ij} = \text{diag} (R_1^2, R_2^2, \dots, R_D^2), \quad b_{ij} = 0. \quad (2.59)$$

- A duality transformation acting on the background (2.59) via the matrix $\mathcal{O}_{\pm i}$ gives the dual background

$$\tilde{g}_{ij} = \text{diag} \left(R_1^2, \dots, \frac{\alpha'^2}{R_i^2}, \dots, R_D^2 \right), \quad \tilde{b}_{ij} = 0, \quad (2.60)$$

and hence $\mathcal{O}_{\pm i}$ corresponds to a T-duality transformation (2.14) along the direction labelled by i .

- As a second example we consider the two $O(D, D, \mathbb{Z})$ elements given in (2.55). For these transformations the action acquires an overall minus sign

$$\partial_+ X_L^T (g - b) \partial_- X_R \quad \longrightarrow \quad - \partial_+ X_L^T (g - b) \partial_- X_R, \quad (2.61)$$

implying that \mathcal{O}_{\pm} -transformations are not a symmetry of the action. Moreover, for the example of the rectangular torus with vanishing B -field shown in (2.59), the transformations (2.55) result in the dual background [25, 24]

$$\tilde{g}_{ij} = \text{diag} \left(\frac{\alpha'^2}{R_1^2}, \frac{\alpha'^2}{R_2^2}, \dots, \frac{\alpha'^2}{R_D^2} \right), \quad \tilde{b}_{ij} = 0, \quad (2.62)$$

and therefore correspond to a collective T-duality transformation along all directions of the torus.

- As a third example, let us consider a β -transformation acting on the background (2.59). For the anti-symmetric matrix β we choose as the only non-vanishing entries $\beta_{12} = -\beta_{21} = \beta$, and for the transformed background we find

$$\begin{aligned} \tilde{g}_{ij} &= \text{diag} \left(\frac{\alpha'^2 R_1^2}{\alpha'^2 + \beta^2 R_1^2 R_2^2}, \frac{\alpha'^2 R_2^2}{\alpha'^2 + \beta^2 R_1^2 R_2^2}, R_3^2, \dots, R_D^2 \right), \\ \tilde{b}_{12} &= -\tilde{b}_{21} = -\frac{\alpha' \beta R_1^2 R_2^2}{\alpha'^2 + \beta^2 R_1^2 R_2^2}, \end{aligned} \quad (2.63)$$

while all other components of \tilde{b}_{ij} are vanishing.

Remarks

We close our discussion with the following three remarks:

- In this section we have studied $O(D, D, \mathbb{Z})$ transformations for torus compactifications of the closed string. We have seen that a subset of these is symmetries of the action, whereas in general $O(D, D, \mathbb{Z})$ transformations

(a) D2-brane on \mathbb{T}^2 with constant gauge flux \mathcal{F}_{12}

(b) D1-brane wrapping \mathbb{T}^2 at an angle φ

Figure 4: Illustrations of a D2- and a D1-brane wrapping a rectangular two-torus. In figure 4a a D2-brane with a constant gauge flux \mathcal{F}_{12} is shown, and in figure 4b a D1-brane wrapping the \mathbb{T}^2 at an angle φ is illustrated. Under T-duality along one of the circles these two configurations are interchanged.

are duality transformations which only leave the spectrum invariant. In the literature $O(D, D, \mathbb{Z})$ is often called the T-duality group, although not all of these transformations are dualities in the sense of our definition at the beginning of section 1.2.

- The moduli space of toroidal compactifications of the closed string is naively of the form $O(D, D, \mathbb{R})/[O(D, \mathbb{R}) \times O(D, \mathbb{R})]$ [28], where the D^2 degrees of freedom of the metric and B -field correspond to $O(D, D, \mathbb{R})$. Since the spectrum is invariant under separate $O(D, \mathbb{R})$ rotations of the left- and right-moving sector, this part has been divided out.

Furthermore, as we discussed in this section, points in moduli space related by $O(D, D, \mathbb{Z})$ transformations are physically equivalent. The true moduli space therefore takes the form

$$\frac{O(D, D, \mathbb{R})}{O(D, \mathbb{R}) \times O(D, \mathbb{R})} \Big/ O(D, D, \mathbb{Z}). \quad (2.64)$$

- For open strings, a discussion similar to the one on page 19 applies. However, for toroidal compactifications with $D \geq 2$ the open-string gauge field a_μ can be non-constant thus leading to a non-vanishing field-strength $F = da$ on the D-brane. This field strength is usually combined with the Kalb-Ramond field into the gauge-invariant open-string field strength \mathcal{F} as

$$2\pi\alpha'\mathcal{F} = B + 2\pi\alpha'F. \quad (2.65)$$

Furthermore, D-branes can wrap the torus with non-trivial winding numbers along the torus directions. These situations have been illustrated for a two-torus in figures 4.

Under a T-duality transformation along one of the circles of the \mathbb{T}^2 , a D2-brane with constant gauge flux \mathcal{F}_{12} is mapped to a D1-brane wrapping the \mathbb{T}^2 at an angle φ determined by

$$\cot \varphi = 2\pi\alpha'\mathcal{F}_{12}, \tag{2.66}$$

and vice versa. For more details we refer the reader to [29, 30], and for a textbook discussion for instance to [18].

3 Buscher rules

In this section we extend the previous discussion of T-duality from toroidal compactifications to curved backgrounds. For the latter a CFT description is usually not available, which makes it difficult to quantise the theory and determine how duality transformations act on the spectrum. However, a way to derive T-duality transformations for curved backgrounds is via Buscher's procedure [31, 32], which gives the dual background at leading order in string-length perturbation theory.

3.1 Single T-duality

We first describe the general strategy for studying T-duality transformations of curved backgrounds. We consider T-duality along a single direction, but generalise this discussion to multiple directions in the next section.

World-sheet action

The world-sheet action of the closed bosonic string has been given in equation (2.1). However, for later convenience let us perform a Wick rotation $\sigma^0 \rightarrow -i\sigma^0$ and go to an Euclidean world-sheet. For the action this implies $\mathcal{S} \rightarrow -i\mathcal{S}_E$, where the Euclidean action is given by

$$\mathcal{S}_E = -\frac{1}{4\pi\alpha'} \int_{\Sigma} \left[G_{\mu\nu} dX^\mu \wedge \star dX^\nu - iB_{\mu\nu} dX^\mu \wedge dX^\nu + \alpha' R \phi \star 1 \right], \quad (3.1)$$

but in the following we drop the subscript E. The world-sheet Σ is a two-dimensional (orientable) manifold without boundary, and the Hodge star-operator has been defined in (2.2). The fields X^μ can be considered as maps from the world-sheet Σ to a target space, and the B -field appearing in (3.1) should be understood as the pullback of the target-space quantity B to the world-sheet, i.e. the proper expression reads $\int_{\Sigma} X^*B$. For notational simplicity we however assume that the distinction between world-sheet and target-space quantities is clear from the context. Furthermore, we consider target space-times of the form

$$\mathbb{R}^{1,25-D} \times \mathcal{M}, \quad (3.2)$$

where \mathcal{M} is a D -dimensional compact manifold parametrised by local coordinates X^i with $i = 1, \dots, D$. The non-compact part will not play a role in the discussion in this section.

The equations of motion for the fields X^i are obtained in the usual way from the variation of the action with respect to X^i . For infinitesimal variations $\delta X^i \ll 1$ we find from (3.1)

$$0 = d \star dX^i + \Gamma_{mn}^i dX^m \wedge \star dX^n + \frac{i}{2} H^i{}_{mn} dX^m \wedge dX^n - \frac{\alpha'}{2} G^{im} \partial_m \phi R \star 1, \quad (3.3)$$

where Γ_{jk}^i are the Christoffel symbols computed from the target-space metric G_{ij} , $H = dB$ denotes the field strength of the Kalb-Ramond field B , and the index of H_{ijk} has been raised using the inverse of the metric G_{ij} .

Global symmetry

In order to apply Buscher's procedure and derive the T-duality transformation rules, we require the compact manifold \mathcal{M} to "contain a circle". In more precise terms, we assume that the world-sheet action (3.1) is invariant under a global symmetry of the form

$$\delta_\epsilon X^i = \epsilon k^i(X), \quad (3.4)$$

where $\epsilon \ll 1$ is constant. The action (3.1) is invariant under (3.4) if three conditions are met: 1) $k = k^i \partial_i$ is a Killing vector of the target-space metric G , 2) there exist a one-form v (globally defined on Σ) such that $\mathcal{L}_k B = dv$ [33, 34], and 3) the Lie derivative of the dilaton ϕ in the direction k vanishes. In terms of equations, these three conditions can be summarised as

$$\mathcal{L}_k G = 0, \quad \mathcal{L}_k B = dv, \quad \mathcal{L}_k \phi = 0, \quad (3.5)$$

where $G = \frac{1}{2} G_{ij} dX^i \vee dX^j$ and $B = \frac{1}{2} B_{ij} dX^i \wedge dX^j$ are interpreted as target-space quantities,¹ and where the Lie derivative is given by $\mathcal{L}_k = d \circ \iota_k + \iota_k \circ d$ with ι_k the contraction operator acting as $\iota_{\partial_i} dX^j = \delta_i^j$. The requirement of v being globally-defined restricts the allowed B -field configurations, and we come back to this point on page 37.

Local symmetry

Following Buscher's procedure, we now gauge the global symmetry (3.4), that is, we allow the infinitesimal parameter ϵ to depend on the world-sheet coordinates σ^a . To do so, we introduce a world-sheet gauge field A and replace $dX^i \rightarrow dX^i + k^i A$ for the term involving the metric. For the B -field term the gauging is different due to the one-form v . We furthermore introduce an additional scalar field χ whose role will become clear shortly. The resulting gauged action (restricted to the compact target-space manifold \mathcal{M}) reads

$$\hat{\mathcal{S}} = -\frac{1}{2\pi\alpha'} \int_\Sigma \left[\frac{1}{2} G_{ij} (dX^i + k^i A) \wedge \star (dX^j + k^j A) - \frac{i}{2} B_{ij} dX^i \wedge dX^j - i(v - \iota_k B + d\chi) \wedge A \right], \quad (3.6)$$

¹ The symmetrisation and anti-symmetrisation of the tensor product of differential forms are defined as $dX^i \vee dX^j = dX^i \otimes dX^j + dX^j \otimes dX^i$ and $dX^i \wedge dX^j = dX^i \otimes dX^j - dX^j \otimes dX^i$.

where we ignored the dilaton term which does not get modified in the gauging procedure. The corresponding local symmetry transformations are

$$\hat{\delta}_\epsilon X^i = \epsilon k^i, \quad \hat{\delta}_\epsilon A = -d\epsilon, \quad \hat{\delta}_\epsilon \chi = -\epsilon \iota_k v, \quad (3.7)$$

and the variation of the action (3.6) with respect to (3.7) gives

$$\hat{\delta}_\epsilon \hat{\mathcal{S}} = +\frac{i}{2\pi\alpha'} \int_\Sigma d[\epsilon(v + d\chi)] = 0. \quad (3.8)$$

In the last step we have assumed that the integrand is globally-defined on Σ and we have employed Stokes' theorem.

Simplifying assumptions

Before we proceed let us make some simplifying assumptions. More general situations are considered below.

- We perform a change of coordinates to so-called adapted coordinates, in which the Killing vector takes the form

$$k^i = (1, 0, \dots, 0)^T. \quad (3.9)$$

Locally on the target-space manifold this can always be achieved, provided that $|k| \neq 0$ at that point. The Killing property then implies that

$$k^m \partial_m G_{ij} = \partial_1 G_{ij} = 0, \quad k^m \partial_m H_{ijk} = \partial_1 H_{ijk} = 0, \quad (3.10)$$

and hence the components of the metric and of the H -flux do not depend on the coordinate X^1 .

- We also choose a gauge for the B -field in which the one-form v vanishes. Together with (3.10) this implies that the components B_{ij} do not depend on the variable X^1 , that is

$$\mathcal{L}_k B = 0 \quad \longrightarrow \quad \partial_1 B_{ij} = 0. \quad (3.11)$$

We assume that the above gauge choice can be achieved via a gauge transformation on B , in particular by $B \rightarrow B + d\Lambda$ with Λ a globally-defined one-form satisfying $d\iota_k d\Lambda = dv$.

Back to the ungauged action

We now come to the role of the scalar field χ in the gauged action (3.6). In Buscher's procedure we use χ as a Lagrange multiplier to ensure that during the gauging procedure no additional degrees of freedom are introduced [35–37]. The latter implies that A has to be pure gauge, i.e. $A = d\lambda$ where λ is a globally-defined function on Σ .

In order to discuss this procedure, we need to introduce some notation. We denote a basis of harmonic one-forms on the two-dimensional world-sheet Σ (oriented, without boundary) by

$$\omega^{\mathbf{m}} \in \mathcal{H}^1(\Sigma, \mathbb{R}) \quad \mathbf{m} = 1, \dots, 2g, \quad (3.12)$$

where g denotes the genus of Σ . The group of harmonic one-forms is isomorphic to the first de Rham cohomology group $H^1(\Sigma, \mathbb{R})$, and a basis for the corresponding first homology group will be denoted by $\gamma_{\mathbf{m}} \in H_1(\Sigma, \mathbb{Z})$. The one-cycles and one-forms can be chosen such that $\int_{\gamma_{\mathbf{m}}} \omega^{\mathbf{n}} = \delta_{\mathbf{m}^{\mathbf{n}}}$ and $\int_{\Sigma} \omega^{\mathbf{m}} \wedge \omega^{\mathbf{n}} = J^{\mathbf{m}\mathbf{n}}$, where $J^{\mathbf{m}\mathbf{n}}$ is a non-degenerate matrix with integer entries whose inverse also has integer entries (see for instance page 250 in [38]). Now, using the Hodge decomposition theorem we can express the closed one-form $d\chi$ as

$$d\chi = d\chi_{(0)} + \chi_{(\mathbf{m})}\omega^{\mathbf{m}}, \quad (3.13)$$

where $\chi_{(0)}$ is a globally-defined function on Σ and $\chi_{(\mathbf{m})} \in \mathbb{R}$ are constants, and where a summation over $\mathbf{m} = 1, \dots, 2g$ is understood.

Let us now determine the equation of motion for the Lagrange multiplier by varying the gauged action (3.6) with respect to $\chi_{(0)}$

$$\delta_{\chi_{(0)}} \hat{\mathcal{S}} = -\frac{i}{2\pi\alpha'} \int_{\Sigma} \delta\chi_{(0)} dA \stackrel{!}{=} 0 \quad \longrightarrow \quad F = dA = 0. \quad (3.14)$$

On a topologically-trivial world-sheet a vanishing field strength means that A has to be pure gauge, however, this is not true in general. Indeed, for the closed one-form A we can again perform a Hodge decomposition as

$$A = da_{(0)} + a_{(\mathbf{m})}\omega^{\mathbf{m}}, \quad (3.15)$$

where $a_{(0)}$ is a globally-defined function on Σ and $a_{(\mathbf{m})} \in \mathbb{R}$ correspond to possible Wilson loops $W_{\gamma} = \exp(2\pi i \oint_{\gamma} A)$ of A around one-cycles $\gamma \in H_1(\Sigma, \mathbb{Z})$. Performing now a variation of the action (3.6) with respect to $\chi_{(\mathbf{m})}$ we find

$$\delta_{\chi_{(\mathbf{m})}} \hat{\mathcal{S}} = \frac{i}{2\pi\alpha'} \delta\chi_{(\mathbf{m})} J^{\mathbf{m}\mathbf{n}} a_{(\mathbf{n})} \stackrel{!}{=} 0 \quad \longrightarrow \quad a_{(\mathbf{m})} = 0, \quad (3.16)$$

and A is therefore pure gauge. Using then the gauge symmetry (3.7) we can set $A = 0$ and recover the original action (3.1).

Dual action

In order to obtain the dual action, we integrate out the gauge field A . Since A does not have a kinetic term and is therefore non-dynamical, we can solve for A algebraically. The variation of the action (3.6) with respect to A takes the form

$$\hat{\delta}_A \hat{\mathcal{S}} = +\frac{1}{2\pi\alpha'} \int_{\Sigma} \delta A \wedge \left[G_{11} \star A + \star G_{1i} dX^i + i(d\chi - B_{1i} dX^i) \right], \quad (3.17)$$

leading to the following solution of the equation of motion

$$A = -\frac{1}{G_{11}} \left[G_{1i} dX^i - i \star (d\chi - B_{1i} dX^i) \right], \quad (3.18)$$

where we used that $\star^2 = -1$ acting on a one-form in an Euclidean two-dimensional space. Defining then

$$d\tilde{X}^1 = \pm \frac{1}{\alpha'} d\chi, \quad (3.19)$$

and using (3.18) in the action (3.6), we find

$$\begin{aligned} \check{\mathcal{S}} = -\frac{1}{2\pi\alpha'} \int_{\Sigma} \left[\frac{1}{2} \left(G_{mn} - \frac{G_{m1}G_{n1} - B_{m1}B_{n1}}{G_{11}} \right) dX^m \wedge \star dX^n \right. \\ \left. + \frac{1}{2} \frac{\alpha'^2}{G_{11}} d\tilde{X}^1 \wedge \star d\tilde{X}^1 \pm \alpha' \frac{B_{m1}}{G_{11}} d\tilde{X}^1 \wedge \star dX^m \right. \\ \left. - \frac{i}{2} \left(B_{mn} - \frac{B_{m1}G_{n1} - G_{m1}B_{n1}}{G_{11}} \right) dX^m \wedge dX^n \right. \\ \left. \mp i \alpha' \frac{G_{m1}}{G_{11}} dX^m \wedge d\tilde{X}^1 \mp i \alpha' dX^1 \wedge d\tilde{X}^1 \right], \quad (3.20) \end{aligned}$$

where $m, n = 2, \dots, D$. Due to (3.10) and (3.11) we note that the components G_{ij} and B_{ij} in (3.20) do not depend on the variable X^1 . From (3.20) we can now read-off the dual background fields. Labelling the \tilde{X}^1 -direction again by 1, we find

$$\begin{aligned} \check{G}_{11} &= \frac{\alpha'^2}{G_{11}}, \\ \check{G}_{m1} &= \pm \alpha' \frac{B_{m1}}{G_{11}}, & \check{B}_{m1} &= \pm \alpha' \frac{G_{m1}}{G_{11}}, \\ \check{G}_{mn} &= G_{mn} - \frac{G_{m1}G_{n1} - B_{m1}B_{n1}}{G_{11}}, & \check{B}_{mn} &= B_{mn} - \frac{B_{m1}G_{n1} - G_{m1}B_{n1}}{G_{11}}. \end{aligned} \quad (3.21)$$

These expressions agree with the ones in (2.51), and we have therefore shown that through Buscher's procedure we can recover the known transformation rules of T-duality for a circle.

Momentum/winding modes

Note that we have not yet addressed the last term in the integrated out action (3.20). To do so, we first perform a Hodge decomposition of the closed one-form $dX^1 \in T^*\Sigma$ as

$$dX^1 = dX_{(0)}^1 + X_{(m)}^1 \omega^m, \quad (3.22)$$

where $X_{(0)}^1$ is again a globally-defined function on Σ and $X_{(m)}^1 \in \mathbb{R}$ are constants. Comparing this expression to the mode expansion of the closed string shown for instance in (2.6), we see that the exact part corresponds to the oscillator terms while the harmonic part corresponds to the momentum/winding terms. More specifically, let us assume that the direction X^1 is compactified via the identification

$$X^1 \sim X^1 + 2\pi n, \quad n \in \mathbb{Z}. \quad (3.23)$$

For the mode expansion of X^1 this implies that when going around a basis one-cycle $\gamma_m \subset \Sigma$ on the world-sheet Σ , the function $X^1(\sigma^a)$ does not need to be single-valued but can have integer shifts according to (3.23). In formulas this is expressed as

$$\oint_{\gamma_m} dX^1 = 2\pi n_{(m)}, \quad n_{(m)} \in \mathbb{Z}. \quad (3.24)$$

Therefore, for compactifications (3.23) the coefficients of the harmonic terms in the expansion (3.22) are quantised as $X_{(m)}^1 = 2\pi n_{(m)}$ and $n_{(m)}$ are called the momentum/winding numbers.²

Now, when integrating out the gauge field from the action (3.6) we actually perform the path integral over A . Schematically this path integral reads

$$\hat{\mathcal{Z}} \sim \int \frac{[DX^i][D\chi][DA]}{\mathcal{V}_{\text{gauge}}} e^{\hat{\mathcal{S}}[X,\chi,A]}, \quad (3.25)$$

where $\hat{\mathcal{S}}$ is the gauged action (3.6) and $\mathcal{V}_{\text{gauge}}$ denotes the (infinite) volume of the gauge group. Performing the integration over A leads to the following expression

$$\check{\mathcal{Z}} \sim \int \frac{[DX^1][DX^m][D\chi]}{\mathcal{V}_{\text{gauge}}} e^{\check{\mathcal{S}}[X,\chi]}, \quad (3.26)$$

where $\check{\mathcal{S}}$ is the integrated out action (3.20) and $m = 2, \dots, D$. Let us focus on the X^1 -dependent terms in (3.26). Taking into account the decomposition (3.22) and

² For a two-dimensional world-sheet with Euclidean signature there is no preferred time or space direction, and hence there is no distinction between momentum and winding numbers.

that the $X_{(m)}^1 \in 2\pi\mathbb{Z}$ are quantised, we compute

$$\begin{aligned}
& \int \frac{[DX^1]}{\mathcal{V}_{\text{gauge}}} \exp\left(\frac{i}{2\pi\alpha'} \int_{\Sigma} dX^1 \wedge d\chi\right) \\
&= \int \frac{[DX_{(0)}^1]}{\mathcal{V}_{\text{gauge}}} \sum_{X_{(m)}^1 \in 2\pi\mathbb{Z}} \exp\left(\frac{i}{2\pi\alpha'} \int_{\Sigma} X_{(m)}^1 \omega^m \wedge \chi_{(n)} \omega^n\right) \\
&= \sum_{k^{(m)} \in \mathbb{Z}} \delta\left(\frac{1}{2\pi\alpha'} J^{mn} \chi_{(n)} - k^{(m)}\right).
\end{aligned} \tag{3.27}$$

In the first step we performed an integration by parts to eliminate $X_{(0)}^1$ from the action, and in the second step the integral over $X_{(0)}^1$ was cancelled by $\mathcal{V}_{\text{gauge}}$. The sum over $X_{(m)}^1$ produces then a periodic Kronecker-symbol [35]. Recalling that the inverse of J^{mn} is again a matrix with integer entries and using (3.27) in the path integral (3.26), we see that the coefficients $\chi_{(m)}$ appearing in the Hodge decomposition (3.13) are quantised as

$$\chi_{(m)} \in 2\pi\alpha' \mathbb{Z}. \tag{3.28}$$

For the dual variable \tilde{X}^1 defined via (3.19) this implies that its harmonic part is quantised in units of 2π , and therefore \tilde{X}^1 describes again a compact direction. To summarise, if the direction along which a T-duality transformation is performed is compact with identifications (3.23), then also the dual background has a compact direction as

$$X^1 \sim X^1 + 2\pi n, \quad \implies \quad \tilde{X}^1 \sim \tilde{X}^1 + 2\pi \tilde{n}, \quad n, \tilde{n} \in \mathbb{Z}. \tag{3.29}$$

Dilaton

The relations in (3.21) show how the dual metric and B -field can be expressed in terms of the original background fields. The transformation of the dilaton is however not yet included. The transformation behaviour of the dilaton can be determined via a one-loop path-integral computation, which we will not review here. We only quote the following result for the dual dilaton from [31, 32] as

$$\check{\phi} = \phi - \frac{1}{4} \log \frac{\det G}{\det \tilde{G}}. \tag{3.30}$$

Note that this transformation leaves the combination $e^{-2\phi} \sqrt{\det G}$ invariant. At higher loops the relation (3.30) is modified, which has been discussed in [39].

Conformal symmetry

String theory is a two-dimensional conformal field theory, which for the flat backgrounds with constant B -field and dilaton discussed in section 2 can easily be verified. However, for curved backgrounds with non-constant B -field and dilaton conformality imposes restrictions on the background. In particular, the action (3.1) is conformal (at linear order in α') if the following β -functionals vanish

$$\begin{aligned}
0 &= \beta_{\mu\nu}^G = \alpha' R_{\mu\nu} + 2\alpha' \nabla_\mu \nabla_\nu \phi - \frac{\alpha'}{4} H_{\mu\rho\sigma} H_\nu{}^{\rho\sigma} + \mathcal{O}(\alpha'^2), \\
0 &= \beta_{\mu\nu}^B = -\frac{\alpha'}{2} \nabla^\rho H_{\rho\mu\nu} + \alpha' (\nabla^\rho \phi) H_{\rho\mu\nu} + \mathcal{O}(\alpha'^2), \\
0 &= \beta^\phi = \frac{D - D^{\text{crit.}}}{6} - \frac{\alpha'}{2} \nabla^\rho \nabla_\rho \phi + \alpha' (\nabla^\rho \phi) (\nabla_\rho \phi) - \frac{\alpha'}{24} H_{\rho\sigma\lambda} H^{\rho\sigma\lambda} + \mathcal{O}(\alpha'^2),
\end{aligned} \tag{3.31}$$

where ∇_μ denotes the covariant derivative with respect to the target-space metric $G_{\mu\nu}$, and $D^{\text{crit.}}$ is the critical dimension of the string ($D^{\text{crit.}} = 26$ for the bosonic string under consideration). Since T-duality should “leave the physics invariant”, equations (3.31) have to be invariant under the transformations (3.21) and (3.30). This can indeed be checked.

Global properties of B and v

In Buscher’s procedure for performing T-duality transformations, we have assumed that the world-sheet action has a global symmetry. This imposes restrictions on the background fields which we summarised in equation (3.5). In particular, the Kalb-Ramond field has to satisfy $\mathcal{L}_k B = dv$ with v a globally-defined one-form. However, since in general the two-form gauge field B is not globally-defined also v is in general not globally-defined [40].

To address this point, let us first note that mathematically the Kalb-Ramond field is a gerbe connection and let us summarise some properties of B (see for instance [41–43]). We consider open sets $U_a \subset \mathcal{M}$ and we let $\{U_a\}$ be a good open covering of the compact space \mathcal{M} .³ On n -fold overlaps $U_{a_1} \cap U_{a_2} \cap \dots \cap U_{a_n}$ the B -field has the following properties:

- The field strength of the Kalb-Ramond field (in an open set U_a) is given by $H_a = dB_a$. The field strength is closed, that is $dH_a = 0$.
- On the two-fold overlap of two covers U_a and U_b , with Λ_{ab} a one-form the Kalb-Ramond field satisfies

$$B_a = B_b + d\Lambda_{ab}. \tag{3.32}$$

³In this paragraph the subscripts a, b, c, \dots label the open covers U_a .

- On three-fold overlaps we use (3.32) to derive that $B_a = B_b + d\Lambda_{ab} = B_c + d\Lambda_{bc} + d\Lambda_{ab} = B_a + d\Lambda_{ca} + d\Lambda_{bc} + d\Lambda_{ab}$. Since locally every closed form is exact, on three-fold overlaps the one-forms Λ_{ab} satisfy with λ_{abc} a zero-form

$$\Lambda_{ab} + \Lambda_{bc} + \Lambda_{ca} = d\lambda_{abc}. \quad (3.33)$$

- Similarly, on four-fold overlaps the functions λ_{abc} are required to satisfy

$$\lambda_{bcd} - \lambda_{acd} + \lambda_{abd} - \lambda_{abc} = n_{abcd}, \quad (3.34)$$

where n_{abcd} are constants. If furthermore $n_{abcd} \in 2\pi\mathbb{Z}$, then the field strength H is quantised and $H \in H^3(\mathcal{M}, \mathbb{Z})$.

Let us now turn to the one-form v defined via the second relation in (3.5). On two-fold overlaps we infer from (3.32) that $dv_a = dv_b + d\iota_k d\Lambda_{ab}$, which can be solved by $v_a = v_b + \iota_k d\Lambda_{ab} + d\omega_{ab}$. Here ω_{ab} are functions on two-fold overlaps which satisfy $\omega_{ab} + \omega_{bc} + \omega_{ca} = \text{const.}$ on three-fold overlaps. Choosing then for convenience $\omega_{ab} = \iota_k \Lambda_{ab}$, we arrive at

$$v_a = v_b + \mathcal{L}_k \Lambda_{ab}, \quad \mathcal{L}_k(\Lambda_{ab} + \Lambda_{bc} + \Lambda_{ca}) = 0, \quad (3.35)$$

on two- and three-fold overlaps, respectively. Now, if the background admits an open covering such that on two-fold overlaps the one-forms Λ_{ab} appearing in (3.32) satisfy

$$\mathcal{L}_k \Lambda_{ab} = 0 \quad \longrightarrow \quad v_a = v_b, \quad (3.36)$$

then the one-form v can be made globally-defined. This is the situation to which we have restricted our analysis in this section. A more detailed discussion of global properties of the B -field in relation to T-duality can be found in [40, 41].

Remark

We close this section with the following remarks.

- T-duality transformations can also be viewed as canonical transformations on the world-sheet. This approach has been discussed for instance in the papers [44, 45].
- T-duality for open strings via Buscher's procedure has been studied in [46–48] and more recently in [49, 50], and via canonical transformations in [51, 52]. From an effective field theory point this has been investigated for instance in [53–55].

- In order to perform a T-duality transformation via Buscher's formalism, a (compact) direction of isometry is needed. This includes in particular the case of an angular isometry. To illustrate this point, let us consider the two-dimensional plane in polar coordinates with vanishing B -field and constant dilaton [35]. The background takes the form

$$ds^2 = dr^2 + r^2 d\theta^2, \quad B = 0, \quad \phi = \phi_0, \quad (3.37)$$

with $r \in [0, \infty)$ and $\theta \in [0, 2\pi)$. The vector $k = \partial_\theta$ is a Killing vector of the metric along which we can T-dualise, and using the Buscher rules (3.21) together with (3.30) we find for the dual model

$$\check{d}s^2 = dr^2 + \frac{\alpha'^2}{r^2} d\theta^2, \quad B = 0, \quad \phi = \phi_0 - \log \frac{r}{\sqrt{\alpha'}}. \quad (3.38)$$

From here we see that at the dual metric is singular at the origin. However, since (3.38) is related to (3.37) by a duality transformation, the dual background is expected to be well-defined.

We also mention that T-duality along angular isometries does not necessarily lead to singular dual geometries, which has been exemplified in [56] for the NS5-brane solution.

3.2 Collective T-duality

We now want to generalise the discussion of the previous section to gauging multiple isometries and performing a collective T-duality transformation. In this section we employ a Wess-Zumino-(Novikov-)Witten (WZW) formulation [7–9] of the world-sheet action, in which the field strength H instead of the Kalb-Ramond field B appears. The reason is that

1. this approach avoids subtleties concerning the gauge choice for the Kalb-Ramond field B and the global restrictions shown in (3.36), and
2. from the point of view of the β -functionals (3.31) the field strength H is the relevant quantity and not the gauge potential B .

World-sheet action

The sigma-model action for the closed string is usually defined on a compact two-dimensional manifold without boundaries. However, in order to incorporate non-trivial field strengths $H \neq 0$ for the Kalb-Ramond field, it turns out to be convenient to work with a Wess-Zumino term which is defined on a compact three-dimensional Euclidean world-sheet Ξ with two-dimensional boundary $\partial\Xi = \Sigma$. In

this case, the action (restricted to the compact target-space manifold \mathcal{M} in the splitting (3.2)) takes the form

$$\begin{aligned} \mathcal{S} = & -\frac{1}{2\pi\alpha'} \int_{\Sigma} \left[\frac{1}{2} G_{ij} dX^i \wedge \star dX^j + \frac{\alpha'}{2} \mathbf{R} \phi \star 1 \right] \\ & - \frac{i}{2\pi\alpha'} \int_{\Xi} \frac{1}{3!} H_{ijk} dX^i \wedge dX^j \wedge dX^k, \end{aligned} \quad (3.39)$$

where the Hodge star-operator \star is defined on Σ , and the differential is understood as $dX^i(\sigma^a) = \partial_a X^i d\sigma^a$ with σ^a coordinates on Σ or on Ξ , depending on the context. The indices take values $i, j, k = 1, \dots, D$ with D the dimension of the compact target space \mathcal{M} , and \mathbf{R} denotes the curvature scalar corresponding to the world-sheet metric $h_{\alpha\beta}$ on Σ .

Note that the choice of three-manifold Ξ for a given boundary $\Sigma = \partial\Xi$ is not unique. However, if the field strength H is quantised, the path integral only depends on the data of the two-dimensional theory [57]. In the above conventions, the quantisation condition reads

$$\frac{1}{2\pi\alpha'} \int_{\Xi} H \in 2\pi\mathbb{Z}. \quad (3.40)$$

Global symmetry

As before, we require that the compact target-space manifold contains at least one circle. More precisely, we assume that the world-sheet action (3.39) is invariant under global transformations of the form

$$\delta_{\epsilon} X^i = \epsilon^{\alpha} k_{\alpha}^i(X) \quad (3.41)$$

for ϵ^{α} constant and $\alpha = 1, \dots, N$. This is indeed the case, if the following three conditions are satisfied [33, 34]

$$\mathcal{L}_{k_{\alpha}} G = 0, \quad d(\iota_{k_{\alpha}} H) = 0, \quad \mathcal{L}_{k_{\alpha}} \phi = 0, \quad (3.42)$$

where we used the Bianchi identity $dH = 0$. The isometry algebra generated by the Killing vectors is in general non-abelian with structure constants $f_{\alpha\beta}{}^{\gamma}$, which is encoded in the Lie bracket

$$[k_{\alpha}, k_{\beta}] = f_{\alpha\beta}{}^{\gamma} k_{\gamma}. \quad (3.43)$$

Local symmetries

Let us now promote the global symmetries (3.41) to local ones, with ϵ^α depending on the world-sheet coordinates σ^a . To do so, we introduce world-sheet gauge fields A^α and as well as Lagrange multipliers χ_α , and we solve the second relation in (3.42) as

$$\iota_{k_\alpha} H = dv_\alpha, \quad (3.44)$$

where v_α are one-forms (defined up to closed terms). Note that the v_α are in general *not* globally-defined, however, we require the combination $v_\alpha + d\chi_\alpha$ to be a globally-defined one-form in Ξ [40]. We come back to this point on page 46. The resulting gauged action reads

$$\begin{aligned} \hat{\mathcal{S}} = & -\frac{1}{2\pi\alpha'} \int_{\Sigma} \frac{1}{2} G_{ij} (dX^i + k_\alpha^i A^\alpha) \wedge \star (dX^j + k_\beta^j A^\beta) \\ & - \frac{i}{2\pi\alpha'} \int_{\Xi} \frac{1}{3!} H_{ijk} dX^i \wedge dX^j \wedge dX^k \\ & - \frac{i}{2\pi\alpha'} \int_{\Sigma} \left[(v_\alpha + d\chi_\alpha) \wedge A^\alpha + \frac{1}{2} (\iota_{k_{[\underline{\alpha}}} v_{\underline{\beta}]}) + f_{\alpha\beta}{}^\gamma \chi_\gamma \right) A^\alpha \wedge A^\beta \right], \end{aligned} \quad (3.45)$$

where we again omitted the dilaton term which does not get modified. The local symmetry transformations take the following form

$$\begin{aligned} \hat{\delta}_\epsilon X^i &= \epsilon^\alpha k_\alpha^i, \\ \hat{\delta}_\epsilon A^\alpha &= -d\epsilon^\alpha - \epsilon^\beta A^\gamma f_{\beta\gamma}{}^\alpha, \\ \hat{\delta}_\epsilon \chi_\alpha &= -\iota_{k_{(\underline{\alpha}}} v_{\underline{\beta})} \epsilon^\beta - f_{\alpha\beta}{}^\gamma \epsilon^\beta \chi_\gamma. \end{aligned} \quad (3.46)$$

For the abelian case, this realisation appeared in [37, 40], but here we include the generalisation to the non-abelian case [58]. The action (3.45) is invariant under (3.46) if the following additional restrictions are met

$$\mathcal{L}_{k_{[\underline{\alpha}}} v_{\underline{\beta}]} = f_{\alpha\beta}{}^\gamma v_\gamma, \quad \iota_{k_{[\underline{\alpha}}} f_{\underline{\beta}\underline{\gamma}]}^\delta v_\delta = \frac{1}{3} \iota_{k_\alpha} \iota_{k_\beta} \iota_{k_\gamma} H. \quad (3.47)$$

Note that in the literature sometimes the stronger condition $\iota_{k_{(\underline{\alpha}}} v_{\underline{\beta})} = 0$ is required, which results in the second relation in (3.47) being automatically satisfied and, in the case of an abelian symmetry, the Lagrange multipliers not transforming. Turning to the variation of the action (3.45) with respect to (3.46), we find

$$\hat{\delta}_\epsilon \hat{\mathcal{S}} = -\frac{i}{2\pi\alpha'} \int_{\Sigma} d\epsilon^\alpha \wedge (v_\alpha + d\chi_\alpha) - \frac{i}{2\pi\alpha'} \int_{\Xi} d\epsilon^\alpha \wedge dv_\alpha. \quad (3.48)$$

Recalling that the combination $v_\alpha + d\chi_\alpha$ is required to be globally-defined on Ξ , using Stoke's theorem for the first term we see that the variation (3.48) vanishes, that is $\hat{\delta}_\epsilon \hat{\mathcal{S}} = 0$, and hence (3.46) are symmetries of the gauged action (3.45).

Simplifying assumptions

In order to proceed, we again make some simplifying assumptions. More concretely:

- For most of the formulas in this section we allow for non-abelian isometry algebras with non-vanishing structure constants $f_{\alpha\beta}{}^\gamma$ (as defined in (3.43)), however, eventually we have to restrict to an abelian algebra with $f_{\alpha\beta}{}^\gamma = 0$. An approach to non-abelian T-duality will be discussed in section 4.
- We make a choice of coordinates such that $k_\alpha^m = 0$ for $m = N + 1, \dots, D$. Since the Killing vectors are required to be linearly independent, this implies that the matrix $(k_\alpha)^\beta$ is invertible.
- We assume that the symmetric $N \times N$ matrix $\iota_{(k_\alpha v_{\bar{\beta}})}$ is constant.

Back to the ungauged action

In order to recover the original action from the gauged one, we integrate out the Lagrange multipliers χ_α . The equation of motion for χ_α is obtained by varying the action (3.45) with respect to χ_α , and we find

$$\delta_\chi \hat{\mathcal{S}} = +\frac{i}{2\pi\alpha'} \int_\Sigma \delta\chi_\alpha \left(dA^\alpha - \frac{1}{2} f_{\beta\gamma}{}^\alpha A^\beta \wedge A^\gamma \right), \quad (3.49)$$

from which we can read off the equations of motion as

$$0 = dA^\alpha - \frac{1}{2} f_{\beta\gamma}{}^\alpha A^\beta \wedge A^\gamma. \quad (3.50)$$

Since we have restricted our discussion to abelian isometries, the structure constants $f_{\alpha\beta}{}^\gamma$ vanish and we effectively arrive at the situation discussed in the previous section on page 33. In particular, the equations of motion of each Lagrange multiplier χ_α restricts each A^α to be pure gauge, which can then be set to zero using the local symmetries (3.46). In this way the ungauged action (3.39) is recovered from the gauged one (3.45).

For the non-abelian case a vanishing field strength F^α means that the gauge fields A^α are in general not closed. The Hodge decomposition of A^α then contains coexact terms which makes the analysis more involved. We have therefore restricted ourselves to abelian isometries.

Dual action

Turning now to the dual action, we integrate out the gauge fields A^α from the gauged action (3.45). Due to the absence of a kinetic term for the gauge fields,

the equations of motion are algebraic and can be expressed in the following way

$$0 = \mathcal{G}_{\alpha\beta} \star A^\beta + i \mathcal{D}_{\alpha\beta} A^\beta + \star \mathbf{k}_\alpha + i \xi_\alpha, \quad (3.51)$$

where we used the definitions

$$\begin{aligned} \mathcal{G}_{\alpha\beta} &= k_\alpha^i G_{ij} k_\beta^j, & \xi_\alpha &= d\chi_\alpha + v_\alpha, \\ \mathcal{D}_{\alpha\beta} &= \iota_{k_{[\underline{\alpha}}} v_{\underline{\beta}]} + f_{\alpha\beta}{}^\gamma \chi_\gamma, & \mathbf{k}_\alpha &= k_\alpha^i G_{ij} dX^j. \end{aligned} \quad (3.52)$$

The relation (3.51) is sufficient to eliminate the gauge field A^α from (3.45), and the action with A^α integrated out takes the general form

$$\check{\mathcal{S}} = -\frac{1}{2\pi\alpha'} \int_\Sigma \left(\check{G} + \frac{\alpha'}{2} \mathbf{R} \check{\phi} \star 1 \right) - \frac{i}{2\pi\alpha'} \int_\Xi \check{H}, \quad (3.53)$$

where we defined world-sheet quantities

$$\begin{aligned} \check{G} &= G - \frac{1}{2} (\mathbf{k} + \xi)^T (\mathcal{G} + \mathcal{D})^{-1} \wedge \star (\mathbf{k} - \xi), \\ \check{H} &= H - \frac{1}{2} d \left[(\mathbf{k} + \xi)^T (\mathcal{G} + \mathcal{D})^{-1} \wedge (\mathbf{k} - \xi) \right]. \end{aligned} \quad (3.54)$$

Here, matrix multiplication in the indices α, β, \dots is understood and we use the convention $G = \frac{1}{2} G_{ij} dX^i \wedge \star dX^j$ and $H = \frac{1}{3!} H_{ijk} dX^i \wedge dX^j \wedge dX^k$.

Dual background

From a target-space perspective, the fields in (3.54) depend on the D original one-forms dX^i as well as on the N one-forms $d\chi_\alpha$. The components of \check{G} can hence be interpreted as a ‘‘metric’’ on an enlarged $(D+N)$ -dimensional tangent-space locally spanned by $\{dX^i, d\chi_\alpha\}$, and \check{H} can be interpreted as a corresponding field strength [58]. However, the symmetric matrix \check{G} has N eigenvectors \check{n}_α with vanishing eigenvalue and similarly the contraction of \check{H} with \check{n}_α vanishes. Introducing a basis $dX^I = \{dX^i, d\chi_\alpha\}$ with $I = 1, \dots, D+N$, we can indeed verify that

$$\check{G}_{IJ} \check{n}_\alpha^J = 0, \quad \check{H}_{IJK} \check{n}_\alpha^K = 0, \quad (3.55)$$

where the N vectors are given by

$$\check{n}_\alpha = k_\alpha^i \frac{\partial}{\partial X^i} + (\mathcal{D}_{\alpha\beta} - \iota_{k_\alpha} v_\beta) \frac{\partial}{\partial \chi_\beta}. \quad (3.56)$$

This means that \check{G} and \check{H} are non-vanishing only on a D -dimensional subspace of the enlarged $(D+N)$ -dimensional tangent-space. In order to make this explicit, we perform a change of basis in the following way:

- For the symmetric matrix \check{G}_{IJ} we define an invertible matrix \mathcal{T} and perform the transformation

$$\check{G}_{IJ} = (\mathcal{T}^T \check{G} \mathcal{T})_{IJ}, \quad \mathcal{T}^I{}_J = \left(\begin{array}{ccc|cc} \check{n}_1^1 & \dots & \check{n}_N^1 & & \\ \vdots & & \vdots & 0 & 0 \\ \check{n}_1^N & \dots & \check{n}_N^N & & \\ \vdots & & \vdots & & \\ \check{n}_1^D & \dots & \check{n}_N^D & \mathbf{1} & 0 \\ \hline \vdots & & \vdots & & \\ \check{n}_1^{D+N} & \dots & \check{n}_N^{D+N} & 0 & \mathbf{1} \end{array} \right). \quad (3.57)$$

In the transformed matrix \check{G}_{IJ} all entries along the $I, J = 1, \dots, N$ directions vanish, and we therefore arrive at the expression

$$\check{G}_{IJ} = \left(\begin{array}{cc|cc} 0 & 0 & & \\ \hline 0 & \check{G}_{mn} & \check{G}_m{}^\beta & \\ \hline 0 & \check{G}^\alpha{}_n & \check{G}^{\alpha\beta} & \end{array} \right), \quad (3.58)$$

where $m, n = N + 1, \dots, D + N$ and $\alpha, \beta = 1, \dots, N$. The non-vanishing $D \times D$ block-matrix in (3.58) then corresponds to the dual metric, which takes the explicit form

$$\begin{aligned} \check{G}_{mn} &= G_{mn} - \mathbf{k}_{\alpha m} [(\mathcal{G} + \mathcal{D})^{-1} \mathcal{G} (\mathcal{G} - \mathcal{D})^{-1}]^{\alpha\beta} \mathbf{k}_{\beta n} \\ &\quad - \mathbf{k}_{\alpha m} [(\mathcal{G} + \mathcal{D})^{-1} \mathcal{D} (\mathcal{G} - \mathcal{D})^{-1}]^{\alpha\beta} v_{\beta n} \\ &\quad + v_{\alpha m} [(\mathcal{G} + \mathcal{D})^{-1} \mathcal{D} (\mathcal{G} - \mathcal{D})^{-1}]^{\alpha\beta} \mathbf{k}_{\beta n} \\ &\quad + v_{\alpha m} [(\mathcal{G} + \mathcal{D})^{-1} \mathcal{G} (\mathcal{G} - \mathcal{D})^{-1}]^{\alpha\beta} v_{\beta n}, \end{aligned} \quad (3.59)$$

$$\begin{aligned} \check{G}^\alpha{}_n &= + [(\mathcal{G} + \mathcal{D})^{-1} \mathcal{D} (\mathcal{G} - \mathcal{D})^{-1}]^{\alpha\beta} \mathbf{k}_{\beta n} \\ &\quad + [(\mathcal{G} + \mathcal{D})^{-1} \mathcal{G} (\mathcal{G} - \mathcal{D})^{-1}]^{\alpha\beta} v_{\beta n}, \end{aligned}$$

$$\check{G}^{\alpha\beta} = + [(\mathcal{G} + \mathcal{D})^{-1} \mathcal{G} (\mathcal{G} - \mathcal{D})^{-1}]^{\alpha\beta}.$$

- For the field strength a similar analysis applies. Using the matrix \mathcal{T} defined in (3.57) we determine

$$\check{H}_{IJK} = \check{H}_{LMN} \mathcal{T}^L{}_I \mathcal{T}^M{}_J \mathcal{T}^N{}_K, \quad (3.60)$$

for which we find that the components along the directions X^α vanish

$$\check{H}_{\alpha JK} = 0. \quad (3.61)$$

Due to the derivative appearing for the dual field strength the explicit expressions for the components of \check{H} are more involved and will not be presented here. However, below we discuss the case of a T-duality along a single direction for which we give explicit formulas.

- The components of the dual metric \check{G} and the dual field strength \check{H} may still depend on the coordinates X^α along which the duality transformation has been performed. However, using the local symmetries (3.46) we can set this dependence to zero (in the abelian case).
- We also determine the transformed basis on the enlarged tangent-space, which is given by $e^I = (\mathcal{T}^{-1})^I_J dX^J$. In general, these one-forms take the form

$$\begin{aligned} e^\alpha &= (k^{-1})^\alpha_\beta dX^\beta, \\ e^m &= dX^m - k_\alpha^m (k^{-1})^\alpha_\beta dX^\beta, \\ e_\alpha &= d\chi_\alpha + (\iota_{(k_\alpha^\beta v_\beta)} + f_{\alpha\beta}{}^\gamma \chi_\gamma) (k^{-1})^\beta_\gamma dX^\gamma. \end{aligned} \quad (3.62)$$

The exterior algebra of the dual one-forms $\{e^m, e_\alpha\}$ does not close among itself. However, with the assumptions made on page 42 we see that these forms are closed, that is

$$de^\alpha = 0, \quad de^m = 0, \quad de_\alpha = 0. \quad (3.63)$$

We finally remark that the dual dilaton $\check{\phi}$ is determined by the same expression as given already in equation (3.30).

Example I – single T-duality

We now want to illustrate the above formalism for the case of T-duality along a single direction. We assume that we can use adapted coordinates in which the Killing vector takes the form

$$k = \partial_1, \quad (3.64)$$

and we note that due to having only one isometry the conditions (3.47) are trivially satisfied. For \check{G} given in (3.54) we compute

$$\check{G} = G - \frac{1}{2G_{11}} \left[\mathbf{k} \wedge \star \mathbf{k} - (d\chi + v) \wedge \star(d\chi + v) \right], \quad (3.65)$$

and performing the change of basis (3.57) gives

$$\begin{aligned} \check{G} = & \frac{1}{2G_{11}} e_1 \wedge \star e_1 + \frac{v_n}{G_{11}} e_1 \wedge \star e^n \\ & + \frac{1}{2} \left(G_{mn} - \frac{G_{1m}G_{1n} - v_m v_n}{G_{11}} \right) e^m \wedge \star e^n, \end{aligned} \quad (3.66)$$

where $e_1 = d\chi + v_1 dX^1$ and $e^m = dX^m$. Note that v_1 is assumed to be constant and can therefore be absorbed into the definition of χ . For the field strength we determine

$$\begin{aligned} \check{H} = & \left[\frac{1}{6} H_{mnk} - \frac{1}{2} \frac{G_{1[m} H_{1|nk]}}{G_{11}} + \partial_{[m} \left(\frac{G_{1|n]} v_{k]} \right) \right] e^m \wedge e^n \wedge e^k \\ & + \partial_{[m} \left(\frac{G_{1|n]} \right) e_1 \wedge e^m \wedge e^n. \end{aligned} \quad (3.67)$$

Global properties of H and v_α

Similarly as on page 37, let us also discuss the global properties of H and v_α . Since H is a globally-defined three-form, on the overlap of two open covers U_a and U_b the field strength satisfies $H_a = H_b$ with $H_a \equiv H|_{U_a}$. Assuming the Killing vectors k_α to be globally-defined, we infer from (3.44) that on two-fold overlaps we have

$$\left(\iota_{k_\alpha} H \right)_a = dv_{\alpha|a} = dv_{\alpha|b} = \left(\iota_{k_\alpha} H \right)_b, \quad (3.68)$$

which can be solved by

$$v_{\alpha|a} = v_{\alpha|b} + d\omega_{\alpha|ab}. \quad (3.69)$$

Here, $\omega_{\alpha|ab}$ are functions on two-fold overlaps which satisfy on three-fold overlaps $\omega_{\alpha|ab} + \omega_{\alpha|bc} + \omega_{\alpha|ca} = \text{const}$. Equation (3.69) implies that the one-forms v_α are in general *not* globally-defined. However, if we require the Lagrange multipliers χ_α introduced in the gauged action (3.45) to satisfy on two-fold overlaps [40]

$$\chi_{\alpha|a} = \chi_{\alpha|b} - \omega_{\alpha|ab}, \quad (3.70)$$

it follows that $v_{\alpha|a} + d\chi_{\alpha|a} = v_{\alpha|b} + d\chi_{\alpha|b}$ and hence the combinations $v_\alpha + d\chi_\alpha$ are globally-defined one-forms as required above. For more details on the global properties of H and v_α we again refer the reader to [40, 41].

Example II – $SU(2)$ WZW model

As another example for the formalism described above, let us discuss T-duality for the $SU(2)$ WZW model. This example has been considered for instance in [59,37,17,60,61], and corresponds to a three-sphere with H -flux. It can be specified as follows

$$\begin{aligned} G &= \frac{R^2}{2} \left(d\eta^2 + \sin^2 \eta d\zeta_1^2 + \cos^2 \eta d\zeta_2^2 \right), \\ H &= 2R^2 \sin \eta \cos \eta d\eta \wedge d\zeta_1 \wedge d\zeta_2, \\ \phi &= \phi_0. \end{aligned} \tag{3.71}$$

Here $\zeta_{1,2} \in [0, 2\pi)$ and $\eta \in [0, \pi/2]$, and R denotes the radius of the three-sphere. Our conventions for the metric are again $G = \frac{1}{2} G_{ij} dX^i \vee dX^j$, where the product \vee is however left implicit. The dilaton is taken to be constant, and the corresponding β -functionals (3.31) are vanishing (up to a constant contribution in β^ϕ). The quantisation condition shown in equation (3.40) implies that

$$R^2 = h\alpha', \quad h \in \mathbb{Z}, \tag{3.72}$$

and the isometry algebra of the three-sphere is $\mathfrak{so}(4) \simeq \mathfrak{su}(2) \times \mathfrak{su}(2)$, which contains a $\mathfrak{u}(1) \times \mathfrak{u}(1)$ abelian sub-algebra.

We now want to perform (collective) T-duality transformations along one and two directions for this background.

- Let us start with a duality transformation along the direction $k = \partial_{\zeta_1} + \partial_{\zeta_2}$, which corresponds to the Hopf-fibre of the three-sphere (see for instance [60, 56]). Note that k is globally well-defined and nowhere vanishing. Using the above formalism, the dual background can be obtained as

$$\begin{aligned} \check{G} &= \frac{1}{2} \left[\frac{R^2}{4} \left(d\tilde{\eta}^2 + \sin^2 \tilde{\eta} d\tilde{\zeta}^2 \right) + \frac{4}{R^2} \xi^2 \right], \\ \check{H} &= \alpha' \sin \tilde{\eta} d\tilde{\zeta} \wedge d\tilde{\eta} \wedge \xi, \\ \check{\phi} &= \phi_0 + \frac{1}{2} \log \frac{\alpha'}{R^2}, \end{aligned} \tag{3.73}$$

where $\tilde{\eta} = 2\eta$ and $\tilde{\zeta} = \zeta_1 + \zeta_2$, and where the one-form ξ satisfies

$$d\xi = -\frac{R^2}{4} \sin \tilde{\eta} d\tilde{\eta} \wedge d\tilde{\zeta}. \tag{3.74}$$

The form of the dual dilaton has been determined using (3.30). This background corresponds to a circle fibred over a two-sphere [60], which in general

is a so-called lens space. We come back to this point in section 10.4. Furthermore, the β -functionals (3.31) corresponding to (3.73) are vanishing (up to the same constant contribution to β^ϕ) and hence the dual model is again a CFT.

We also note that for $h = 1$ – or alternatively $R^2 = \alpha'$ – the original and T-dual background are related by a change of coordinates. The $SU(2)$ WZW model is therefore self-dual under one T-duality for $R^2 = \alpha'$, i.e. at level $h = 1$.

- We can also perform two T-duality transformations for the three-sphere with H -flux. As Killing vectors we choose $k_1 = \partial_{\zeta_1}$ and $k_2 = \partial_{\zeta_2}$ – which vanish at the isolated points $\eta = 0$ and $\eta = \pi/2$ – and for the corresponding one-forms v_α we make the choice

$$\begin{aligned} v_1 &= +R^2 \left(\cos^2 \eta + \frac{\rho-1}{2} \right) d\zeta_2, \\ v_2 &= -R^2 \left(\cos^2 \eta + \frac{\rho-1}{2} \right) d\zeta_1, \end{aligned} \tag{3.75}$$

where $\rho \in \mathbb{R}$ is a parameter related to the gauge freedom in v_α . Using then (3.59) and (3.60), for the dual background we obtain [56]

$$\begin{aligned} \check{G} &= \frac{1}{2} \left[R^2 d\eta^2 + \frac{4\alpha'^2}{R^2} \frac{1}{\Delta} \left(\sin^2 \eta d\tilde{\zeta}_1^2 + \cos^2 \eta d\tilde{\zeta}_2^2 \right) \right], \\ \check{H} &= \frac{8\alpha'^2}{R^2} \frac{1-\rho^2}{\Delta^2} \sin \eta \cos \eta d\eta \wedge d\tilde{\zeta}_1 \wedge d\tilde{\zeta}_2, \\ \check{\phi} &= \phi_0 - \frac{1}{2} \log \Delta, \end{aligned} \tag{3.76}$$

where $\tilde{\zeta}_{1,2}$ are the coordinates dual to $\zeta_{1,2}$ defined via $\alpha' d\tilde{\zeta}_1 = d\chi_2$ and $\alpha' d\tilde{\zeta}_2 = d\chi_1$, and Δ is given by

$$\Delta = (1 + \rho)^2 \cos^2 \eta + (1 - \rho)^2 \sin^2 \eta. \tag{3.77}$$

For this background the β -functionals (3.31) are again vanishing. The parameter ρ only arises when performing a collective T-duality transformation and corresponds to a gauge choice for $\nu_{k_{[\alpha} v_{\beta]}}$ in $\mathcal{D}_{\alpha\beta}$ shown in (3.52). On the dual side it cannot be removed by diffeomorphisms, and it is interpreted as parametrising a β -transformations in the context of T-duality for curved backgrounds [56].

We also note that for $\rho = 0$ and $R^2 = 2\alpha'$, the dual background (3.76) agrees with the original background (3.71) and hence the model is self-dual under two T-dualities for $R^2 = 2\alpha'$, that is at level $h = 2$.

Comments on non-abelian T-duality

After performing one and two abelian T-dualities for the $SU(2)$ WZW model, it is natural to try to perform a collective (non-abelian) T-duality transformations along three directions. This has been studied for instance in the papers [62, 36, 37, 63–66, 45, 67] from different perspectives.

For the present context we note that the Killing vectors k_α which – together with corresponding one-forms v_α – satisfy the gauging requirements (3.47) belong to the so-called vectorial $\mathfrak{su}(2)$ sub-algebra of the $\mathfrak{su}(2) \times \mathfrak{su}(2)$ isometry algebra. However, in this case the matrix \mathcal{T} shown in (3.57) is singular, and the dual model cannot be obtained. Correspondingly, as explained for instance in [36], if the dual background is obtained by a gauge-fixing procedure then in the case of the above non-abelian T-duality transformation the gauge symmetry does not allow to set the original coordinates to zero and hence the dual model is not obtained. These observations extend to WZW models based on general Lie groups G . Let us comment on two possibilities to avoid this issue:

- The non-abelian T-dual of a WZW model can be obtained by starting from a coset construction and performing a limiting procedure. This approach has been developed in [64].
- Another possibility is to consider principle chiral models, for which the Wess-Zumino term of a WZW model is set to zero. This implies that the H -flux vanishes and that the NS-NS sector of the background does not correspond to a CFT. However, when turning on Ramond-Ramond (R-R) fluxes the β -functionals (3.31) are modified and it is possible to obtain vanishing β -functionals with zero H -flux and non-zero R-R fluxes. In this case the gauging constraints (3.47) are trivially satisfied, and for the $SU(2)$ model one can choose to gauge one of the $\mathfrak{su}(2)$ isometry algebras. For more details we refer to the papers [68–71].

However, in both approaches the full equivalence of the original and dual theory have not been established. Moreover, in many cases the isometry algebra of the dual model is completely broken, and one cannot invert the duality transformation. Nevertheless, non-abelian T-duality is a very useful solution-generating technique at the level of supergravity [72–74]. We finally mention that using a different approach, non-abelian T-duality transformations can be described using Poisson-Lie duality which we discuss in section 4.

3.3 Equivalence of T-dual theories

In section 2 we have discussed T-duality transformations for toroidal string-theory compactifications with constant Kalb-Ramond and dilaton field. In particular, we

have shown that the spectrum – encoded in the torus partition function of the closed string – is invariant under T-duality. (For higher-genus partition functions the invariance under T-duality has been discussed in section 2.3 of [17].) On the other hand, for curved backgrounds a CFT description is usually not available and showing that the spectrum is invariant under T-duality is therefore more difficult. However, we have mentioned that the Buscher rules (3.21) leave the β -functionals (3.31) invariant at linear order in α' . These results indicate that the original and T-dual theory are equivalent, but especially for curved backgrounds further evidence would be desirable. In this respect we note the following:

- T-duality transformations can be argued to be the discrete part of a gauge symmetry [75, 27, 76]. In particular, the original and dual model are related by a gauge transformation, which makes them equivalent as conformal field theories. A detailed discussion of this reasoning can be found for instance in section 2.6 of [17].
- Another approach is to interpret T-duality transformations as a discrete symmetry of a higher-dimensional theory. In particular, in [77–79] it was observed that the so-called axial- and vector-gaugings of an abelian chiral symmetry of a world-sheet sigma-model give two dual versions of that model. As shown in [59], the coset constructions of these two gaugings (that is, the model obtained after integrating out the corresponding gauge field) correspond to the same CFT. This result has been used in [35, 80] to show that T-duality is a symmetry of the conformal field theory, and we discuss this idea in more detail below.
- We also mention that abelian T-duality for WZW models leaves the spectrum invariant, as has been shown explicitly in [81]. The T-dual theory is a certain orbifold of the original WZW model.

In the remainder of this section we explain in some more detail the second approach for showing the equivalence of the original and T-dual theories.

Setting

Following the work of [77–79], the main idea in [35] is to consider a two-torus fibration over a $(D - 1)$ -dimensional base manifold. The $(D + 1)$ -dimensional background is required to have two isometries along the \mathbb{T}^2 -fibre which, similarly as in section 3.1, correspond to symmetries of the world-sheet theory. Depending on which of these two symmetries is gauged and integrated out, one obtains two D -dimensional backgrounds which are related via T-duality. This setting is illustrated in figure 5.

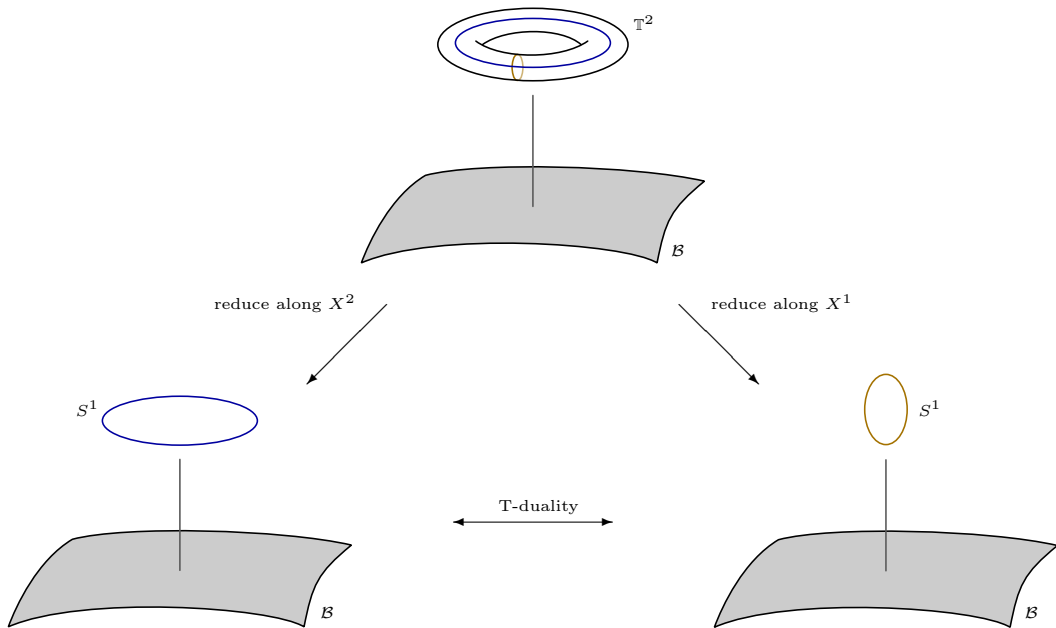

Figure 5: Illustration of the main setting in this section. On top, a \mathbb{T}^2 -fibration over a $(D - 1)$ -dimensional base manifold \mathcal{B} is shown. If one reduces (gauge the corresponding isometry and integrate out the gauge field) along either of the two circles of the two-torus, one obtains two circle-fibrations over \mathcal{B} . These two D -dimensional backgrounds are related via T-duality.

Let us make this more concrete and consider a two-dimensional non-linear sigma-model for a $(D + 1)$ -dimensional target-space. Using indices I, J with values $I = 1, \dots, D + 1$ the action reads

$$\mathcal{S} = -\frac{1}{2\pi\alpha'} \int_{\Sigma} \left[\frac{1}{2} G_{IJ} dX^I \wedge \star dX^J - \frac{i}{2} B_{IJ} dX^I \wedge dX^J + \frac{\alpha'}{2} R \phi \star 1 \right], \quad (3.78)$$

where Σ denotes a two-dimensional world-sheet without boundary. The metric and Kalb-Ramond field take the following explicit form

$$G_{IJ} = \begin{pmatrix} \frac{\alpha'+B}{2} & 0 & \frac{1}{2} G_b^+ \\ 0 & \frac{\alpha'-B}{2} & \frac{1}{2} G_b^- \\ \frac{1}{2} G_a^+ & \frac{1}{2} G_a^- & g_{ab} \end{pmatrix}, \quad B_{IJ} = \begin{pmatrix} 0 & +\frac{1}{2} B & -\frac{1}{2} G_b^- \\ -\frac{1}{2} B & 0 & -\frac{1}{2} G_b^+ \\ +\frac{1}{2} G_a^- & +\frac{1}{2} G_a^+ & b_{ab} \end{pmatrix}, \quad (3.79)$$

and we assume the functions B , G_a^\pm , g_{ab} and b_{ab} to only depend on $(D - 1)$ coordinates X^a with $a = 3, \dots, D + 1$. Note that G_{IJ} and B_{IJ} do not constitute the most general $(D + 1)$ -dimensional sigma-model background but are of rather restricted

form. In particular, they describe a \mathbb{T}^2 -fibration over a $(D - 1)$ -dimensional background with fibre coordinates X^1 and X^2 . Given that the metric G_{IJ} in (3.79) does not depend on X^1 and X^2 , it has at least two abelian isometries generated by the Killing vectors

$$k_{(1)}^I = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} \quad \text{and} \quad k_{(2)}^I = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}. \quad (3.80)$$

We also observe that the action (3.78) with metric and B -field (3.79) is invariant under the following \mathbb{Z}_2 transformation

$$X^1 \longleftrightarrow X^2, \quad B \longleftrightarrow -B, \quad G_a^+ \longleftrightarrow G_a^-. \quad (3.81)$$

As we will show below, this symmetry corresponds to T-duality via the Buscher rules given in (3.21) for the D -dimensional theories.

Reduced background

Let us now reduce the above background from $D + 1$ to D dimensions by gauging one of these isometries (3.80) and integrating out the corresponding gauge field. To do so, we first note that the action (3.78) is invariant under global transformations $\delta X^i = \epsilon k^i$ since

$$\mathcal{L}_k G = 0, \quad \mathcal{L}_k B = dv, \quad \mathcal{L}_k \phi = 0, \quad (3.82)$$

where we included the possibility of a globally-defined one-form v . The gauged action takes the following form

$$\hat{\mathcal{S}} = -\frac{1}{2\pi\alpha'} \int_{\Sigma} \left[\frac{1}{2} G_{IJ} (dX^I + k^I A) \wedge \star (dX^J + k^J A) - \frac{i}{2} B_{IJ} dX^I \wedge dX^J - i(v - \iota_k B) \wedge A \right], \quad (3.83)$$

which is invariant under the local symmetry transformations $\hat{\delta}_\epsilon X^I = \epsilon k^I$ and $\hat{\delta}_\epsilon A = -d\epsilon$ provided that $\iota_k v = 0$. Note that in contrast to our discussion in section 3.1 we have not included a Lagrange multiplier in the gauged action. We recall that the latter was used to impose that the gauge field A is closed, which we require here by hand. Up to rescalings, this leaves the following two possible choices for k and v [35, 82]

$$\begin{aligned} (1) \quad & k = \partial_1, \quad v = \frac{\alpha'}{2} dX^2, \\ (2) \quad & k = \partial_2, \quad v = \frac{\alpha'}{2} dX^1. \end{aligned} \quad (3.84)$$

Integrating out the gauge field, we obtain a world-sheet action describing a D -dimensional target space characterised by the following metric and B -field

$$\check{G}_{ij} = \begin{pmatrix} \alpha' \frac{\alpha' \mp B}{\alpha' \pm B} & + \frac{\alpha}{\alpha' \pm B} G_b^\mp \\ + \frac{\alpha}{\alpha' \pm B} G_a^\mp & g_{ab} \mp \frac{1}{2} \frac{G_a^+ G_b^+ - G_a^- G_b^-}{\alpha' \pm B} \end{pmatrix}, \quad (3.85)$$

$$\check{B}_{ij} = \begin{pmatrix} 0 & - \frac{\alpha'}{\alpha' \pm B} G_b^\pm \\ + \frac{\alpha'}{\alpha' \pm B} G_a^\pm & b_{ab} \mp \frac{1}{2} \frac{G_a^- G_b^+ - G_a^+ G_b^-}{\alpha' \pm B} \end{pmatrix}.$$

The first choice in (3.84) corresponds to the upper sign in (3.85) for which the indices take values $i = 2, 3, \dots, D + 1$, while the second choice corresponds to the lower sign with indices $i = 1, 3, \dots, D + 1$.

T-duality

We now observe that the reduced metric and B -field shown in (3.85) for the two choices (3.84) are related by the Buscher rules (3.21). For instance, we can easily check that

$$\check{G}_{22}|_{(1)} = \frac{\alpha'^2}{\check{G}_{11}|_{(2)}}, \quad (3.86)$$

and similarly for the other relations of the Buscher rules. We also see that the two backgrounds in (3.85) are related by (3.81), which was a symmetry of the $(D + 1)$ -dimensional theory. Hence, T-duality between two D -dimensional backgrounds can be interpreted as a symmetry of a $(D + 1)$ -dimensional theory, and in this way the two T-dual theories are equivalent.

GKO construction

We can also interpret T-duality from a conformal-field-theory point of view [27, 77, 35]. Let us first note that the conserved current corresponding to the symmetry $\delta X^i = \epsilon k^i$ of the action (3.78) is given by

$$J = \star \mathbf{k} + i(v - \iota_k B), \quad (3.87)$$

where $\mathbf{k} = k^I G_{IJ} dX^J$ is the one-form dual to the vector k and \star denotes the Hodge star-operator on the two-dimensional world-sheet Σ . Assuming the world-sheet theory to be conformal, we can choose the world-sheet metric to be flat and

introduce a complex coordinate $z = \sigma^0 + i\sigma^1$. For the two choices in (3.84) the current J then takes the form

$$\begin{aligned} (1) \quad J &= -J_z dz + J_{\bar{z}} d\bar{z}, \\ (2) \quad J &= +J_z dz + J_{\bar{z}} d\bar{z}, \end{aligned} \tag{3.88}$$

where we defined the holomorphic and anti-holomorphic currents

$$\begin{aligned} J_z &= \frac{i}{2} \left[\alpha' (\partial X^1 - \partial X^2) + B (\partial X^1 + \partial X^2) + (G_a^+ - G_a^-) \partial X^a \right], \\ J_{\bar{z}} &= \frac{i}{2} \left[\alpha' (\bar{\partial} X^1 + \bar{\partial} X^2) + B (\bar{\partial} X^1 - \bar{\partial} X^2) + (G_a^+ + G_a^-) \bar{\partial} X^a \right]. \end{aligned} \tag{3.89}$$

Here we employed the conventions $\star dz = -i dz$ and $\star d\bar{z} = +i d\bar{z}$ as well as $\partial \equiv \partial_z$ and $\bar{\partial} \equiv \partial_{\bar{z}}$, and we note that the currents J_z and $J_{\bar{z}}$ are separately conserved, that is $\bar{\partial} J_z = 0$ and $\partial J_{\bar{z}} = 0$. These currents therefore generate at $\mathfrak{u}(1) \times \mathfrak{u}(1)$ current algebra.

Now, following [35], the gauging and integrating out of the two isometries (3.80) corresponds to a generalisation of the GKO coset construction [83, 84] in which one mods out by the holomorphic and anti-holomorphic currents (3.89). In particular, one keeps only those fields which are primary with respect to the current algebra. The only difference between the two possibilities (3.84) is the sign of the holomorphic charge in (3.88), and one can go from one model to the other by flipping this sign. However, since conformal dimensions and OPEs only depend on quadratic combinations of the charges (see for instance [1]), the correlation functions are invariant under this operation. Hence, T-duality is a symmetry at the level of the conformal field theory.

Remarks

We close this section with the following remarks:

- A generalisation of the analysis discussed in this section to \mathbb{T}^{2n} -fibrations, which corresponds to T-duality transformations along multiple directions, can be found in [82].
- In this section we have implicitly assumed that the two-dimensional world-sheet Σ has a trivial topology. In order to extend this analysis to non-trivial topologies we have to address the term

$$\hat{\mathcal{S}} \supset -\frac{i}{2\pi\alpha'} \int_{\Sigma} (\pm\alpha' dX^1 \wedge dX^2), \tag{3.90}$$

which arises when integrating out the gauge field from the action (3.83). Since dX^1 and dX^2 are closed, we can perform a Hodge decomposition using the notation introduced on page 33 as

$$dX^1 = dX_{(0)}^1 + X_{(m)}^1 \omega^m, \quad dX^2 = dX_{(0)}^2 + X_{(m)}^2 \omega^m, \quad (3.91)$$

and the term shown in (3.90) then becomes

$$\hat{\mathcal{S}} \supset \mp \frac{i}{2\pi} X_{(m)}^1 J^{mn} X_{(n)}^2. \quad (3.92)$$

If the coordinates X^1 and X^2 are compactified via the identification $X \sim X + 2\pi n$ with $n \in \mathbb{Z}$, in the Hodge decomposition we have $X_{(m)}^{1,2} \in 2\pi\mathbb{Z}$ and the exponential of (3.90) gives one. Hence, it does not contribute to the path integral.

3.4 Type II string theories

In the above sections we have studied how T-duality transformations act on the metric, Kalb-Ramond field and dilaton – which comprise the massless sector of the bosonic string. In this section we are interested in type II superstring theories, where the space-time bosons originate from the Neveu-Schwarz–Neveu-Schwarz (NS-NS) and Ramond-Ramond (R-R) sectors. The massless fields of the NS-NS sector are again given by G , B and ϕ , for which we already discussed the behaviour under T-duality. We therefore now turn to the R-R sector and determine the remaining transformation rules. We note that the Ramond-Ramond sector will not play a role in our discussion of non-geometric backgrounds, but we include this topic for completeness.

Type II superstring

Let us start by briefly recalling some aspects of type II superstring theory (for a textbook introduction we refer for instance to [85, 18]). In addition to bosonic world-sheet fields $X^\mu(\sigma^\alpha)$, for the type II string one considers fermionic fields $\psi^\mu(\sigma^\alpha)$ and one requires the resulting world-sheet theory to be supersymmetric. For closed-string world-sheets of the form $\Sigma = \mathbb{R} \times S^1$ these fermions can have periodic (Ramond) or anti-periodic (Neveu-Schwarz) boundary conditions along the S^1 , which can be chosen independently for the left- and right-moving components ψ_L^μ and ψ_R^μ of the two-component spinor ψ^μ . One is therefore left with the following four combinations of boundary conditions between the left- and right-moving

sectors

Neveu-Schwarz–Neveu-Schwarz	NS-NS	space-time bosons,	
Neveu-Schwarz–Ramond	NS-R	space-time fermions,	(3.93)
Ramond–Neveu-Schwarz	R-NS	space-time fermions,	
Ramond–Ramond	R-R	space-time bosons.	

After quantising the theory, fields in the NS-NS and R-R sectors correspond to space-time bosons whereas fields in the NS-R and R-NS sectors give rise to space-time fermions. The critical dimension of the type II superstring is $D = 10$.

We furthermore note that for consistency of the theory (e.g. modular invariance) one has to perform a GSO projection, which is achieved using world-sheet fermion-number operators F_L and F_R . In particular, two interesting theories are obtained by only keeping contributions $|\phi_L\rangle \otimes |\phi_R\rangle$ (belonging to the four sectors shown in (3.93)) which satisfy

$$\begin{aligned}
\text{type IIA} \quad & (-1)^{F_L} |\phi_L\rangle_{\text{NS}} = +|\phi_L\rangle_{\text{NS}}, & (-1)^{F_R} |\phi_R\rangle_{\text{NS}} = +|\phi_R\rangle_{\text{NS}}, \\
& (-1)^{F_L} |\phi_L\rangle_{\text{R}} = +|\phi_L\rangle_{\text{R}}, & (-1)^{F_R} |\phi_R\rangle_{\text{R}} = -|\phi_R\rangle_{\text{R}}, \\
\text{type IIB} \quad & (-1)^{F_L} |\phi_L\rangle_{\text{NS}} = +|\phi_L\rangle_{\text{NS}}, & (-1)^{F_R} |\phi_R\rangle_{\text{NS}} = +|\phi_R\rangle_{\text{NS}}, \\
& (-1)^{F_L} |\phi_L\rangle_{\text{R}} = +|\phi_L\rangle_{\text{R}}, & (-1)^{F_R} |\phi_R\rangle_{\text{R}} = +|\phi_R\rangle_{\text{R}},
\end{aligned} \tag{3.94}$$

where we emphasise the sign difference for $(-1)^{F_R}$ in the Ramond sector. Now, the massless spectrum in the NS-NS sector consists of the space-time metric $G_{\mu\nu}$, the two-form Kalb-Ramond gauge field $B_{\mu\nu}$ and the dilaton scalar field ϕ , which applies both to the type IIA and type IIB theories. In the R-R sector the massless fields are a one-form and a three-form gauge potential C_1 and C_3 for type IIA, and a zero-form, a two-form and a self-dual four-form potential C_0 , C_2 and C_4 for type IIB

superstring theory	massless bosonic field content	
type IIA	$G, B, \phi, C_1, C_3,$	(3.95)
type IIB	$G, B, \phi, C_0, C_2, C_4.$	

The effective theory for these fields (and their space-time fermionic superpartners) is given by type II supergravity, to which we come back in section 8.4.⁴

⁴ For the type II superstring one should distinguish two appearances of supersymmetry: 1) the two-dimensional world-sheet theory has $N = (1, 1)$ world-sheet supersymmetry and $X^\mu(\sigma^\alpha)$ and $\psi^\mu(\sigma^\alpha)$ are superpartners; 2) the ten-dimensional target-space theory has $\mathcal{N} = 2$ space-time supersymmetry, which is the reason for calling it type II.

T-duality I

Let us now compactify the type II string on a circle of radius R by identifying say $X^9 \sim X^9 + 2\pi R$ similarly as in section 2 (recall that the critical space-time dimension for the superstring is $D = 10$). When performing a T-duality transformation along the circle we noted in equation (2.16) that the bosonic world-sheet fields transform as $(X_R^9, X_L^9) \rightarrow (-X_R^9, +X_L^9)$. Now, since in the present case the world-sheet theory is supersymmetric one can expect that the world-sheet superpartners of X^9 transforms similarly, that is

$$(\psi_R^9, \psi_L^9) \rightarrow (-\psi_R^9, +\psi_L^9). \quad (3.96)$$

Let us then recall the GSO projection shown in (3.94) and note that $(-1)^{F_R}$ in the Ramond sector (in light-cone quantisation) is given by $(-1)^{F_R} = 16 \prod_{i=2}^9 b_0^i$ with b_0^i the zero modes of ψ_R^i [18]. Due to (3.96) a T-duality transformation changes the sign of b_0^9 in the right-moving sector and therefore changes the sign of $(-1)^{F_R}$ acting on $|\phi\rangle_R$. This means that T-duality maps the type IIA theory to type IIB and vice versa

$$\text{type IIA on } S^1 \quad \xleftrightarrow{\text{T-duality}} \quad \text{type IIB on } \tilde{S}^1, \quad (3.97)$$

with S^1 and \tilde{S}^1 two T-dual circles. We note that our argumentation here is somewhat heuristic, however, the mapping (3.97) can be checked explicitly.

T-duality II

Let us now turn to the open-string sector for the derivation of the R-R sector transformation rules [54, 55]. We recall from page 19 that T-duality interchanges Dirichlet and Neumann boundary conditions, in particular, performing a T-duality along a direction perpendicular to a Dp -brane results in a $D(p+1)$ -brane whereas T-duality along a longitudinal direction gives a $D(p-1)$ -brane. We also note that in an effective theory D-branes can be described by their world-volume action. We will become more concrete about such actions in section 8.6, but let us state already here that they contain couplings of the schematic form

$$\mathcal{S}_{Dp} \supset \int_{\Gamma_{p+1}} \left(C_{p+1} + C_{p-1} \wedge B + \frac{1}{2} C_{p-3} \wedge B \wedge B + \dots \right), \quad (3.98)$$

where Γ_{p+1} denotes the $(p+1)$ -dimensional world-volume of the Dp -brane and C_p are the R-R gauge potentials mentioned above. Under a T-duality transformation along Γ_{p+1} the D-brane world-volume is mapped to Γ_p and – ignoring for a moment the B -field – correspondingly the R-R potentials should transform as $C_{p+1} \rightarrow C_p$.

Similarly, a T-duality perpendicular to Γ_{p+1} results in Γ_{p+2} together with $C_{p+1} \rightarrow C_{p+2}$. This mapping agrees with our observation (3.97) that T-duality along a single direction interpolates between type IIA and type IIB string theory, as all R-R potentials of IIA are odd while the potentials in IIB are of even degree.

We now want to make the above argumentation more precise and take into account the Kalb-Ramond B -field. We consider a compactification on a circle along the X^9 -direction and assume that the components B_{ij} are independent of X^9 . This means we can employ our results from section 3.1, in particular, the transformation rules for the NS-NS sector given in equation (3.21). Denoting the components of C_p by $C_{p|i_1\dots}$ and taking $i_n \neq 9$, for the transformation of the R-R potentials under T-duality one finds that [86]

$$\begin{aligned}\check{C}_{p|9i_2\dots i_p} &= C_{p-1|i_2\dots i_p} - (p-1) \frac{G_{9[i_2} C_{p-1|9i_3\dots i_p]}}{G_{99}}, \\ \check{C}_{p|i_1\dots i_p} &= C_{p+1|9i_1\dots i_p} - p B_{9[\underline{\mu}_1} \check{C}_{p|9i_2\dots i_p]}.\end{aligned}\tag{3.99}$$

Here we underlined the indices which are part of the anti-symmetrisation, we made a particular choice of sign as compared to [86], and we note that the second line is defined recursively in terms of the first.

Remarks

We close this section with the following remarks:

- The transformation rules of the R-R potentials in type II theories were first derived from a supergravity point of view in [87, 88], and were later generalised in [89]. The D-brane approach described above has been employed in [54, 55], and in [86, 90] the transformation of the R-R potentials has been determined via the supersymmetry transformations of fermions.
- From a world-sheet perspective the transformation rules have been studied in [91, 92] via the Green-Schwarz formalism, in [93] via the pure spinor formalism of [94], and in [95] via canonical transformations. To our knowledge, however, global properties of the world-sheet and of R-R fluxes have not been discussed in the same detail as for the NS-NS sector.

4 Poisson-Lie duality

In this section we discuss Poisson-Lie T-duality, which is a framework for describing non-abelian T-duality transformations. Poisson-Lie T-duality has been developed in the papers [66,96,97] and here we give an overview of the main idea. Poisson-Lie duality will not play a role in our discussion of non-geometric backgrounds, but we include this topic for completeness.

Variation of the action

We start from the Euclidean world-sheet action of a closed string given in (3.1), which we recall for convenience as

$$\mathcal{S} = -\frac{1}{2\pi\alpha'} \int_{\Sigma} \left[\frac{1}{2} G_{ij} dX^i \wedge \star dX^j - \frac{i}{2} B_{ij} dX^i \wedge dX^j + \frac{\alpha'}{2} R \phi \star 1 \right], \quad (4.1)$$

with G_{ij} and B_{ij} the components of the target-space metric and Kalb-Ramond field. The dilaton is denoted by ϕ . We then perform a variation of the action (4.1) with respect to infinitesimal local transformations

$$\delta_{\epsilon} X^i = \epsilon^{\alpha} k_{\alpha}^i(X), \quad (4.2)$$

where $\epsilon^{\alpha} \equiv \epsilon^{\alpha}(\sigma^a) \ll 1$ depend on the coordinates σ^a of the two-dimensional world-sheet Σ and $\alpha = 1, \dots, N$. The vector-fields k_{α} are required to satisfy a Lie algebra \mathfrak{g} with structure constants $f_{\alpha\beta}{}^{\gamma}$ specified in the following way

$$[k_{\alpha}, k_{\beta}] = f_{\alpha\beta}{}^{\gamma} k_{\gamma}. \quad (4.3)$$

Employing the notation $G = \frac{1}{2} G_{ij} dX^i \wedge \star dX^j$ and $B = \frac{1}{2} B_{ij} dX^i \wedge dX^j$, the variation of the action with respect to (4.2) can be expressed as

$$\delta_{\epsilon} \mathcal{S} = -\frac{1}{2\pi\alpha'} \int_{\Sigma} \epsilon^{\alpha} \mathcal{L}_{k_{\alpha}} \left(G - iB + \frac{\alpha'}{2} R \phi \star 1 \right) + \frac{1}{2\pi\alpha'} \int_{\Sigma} \epsilon^{\alpha} dJ_{\alpha}, \quad (4.4)$$

where $\mathcal{L}_{k_{\alpha}} G = \frac{1}{2} (\mathcal{L}_{k_{\alpha}} G)_{ij} dX^i \wedge \star dX^j$ and \mathcal{L}_k denotes the target-space Lie derivative along the direction k ; similar expressions apply to B and ϕ . The currents J_{α} are defined up to closed terms and read

$$J_{\alpha} = \star k_{\alpha} - i \iota_{k_{\alpha}} B, \quad (4.5)$$

where $k_{\alpha} = k_{\alpha}^i G_{ij} dX^j$ are the one-forms dual to the vector-fields k_{α} . Let us note that using the equations of motion for X^i given in (3.3), on-shell the variation (4.4) vanishes.

Furthermore, we make the assumption that the dilaton obeys $\mathcal{L}_{k_\alpha}\phi = 0$. If this condition is not satisfied, technical subtleties appear which have been addressed for instance in [98–102]. However, with the Lie derivative of the dilaton vanishing we can then summarise that on-shell

$$0 = \mathcal{L}_{k_\alpha}(G - iB) - dJ_\alpha \Big|_{\text{on-shell}}. \quad (4.6)$$

(Non-conserved) Noether currents

If the Lie derivative acting on G , B and ϕ vanishes, it follows from (4.4) that the currents J_α have to be closed. This is basically the situation we have studied in section 3 (modulo subtleties regarding the one-forms v_α). In particular, the vector-fields k_α have to be Killing vector-fields and T-duality is along a direction of isometry. However, it turns out that imposing a more general condition on the currents leads to an interesting structure. In particular, let us demand that on-shell

$$0 = dJ_\alpha - \frac{i}{2} \tilde{f}_\alpha^{\beta\gamma} J_\beta \wedge J_\gamma, \quad (4.7)$$

where $\tilde{f}_\alpha^{\beta\gamma}$ are structure constants of some Lie algebra $\tilde{\mathfrak{g}}$ (which we come back to below). In this case $\mathcal{L}_{k_\alpha}(G - iB)$ no longer vanishes on-shell and the k_α do not correspond to isometries. If the currents J_α are not closed on-shell but satisfy (4.7), the world-sheet theory is said to have a Poisson-Lie symmetry [66, 96, 97] or to have a non-commutative conservation law [66].

Let us now use the integrability condition for the Lie derivative given by $[\mathcal{L}_{k_\alpha}, \mathcal{L}_{k_\beta}] = \mathcal{L}_{[k_\alpha, k_\beta]}$ together with (4.7) and the equation of motion (3.3). More concretely, we evaluate using the relation (4.7)

$$[L_{k_\alpha}, L_{k_\beta}](G - iB) = \mathcal{L}_{[k_\alpha, k_\beta]}(G - iB). \quad (4.8)$$

This leads to a restrictions on the structure constants of the Lie algebras \mathfrak{g} and $\tilde{\mathfrak{g}}$ of the form

$$0 = \tilde{f}_\gamma^{\mu\nu} f_{\alpha\beta}^\gamma - \tilde{f}_\alpha^{\gamma\mu} f_{\beta\gamma}^\nu + \tilde{f}_\beta^{\gamma\mu} f_{\alpha\gamma}^\nu \\ + \tilde{f}_\alpha^{\gamma\nu} f_{\beta\gamma}^\mu - \tilde{f}_\beta^{\gamma\nu} f_{\alpha\gamma}^\mu, \quad (4.9)$$

where all indices take values $1, \dots, N$. Note that these conditions are invariant under the exchange $f_{\alpha\beta}^\gamma \leftrightarrow \tilde{f}_\gamma^{\alpha\beta}$, which suggests that there should exist a “dual” world-sheet theory in which the roles of $\tilde{f}_\alpha^{\beta\gamma}$ and $f_{\alpha\beta}^\gamma$ are interchanged. In particular, the dual currents \tilde{J}^α in the dual theory should satisfy

$$0 = d\tilde{J}^\alpha - \frac{i}{2} f_{\beta\gamma}^\alpha \tilde{J}^\beta \wedge \tilde{J}^\gamma, \quad (4.10)$$

and the analogue of (4.6) imposes restrictions on a dual metric and Kalb-Ramond field via

$$\mathcal{L}_{\tilde{k}^\alpha}(\tilde{G} - i\tilde{B}) = d\tilde{J}^\alpha, \quad (4.11)$$

with dual vector-fields \tilde{k}^α obeying the algebra

$$[\tilde{k}^\alpha, \tilde{k}^\beta] = \tilde{f}_\gamma^{\alpha\beta} \tilde{k}^\gamma. \quad (4.12)$$

Drinfeld double and Manin triples

Let us come back to the relations shown in (4.9), where $f_{\alpha\beta}^\gamma$ are the structure constants of a Lie algebra \mathfrak{g} and $\tilde{f}_\alpha^{\beta\gamma}$ correspond to a Lie algebra $\tilde{\mathfrak{g}}$. These equations are the standard relations which have to be obeyed by the structure constants of a Lie bi-algebra $(\mathfrak{g}, \tilde{\mathfrak{g}})$ [103–105].

A special case of a Lie bi-algebra is the so-called Drinfeld double, which will become important below. A Drinfeld double is any Lie group D such that its Lie algebra \mathfrak{d} can be decomposed into a pair of maximally isotropic sub-algebras $(\mathfrak{g}, \tilde{\mathfrak{g}})$ with respect to a non-degenerate invariant bilinear form $\langle \cdot, \cdot \rangle$ on \mathfrak{d} [103, 96]. Let us explain this terminology: an isotropic subspace of \mathfrak{d} is such that the bilinear pairing of any two of its elements vanishes, and maximally isotropic means that the subspace cannot be enlarged while preserving the property of isotropy. Together with the choice of a canonical pairing between \mathfrak{g} and $\tilde{\mathfrak{g}}$ this reads in formulas

$$\langle t_\alpha, t_\beta \rangle = 0, \quad \langle \tilde{t}^\alpha, \tilde{t}^\beta \rangle = 0, \quad \langle t_\alpha, \tilde{t}^\beta \rangle = \delta_\alpha^\beta, \quad (4.13)$$

where $t_\alpha \in \mathfrak{g}$ and $\tilde{t}^\alpha \in \tilde{\mathfrak{g}}$ are the generators of the two Lie algebras. The structure constants are defined via the commutators in the following way

$$\begin{aligned} [t_\alpha, t_\beta] &= i f_{\alpha\beta}^\gamma t_\gamma, & [t_\alpha, \tilde{t}^\beta] &= -i f_{\alpha\gamma}^\beta \tilde{t}^\gamma + i \tilde{f}_\alpha^{\beta\gamma} t_\gamma, \\ [\tilde{t}^\alpha, \tilde{t}^\beta] &= i \tilde{f}_\gamma^{\alpha\beta} \tilde{t}^\gamma, \end{aligned} \quad (4.14)$$

where we also included the mixed commutator. The latter follows from the invariance of the pairing $\langle \cdot, \cdot \rangle$ on \mathfrak{d} , but can also be determined by comparing the mixed Jacobi identity in \mathfrak{d} to (4.9). Finally, any such decomposition of \mathfrak{d} into such subspaces is called a Manin triple, and there are at least two of them: $\mathfrak{d} = \mathfrak{g} + \tilde{\mathfrak{g}}$ and $\mathfrak{d} = \tilde{\mathfrak{g}} + \mathfrak{g}$.

However, in general a given Drinfeld double Lie algebra \mathfrak{d} can be decomposed into bi-algebras in several ways [66], which leads to the concept of so-called Poisson-Lie *plurality* [99]. In six dimensions, for instance, the Drinfeld doubles have been classified in [106, 107]. Furthermore, the relation between the $O(D, D, \mathbb{Z})$ transformations discussed in section 2.3 and Poisson-Lie duality has been studied in [108].

Duality transformation

So far we have observed that the consistency condition (4.9) is invariant under exchanging the algebras \mathfrak{g} and $\tilde{\mathfrak{g}}$, and hence there should exist a dual model with their roles interchanged. We now want to make this more precise and construct the mapping between the two models. To do so we restrict our discussion to world-sheet theories with group manifolds as target-spaces, though we will present a generalisation below.

We consider a two-dimensional world-sheet theory which has a group G as an N -dimensional target-space. The left- and right-invariant forms for the group G can then be written in terms of $g \equiv g(\sigma^a) \in G$ as

$$\omega_L = g^{-1}(dg) = \omega_L^\alpha t_\alpha, \quad \omega_R = (dg)g^{-1} = \omega_R^\alpha t_\alpha, \quad (4.15)$$

and they satisfy the Maurer-Cartan equations as follows

$$0 = d\omega_L^\alpha + \frac{i}{2} f_{\beta\gamma}{}^\alpha \omega_L^\beta \wedge \omega_L^\gamma, \quad 0 = d\omega_R^\alpha - \frac{i}{2} f_{\beta\gamma}{}^\alpha \omega_R^\beta \wedge \omega_R^\gamma. \quad (4.16)$$

Similar expressions apply for the dual Lie group \tilde{G} with corresponding algebra $\tilde{\mathfrak{g}}$. The world-sheet action for the present situation can then be expressed schematically as

$$\mathcal{S} = \frac{1}{2\pi\alpha'} \int_\Sigma \left[\frac{1}{2} G_{\alpha\beta} \omega_L^\alpha \wedge \star \omega_L^\beta + \frac{i}{2} B_{\alpha\beta} \omega_L^\alpha \wedge \omega_L^\beta \right], \quad (4.17)$$

where $G_{\alpha\beta}$ and $B_{\alpha\beta}$ are the components of the target-space metric and Kalb-Ramond field. The current (4.5) satisfying (4.7) is given in terms of the right-invariant Maurer-Cartan form of the dual group as

$$J_\alpha = \tilde{\omega}_{R\alpha}, \quad (4.18)$$

which indeed satisfies (4.7) as can be seen from the second relation in (4.16) applied to the dual algebra. Now, given a solution $g \equiv g(\sigma^a) \in G$ to the equations of motion of the sigma model (4.17), we can lift this solution to the Drinfeld double D . More concretely, we can express $d \in D$ as

$$d = g \cdot \tilde{g}, \quad g \in G, \quad \tilde{g} \in \tilde{G}, \quad (4.19)$$

where the multiplication is done in D . It is known [104] that for every $d \in D$ there are two decompositions applicable, namely

$$d = g \cdot \tilde{g} = \tilde{h} \cdot h. \quad (4.20)$$

One can then show that $\tilde{h} \equiv \tilde{h}(\sigma^a) \in \tilde{G}$ is a solution of the dual sigma-model and $h \equiv h(\sigma^a) \in G$ gives rise to the dual analogue of (4.18) [66].

Let us now give some more concrete formulas for the dual sigma model. To do so, we are going to work with the matrix

$$E_{\alpha\beta}(g) = G_{\alpha\beta}(g) + B_{\alpha\beta}(g), \quad (4.21)$$

which contains the information about the target-space background. The dependence on $g \in G$ specifies the position on the group manifold – and since G acts transitively on the target-space, we can consider $E_{\alpha\beta}$ say at the origin $g = e$ where e is the identity element, and obtain the full dependence via the adjoint action. More concretely, for the adjoint action of G on $\mathfrak{d} = \mathfrak{g} + \tilde{\mathfrak{g}}$ we define

$$g^{-1} \begin{pmatrix} t^\alpha \\ \tilde{t}_\alpha \end{pmatrix} g = \begin{pmatrix} a^\alpha{}_\beta(g) & b^{\alpha\beta}(g) \\ 0 & d_\alpha{}^\beta(g) \end{pmatrix} \begin{pmatrix} t^\beta \\ \tilde{t}_\beta \end{pmatrix}, \quad (4.22)$$

where $a(g)$, $b(g)$ and $d(g)$ are $N \times N$ -dimensional matrices. The dependence of (4.21) on g can be expressed using matrix notation as [66, 96]

$$E(g) = [a^T(g) + E(e)b^T(g)]^{-1} E(e)d^T(g), \quad (4.23)$$

and for the dual background the corresponding matrix $\tilde{E}^{\alpha\beta}(\tilde{g})$ can be expressed in a similar way, namely

$$\tilde{E}(\tilde{g}) = [\tilde{a}^T(\tilde{g}) + \tilde{E}(\tilde{e})\tilde{b}^T(\tilde{g})]^{-1} \tilde{E}(\tilde{e})\tilde{d}^T(\tilde{g}), \quad (4.24)$$

where the roles of t_α and \tilde{t}^α have been interchanged. The final point is that at the origin $e \in D$ of the Drinfeld double D the matrix $E_{\alpha\beta}(e)$ can be regarded as a map $E(e) : \mathfrak{g} \rightarrow \tilde{\mathfrak{g}}$, and the matrix $\tilde{E}^{\alpha\beta}(\tilde{e})$ is a map $\tilde{E}(\tilde{e}) : \tilde{\mathfrak{g}} \rightarrow \mathfrak{g}$, where $e \in D$ is also the unit $e \in G$ and $\tilde{e} \in \tilde{G}$. By comparing for instance with the abelian situation discussed around equation (2.55), we see that \tilde{E} should be the inverse of E

$$E(e)\tilde{E}(\tilde{e}) = \tilde{E}(\tilde{e})E(e) = \mathbf{1}. \quad (4.25)$$

This relation has been derived via the equations of motion in [66] and via a doubled sigma-model (cf. section 9) in [97, 109], and in this way we see that using (4.25) we can express (4.24) in terms of (4.23). In particular, the dual background can be written as (we simply replace $\tilde{E}(\tilde{e})$ by $E^{-1}(e)$ in (4.24))

$$\tilde{E}(\tilde{g}) = [\tilde{a}^T(\tilde{g}) + E^{-1}(e)\tilde{b}^T(\tilde{g})]^{-1} E^{-1}(e)\tilde{d}^T(\tilde{g}). \quad (4.26)$$

Example

As an example for a Poisson-Lie duality, let us take \mathfrak{g} to be a non-abelian Lie algebra and $\tilde{\mathfrak{g}}$ to be an abelian one. In this case, the constraint (4.9) is trivially satisfied. The standard example is given by a so-called principal chiral model on a simple group G [62, 110, 111], for which the matrix (4.18) takes the form

$$E_{\alpha\beta} = k \delta_{\alpha\beta}, \quad (4.27)$$

where $k \in \mathbb{Z}^+$ denotes the level of the group G . Going then through the dualisation procedure discussed above, one finds for the Poisson-Lie dual the expression

$$(\tilde{E}^{-1})_{\alpha\beta} = \delta_{\alpha\beta} + f_{\alpha\beta}{}^\gamma \chi_\gamma, \quad (4.28)$$

where $f_{\alpha\beta}{}^\gamma$ are the structure constants of \mathfrak{g} and χ_α are N coordinates for the dual circles. The dual metric and B -field correspond to the symmetric and anti-symmetric part in (4.28), which agree with the expressions found in [62, 110, 111]. In particular, for $G = SU(2)$ with $f_{\alpha\beta}{}^\gamma = \epsilon_{\alpha\beta}{}^\gamma$ one finds

$$\tilde{G}^{\alpha\beta} = \frac{1}{k(k^2 + \chi^2)} (k^2 \delta^{\alpha\beta} + \chi^\alpha \chi^\beta), \quad \tilde{B}^{\alpha\beta} = -\frac{1}{k^2 + \chi^2} \epsilon^{\alpha\beta}{}_\gamma \chi^\gamma, \quad (4.29)$$

where $\chi^\alpha = \delta^{\alpha\beta} \chi_\beta$ and $\chi^2 = \chi_1^2 + \chi_2^2 + \chi_3^2$.

Generalisation

Instead of considering an N -dimensional Lie group G as a target-space, we can also study manifolds where G is fibered over a base-manifold \mathcal{B} . Let us denote local coordinates in the base by y^m with $m = 1, \dots, d_{\mathcal{B}}$. The generalisation of (4.18) then takes the form

$$E_{IJ}(g, y) = \begin{pmatrix} E_{\alpha\beta}(g, y) & E_{\alpha n}(g, y) \\ E_{m\beta}(g, y) & E_{mn}(y) \end{pmatrix}, \quad (4.30)$$

where we used the combined index $I = \{\alpha, m\}$ and the corresponding basis of one-forms reads $\{\omega_E^\alpha, dy^m\}$. For the analogue of (4.23) we then define

$$A(g) = \begin{pmatrix} a(g) & 0 \\ 0 & \mathbf{1} \end{pmatrix}, \quad B(g) = \begin{pmatrix} b(g) & 0 \\ 0 & 0 \end{pmatrix}, \quad D(g) = \begin{pmatrix} d(g) & 0 \\ 0 & \mathbf{1} \end{pmatrix}, \quad (4.31)$$

and we find

$$E(g, y) = [A^T(g) + E(e, y) B^T(g)]^{-1} E(e, y) D^T(g). \quad (4.32)$$

The background after dualisation along the fibre is encoded in the generalisation of (4.26), namely

$$\tilde{E}(\tilde{g}, y) = [\tilde{A}^T(\tilde{g}, y) + E^{-1}(e, y) \tilde{B}^T(\tilde{g})]^{-1} E^{-1}(e, y) \tilde{D}^T(\tilde{g}, y). \quad (4.33)$$

Remarks

Many aspects of Poisson-Lie duality and generalisations thereof have been discussed in the literature. Here we want to briefly mention some of them:

- As one can see from the last relation in (4.13), the Lie algebras \mathfrak{g} and $\tilde{\mathfrak{g}}$ are dual to each other. The latter can therefore be identified with the dual space \mathfrak{g}^* , and one is led to the framework of Courant algebroids (to be discussed in section 7.2). This has been investigated for instance in [112].
- Poisson-Lie duality can also be understood at the classical level as a canonical transformation. This has been discussed in [113], where the explicit form of the generating functional is given, and for Poisson-Lie plurality this has been addressed in [114].
- In order to establish Poisson-Lie duality not only at the classical but also at the quantum level, a path-integral derivation of the duality is needed. This has been investigated in [115, 98].
- Poisson-Lie duality in the context of open strings and D-branes has been discussed in [116, 117], and in [118] the transformation of the Ramond-Ramond sector of type II string theory under Poisson-Lie duality has been studied (using the framework of double field theory, cf. section 9.3).

5 Non-geometry

After having studied T-duality transformations from different perspectives, we now turn to non-geometric backgrounds. In this section we discuss the standard example for a non-geometric background, namely the three-torus with H -flux [119, 120, 16, 121] with its T-dual configurations, and in later sections generalise this example.

5.1 Three-torus with H -flux

Let us consider a flat three-torus \mathbb{T}^3 with non-trivial field strength $H = dB$ for the Kalb-Ramond B -field. The components of the metric in the coordinate basis of one-forms $\{dX^1, dX^2, dX^3\}$ are taken to be of the form

$$G_{ij} = \begin{pmatrix} R_1^2 & 0 & 0 \\ 0 & R_2^2 & 0 \\ 0 & 0 & R_3^2 \end{pmatrix}, \quad (5.1)$$

and the topology is characterised by the identifications $X^i \simeq X^i + 2\pi$ for $i = 1, 2, 3$. The components of the field strength H are chosen to be constant, which, keeping in mind the quantisation condition (3.40), leads to

$$H = \frac{\alpha'}{2\pi} h dX^1 \wedge dX^2 \wedge dX^3, \quad h \in \mathbb{Z}. \quad (5.2)$$

The dilaton for this background is also taken to be constant, that is $\phi = \phi_0 = \text{const}$. We note that in the basis $\{\partial_1, \partial_2, \partial_3\}$ dual to the one-forms dX^i , the Killing vectors respecting the periodic identification of the torus can be chosen as

$$k_1^i = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}, \quad k_2^i = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}, \quad k_3^i = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}, \quad (5.3)$$

which satisfy an abelian algebra and hence $[k_\alpha, k_\beta] = 0$. Note that the Killing vectors k_α can be rescaled by non-vanishing constants, which however does not change the results discussed below. Finally, for later reference let us also introduce a vielbein basis e^a with $a = 1, 2, 3$ for the metric (5.1) as

$$e^1 = R_1 dX^1, \quad e^2 = R_2 dX^2, \quad e^3 = R_3 dX^3, \quad (5.4)$$

which satisfies $G = \frac{1}{2} G_{ij} dX^i \vee dX^j = \frac{1}{2} \delta_{ab} e^a \vee e^b$. The H -flux (5.2) in this basis is expressed as

$$H = \frac{\alpha'}{2\pi} \frac{h}{R_1 R_2 R_3} e^1 \wedge e^2 \wedge e^3. \quad (5.5)$$

5.2 Twisted torus

We now perform a T-duality transformation along one of the Killing vectors shown in (5.3) and discuss the resulting background.

The background

Let us consider say the Killing vector $k_1 = \partial_1$ in (5.3) and perform a T-duality transformation along this direction. Using either the Buscher rules (3.21) or following the approach of section 3.2, we find that the dual background is given by

$$\begin{aligned}\check{G} &= \frac{\alpha'^2}{R_1^2} \xi \otimes \xi + R_2^2 dX^2 \otimes dX^2 + R_3^2 dX^3 \otimes dX^3, \\ \check{H} &= 0, \\ \check{\phi} &= \phi_0 - \log \left[\frac{R_1}{\sqrt{\alpha'}} \right].\end{aligned}\tag{5.6}$$

Note that the one-form ξ employed in (5.6) satisfies

$$d\xi = \frac{h}{2\pi} dX^2 \wedge dX^3,\tag{5.7}$$

which means that ξ depends on the X^2 - or X^3 -direction. In fact, (5.6) together with (5.7) describes a principal $U(1)$ -bundle over a two-dimensional base, which is also known as a twisted three-torus [119, 120].

To be more concrete, let us choose the following parametrisation of ξ (more details on the choice of parametrisation can be found for instance in [61])

$$\xi = d\tilde{X}^1 - \frac{h}{2\pi} X^3 dX^2,\tag{5.8}$$

where \tilde{X}^1 denotes the dual coordinate. From here we can infer the global structure of the twisted three-torus by demanding the metric \check{G} in (5.6) to be well-defined. In particular, we find

$$\begin{aligned}1) \quad & \tilde{X}^1 \rightarrow \tilde{X}^1 + 2\pi, \\ 2) \quad & X^2 \rightarrow X^2 + 2\pi, \\ 3) \quad & X^3 \rightarrow X^3 + 2\pi, \quad \tilde{X}^1 \rightarrow \tilde{X}^1 + hX^2,\end{aligned}\tag{5.9}$$

which describes a two-torus along the direction \tilde{X}^1 and X^2 which is twisted when going around the circle in the X^3 -direction. This \mathbb{T}^2 -fibration over S^1 is called a twisted torus.

Geometric flux

The background we started from carries a non-vanishing H -flux, and one can ask whether a similar quantity can be defined for the twisted torus. Clearly, for the dual background we have a vanishing H -flux $\check{H} = 0$, but we also observed a non-trivial twisting (5.7) of the geometry. To investigate this point, we introduce a vielbein-basis \check{e}^a for the dual metric \check{G} in (5.6) as follows

$$\check{e}^1 = \frac{\alpha'}{R_1} \xi, \quad \check{e}^2 = R_2 dX^2, \quad \check{e}^3 = R_3 dX^3. \quad (5.10)$$

The exterior algebra of these vielbeins is given by

$$d\check{e}^1 = \frac{\alpha'}{2\pi} \frac{h}{R_1 R_2 R_3} e^2 \wedge e^3, \quad d\check{e}^2 = 0, \quad d\check{e}^3 = 0, \quad (5.11)$$

from which we can read-off the (torsion-free) spin connection. Using the convention $de^a = \frac{1}{2} f_{bc}{}^a e^b \wedge e^c$, from (5.11) we can find the non-vanishing structure constants as

$$f_{23}{}^1 = \frac{\alpha'}{2\pi} \frac{h}{R_1 R_2 R_3}. \quad (5.12)$$

Comparing now with (5.5) we see that the flux h of the original model is encoded in the structure constants, and for this reason $f_{ab}{}^c$ is also called a geometric flux. We come back to this point below.

Global properties

Let us remark on the global properties of the twisted torus. First we note that in general the Buscher rules discussed in section 3 give the dual metric and B -field only locally. That means, the identifications which describe the global structure of the dual background are not always known.

- In particular, let us recall from page 35 that if the circle along which one T-dualises allows for the standard quantisation of the corresponding coordinate X^i with momentum and winding modes, then also the dual direction will be compact with an appropriate quantisation (3.29). In the present situation of a three-torus with H -flux as the starting point, we see that the corresponding equation of motion (3.3) is not a wave equation but reads for say the X^1 -coordinate

$$0 = d \star dX^1 + i \frac{\alpha'}{2\pi} \frac{h}{R_1^2} dX^2 \wedge dX^3. \quad (5.13)$$

In general it is not known how to quantise this theory and deduce the momentum and winding modes. Strictly speaking, we therefore cannot conclude that the dual coordinate is compact with identification $\tilde{X}^1 \rightarrow \tilde{X}^1 + 2\pi$ — although this is very strongly expected.

- Let us also recall our discussion from page 46 and compare (5.8) with (3.52) to deduce the one-form

$$v = -\frac{\alpha'}{2\pi} h X^3 dX^2 \quad (5.14)$$

for the H -flux background. This one-form is not globally-defined, however, in the dualisation procedure only the combination $v + d\chi$ is required to be globally-defined. Noting that we have relabelled the dual coordinate as $\tilde{X}^1 \equiv \chi/\alpha'$, we can therefore conclude that under $X^3 \rightarrow X^3 + 2\pi$ we have to demand that

$$\tilde{X}^1 \rightarrow \tilde{X}^1 + h X^2, \quad (5.15)$$

which agrees with the identifications of the twisted torus shown in the third line of equation (5.9).

5.3 T-fold

After a first T-duality transformation on the three-torus with H -flux which resulted in the twisted torus, we now perform a second T-duality transformation along the direction $k_2 = \partial_2$.

The background

The T-dual background can be obtained either by applying the Buscher rules (3.21) to the twisted torus (5.6) [120,122], or by performing a collective T-duality transformation along two directions for the three-torus with H -flux given below (5.1) [58]. The result of both approaches is the same. If we define the quantity

$$\rho = \frac{R_1^2 R_2^2}{\alpha'^2} + \left[\frac{h}{2\pi} X^3 \right]^2, \quad (5.16)$$

we find for the dual background

$$\begin{aligned} \check{G} &= \frac{1}{\rho} \left[R_2^2 d\tilde{X}^1 \otimes d\tilde{X}^1 + R_1^2 d\tilde{X}^2 \otimes d\tilde{X}^2 \right] + R_3^2 dX^3 \otimes dX^3, \\ \check{H} &= -\frac{\alpha'}{2\pi} \frac{h}{\rho^2} \left(\frac{R_1^2 R_2^2}{\alpha'^2} - \left[\frac{h}{2\pi} X^3 \right]^2 \right) d\tilde{X}^1 \wedge d\tilde{X}^2 \wedge dX^3, \\ \check{\phi} &= \phi_0 - \frac{1}{2} \log \rho, \end{aligned} \quad (5.17)$$

where \tilde{X}^1 and \tilde{X}^2 denote the dual coordinates. The metric and field strength shown in (5.17) describe the so-called T-fold [16].

Note that the background (5.17) is peculiar: in order to make it globally well-defined, we would need a diffeomorphism which relates $\check{\mathbb{G}}$ at $X^3 = 2\pi$ to $X^3 = 0$. However, no such diffeomorphism exists – which can be seen from the Ricci scalar corresponding to $\check{\mathbb{G}}$ given by

$$\check{R} = \frac{h^2}{\pi^2 R_3^2} \frac{1}{\rho^2} \left(\frac{R_1^2 R_2^2}{\alpha'^2} - \frac{5}{2} \left[\frac{h}{2\pi} X^3 \right]^2 \right). \quad (5.18)$$

More concretely, since the Ricci scalar should be invariant under diffeomorphisms, the expression (5.18) should be invariant under $X^3 \rightarrow X^3 + 2\pi$ if the background admits a description in terms of Riemannian geometry. Since this is not the case, we can conclude that the above background does not allow for a geometric description and is therefore non-geometric.

Duality transformations

The geometric symmetries of a string-theory background include diffeomorphisms as well as gauge transformations of the Kalb-Ramond B -field. However, if we enlarge these symmetry transformation and include duality transformations, we can obtain a well-defined interpretation of the T-fold.

To illustrate this point, let us choose a particular gauge for the B -field and write the components of the dual metric and Kalb-Ramond field as follows

$$\begin{aligned} \check{\mathbb{G}}_{ij} &= \frac{1}{\rho} \begin{pmatrix} R_2^2 & 0 & 0 \\ 0 & R_1^2 & 0 \\ 0 & 0 & \rho R_3^2 \end{pmatrix}, \\ \check{\mathbb{B}}_{ij} &= \frac{1}{\rho} \begin{pmatrix} 0 & -\frac{\alpha'}{2\pi} h X^3 & 0 \\ +\frac{\alpha'}{2\pi} h X^3 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}. \end{aligned} \quad (5.19)$$

Next, we recall that part of the $O(D, D, \mathbb{Z})$ duality transformations discussed in section 2.3 are β -transformations. They act on the generalised metric \mathcal{H} – which encodes the metric and B -field as shown in (2.27) – via the matrix given in equation (2.54). Using (2.35), we can then check that

$$\begin{aligned} \check{\mathbb{G}}_{ij}(X^3 + 2\pi) &= \beta\text{-transform} \left[\check{\mathbb{G}}(X^3) \right]_{ij}, \\ \check{\mathbb{B}}_{ij}(X^3 + 2\pi) &= \beta\text{-transform} \left[\check{\mathbb{B}}(X^3) \right]_{ij}, \end{aligned} \quad \beta = \begin{pmatrix} 0 & -h & 0 \\ +h & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}. \quad (5.20)$$

This means, we can make the space globally-defined by using a β -transformation as a transition function. Because these transformations are not part of the geometric transformations, the space is non-geometric. However, since locally we do have a description in terms of a metric and only globally Riemannian geometry fails, the space is also called *globally non-geometric*.

Non-geometric flux

As in the previous cases, we want to identify a flux for this background. Since the H -flux is not well-defined under $X^3 \rightarrow X^3 + 2\pi$, and since similarly the vielbein one-forms are not well-defined, we should look for a different quantity. The required formalism will be discussed in section 7.6, but let us already now define a metric \mathbf{g}^{ij} and an anti-symmetric bivector-field β^{ij} via

$$[\check{\mathbf{G}} - \check{\mathbf{B}}]^{-1} = \mathbf{g} - \beta. \quad (5.21)$$

For the T-fold background (5.19) this leads to

$$\mathbf{g}^{ij} = \frac{1}{\alpha'^2} \begin{pmatrix} R_1^2 & 0 & 0 \\ 0 & R_2^2 & 0 \\ 0 & 0 & \frac{\alpha'^2}{R_3^2} \end{pmatrix}, \quad \beta^{ij} = \frac{1}{\alpha'^2} \begin{pmatrix} 0 & +\frac{\alpha'}{2\pi} h X^3 & 0 \\ -\frac{\alpha'}{2\pi} h X^3 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad (5.22)$$

which allows us to define the so-called Q -flux (in the coordinate basis) as follows

$$Q_i{}^{jk} = \partial_i \beta^{jk}. \quad (5.23)$$

However, in order to compare $Q_i{}^{jk}$ with the expressions in the vielbein basis (5.5) and (5.12), let us use the vielbein basis

$$\mathbf{e}^i{}_a = \frac{1}{\alpha'} \begin{pmatrix} R_1 & 0 & 0 \\ 0 & R_2 & 0 \\ 0 & 0 & \frac{\alpha'}{R_3} \end{pmatrix}, \quad (5.24)$$

corresponding to the metric in (5.22) as $\mathbf{g}^{ij} = \mathbf{e}^i{}_a \delta^{ab} e_b{}^j$. In this basis, the Q -flux reads $Q_a{}^{bc} = Q_i{}^{jk} \mathbf{e}^i{}_a e_b{}^j e_c{}^k$ and we find for the example of the T-fold in the vielbein basis

$$Q_3{}^{12} = \frac{\alpha'}{2\pi} \frac{h}{R_1 R_2 R_3}. \quad (5.25)$$

Thus, for the T-fold background the flux-quantum h is now encoded in a so-called non-geometric Q -flux. We also note that because the vielbein matrices (5.24) are constant, a corresponding geometric flux $f^{ab}{}_c$ vanishes.

Remarks

Let us close this section about the T-fold with the following two remarks.

- The dilaton for the T-fold background is shown in (5.17), which depends on the coordinate X^3 . It is somewhat involved to derive the transformation rules of the dilaton under β -transformations from first principles, however, the transformation under T-duality was given in (3.30). The latter implies that the combination

$$e^{-2\phi}\sqrt{\det G} \quad (5.26)$$

is invariant under T-duality. Since T-duality and β -transformations (for toroidal backgrounds with constant B -field) are both part of the duality group $O(D, D, \mathbb{Z})$, it is natural to require (5.26) to be invariant also under β -transformations. Using this requirement, for the T-fold we then determine

$$e^{-2\check{\phi}}\sqrt{\det \check{G}} = R_1 R_2 R_3 e^{-2\phi_0}, \quad (5.27)$$

which does not depend on X^3 . From here we can derive the transformation of the dilaton using (5.20), for which we can conclude that

$$\check{\phi}(X^3 + 2\pi) = \beta\text{-transform}[\check{\phi}(X^3)]. \quad (5.28)$$

- Let us also apply our discussion on page 46 to the T-fold background. If we consider a collective T-duality transformation acting on the three-torus with H -flux along the directions k_1 and k_2 (defined in (5.3)), then the two one-forms v_α can be chosen as

$$v_1 = -\frac{\alpha'}{2\pi} h X^3 dX^2, \quad v_2 = +\frac{\alpha'}{2\pi} h X^3 dX^1. \quad (5.29)$$

These are not globally-defined on the H -flux background, but only the combinations $d\chi_\alpha + v_\alpha$ are required to be globally-defined. This leads to the identifications

$$X^3 \rightarrow X^3 + 2\pi, \quad \begin{cases} \tilde{X}^1 \rightarrow \tilde{X}^1 + h X^2, \\ \tilde{X}^2 \rightarrow \tilde{X}^2 - h X^1, \end{cases} \quad (5.30)$$

where $\tilde{X}^1 = \chi_1/\alpha'$ and $\tilde{X}^2 = \chi_2/\alpha'$ are the dual coordinates and X^1 and X^2 are the original ones. We therefore see that for the T-fold background the original and dual coordinates are mixed when going around the circle in the X^3 -direction, which suggests that the background should be thought of as a twisted torus involving the original as well as the dual coordinates. The corresponding framework to describe such configurations is called doubled geometry [16], which we discuss in section 9.

5.4 R -space

In order to arrive at the T-fold background discussed in the previous section, we have performed two T-duality transformations on the three-torus with H -flux. Given that the original space is three-dimensional, it is natural to try to perform a third duality transformations and arrive at a so-called non-geometric R -space.

Duality transformations

To arrive at the R -space we would either collectively T-dualise along all directions of the three-torus, or alternatively perform a T-duality transformation along the X^3 -direction of the T-fold. However, both of these approaches violate consistency requirements:

- For the three-torus with H -flux defined in (5.1) and (5.2), the constraint for gauging (3.47) is not satisfied. Indeed, as the Killing vectors (5.3) are abelian, we have

$$3 \iota_{k_{[\alpha}} f_{\beta\gamma]}{}^\delta v_\delta = \iota_{k_\alpha} \iota_{k_\beta} \iota_{k_\gamma} H \quad \longrightarrow \quad 0 = h, \quad (5.31)$$

which can only be solved for vanishing H -flux. A collective T-duality transformation along three directions for the \mathbb{T}^3 with H -flux is therefore not allowed.

- Correspondingly, when trying to perform a single T-duality transformation along the X^3 -direction of the T-fold background (5.19), we see that the direction along ∂_3 is not an isometry. Indeed, we determine

$$\mathcal{L}_{\partial_3} \check{\mathbb{G}}_{\text{T-fold}} = -\frac{h^2 X^3}{2\pi^2 \rho^2} \left[R_2^2 d\tilde{X}^1 \otimes d\tilde{X}^1 + R_1^2 d\tilde{X}^2 \otimes d\tilde{X}^2 \right] \neq 0. \quad (5.32)$$

On the other hand, the structure which we have observed so far is rather suggestive. In particular, let us summarise the family of backgrounds discussed in this section as follows

$$\begin{array}{ccc}
 \boxed{\begin{array}{c} \text{three-torus } \mathbb{T}^3 \\ \text{flux: } H_{123} \end{array}} & \xrightarrow{\text{T-duality } T_1} & \boxed{\begin{array}{c} \text{twisted torus} \\ \text{flux: } f_{23}{}^1 \end{array}} \\
 & \xrightarrow{\text{T-duality } T_{12}} & \boxed{\begin{array}{c} \text{T-fold} \\ \text{flux: } Q_3{}^{12} \end{array}} \\
 & \xrightarrow{\text{T-duality } T_{123}} & \dots
 \end{array} \quad (5.33)$$

Thus, continuing this line, we can conjecture that three duality transformations on the three-torus with H -flux will lead to a space characterised by an object with three anti-symmetric upper indices. Taking the letter following Q , this object is usually called the R -flux R^{ijk} [121,123]. Comparing with (5.5), (5.12) and (5.25), in the present case the flux (in an appropriate vielbein basis) is then expected to take the form

$$R^{123} = \frac{\alpha'}{2\pi} \frac{h}{R_1 R_2 R_3}. \quad (5.34)$$

Non-geometric properties

Since we cannot reach the R -space through application of the Buscher rules, its properties are not well-understood. However, we can make the following observation [124]:

- Let us start from the H -flux background introduced in section 5.1 and consider a D3-brane wrapping the three-torus \mathbb{T}^3 and extending along the external time direction. Due to the Freed-Witten anomaly [125], such a configuration is not allowed.
- Nevertheless, when performing three T-duality transformations along the three-torus the D3-brane is expected to become a D0-brane. The latter is point-like in the three-dimensional R -space.
- Since the original configuration is forbidden, also a point-like D0-brane on the R -space has to be forbidden. This suggests that a description of the R -space in terms of ordinary Riemann geometry of point particles is not possible, and hence we are led to the notion of a *locally non-geometric space*.

5.5 Summary

Let us summarise the discussion of this section: starting from the three-torus with H -flux we have performed T-duality transformations leading to the twisted torus, the T-fold and the R -space. To each of these backgrounds we can associate a flux which was given in equations (5.5), (5.12), (5.25) and (5.34). Generalising this example to higher-dimensional tori with H -flux, schematically the chain of T-duality transformations can be expressed as [120,121]

$$H_{ijk} \xrightarrow{T_i} f_{jk}{}^i \xrightarrow{T_j} Q_k{}^{ij} \xrightarrow{T_k} R^{ijk}. \quad (5.35)$$

The example discussed in this section should be understood as a toy example, which illustrates the main properties of a non-geometric background. Up to this point it is however not a rigorous construction:

- The H -flux background shown in (5.1) and (5.2) does not solve the string-theoretical equations of motion (3.31). It is therefore not a proper string-theory background and applying T-duality transformations is a priori not justified. Furthermore, when performing a similar analysis for the three-sphere with H -flux – which does solve the equations of motion (3.31) – then no non-geometric features arise (see equation (3.76)). In fact, for the three-sphere the question whether a T-fold analogue appears can be traced to the question whether the string-equations of motion are satisfied [58].
- The vanishing of the β -functionals (3.31) can be interpreted as the equations of motion of an effective theory. For superstring theory this is for instance type IIA or type IIB supergravity. In these theories it is possible to turn on also Ramond-Ramond fluxes, which do allow for configurations solving the equations of motion. However, even though such backgrounds can be solutions to the supergravity equations of motion, a string-theoretical CFT description is usually difficult.

On the other hand, there is evidence from a variety of examples that non-geometric spaces are indeed relevant backgrounds for string theory. We mention some of them here, and discuss these in more detail in the subsequent sections.

- The example of the three-torus with H -flux is a particular example of a parabolic \mathbb{T}^2 -fibration over a circle, which contains the T-fold as one of its T-dual backgrounds. However, also so-called elliptic fibrations exist which do solve the string-theory equations of motion. We discuss these backgrounds in section 6.4.
- From a supergravity point of view, upon compactification the fluxes appearing in (5.35) give rise to gauged supergravity theories. In particular, the charges corresponding to the local gauge symmetries are related to the various fluxes. Moreover, in order to reproduce all gaugings which are possible from a supergravity point of view, non-geometric fluxes are needed. We discuss this point in section 8.
- T-duality transformations can be described using the framework of generalised geometry. In this approach, non-geometric fluxes appear naturally and can be given a microscopic description. We explain this point in section 7.

6 Torus fibrations

After having studied the three-torus with H -flux and its T-dual configurations, in this section we discuss non-geometric backgrounds in a more systematic way. We consider n -dimensional torus fibrations over various base manifolds, and first revisit in section 6.1 the three-torus example in this framework. In the following sections we study more general \mathbb{T}^2 -fibrations over the circle, over \mathbb{P}^1 and over the punctured plane, and we connect some of these fibrations to the compactified NS5-brane, Kaluza-Klein monopole and non-geometric 5_2^2 -brane.

Setting and notation

The setting we are interested in is that of n -dimensional torus fibrations \mathcal{M} over a $(D - n)$ -dimensional base-manifold \mathcal{B}

$$\begin{array}{ccc} \mathbb{T}^n & \hookrightarrow & \mathcal{M} \\ & & \downarrow \\ & & \mathcal{B} \end{array} \quad (6.1)$$

Local coordinates on the base-manifold will be denoted by x^m with $m = 1, \dots, D - n$ and coordinates in the fibre are y^a with $a = 1, \dots, n$. The metric and B -field are assumed to only depend on the coordinates x^m of the base. We furthermore assume that the base-manifold \mathcal{B} has at least one non-contractible one-cycle γ , and examples for such manifolds are $\mathcal{B} = S^1$ and $\mathcal{B} = \mathbb{R}^2 \setminus \{0\}$. The non-triviality of the fibration is encoded in the monodromy of the metric and B -field along the cycle γ . In particular, if we parametrise going around γ as $x \rightarrow x + 2\pi$ we can ask how $(G_{ab}, B_{ab})(x + 2\pi)$ is related to $(G_{ab}, B_{ab})(x)$:

- In an ordinary geometric background, we can use the symmetries of the theory to relate the torus fibre at $x + 2\pi$ to x [126–130]. These symmetries are diffeomorphisms and gauge transformations, which are sometimes referred to as geometric transformations.
- However, for non-geometric backgrounds also proper T-duality transformations can be used to relate the fibre at $x + 2\pi$ to x [16, 131], which mix the metric and the B -field. These are also called non-geometric transformations.

Note that both, the symmetry and duality transformations are part of the duality group of the n -dimensional torus fibre, which in the present case is $O(n, n, \mathbb{Z})$. The monodromy along the cycle $\gamma \subset \mathcal{B}$ and the patching of the fibre are illustrated in figure 6.

Figure 6: Illustration of how a torus fibration over a circle can be patched in order to obtain a globally well-defined space. For a geometric background the $O(n, n, \mathbb{Z})$ transformations can be diffeomorphisms and gauge transformations, whereas for a non-geometric background for instance also β -transformations are allowed.

6.1 \mathbb{T}^2 -fibrations over the circle I

To start, let us revisit the example of the three-torus with H -flux from the previous section. In the present notation the local coordinates are $\{y^1, y^2, x\}$, which are normalised as $y^a \sim y^a + 2\pi$ and $x \sim x + 2\pi$. The metric and B -field can be brought into the following general form

$$G_{ij} = \begin{pmatrix} G_{ab}(x) & 0 \\ 0 & R_3^2 \end{pmatrix}, \quad B_{ij} = \begin{pmatrix} B_{ab}(x) & 0 \\ 0 & 0 \end{pmatrix}. \quad (6.2)$$

$O(2, 2, \mathbb{Z})$ transformations

Let us now focus on the two-dimensional toroidal part and the corresponding $O(2, 2, \mathbb{Z})$ duality group, and investigate how the fibre at the point $x + 2\pi$ on the base is related to the point x .

- We begin with the three-torus with non-vanishing H -flux. The \mathbb{T}^2 -fibre of this background can be described by

$$H\text{-flux:} \quad G_{ab} = \begin{pmatrix} R_1^2 & 0 \\ 0 & R_2^2 \end{pmatrix}, \quad B_{ab} = \begin{pmatrix} 0 & +\frac{\alpha'}{2\pi} hx \\ -\frac{\alpha'}{2\pi} hx & 0 \end{pmatrix}, \quad (6.3)$$

with $h \in \mathbb{Z}$. Let us then employ the framework from section 2.3 and consider

an $O(2, 2, \mathbb{Z})$ transformation. Defining

$$\mathcal{O}_B = \begin{pmatrix} \mathbb{1} & 0 \\ B & \mathbb{1} \end{pmatrix}, \quad B = \begin{pmatrix} 0 & +h \\ -h & 0 \end{pmatrix}, \quad (6.4)$$

with $\mathcal{O}_B \in O(2, 2, \mathbb{Z})$, we can check that the generalised metric \mathcal{H}_H corresponding to (6.3) transforms as

$$\mathcal{H}_H(x + 2\pi) = \mathcal{O}_B^{-T} \mathcal{H}_H(x) \mathcal{O}_B^{-1}. \quad (6.5)$$

This transformation describes a gauge transformation of the B -field, which is needed to relate the \mathbb{T}^2 -fibre at $x + 2\pi$ to x . This is a geometric transformation.

- Next, we turn to the twisted torus. The metric and B -field of the torus fibre can be determined from (5.6) as follows

$$f\text{-flux:} \quad G_{ab} = \begin{pmatrix} \frac{\alpha'^2}{R_1^2} & -\frac{\alpha'^2}{R_1^2} \frac{h}{2\pi} x \\ -\frac{\alpha'^2}{R_1^2} \frac{h}{2\pi} x & R_2^2 + \frac{\alpha'^2}{R_1^2} \left[\frac{h}{2\pi x} \right]^2 \end{pmatrix}, \quad B_{ab} = 0. \quad (6.6)$$

The $O(2, 2, \mathbb{Z})$ transformation of interest is given by

$$\mathcal{O}_A = \begin{pmatrix} A^{-1} & 0 \\ 0 & A^T \end{pmatrix}, \quad A = \begin{pmatrix} 1 & -h \\ 0 & 1 \end{pmatrix}, \quad (6.7)$$

and for the generalised metric \mathcal{H}_f corresponding to (6.6) we can compute

$$\mathcal{H}_f(x + 2\pi) = \mathcal{O}_A^{-T} \mathcal{H}_f(x) \mathcal{O}_A^{-1}. \quad (6.8)$$

This transformation describes a diffeomorphism, which is used to make the twisted torus a globally-defined space. Again, this is a geometric transformation.

- We finally turn to T-fold background specified in (5.17). The corresponding metric and B -field of the \mathbb{T}^2 -fibre along the \tilde{X}^1 - and \tilde{X}^2 -direction can be determined from (5.19) as

$$Q\text{-flux:} \quad G_{ab} = \frac{1}{\rho} \begin{pmatrix} R_2^2 & 0 \\ 0 & R_1^2 \end{pmatrix}, \quad B_{ab} = \frac{1}{\rho} \begin{pmatrix} 0 & -\frac{\alpha'}{2\pi} h x \\ +\frac{\alpha'}{2\pi} h x & 0 \end{pmatrix}, \quad (6.9)$$

where ρ was defined in equation (5.16). We have already discussed that in the case of the T-fold a β -transformation is needed to make the background globally-defined. In particular, for

$$\mathcal{O}_\beta = \begin{pmatrix} \mathbb{1} & \beta \\ 0 & \mathbb{1} \end{pmatrix}, \quad \beta = \begin{pmatrix} 0 & +h \\ -h & 0 \end{pmatrix}, \quad (6.10)$$

we can check that

$$\mathcal{H}_Q(x + 2\pi) = \mathcal{O}_\beta^{-T} \mathcal{H}_Q(x) \mathcal{O}_\beta^{-1}. \quad (6.11)$$

As we discussed on page 26, such a transformation is not a symmetry but a duality transformation. The T-fold background is therefore a non-geometric background.

Chain of duality transformations

Let us also revisit the chain of T-duality transformations shown in (5.35). Applying a first T-duality transformation to the H -flux background along the X^1 -direction gives a twisted torus with geometric f -flux, and performing a second T-duality transformation along the X^2 -direction results in a T-fold with Q -flux. In terms of $O(2, 2, \mathbb{Z})$ transformations acting on the generalised metric this reads in formulas

$$\mathcal{H}_f = \mathcal{O}_{+1}^{-T} \mathcal{H}_H \mathcal{O}_{+1}^{-1}, \quad \mathcal{H}_Q = \mathcal{O}_{+2}^{-T} \mathcal{H}_f \mathcal{O}_{+2}^{-1}, \quad (6.12)$$

where subscript of \mathcal{H} indicates the corresponding background and where the matrices $\mathcal{O}_{\pm i}$ have been defined in (2.50).⁵ We therefore arrive at the following picture

$$\begin{array}{ccccc}
 \mathcal{O}_B & & \mathcal{O}_A & & \mathcal{O}_\beta \\
 \circlearrowleft & & \circlearrowleft & & \circlearrowleft \\
 \boxed{H\text{-flux}} & \xleftarrow{\mathcal{O}_E} & \boxed{f\text{-flux}} & \xleftarrow{\mathcal{O}_E} & \boxed{Q\text{-flux}}
 \end{array} \quad (6.13)$$

with \mathcal{O}_B , \mathcal{O}_A and \mathcal{O}_β denoting the patching-transformations. From (6.13) it becomes also clear how the latter are related. For instance, the transformation \mathcal{O}_A for the f -flux background or \mathcal{O}_β for the Q -flux background is determined by conjugation as

$$\mathcal{O}_A^{(f)} = \mathcal{O}_{+1}^{-1} \mathcal{O}_B^{(H)} \mathcal{O}_{+1}, \quad \mathcal{O}_\beta^{(Q)} = \mathcal{O}_{+2}^{-1} \mathcal{O}_A^{(f)} \mathcal{O}_{+2}. \quad (6.14)$$

Note that in (6.13) all generators of $O(2, 2, \mathbb{Z})$ play a role, and that we have not included the R -space background. In order to obtain the latter a T-duality transformation along the base-manifold – that is the x -direction in (6.2) – has to be performed, which cannot be described within the present framework.

⁵ Using \mathcal{O}_{-1} and \mathcal{O}_{-2} reverses the sign of the flux quantum number, which corresponds to the parity symmetry Ω of the world-sheet theory.

Three-torus with H -, f - and Q -flux

We also want to briefly discuss a generalisation of three-torus example, where we consider H -, f - and Q -flux simultaneously. The metric and Kalb-Ramond field for this example are specified by

$$G_{\text{ab}} = \frac{1}{1 + \left[\frac{R_1 R_2}{\alpha'} \frac{qx}{2\pi}\right]^2} \begin{pmatrix} R_1^2 & R_1^2 \frac{fx}{2\pi} \\ R_1^2 \frac{fx}{2\pi} & R_2^2 + R_1^2 \left[\frac{fx}{2\pi}\right]^2 \end{pmatrix}, \quad (6.15)$$

$$B_{\text{ab}} = \alpha' \begin{pmatrix} 0 & +\frac{hx}{2\pi} \\ -\frac{hx}{2\pi} & 0 \end{pmatrix} + \frac{\alpha'}{\frac{\alpha'^2}{R_1^2 R_2^2} + \left[\frac{qx}{2\pi}\right]^2} \begin{pmatrix} 0 & -\frac{qx}{2\pi} \\ +\frac{qx}{2\pi} & 0 \end{pmatrix},$$

where $h, f, q \in \mathbb{Z}$ denote the corresponding flux quanta. Note that setting two of these fluxes to zero reproduces the above backgrounds (up to inversion of the radii and changing the sign of the geometric flux). The $O(2, 2, \mathbb{Z})$ transformation connecting the torus fibre at $x + 2\pi$ to x is naively expected to be a combination of the transformations discussed above. However, only for

$$\tilde{\mathcal{O}} = \mathcal{O}_{\text{B}(h)} \mathcal{O}_{\text{A}(f)} \mathcal{O}_{\beta(q)} \quad \text{with } hq = 0 \quad (6.16)$$

this is possible. The situation with $hq \neq 0$ requires a more involved construction, and we address this question in the next section. Let us however summarise that

- the background (6.15) with $q = 0$ and $h, f \neq 0$ describes a twisted three-torus with H -flux,
- the background (6.15) with $h = 0$ and $f, q \neq 0$ describes a T-fold with geometric flux.

Remarks

- As we have mentioned earlier, the non-triviality of the fibration is encoded in the various geometric and non-geometric fluxes. In particular, from the monodromies \mathcal{O}_{B} , \mathcal{O}_{A} and \mathcal{O}_{β} shown in (6.4), (6.7) and (6.10) we can read off the H -, f - and Q -flux of the corresponding background. For more general monodromies it might be more difficult to identify the fluxes, and we come back to this question below.
- The transformations \mathcal{O}_{A} , \mathcal{O}_{B} and \mathcal{O}_{β} belong to the $\det \mathcal{O} = +1$ part of $O(2, 2, \mathbb{Z})$ and are connected to the identity. The fibration can therefore be constructed as a continuous path starting from the identity, which we explain in more detail in the next section. However, T-duality transformations \mathcal{O}_{E}

have determinant $\det \mathcal{O}_E = -1$ and thus belong to the disconnected part of the group. This means that fibrations with monodromies of the form \mathcal{O}_E cannot be constructed in the same way.

- Since the geometric and non-geometric backgrounds discussed in this section are related by duality transformations, according to our definition 4 on page 9 this family of backgrounds is called geometric. However, according to our definition 3 the T-fold is a non-geometric background.

6.2 \mathbb{T}^2 -fibrations over the circle II

In section 6.1 we have formulated the three-torus with H -flux and its T-dual configurations as \mathbb{T}^2 -fibrations over a circle. This example falls into a particular category of fibrations – so-called parabolic fibrations – but more general constructions are possible. In this section we now want to take a different approach and first specify the monodromy of the \mathbb{T}^2 -fibre along the base-circle, and then construct a corresponding metric and Kalb-Ramond field. Our notation follows [132], which in parts is based on [130].

Kähler and complex-structure moduli

Let us start by characterising the two-torus background in terms of its complex-structure modulus τ and the complexified Kähler modulus ρ . These moduli are defined in terms of the metric and Kalb-Ramond field in the following way

$$\tau = \frac{G_{12}}{G_{22}} + i \frac{\sqrt{\det G}}{G_{22}}, \quad \rho = \frac{1}{\alpha'} \left(B_{12} + i \sqrt{\det G} \right). \quad (6.17)$$

Roughly speaking, τ encodes the shape of the \mathbb{T}^2 and ρ determines its volume plus the B -field. Next, we note that the duality group $O(2, 2, \mathbb{Z})$ of the two-torus is isomorphic to

$$O(2, 2, \mathbb{Z}) \simeq SL(2, \mathbb{Z}) \times SL(2, \mathbb{Z}) \times \mathbb{Z}_2 \times \mathbb{Z}_2, \quad (6.18)$$

and for a more detailed discussion we refer for instance to [17]. The duality group acts on the two moduli in the following way:

- The two $SL(2, \mathbb{Z})$ factors are Möbius transformations on the complex-structure and complexified Kähler modulus

$$\begin{aligned} \tau &\rightarrow \frac{a\tau + b}{c\tau + d}, & M_\tau &= \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in SL(2, \mathbb{Z}), \\ \rho &\rightarrow \frac{\tilde{a}\rho + \tilde{b}}{\tilde{c}\rho + \tilde{d}}, & M_\rho &= \begin{pmatrix} \tilde{a} & \tilde{b} \\ \tilde{c} & \tilde{d} \end{pmatrix} \in SL(2, \mathbb{Z}). \end{aligned} \quad (6.19)$$

Note that $SL(2, \mathbb{Z})$ is generated by T - and S -transformations, which for τ and ρ means

$$\begin{aligned} T : \quad \tau &\rightarrow \tau + 1, & \tilde{T} : \quad \rho &\rightarrow \rho + 1, \\ S : \quad \tau &\rightarrow -\frac{1}{\tau}, & \tilde{S} : \quad \rho &\rightarrow -\frac{1}{\rho}. \end{aligned} \tag{6.20}$$

Let us emphasise that $SL(2, \mathbb{Z})$ transformations of τ are large diffeomorphisms of the two-torus and therefore correspond to geometric symmetries. A \tilde{T} -transformation acting on ρ can be interpreted as a gauge transformation which is again geometric, but a \tilde{S} -transformation acting on ρ will in general invert the volume of the \mathbb{T}^2 and is not a geometric transformation.

- One of the \mathbb{Z}_2 factors in (6.18) corresponds to mirror symmetry $(\tau, \rho) \rightarrow (\rho, \tau)$. This is a T-duality transformation, which can be seen for a particular case by setting G_{12} and B_{12} to zero in (6.17).
- The remaining \mathbb{Z}_2 factor in (6.18) corresponds to a reflection of the form $(\tau, \rho) \rightarrow (-\bar{\tau}, -\bar{\rho})$.

Including in addition the world-sheet parity transformation Ω which acts on the Kalb-Ramond field as $B_{12} \rightarrow -B_{12}$ and leaves the metric invariant, the minimal set of generators of the duality group (6.18) turns out to be [17]

$$\begin{aligned} 1) \quad & \tau \rightarrow -\frac{1}{\tau}, & \rho &\rightarrow \rho, \\ 2) \quad & \tau \rightarrow \tau + 1, & \rho &\rightarrow \rho, \\ 3) \quad & \tau \rightarrow \rho, & \rho &\rightarrow \tau, \\ 4) \quad & \tau \rightarrow \tau, & \rho &\rightarrow -\bar{\rho}. \end{aligned} \tag{6.21}$$

$O(2, 2, \mathbb{Z})$ **versus** $SL(2, \mathbb{Z}) \times SL(2, \mathbb{Z}) \times \mathbb{Z}_2 \times \mathbb{Z}_2$

In order to compare our present discussion to the results in section 6.1, it is useful to translate $O(2, 2, \mathbb{Z})$ transformations into transformations acting on τ and ρ . To do so, we express the metric and Kalb-Ramond field of the two-torus in terms of the complex-structure and complexified Kähler modulus $\tau = \tau_1 + i\tau_2$ and $\rho = \rho_1 + i\rho_2$ as

$$G_{ab} = \alpha' \frac{\rho_2}{\tau_2} \begin{pmatrix} \tau_1^2 + \tau_2^2 & \tau_1 \\ \tau_1 & 1 \end{pmatrix}, \quad B_{ab} = \alpha' \begin{pmatrix} 0 & +\rho_1 \\ -\rho_1 & 0 \end{pmatrix}. \tag{6.22}$$

Using these relations, we can write the transformations we encountered in section 6.1 as follows

$$\begin{aligned}
\text{transformation (6.4)} \quad \mathcal{O}_B &: \quad \tau \rightarrow \tau, & \rho &\rightarrow \rho + h, \\
\text{transformation (6.7)} \quad \mathcal{O}_A &: \quad \tau \rightarrow \frac{\tau}{-h\tau + 1}, & \rho &\rightarrow \rho, \\
\text{transformation (6.10)} \quad \mathcal{O}_\beta &: \quad \tau \rightarrow \tau, & \rho &\rightarrow \frac{\rho}{-h\rho + 1}, \quad (6.23) \\
\text{transformation} \quad \mathcal{O}_{+1} &: \quad \tau \rightarrow -\frac{1}{\rho}, & \rho &\rightarrow -\frac{1}{\tau}, \\
\text{transformation} \quad \mathcal{O}_{+2} &: \quad \tau \rightarrow \rho, & \rho &\rightarrow \tau.
\end{aligned}$$

The last two lines show how a T-duality transformation along the two directions y^1 and y^2 of the two-torus act on the moduli.

Constructing the background from the monodromy

We now want to construct a metric and Kalb-Ramond field for the two-torus from a given monodromy transformation acting on the complex-structure modulus τ and the complexified Kähler modulus ρ . Let us consider say $M_\tau \in SL(2, \mathbb{Z})$ acting on τ via Möbius transformations (6.19). We let $\tau \equiv \tau(x)$ vary over the base-circle and impose that [129]

$$\tau(0) = \tau_0, \quad \tau(2\pi) = M_\tau[\tau_0]. \quad (6.24)$$

The coordinate dependence of $\tau(x)$ is contained in $M_\tau(x)$ such that $M_\tau(2\pi) = M_\tau$. In order to construct $M_\tau(x)$ we consider an element $\mathfrak{m} = \log M_\tau$ in the Lie algebra $\mathfrak{sl}(2, \mathbb{R})$ and exponentiate, that is $M_\tau(x) = \exp(\mathfrak{m}x/2\pi)$. The x -dependence of $\tau(x)$ is then given by

$$\tau(x) = M_\tau(x)[\tau_0], \quad (6.25)$$

which indeed satisfies (6.24). For the complexified Kähler modulus ρ a similar discussion with a corresponding monodromy matrix M_ρ applies. However, for the two \mathbb{Z}_2 factors in (6.18) – containing a T-duality transformation – such a construction is not possible since these are not connected to the identity. Using then $\tau(x)$ and $\rho(x)$ in (6.22) together with (6.2) determines the metric and B -field of the full background.

Let us now classify $SL(2, \mathbb{Z})$ transformations. As we have seen, such transformations can be described by two-by-two matrices $M \in SL(2, \mathbb{Z})$ according to (6.19), which fall into three classes:

1. *Elliptic type*, for which the trace of M satisfies $|\text{tr } M| < 2$.
2. *Parabolic type*, for which the trace of M satisfies $|\text{tr } M| = 2$.
3. *Hyperbolic type*, for which the trace of M satisfies $|\text{tr } M| > 2$.

Elliptic transformations are of finite order, in particular of order six, four or three, and there are six conjugacy classes. Parabolic transformations are of infinite order, and there is an infinite number of conjugacy classes. For hyperbolic transformations there is a conjugacy class for each value of the trace plus additional sporadic classes. More details can be found for instance in [133, 129, 132].

Following the procedure outlined above, one can now construct the background for a given monodromy in τ and ρ . Depending on the type of the $SL(2, \mathbb{Z})$ transformation, the resulting expressions for $\tau(x)$ and $\rho(x)$ differ significantly. We do not want to give general discussion of such solutions but refer for instance to [130, 132]. However, below we illustrate some features of more general \mathbb{T}^2 -fibrations through the example of the three-torus with simultaneous H -, geometric and Q -flux.

Three-torus with H -, f - and Q -flux – revisited

Let us recall (6.23) and note that the $O(2, 2, \mathbb{Z})$ transformations \mathcal{O}_B , \mathcal{O}_A and \mathcal{O}_β individually are all of parabolic type both in τ and ρ . For these we have discussed the corresponding (non-)geometric backgrounds in section 6.1. In equation (6.15) we have also shown a three-dimensional background with either H - and geometric flux or geometric and Q -flux. As one can see from (6.23), the corresponding transformations $\mathcal{O}_{B(h)}$, $\mathcal{O}_{A(f)}$ and $\mathcal{O}_{\beta(q)}$ are again of parabolic type.

However, when all three types of fluxes are present simultaneously we expect to have a monodromy transformation of the form

$$\tilde{\mathcal{O}} = \mathcal{O}_{B(h)} \mathcal{O}_{A(f)} \mathcal{O}_{\beta(q)} : \quad \tau \rightarrow \frac{\tau}{f\tau + 1}, \quad \rho \rightarrow \frac{(1 - hq)\rho + h}{-q\rho + 1}, \quad (6.26)$$

which are of parabolic type for τ but which are of varying type for ρ depending on the value of hq . This can be seen from the corresponding $SL(2, \mathbb{Z})$ matrices

$$M_\tau = \begin{pmatrix} 1 & 0 \\ f & 1 \end{pmatrix}, \quad M_\rho = \begin{pmatrix} 1 - hq & h \\ -q & 1 \end{pmatrix}. \quad (6.27)$$

Depending on the type of monodromy transformation for ρ , the functional form of $\rho(x)$ is different for each of the three cases mentioned above. In the following we do not determine the background for general choices of fluxes (h, f, q) , but only want to illustrate the main features through some examples.

- $(h, f, q) = (+1, f, +1)$: For this choice of fluxes the τ -transformation is parabolic and the ρ -transformation is of elliptic type of order six. The corresponding metric and B -field of the torus fibre (recall (6.2) for our notation) read

$$\begin{aligned}
G_{\text{ab}}^{(+1,+1)} &= \frac{3\alpha'^2}{\Omega^{(+1,+1)}} \begin{pmatrix} R_1^2 & R_1^2 \frac{fx}{2\pi} \\ R_1^2 \frac{fx}{2\pi} & R_2^2 + R_1^2 \left[\frac{fx}{2\pi}\right]^2 \end{pmatrix}, \\
B_{12}^{(+1,+1)} &= \frac{2\alpha'}{\Omega^{(+1,+1)}} \sin\left[\frac{x}{6}\right] \left((\alpha'^2 + R_1^2 R_2^2) \sin\left[\frac{x}{6}\right] + \sqrt{3}(\alpha'^2 - R_1^2 R_2^2) \cos\left[\frac{x}{6}\right] \right), \\
\Omega^{(+1,+1)} &= 2R_1^2 R_2^2 \left(1 - \cos\left[\frac{x}{3}\right]\right) + \alpha'^2 \left(2 + \cos\left[\frac{x}{3}\right] + \sqrt{3} \sin\left[\frac{x}{3}\right]\right).
\end{aligned} \tag{6.28}$$

- $(h, f, q) = (+2, f, +1)$: For this choice the τ -transformation is again parabolic and the ρ -transformation is elliptic of order four. The metric and B -field of the torus fibre read

$$\begin{aligned}
G_{\text{ab}}^{(+2,+1)} &= \frac{2\alpha'^2}{\Omega^{(+2,+1)}} \begin{pmatrix} R_1^2 & R_1^2 \frac{fx}{2\pi} \\ R_1^2 \frac{fx}{2\pi} & R_2^2 + R_1^2 \left[\frac{fx}{2\pi}\right]^2 \end{pmatrix}, \\
B_{12}^{(+2,+1)} &= \frac{2\alpha'}{\Omega^{(+2,+1)}} \sin\left[\frac{x}{4}\right] \left((2\alpha'^2 + R_1^2 R_2^2) \sin\left[\frac{x}{4}\right] + (2\alpha'^2 - R_1^2 R_2^2) \cos\left[\frac{x}{4}\right] \right), \\
\Omega^{(+2,+1)} &= R_1^2 R_2^2 \left(1 - \cos\left[\frac{x}{2}\right]\right) + 2\alpha'^2 \left(1 + \sin\left[\frac{x}{2}\right]\right).
\end{aligned} \tag{6.29}$$

- $(h, f, q) = (+2, f, +2)$: Here the τ -transformation is again parabolic but also the ρ -transformation is parabolic. The metric and B -field take the form

$$\begin{aligned}
G_{\text{ab}}^{(+2,+2)} &= \frac{\alpha'^2}{\Omega^{(+2,+2)}} \begin{pmatrix} R_1^2 & R_1^2 \frac{fx}{2\pi} \\ R_1^2 \frac{fx}{2\pi} & R_2^2 + R_1^2 \left[\frac{fx}{2\pi}\right]^2 \end{pmatrix}, \\
B_{12}^{(+2,+2)} &= \frac{\alpha'}{\Omega^{(+2,+2)}} \frac{x}{\pi} \left((\alpha'^2 + R_1^2 R_2^2) \frac{x}{\pi} - (\alpha'^2 - R_1^2 R_2^2) \right), \\
\Omega^{(+2,+2)} &= R_1^2 R_2^2 \left(\frac{x}{\pi}\right)^2 + \alpha'^2 \left(1 - \frac{x}{\pi}\right)^2.
\end{aligned} \tag{6.30}$$

- $(h, f, q) = (+1, f, -1)$: Finally, this is an example where the τ -transformation is parabolic and where the ρ -transformation is hyperbolic. The metric and

B -field read

$$\begin{aligned}
G_{\text{ab}}^{(+1,-1)} &= \frac{(35 + 15\sqrt{5})(6 + 2\sqrt{5})^{\frac{x}{\pi}} \alpha'^2}{\Omega^{(+1,-1)}} \begin{pmatrix} R_1^2 & R_1^2 \frac{fx}{2\pi} \\ R_1^2 \frac{fx}{2\pi} & R_2^2 + R_1^2 \left[\frac{fx}{2\pi}\right]^2 \end{pmatrix}, \\
B_{12}^{(+1,-1)} &= \frac{\alpha'}{\Omega^{(+1,-1)}} \left((3 + \sqrt{5})^{\frac{x}{\pi}} - 2^{\frac{x}{\pi}} \right) \\
&\quad \left[\left((4 + 2\sqrt{5}) 2^{\frac{x}{\pi}} + (11 + 5\sqrt{5})(3 + \sqrt{5})^{\frac{x}{\pi}} \right) R_1^2 R_2^2 \right. \\
&\quad \left. + \left((4 + 2\sqrt{5})(3 + \sqrt{5})^{\frac{x}{\pi}} + (11 + 5\sqrt{5}) 2^{\frac{x}{\pi}} \right) \alpha'^2 \right], \\
\Omega^{(+1,-1)} &= (7 + 3\sqrt{5}) \left(2^{\frac{x}{\pi}} - (3 + \sqrt{5})^{\frac{x}{\pi}} \right)^2 R_1^2 R_2^2 \\
&\quad + \left((14 + 6\sqrt{5})(6 + 2\sqrt{5})^{\frac{x}{\pi}} + (18 + 8\sqrt{5}) 4^{\frac{x}{\pi}} \right) \alpha'^2.
\end{aligned} \tag{6.31}$$

As one can see from these examples, the form of the background can be rather complicated and depends on the type of $SL(2, \mathbb{Z})$ transformation. These are explicit examples of toroidal backgrounds with simultaneously H -, geometric and Q -flux present.

T-duality transformations

In contrast to the situation discussed in section 6.1, in general T-duality transformations do not simply exchange the various fluxes. Let us illustrate this observation again with the three-torus with H -, geometric and Q -flux simultaneously present. A T-duality transformation along a direction of two-torus fibre changes the monodromy transformation through conjugation, similarly as in (6.14). Starting from (6.26) with $\tilde{\mathcal{O}} = \mathcal{O}_{\text{B}(h)} \mathcal{O}_{\text{A}(f)} \mathcal{O}_{\text{B}(q)}$, we have

$$\begin{aligned}
\tilde{\mathcal{O}} &: \quad \tau \rightarrow \frac{\tau}{f\tau + 1}, \quad \rho \rightarrow \frac{(1 - hq)\rho + h}{-q\rho + 1}, \\
\mathcal{O}_{+1}^{-1} \tilde{\mathcal{O}} \mathcal{O}_{+1} &: \quad \tau \rightarrow \frac{\tau + q}{-h\tau + (1 - hq)}, \quad \rho \rightarrow \rho - f, \\
\mathcal{O}_{+2}^{-1} \tilde{\mathcal{O}} \mathcal{O}_{+2} &: \quad \tau \rightarrow \frac{(1 - hq)\tau + h}{-q\tau + 1}, \quad \rho \rightarrow \frac{\rho}{f\rho - +1}, \\
\mathcal{O}_{+2}^{-1} \mathcal{O}_{+1}^{-1} \tilde{\mathcal{O}} \mathcal{O}_{+1} \mathcal{O}_{+2} &: \quad \tau \rightarrow \tau - f, \quad \rho \rightarrow \frac{\rho + q}{-h\rho + (1 - hq)}.
\end{aligned} \tag{6.32}$$

Figure 7: Illustration of a \mathbb{T}^2 -fibration over a two-sphere \mathbb{P}^1 , with a number of points where the \mathbb{T}^2 -fibre degenerates. Along a path around the point of degeneration the \mathbb{T}^2 undergoes a monodromy transformation.

Let us note that after a T-duality along the y^1 -direction of the \mathbb{T}^2 the resulting monodromy acts on the complexified Kähler modulus as $\rho \rightarrow \rho - f$, which corresponds to a gauge transformation of the B -field. Therefore, this background is geometric – although with a rather complicated transformation behaviour of the complex-structure modulus. According to our definition 4 on page 9, the family of backgrounds would therefore be called geometric.

6.3 \mathbb{T}^2 -fibrations over \mathbb{P}^1

In this section we consider \mathbb{T}^2 -fibrations over the two-sphere \mathbb{P}^1 instead over the circle. We follow the papers [134] and [132], which are based on work in [135].

Setting

More concretely, we consider \mathbb{T}^2 -fibrations over a punctured sphere $\mathbb{P}^1 \setminus \Delta$, where $\Delta = (x_1, \dots, x_n)$ is a set of n points in \mathbb{P}^1 where the fibre is allowed to degenerate. The degeneration of the fibre will be characterised by the monodromy of the complex-structure and Kähler moduli of the two-torus along a path surrounding the corresponding point in \mathbb{P}^1 (see figure 7).

Focusing on a single point of degeneration, locally we can choose a complex coordinate $z \in \mathbb{C}$ such that the degeneration is located at the origin $z = 0$. The geometric data of the \mathbb{T}^2 -fibre is encoded in the complex-structure and (complexified) Kähler moduli, and for a non-trivial fibration we let τ and ρ depend on z . Here, we require this dependence to be holomorphic, which is related to solving

the string equations of motion and to preserving supersymmetry [134, 136, 137].

Degenerations

Let us now outline the general strategy for determining $\tau(z)$ and $\rho(z)$ from a given monodromy. We focus on say the complex-structure modulus, and encircling the degeneration corresponds to $z \rightarrow e^{2\pi i} z$. For a given monodromy M_τ we require that the complex structure at $\tau(z + 2\pi)$ is related to $\tau(z)$ by a $SL(2, \mathbb{Z})$ transformation

$$\tau(e^{2\pi i} z) = M_\tau[\tau(z)] \equiv \frac{a\tau(z) + b}{c\tau(z) + d}. \quad (6.33)$$

In section 6.2 we have encountered a very similar situation. Choosing polar coordinates $z = r e^{i\theta}$, we have already explained how to obtain $\tau(\theta)$ for a fixed value of $r = r_0 > 0$. In particular, recalling (6.25) and denoting by \mathfrak{m} the Lie-algebra element corresponding to M_τ , we have seen that

$$\tau(r_0, \theta) = M_\tau(\theta)[\tau_0(r_0)], \quad M_\tau(x) = \exp(\mathfrak{m}\theta/2\pi). \quad (6.34)$$

Now, in order to determine $\tau(z)$ we allow for arbitrary values of the radius and replace $r_0 \rightarrow r$ in (6.34). Requiring then that τ depends holomorphically on z leads to the Cauchy-Riemann equations

$$\frac{\partial\tau(r, \theta)}{\partial r} + \frac{i}{r} \frac{\partial\tau(r, \theta)}{\partial\theta} = 0. \quad (6.35)$$

For all three classes of $SL(2, \mathbb{Z})$ transformations a solution to these equations always exists, which then determines $\tau(z)$ for a given monodromy M_τ (up to integration constants). Of course, a similar analysis can be performed also for the complexified Kähler modulus ρ and corresponding monodromies $M_\rho \in SL(2, \mathbb{Z})$.

Simple examples

Let us now discuss some examples of \mathbb{T}^2 -fibrations with varying complex structure. The simplest solution for $\tau(z)$ with a non-trivial monodromy is given by [135]

$$\tau = \frac{1}{2\pi i} \log z, \quad (6.36)$$

which, when going around the origin via $z \rightarrow e^{2\pi i} z$, behaves as

$$\tau \rightarrow \tau + 1. \quad (6.37)$$

Other examples for non-trivial monodromies of the complex-structure modulus together with their solutions $\tau(z)$ are the following [132]

$$\begin{array}{lll}
\text{parabolic} & \tau \rightarrow \tau + b, & \tau = \frac{b}{2\pi i} \log z, \\
\text{elliptic order 6} & \tau \rightarrow \frac{\tau + 1}{-\tau}, & \tau = \frac{1 - z^{1/3}}{e^{2\pi i/3} - e^{4\pi i/3} z^{1/3}}, \\
\text{elliptic order 4} & \tau \rightarrow -\frac{1}{\tau}, & \tau = \frac{1 - \sqrt{z}}{i + i\sqrt{z}}, \\
\text{elliptic order 3} & \tau \rightarrow -\frac{1}{\tau + 1}, & \tau = \frac{1 - z^{2/3}}{e^{2\pi i/3} - e^{4\pi i/3} z^{2/3}}.
\end{array} \tag{6.38}$$

Classification

A convenient way to encode the monodromy of the complex structure τ for a certain class of fibrations is by describing the \mathbb{T}^2 -fibre as an elliptic curve satisfying the Weierstrass equation

$$y^2 = x^3 + f(z)x + g(z), \tag{6.39}$$

with z the local coordinate on the base-manifold. The discriminant locus where the fibre degenerates is given by $\Delta : 0 = 4f^3 + 27g^2$. Furthermore, the functional form of $\tau(z)$ is specified implicitly by Klein's j -invariant which is expressed in terms of $f(z)$ and $g(z)$ as

$$j(\tau) = \frac{(12f)^2}{4f^3 + 27g^2}. \tag{6.40}$$

Inverting this relation then gives the form of $f(z)$ and $g(z)$, which determine $\tau(z)$. Degenerations of the complex structure of an elliptic fibration were classified by Kodaira [138–140]. Depending on the functions $f(z)$ and $g(z)$ appearing in (6.39) one can identify a corresponding monodromy around the degeneration point, which we summarise in table 1. Note however, that not all monodromies can be obtained via elliptic fibrations, for instance, hyperbolic monodromies do not appear in Kodaira's classification.

Global model

Let us finally return to the global setting with \mathbb{P}^1 as the base-manifold. There are two conditions we have to impose in order to have a consistent background [134]:

order of singularity	singularity	Kodaira type	monodromy
0	smooth	none	$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$
n	A_{n-1}	I_n	$\begin{pmatrix} 1 & n \\ 0 & 1 \end{pmatrix}$
2	cusp	II	$\begin{pmatrix} 1 & 1 \\ -1 & 0 \end{pmatrix}$
3	A_1	III	$\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$
4	A_2	IV	$\begin{pmatrix} 0 & 1 \\ -1 & -1 \end{pmatrix}$
$6 + n$	D_{4+n}	I_n^*	$\begin{pmatrix} -1 & -n \\ 0 & -1 \end{pmatrix}$
8	E_6	IV^*	$\begin{pmatrix} -1 & -1 \\ 1 & 0 \end{pmatrix}$
9	E_7	III^*	$\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$
10	E_8	II^*	$\begin{pmatrix} 0 & -1 \\ 1 & 1 \end{pmatrix}$

Table 1: Kodaira classification of singularities. The first column lists the vanishing order of the discriminant locus Δ , the second column gives the type of singularity in the total space, the third column lists Kodaira's name for the fibre type, and the last column gives the corresponding monodromy matrix. (For more details see for instance table 1 in [134] or table 2 in [132].)

1. The metric on the base-manifold should be that of a two-sphere. By choosing local complex coordinates z and \bar{z} the metric on \mathbb{P}^1 can always be brought into the form

$$ds^2 = e^{\varphi(z, \bar{z})} dz d\bar{z}, \quad (6.41)$$

where the function φ encodes the monodromy. In the limit $z \rightarrow \infty$ and hence far away from the points of degenerations, the metric should behave as

$$ds^2 \sim \left| \frac{dz}{z^2} \right|^2, \quad (6.42)$$

so that in terms of the variable $u = 1/z$ the point $z = \infty$ is a smooth point $u = 0$ on \mathbb{P}^1 . Since a codimension two singularity has a deficit angle $\pi/6$ [135], a two-sphere is obtained if the orders of the singularities add up to 24.

Figure 8: Illustration of how a contour on a two-sphere encircling a set of marked points can be deformed to a contour encircling none of these points.

2. The second condition which has to be imposed is that the monodromy encircling all singularities should be trivial. More concretely, as illustrated in figure 8, a monodromy surrounding all singularities on a \mathbb{P}^1 can always be deformed such that it surrounds a non-degenerate point and hence should be trivial.

Remark

Let us recall from (6.20) that the $SL(2, \mathbb{Z})$ transformations acting on τ and ρ are generated by T - and S -transformations. Comparing then these transformations with the example of the three-torus (cf. (6.23)), we find⁶

$$\begin{array}{llll}
 \text{three-torus} & \text{with } h = 1 & \tilde{T} & : \rho \rightarrow \rho + 1, \\
 \text{twisted torus} & \text{with } f = 1 & U = STS & : \tau \rightarrow \frac{\tau}{-\tau + 1}, \\
 \text{T-fold} & \text{with } q = 1 & \tilde{U} = \tilde{S}\tilde{T}\tilde{S} & : \rho \rightarrow \frac{\rho}{-\rho + 1}.
 \end{array} \tag{6.43}$$

It is now tempting to identify a monodromy generated by \tilde{T} with one unit of H -flux, a monodromy generated by U with one unit of geometric flux and so on. However, it turns out that a general monodromy in $SL(2, \mathbb{Z})$ can be expressed in multiple ways in terms of T - and S -transformations. Hence, there is no unique assignment of a flux to a given monodromy in this way [132].

6.4 \mathbb{T}^2 -fibrations over \mathbb{R}^2

We also want to discuss \mathbb{T}^2 -fibrations over $\mathbb{R}^2 \setminus \Delta$, where Δ is in general a set of n points in \mathbb{R}^2 at which the \mathbb{T}^2 -fibre is allowed to degenerate. However, in this

⁶A monodromy in τ of the form $T : \tau \rightarrow \tau + 1$ leads to a twisted torus with one unit of geometric flux, in which the coordinates and radii are interchanged as $y^1 \leftrightarrow y^2$, $R_1 \leftrightarrow R_2$ as compared to the twisted torus given in (6.6).

section we focus again on a single point of degeneration located at the origin. Furthermore, we embed these four-dimensional fibrations into ten dimensions in the following way

$$\mathbb{R}^{1,5} \times (\mathcal{B} \times \mathbb{T}^2), \quad \mathcal{B} = \mathbb{C} \setminus \{0\}, \quad (6.44)$$

and require them to be consistent supergravity backgrounds.

Setting

More concretely, we consider ten-dimensional backgrounds with a in general non-trivial metric, Kalb-Ramond B -field and dilaton ϕ which are required to solve the string-theoretical equations of motion given in (3.31). We make the following ansatz

$$\begin{aligned} ds^2 &= \eta_{\mu\nu} dx^\mu dx^\nu + e^{2\varphi_1} \tau_2 \rho_2 \alpha' dz d\bar{z} + G_{ab}(z) dy^a dy^b, \\ B &= \alpha' \rho_1 dy^1 \wedge dy^2, \\ e^{2\phi} &= \rho_2, \end{aligned} \quad (6.45)$$

where x^μ with $\mu = 0, \dots, 5$ denote local coordinates in six-dimensional Minkowski space, $z \in \mathbb{C}$ is a complex coordinate in the base-manifold \mathcal{B} , and y^a with $a = 1, 2$ are local coordinates on the \mathbb{T}^2 -fibre. As before, $\tau = \tau_1 + i\tau_2$ denotes the complex-structure modulus and $\rho = \rho_1 + i\rho_2$ denotes the complexified Kähler modulus of the fibre, and $\varphi = \varphi_1 + i\varphi_2$ is a meromorphic function on \mathbb{C} .⁷ Requiring the metric on \mathcal{B} to be single-valued, one can show that $\varphi(z)$ has to transform as

$$e^{\varphi(z)} \rightarrow e^{\varphi(z)} (c\tau(z) + d), \quad (6.46)$$

under the monodromy M when encircling the defect [134, 141, 136, 137]. In particular, this ensures that – depending on the monodromy – $e^{2\varphi_1} \tau_2$ or $e^{2\varphi_1} \rho_2$ is single-valued. (We do not consider monodromies in τ and ρ simultaneously, for which we refer for instance to [132].)

Examples for τ -monodromies

Let us now discuss examples for the three different cases of elliptic, parabolic and hyperbolic τ -monodromies mentioned on page 83. Additional examples can be found in [142].

⁷In (6.45) the real part of φ appears as a warp factor. The imaginary part is related to supersymmetry transformations [137] which we are not discussing here.

- Let us start with a parabolic monodromy $\tau \rightarrow \tau + 1$ along a path around the origin $z = 0$. We have already discussed the main structure of the solution above, and we find

$$\tau(z) = \frac{1}{2\pi i} \log \left(\frac{z}{\mu} \right), \quad e^{\varphi(z)} = \frac{\alpha'}{R_1^2}, \quad \rho = i \frac{R_1 R_2}{\alpha'}, \quad (6.47)$$

where we included an integration constant μ , $R_{1,2}$ are the radii of the two-torus and where a possible constant B -field has been set to zero. Using polar coordinates for z as $z = r e^{i\theta}$ and (6.45), we can express the corresponding background as follows

$$\begin{aligned} ds^2 &= \eta_{\mu\nu} dx^\mu dx^\nu + h(r) \left[\alpha' (dr^2 + r^2 d\theta^2) + R_1^2 (dy^1)^2 \right] \\ &\quad + \frac{\alpha'}{h(r)} \left(dy^2 + \frac{\theta}{2\pi} dy^1 \right)^2, \\ B &= 0, \\ e^{2\phi} &= \frac{R_1 R_2}{\alpha'}. \end{aligned} \quad (6.48)$$

The function $h(r)$ depends only on the radial direction and is given by

$$h(r) = \frac{R_2}{R_1} \frac{\log \left[\frac{\mu}{r} \right]}{2\pi}. \quad (6.49)$$

This configuration is a solution to the string equations of motion (3.31), and it is known as the semi-flat limit of the compactified Kaluza-Klein monopole. We come back to this point below.

- Next, we consider an elliptic monodromy of order four, which acts on the complex-structure τ as $\tau \rightarrow -1/\tau$ when encircling the degeneration. The solution for the holomorphic functions appearing in (6.45) is given by (see for instance [132])

$$\tau(z) = \frac{1 - e^{\frac{i\kappa}{2}} \sqrt{z}}{i + i e^{\frac{i\kappa}{2}} \sqrt{z}}, \quad e^{\varphi(z)} = \frac{z^{1/4}}{1 - e^{\frac{i\kappa}{2}} \sqrt{z}}, \quad \rho = i \frac{R_1 R_2}{\alpha'}, \quad (6.50)$$

where κ is an integration constant. The singularity is of Kodaira type III, and the explicit form of the background can be obtained using (6.50) in (6.45) and (6.22). Without further discussing this solution, let us simply state the

explicit form

$$\begin{aligned}
ds^2 = & \eta_{\mu\nu} dx^\mu dx^\nu + \frac{R_1 R_2 (r^{3/2} - r^{1/2})}{1 - 2 \cos [\theta + \kappa] r + r^2} (dr^2 + r^2 d\theta^2) \\
& + \frac{R_1 R_2}{r - 1} \left[\begin{aligned} & (1 - 2 \cos [\frac{\theta + \kappa}{2}] \sqrt{r} + r) (dy^1)^2 \\ & - 4 \sin [\frac{\theta + \kappa}{2}] \sqrt{r} dy^1 dy^2 \\ & + (1 - 2 \cos [\frac{\theta + \kappa}{2}] \sqrt{r} + r) (dy^2)^2 \end{aligned} \right], \quad (6.51)
\end{aligned}$$

$$B = 0,$$

$$e^{2\phi} = \frac{R_1 R_2}{\alpha'}.$$

- Let us also give an example for a hyperbolic monodromy in τ . Taking a transformation of the form $\tau \rightarrow -N - 1/\tau$ for $N \geq 3$, the solution for the holomorphic functions is given by (see e.g. [132])

$$\begin{aligned}
\tau(z) &= \frac{1}{\lambda} \left(\frac{(\kappa_1)^{\lambda^2} (\lambda^2 - 1)}{\kappa_1 e^{i\tilde{z}} - (\kappa_1)^{\lambda^2}} - 1 \right), & \rho &= i \frac{R_1 R_2}{\alpha'}, \quad (6.52) \\
e^{\varphi(z)} &= \kappa_2 \lambda e^{-\frac{i}{2}\tilde{z}} \left(\kappa_1 e^{i\tilde{z}} - (\kappa_1)^{\lambda^2} \right),
\end{aligned}$$

where $\kappa_{1,2,3}$ are again integration constants and

$$\begin{aligned}
\tilde{z} &= \kappa_3 (1 - \lambda^2) + \frac{1}{\pi} \log(\lambda) \log(\pi z (\lambda^2 - 1)), \\
\lambda &= \frac{1}{2} \left(N + \sqrt{N^2 - 4} \right). \quad (6.53)
\end{aligned}$$

It is not clear how to interpret such solutions near the point of degeneration, since the imaginary part of τ is highly oscillating near $z = 0$. This is consistent with the fact that diffeomorphisms of hyperbolic type cannot be obtained as monodromies of a degenerating elliptic curve and hence cannot be associated with a degeneration point of the fibre. The resulting background has a rather involved form and will not be presented here.

Examples for ρ -monodromies

We now turn to the discussion of non-trivial monodromies for the complexified Kähler modulus around the point $z = 0$ at which the fibre degenerates. For single-valuedness of the metric now ρ determines the transformation of the warp factor $\varphi(z)$.

- We again start with a parabolic monodromy of the form $\rho \rightarrow \rho + 1$. By comparing with the definition of ρ given in (6.17), we see that this transformation corresponds to a gauge transformation of the B -field. Going through the procedure explained above and fixing the complex structure to a particular form, one obtains the following solution for the holomorphic functions

$$\tau(z) = i \frac{R_1}{R_2}, \quad e^\varphi = \frac{\alpha'}{R_1^2}, \quad \rho = \frac{1}{2\pi i} \log \left(\frac{z}{\mu} \right). \quad (6.54)$$

Using these expressions in (6.45) and changing to polar coordinates via $z = r e^{i\theta}$, we find the following background

$$\begin{aligned} ds^2 &= \eta_{\mu\nu} dx^\mu dx^\nu + h(r) \left[\alpha' (dr^2 + r^2 d\theta^2) + R_1^2 (dy^1)^2 + R_2^2 (dy^2)^2 \right], \\ B &= \alpha' \frac{\theta}{2\pi} dy^1 \wedge dy^2, \\ e^{2\phi} &= \frac{R_1 R_2}{\alpha'} h(r), \end{aligned} \quad (6.55)$$

with

$$h(r) = \frac{\alpha'}{R_1 R_2} \frac{\log \left[\frac{\mu}{r} \right]}{2\pi}. \quad (6.56)$$

As we will explain further below, this is the semi-flat limit of the NS5-brane solution compactified on a two-torus.

- As a second example, we consider a parabolic monodromy of the form $\rho \rightarrow \rho/(1 - \rho)$. The holomorphic functions are now specified by

$$\tau(z) = i \frac{R_1}{R_2}, \quad e^\varphi = \frac{R_2}{2\pi\sqrt{\alpha'}} \log \left(\frac{z}{\mu} \right), \quad \rho = -\frac{2\pi i}{\log \left(\frac{z}{\mu} \right)}. \quad (6.57)$$

This leads to the background

$$\begin{aligned} ds^2 &= \eta_{\mu\nu} dx^\mu dx^\nu + h(r) \alpha' \left[dr^2 + r^2 d\theta^2 \right] \\ &\quad + \frac{h(r)}{h(r)^2 + \left[\frac{R_1 R_2}{\alpha'} \frac{\theta}{2\pi} \right]^2} \left[R_1^2 (dy^1)^2 + R_2^2 (dy^2)^2 \right], \\ B &= -\frac{R_1^2 R_2^2}{2\pi\alpha'} \frac{\theta}{h(r)^2 + \left[\frac{R_1 R_2}{\alpha'} \frac{\theta}{2\pi} \right]^2}, \\ e^{2\phi} &= \frac{R_1 R_2}{\alpha'} \frac{h(r)}{h(r)^2 + \left[\frac{R_1 R_2}{\alpha'} \frac{\theta}{2\pi} \right]^2}, \end{aligned} \quad (6.58)$$

with

$$h(r) = \frac{R_1 R_2}{\alpha'} \frac{\log \left[\frac{\mu}{r} \right]}{2\pi}. \quad (6.59)$$

This is a non-geometric background, which is also known as the 5_2^2 -brane [143, 137, 144].

- An elliptic monodromy in ρ of the form $\rho \rightarrow -1/\rho$ can be obtained by applying a T-duality transformation along the y^2 -direction to the background (6.50). According to (6.23), such a duality transformation interchanges τ and ρ leading to

$$\tau = i \frac{R_1}{R_2}, \quad e^{\varphi(z)} = \frac{z^{1/4}}{1 - e^{\frac{i\kappa}{2}} \sqrt{z}}, \quad \rho(z) = \frac{1 - e^{\frac{i\kappa}{2}} \sqrt{z}}{i + i e^{\frac{i\kappa}{2}} \sqrt{z}}, \quad (6.60)$$

where κ is again an integration constant. The corresponding ten-dimensional solution is obtained by using these expressions in (6.45) for which one finds

$$\begin{aligned} ds^2 &= \eta_{\mu\nu} dx^\mu dx^\nu + \frac{R_1}{R_2} \frac{\alpha' (r^{3/2} - r^{1/2})}{1 - 2 \cos [\theta + \kappa] r + r^2} (dr^2 + r^2 d\theta^2) \\ &\quad + \frac{\alpha' (r - 1)}{1 + 2 \cos \left[\frac{1}{2}(\theta + \kappa) \right] r^{1/2} + r} \left[\frac{R_1}{R_2} (dy^1)^2 + \frac{R_2}{R_1} (dy^2)^2 \right] \\ B &= - \frac{2\alpha' \sin \left[\frac{1}{2}(\theta + \kappa) \right] r^{1/2}}{1 + 2 \cos \left[\frac{1}{2}(\theta + \kappa) \right] r^{1/2} + r} dy^1 \wedge dy^2, \\ e^{2\phi} &= \frac{r - 1}{1 + 2 \cos \left[\frac{1}{2}(\theta + \kappa) \right] r^{1/2} + r}. \end{aligned} \quad (6.61)$$

- Finally, an example for a hyperbolic ρ -monodromy can be obtained by applying again a T-duality transformation to the existing solution (6.52) interchanging ρ and τ . However, we do not discuss this solution further.

Remark

In this section we have embedded \mathbb{T}^2 -fibrations over $\mathbb{R}^2 \setminus \{0\}$ with non-trivial monodromies into ten dimensions. These solutions satisfy the leading-order string equations of motion summarised in (3.31). However, a proper string-theory background will in general have higher-order α' -corrections which are not captured via (3.31). This can be seen also in some of the solutions constructed in this section. For instance, the background (6.51) with an elliptic monodromy in τ has

a singular behaviour near the core of the defect at $r = 1$. This signals that the effective supergravity description breaks down and α' -corrections have to be taken into account. A similar behaviour can be observed for the example of a hyperbolic monodromy in τ given in (6.52).

6.5 The NS5-brane, KK-monopole and 5_2^2 -brane

Comparing the form of the complex-structure and complexified Kähler moduli for the solutions (6.54), (6.47) and (6.57), we see that these are related by T-duality transformations along the fibre-directions. In particular, their monodromies are those of the three-torus with H -flux, the twisted torus and the T-fold, respectively. In this section we now want to study the higher-dimensional origin of these backgrounds.

The NS5-brane

The NS5-brane solution of string theory is a well-known solitonic solution to the ten-dimensional equations of motion (3.31). It is extended along $(5 + 1)$ space-time directions, and has a four-dimensional Euclidean transverse space. The corresponding ten-dimensional background fields take the form

$$\begin{aligned} ds^2 &= \eta_{\mu\nu} dx^\mu dx^\nu + H(\vec{x}) d\vec{x}^2, \\ H &= \star_4 dH(\vec{x}), & H(\vec{x}) &= 1 + \frac{1}{|\vec{x}|^2}, \\ e^{2\phi} &= e^{2\phi_0} H(\vec{x}), \end{aligned} \tag{6.62}$$

where $\mu, \nu = 0, \dots, 5$, $\vec{x} = (x^6, x^7, x^8, x^9)^T$ denote the transversal coordinates and \star_4 is the Hodge star-operator in the transverse space. Furthermore, $e^{\phi_0} = g_s$ is the string-coupling at spatial infinity.

The NS5-brane solution can be compactified on a two-torus by placing it on an infinite array with length $2\pi R_1$ and $2\pi R_2$, as illustrated in figure 9b. This results in an infinite sum of harmonic functions $H(\vec{x})$, which can be regularised as [145]

$$\begin{aligned} h(r) &= 1 + \sum_{\vec{n} \in \mathbb{Z}^2} \frac{1}{r^2 + (y^1 - 2\pi \frac{R_1}{\sqrt{\alpha'}} n_1)^2 + (y^2 - 2\pi \frac{R_2}{\sqrt{\alpha'}} n_2)^2} \\ &\rightarrow \frac{\alpha'}{R_1 R_2} \frac{\log \left[\frac{\mu}{r} \right]}{2\pi} + \mathcal{O}(e^{-r}), \end{aligned} \tag{6.63}$$

where we re-labelled $(x^8, x^9) \rightarrow (y^1, y^2)$ and where $r^2 = (x^6)^2 + (x^7)^2$ denotes the radial distance in the uncompactified two-dimensional transversal space. The constant μ controls the regularisation of the sum. At leading order in r the compactified solution matches with the background given in (6.55) and thus provides

(a) Single NS5-brane.

(b) Infinite array of NS5-branes.

Figure 9: Illustration of the space transversal to the NS5-brane solution for $(x^6, x^7) = (0, 0)$. In figure 9a a single NS5-brane is shown, and in figure 9b an infinite array of NS5-branes is illustrated.

a ten-dimensional origin for this \mathbb{T}^2 -fibration. The limit shown in (6.63) is also called the semi-flat limit [146, 147].

The KK-monopole

Let us now turn to Kaluza-Klein monopole with compact circle direction y^2 . This background is specified by the following field configuration [148, 149]

$$\begin{aligned}
 ds^2 &= \eta_{\mu\nu} dx^\mu dx^\nu + H(\vec{x}) d\vec{x}^2 + \frac{1}{H(\vec{x})} (dy^2 + A)^2, \\
 H &= 0, & dA &= \star_3 dH(\vec{x}), \\
 e^{2\phi} &= e^{2\phi_0},
 \end{aligned} \tag{6.64}$$

where again $\mu, \nu = 0, \dots, 5$ but where now $\vec{x} = (x^6, x^7, x^8)$, and where \star_3 denotes the Hodge star-operator along the non-compact transversal part. The non-triviality of the circle-fibration is encoded in the connection one-form A , and the harmonic function is given by

$$H(\vec{x}) = 1 + \frac{R_2}{2\sqrt{\alpha'} |\vec{x}|}, \tag{6.65}$$

with R_2 denoting the radius of the y^2 -direction. The H -flux vanishes, and the dilaton $\phi = \phi_0$ is constant. An illustration of the space transversal to the KK-monopole can be found in figure 10a.

(a) Single KK-monopole.

(b) Infinite array of KK-monopoles.

Figure 10: Illustration of the space transversal to the KK-monopole solution for $x^6 = 0$. In figure 10a a single KK-monopole is shown, and in figure 10b an infinite array of KK-monopoles is illustrated.

This solution can now be compactified on a circle by placing it on an infinite array with length $2\pi R_1$ (see figure 10b), which results in an infinite sum of harmonic functions. This sum can be regularised as [150]

$$\begin{aligned}
 h(r) &= 1 + \sum_{n \in \mathbb{Z}} \frac{R_2}{2\sqrt{\alpha'} \sqrt{r^2 + (y^1 - 2\pi \frac{R_1}{\sqrt{\alpha'}} n)^2}} \\
 &\rightarrow \frac{R_2}{R_1} \frac{\log \left[\frac{\mu}{r} \right]}{2\pi} + \mathcal{O}(e^{-r}),
 \end{aligned} \tag{6.66}$$

where we re-labelled $x^8 \rightarrow y^1$ and where $r^2 = (x^6)^2 + (x^7)^2$. The constant μ is again related to the regulator, and at leading order in r the harmonic function agrees with (6.49), and the background is the same as shown in (6.48). The limit (6.66) is again called the semi-flat limit.

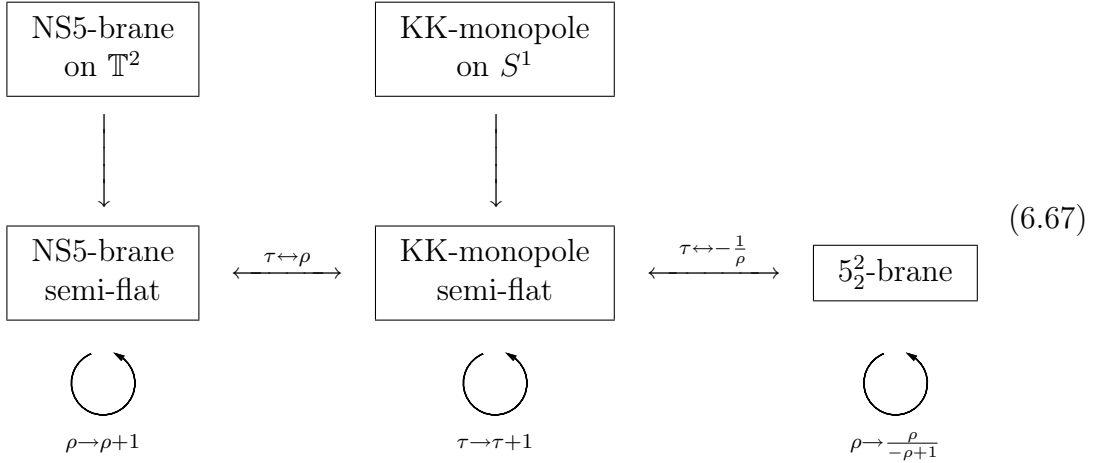

The 5_2^2 -brane

Unfortunately, for the background (6.58) with the non-geometric parabolic monodromy $\rho \rightarrow \rho/(1 - \rho)$ a ten-dimensional origin similarly to the two examples

discussed above is not known. We therefore cannot give a corresponding higher-dimensional solution (within string theory).

Family of solutions

In analogy to the chain of backgrounds connected by T-duality transformations illustrated in (6.13), we can now summarise the above solutions in the following way

where on top we have shown the full NS5-brane and KK-monopole solution compactified on \mathbb{T}^2 and S^1 , respectively. Performing then the semi-flat limit and ignoring higher-order terms in the transversal radius (see equations (6.63) and (6.66)), we arrive at a family of \mathbb{T}^2 -fibrations over $\mathbb{C} \setminus \{0\}$ which are related by T-duality transformations. We furthermore indicated the patching transformations for each of these fibrations.

Remarks

Let us close this section with the following remarks:

- Around equations (6.63) and (6.66) we have illustrated how – at leading-order in r – compactifications of the NS5-brane solution and the KK-monopole correspond to the backgrounds (6.55) and (6.48), respectively. However, taking into account higher-order corrections in r (and thus capturing higher-order α' -corrections) modifies this picture [151]. On the other hand, it has been shown in [152, 153] that corrections to the compactified NS5-brane correspond to instanton corrections. This analysis has been extended in [153–157] to include \mathbb{T}^2 -compactifications.

- We also remark that a discussion of the T-duality chain (6.67) in the context of the heterotic string can be found in [158], and an effective world-volume action for the 5_2^2 -brane has been proposed in [159].
- In this section we have studied the NS5-brane and its T-dual backgrounds. However, string-theory also features S-duality which for instance maps a NS5-brane to a D5-brane. The latter is then related to other Dp -branes via T-duality. This gives rise to a plethora of localised sources, which can have more general non-geometric properties.

The combination of T-duality and S-duality is called U-duality, and an appropriate framework to study corresponding sources is exceptional field theory (EFT). Since it is beyond the scope of this work to discuss EFT, we want to refer the reader to the review [160–162]. We note however that brane solutions obtained from U-duality transformations have been studied for instance in [89, 163–167, 137, 168–171].

6.6 Remarks

In this last section we want to give an overview of further aspects and developments in the context of torus fibrations which we did not cover above.

- A dimensional reduction of the backgrounds studied in section 6.1 and 6.2 along the compact directions corresponds to a generalised Scherk-Schwarz reduction [126, 127]. In the reduced lower-dimensional theory a potential is generated, which can be specified in terms of the monodromy matrix of the fibration [129]. Monodromies of elliptic $SL(2, \mathbb{Z})$ -type have finite order and are conjugate to rotations. This implies that the corresponding potential will always have a stable minimum at the fixed-point of the monodromy. Parabolic monodromies have fixed points which correspond to decompactification limits, and hyperbolic monodromies do not have critical points on the upper half-plane. We discuss this point in detail in section 8.7.
- In the above sections we have focused on \mathbb{T}^2 -fibrations over various base-manifolds. Of course, one can also consider \mathbb{T}^n -fibrations for $n \geq 3$, however, in this case the structure of the monodromy group becomes more involved [172]. Nevertheless, in [147] a number of models in different dimensions are constructed.

More generally, one can also fibre $K3$ -manifolds non-trivially over a base and consider monodromies in the duality group of $K3$. For mirror symmetry such constructions have been called mirror-folds and have been discussed in [173–175].

- Non-geometric backgrounds can also be studied for the heterotic string. A difference to the type II constructions presented in this section is that on the heterotic side also Wilson-moduli have to be taken into account, which enlarge the duality group. For some explicit constructions see for instance [141]. Via the heterotic–F-theory duality, non-geometric heterotic models can be mapped to the F-theory side [176–178, 132, 179, 180]. Here one finds that some of the heterotic non-geometric constructions correspond to geometric F-theory models. This means that non-geometric backgrounds are a natural part of string theory.
- A useful way to understand geometric as well as non-geometric compactifications is by geometrising the duality group. This is inspired by F-theory [181], where the (in general varying) axio-dilaton is interpreted as the complex-structure modulus of a two-torus \mathbb{T}^2 fibred over the space-time. The S-duality group $SL(2, \mathbb{Z})$ then acts on \mathbb{T}^2 in a geometric way as large diffeomorphisms, similarly as we discussed above. For a recent review on F-theory see for instance [182].

For the \mathbb{T}^2 -fibrations considered in the above sections we compactify along the \mathbb{T}^2 -directions such that we are left with a lower-dimensional theory with a complex-structure modulus $\tau(x)$ and a complexified Kähler modulus $\rho(x)$. The corresponding T-duality group is $SL(2, \mathbb{Z}) \times SL(2, \mathbb{Z}) \times \mathbb{Z}_2 \times \mathbb{Z}_2$. Since $SL(2, \mathbb{Z})$ is the modular group of a two-torus, one can associate to the full duality group a degenerate genus two-surface of the form

On this surface the T-duality group acts in a geometric way, namely as the mapping-class group. For larger duality groups a corresponding discussion can be found in [183, 184].

- Instead of restricting oneself to the T-duality group, one can also construct string-theory backgrounds with patching-transformations contained in larger duality groups. For certain type II compactifications this is for instance the U -duality group (a combination of T- and S-duality) [185, 2], and corresponding U -folds have been discussed for instance in [186–189].
- Another way to describe non-geometric \mathbb{T}^n -fibrations is through Hull’s doubled formalism [16] to be discussed in section 9. Here, one doubles the dimension of the torus fibre to \mathbb{T}^{2n} where – roughly speaking – one considers the left- and right-moving modes shown for instance in (2.21) as independent

coordinates. The physical torus-fibre is obtained by choosing a n -dimensional subspace of \mathbb{T}^{2n} , which is also called a polarisation. Duality transformations $O(n, n, \mathbb{Z})$ then change this polarisation within the doubled space, and hence lead to dual configurations. The doubled formalism is particularly useful to describe non-geometric backgrounds and we come back to this question in section 9.

7 Generalised geometry

In this section we take a different perspective on T-duality, non-geometric backgrounds and non-geometric fluxes. The framework we are going to discuss is that of generalised geometry, which has been developed in [190,191]. For a treatment in the physics literature we refer for instance to [192–194,43,195], which we follow in parts in this section.

7.1 Basic concepts

The main motivation for generalised geometry was to combine complex and symplectic manifolds – admitting a complex structure and a symplectic structure, respectively – into a common framework [190,191]. It turns out that this allows to describe diffeomorphisms and gauge transformations of the Kalb-Ramond B -field in a combined way. In this section we introduce the basic concepts of generalised geometry, and in later sections use them for the description of non-geometric backgrounds.

Generalised tangent-bundle

In generalised geometry vector-fields and differential one-forms are combined into a unified framework. The main idea is to consider a so-called generalised tangent-bundle E over a D -dimensional manifold M , which can be introduced via the sequence

$$0 \longrightarrow T^*M \longrightarrow E \longrightarrow TM \longrightarrow 0. \quad (7.1)$$

Locally E is the direct sum $TM \oplus T^*M$ of the tangent-bundle TM and the cotangent-bundle T^*M of a manifold M , and the sections of E are called generalised vectors which contain a vector-part x and a one-form part ξ . Again locally, these can be expressed as

$$X = x + \xi, \quad x \in \Gamma(TM), \quad \xi \in \Gamma(T^*M). \quad (7.2)$$

The non-triviality of the generalised tangent-bundle E is encoded in transition functions between local patches $U_a \subset M$. When going from one patch U_a to another patch U_b , diffeomorphisms are used to relate vectors and one-forms – describing the non-triviality of TM . But, additional transformations of the one-forms encode how T^*M is fibred over TM . In formulas, this reads⁸

$$x_a + \xi_a = A_{ab}^{-1} x_b + \left[A_{ab}^T \xi_b - \iota_{A_{ab}^{-1} x_b} B_{ab} \right], \quad (7.3)$$

⁸In this section we will employ a coordinate-free notation for vector-fields and differential forms for most of the time. However, sometimes we also use $\{\partial_i\} \in \Gamma(TM)$ and $\{dx^i\} \in \Gamma(T^*M)$ as local bases for the tangent- and cotangent-space.

where $A_{ab} \in GL(D, \mathbb{R})$ is an invertible matrix describing diffeomorphisms, B_{ab} is a two-form⁹ and ι_x denotes the contraction with a vector-field x . The notation \mathbf{ab} indicates that we are working on the overlap $U_a \cap U_b$ of two local patches U_a and U_b . Using a two-component notation for the generalised vector and recalling the $2D \times 2D$ matrices (2.43) and (2.46), we can express (7.3) as

$$X_a = \begin{pmatrix} x_a \\ \xi_a \end{pmatrix} = \begin{pmatrix} \mathbf{1} & 0 \\ B_{ab} & \mathbf{1} \end{pmatrix} \begin{pmatrix} A_{ab}^{-1} & 0 \\ 0 & A_{ab}^T \end{pmatrix} \begin{pmatrix} x_b \\ \xi_b \end{pmatrix} = \mathcal{O}_{B_{ab}} \mathcal{O}_{A_{ab}} X_b. \quad (7.4)$$

Furthermore, one usually restricts the two-form as $B_{ab} = d\Lambda_{ab}$, where on the triple overlap $U_a \cap U_b \cap U_c$ the one-forms Λ_{ab} have to satisfy (see also our discussion on page 37)

$$\Lambda_{ab} + \Lambda_{bc} + \Lambda_{ca} = g_{abc}^{-1}(dg_{abc}). \quad (7.5)$$

The function g_{abc} is an element of $U(1)$ and is given by $g_{abc} = e^{i\lambda_{abc}}$, which describes the structure of a gerbe. The generalised tangent-bundle therefore geometrisises diffeomorphisms and B -field gauge transformations.

Bi-linear form and $O(D, D, \mathbb{R})$

Given the generalised tangent-bundle E , there is a natural bilinear form of signature (D, D) . Denoting by ι_x again the contraction with a vector-field x , we have

$$\langle X, Y \rangle = \langle x + \xi, y + \chi \rangle = \frac{1}{2}(\iota_x \chi + \iota_y \xi), \quad (7.6)$$

where $x, y \in \Gamma(TM)$ and $\xi, \chi \in \Gamma(T^*M)$. Employing the $2D$ -component vector-notation shown in (7.4), we can express (7.6) as

$$\langle X, Y \rangle = \frac{1}{2} X^T \eta Y, \quad \eta = \begin{pmatrix} 0 & \mathbf{1} \\ \mathbf{1} & 0 \end{pmatrix}, \quad (7.7)$$

where we adopted the same notation as in equation (2.27). The transformations which leave this inner product invariant are $O(D, D, \mathbb{R})$ transformations \mathcal{O} characterised by $\mathcal{O}^T \eta \mathcal{O} = \eta$. Note that in contrast to our discussion in section 2.3, there are no restrictions on the vector-fields being integers and hence the transformations take values in \mathbb{R} .

Let us now study the basic transformations belonging to the structure group $O(D, D, \mathbb{R})$. This discussion is similar to the one in section 2.3, which we recall here from a slightly different perspective:

⁹In the following we use the notation B both for a two-form $B = \frac{1}{2} B_{ij} dx^i \wedge dx^j$ as well as for its components B_{ij} . The distinction between a two-form and an anti-symmetric matrix should be clear from the context.

- As we already mentioned, diffeomorphisms are described by matrices of the form (2.43), which are expressed in terms of $\mathbf{A} \in GL(D, \mathbb{R})$. On the generalised vectors these act as

$$X' = \mathcal{O}_{\mathbf{A}} X \quad \mathcal{O}_{\mathbf{A}} = \begin{pmatrix} \mathbf{A}^{-1} & 0 \\ 0 & \mathbf{A}^T \end{pmatrix}. \quad (7.8)$$

- The so-called \mathbf{B} -transforms with $O(D, D, \mathbb{R})$ a matrix of the form (2.46) is expressed in terms of an anti-symmetric $D \times D$ matrix \mathbf{B} . Here we have

$$X' = \mathcal{O}_{\mathbf{B}} X, \quad \mathcal{O}_{\mathbf{B}} = \begin{pmatrix} \mathbf{1} & 0 \\ \mathbf{B} & \mathbf{1} \end{pmatrix}, \quad (7.9)$$

$$X = x + \xi \mapsto X' = x + (\xi - \iota_x \mathbf{B}),$$

where in the second line \mathbf{B} is interpreted as a two-form with components given by the anti-symmetric matrix \mathbf{B}_{ij} (cf. footnote 9).

- The so-called β -transforms are described by matrices of the form (2.54), which are expressed in terms of an anti-symmetric $D \times D$ matrix β . For such transformations we have

$$X' = \mathcal{O}_{\beta} X, \quad \mathcal{O}_{\beta} = \begin{pmatrix} \mathbf{1} & \beta \\ 0 & \mathbf{1} \end{pmatrix}, \quad (7.10)$$

$$X = x + \xi \mapsto X' = (x + \beta \lrcorner \xi) + \xi,$$

where the action of the bivector-field $\beta = \frac{1}{2} \beta^{ij} \partial_i \wedge \partial_j$ on forms is defined via the contraction. In particular, for a one-form ξ one has $\beta \lrcorner \xi = -\xi_i \beta^{ij} \partial_j$, where $\{\partial_i\}$ is a local basis on the tangent-space TM .

- Finally, transformations expressed in terms of $O(D, D, \mathbb{R})$ matrices of the form (2.50) interchange vector-field and one-form components. With E_i a $D \times D$ matrix whose only non-vanishing component is $(E_i)_{ii} = 1$, we have the transformations

$$X' = \mathcal{O}_{\pm i} X, \quad \mathcal{O}_{\pm i} = \begin{pmatrix} \mathbf{1} - E_i & \pm E_i \\ \pm E_i & \mathbf{1} - E_i \end{pmatrix}. \quad (7.11)$$

Courant bracket

Similarly to having a Lie bracket for vector-fields on the tangent-space, one can define a corresponding bracket for the generalised tangent-space E . In the present case this is the Courant bracket which is given by [196]

$$[X, Y]_{\mathbf{C}} = [x + \xi, y + \chi]_{\mathbf{C}} = [x, y]_{\mathbf{L}} + \mathcal{L}_x \chi - \mathcal{L}_y \xi - \frac{1}{2} d(\iota_x \chi - \iota_y \xi), \quad (7.12)$$

where $[\cdot, \cdot]_{\text{L}}$ denotes the usual Lie bracket of vector-fields and ι_x denotes the contraction with the vector-field x . Note that the Lie derivative \mathcal{L} and the contraction ι satisfy the following relations

$$\mathcal{L}_x = d\iota_x + \iota_x d, \quad \mathcal{L}_{[x,y]_{\text{L}}} = [\mathcal{L}_x, \mathcal{L}_y], \quad \iota_{[x,y]_{\text{L}}} = [\mathcal{L}_x, \iota_y]. \quad (7.13)$$

The Courant bracket is anti-symmetric and maps two generalised vectors to another generalised vector. In general, however, the Courant bracket is not a Lie bracket as it fails to satisfy the Jacobi identity. The latter can be represented by the Jacobiator

$$\text{Jac}(X, Y, Z)_{\text{C}} = [[X, Y]_{\text{C}}, Z]_{\text{C}} + [[Z, X]_{\text{C}}, Y]_{\text{C}} + [[Y, Z]_{\text{C}}, X]_{\text{C}}, \quad (7.14)$$

with $X, Y, Z \in \Gamma(E)$ three generalised vectors. Let us also define the so-called Nijenhuis operator

$$\text{Nij}(X, Y, Z)_{\text{C}} = \frac{1}{3} \left(\langle [X, Y]_{\text{C}}, Z \rangle + \langle [Z, X]_{\text{C}}, Y \rangle + \langle [Y, Z]_{\text{C}}, X \rangle \right), \quad (7.15)$$

where the inner product was defined in equation (7.6). For the above Courant bracket, one can then show that [191]

$$\text{Jac}(X, Y, Z)_{\text{C}} = d\text{Nij}(X, Y, Z)_{\text{C}}. \quad (7.16)$$

The right-hand side is in general non-vanishing, and imposes a non-trivial constraint. If the Nijenhuis operator vanishes, the generalised structure is said to be integrable.

Transformations which preserve the Courant bracket are diffeomorphisms and B -transforms. Indeed, as one can check we have

$$\mathcal{O}_{\text{A}}([X, Y]_{\text{C}}) = [\mathcal{O}_{\text{A}}X, \mathcal{O}_{\text{A}}Y]_{\text{C}}, \quad \mathcal{O}_{\text{B}}([X, Y]_{\text{C}}) = [\mathcal{O}_{\text{B}}X, \mathcal{O}_{\text{B}}Y]_{\text{C}}, \quad (7.17)$$

for $d\text{B} = 0$ [191]. This explains the restriction on B mentioned below (7.4). These transformations form the so-called geometric group, which is also the group used in the patching (7.3). Elements not belonging to the geometric group – such as β -transformations – change the differentiable structure. Let us however also note that, as we will exemplify on page 122, if the generalised vectors satisfy certain restrictions then the Courant bracket can be preserved also by additional $\mathcal{O}(D, D, \mathbb{R})$ transformations.

Dirac structure

A structure which will be useful later is the so-called Dirac structure. Its definition is that of a subspace $L \subset TM \oplus T^*M$ which is

- maximal (dimension of L is D)
- isotropic ($\eta(V, V) = 0$ for all $V \in L$) and which is
- involutive (closed under the Courant bracket).

It turns out that the Nijenhuis operator defined in (7.15) vanishes for elements in L , and hence the Jacobiator on L vanishes too. This means that on the subspace $L \subset TM \oplus T^*M$ the Courant bracket is a Lie bracket.

Dorfman bracket

Another bracket which is useful in the context of generalised geometry is the Dorfman bracket [197, 191]. It is defined as

$$X \circ Y = [x, y]_L + \mathcal{L}_x \chi - \iota_y d\xi, \quad (7.18)$$

for generalised vectors $X, Y \in \Gamma(E)$. This bracket is not skew-symmetric, but its anti-symmetrisation gives the Courant bracket (7.12). The Dorfman bracket satisfies a Leibniz rule of the form

$$X \circ (Y \circ Z) = (X \circ Y) \circ Z + Y \circ (X \circ Z), \quad (7.19)$$

and can therefore be used to define a so-called generalised Lie derivative as

$$\mathcal{L}_X Y = X \circ Y. \quad (7.20)$$

On functions f the generalised Lie derivative acts as $\mathcal{L}_X f = \iota_x df$.

Generalised metric

We now want to define a positive-definite metric for the generalised tangent-bundle E . Since the inner product (7.6) has split signature, it is not suitable candidate. However, let us choose a D -dimensional sub-bundle $C_+ \subset E$ of the generalised tangent-bundle which is positive definite with respect to the inner product (7.6). The orthogonal complement, which is negative-definite, is denoted by C_- and we have $E = C_+ \oplus C_-$. The generalised metric can then be defined as

$$\mathcal{H} = \eta|_{C_+} - \eta|_{C_-}. \quad (7.21)$$

This decomposition defines a reduction of the structure group from $O(D, D, \mathbb{R})$ to $O(D, \mathbb{R}) \times O(D, \mathbb{R})$. Note that \mathcal{H} is symmetric and non-degenerate. In the basis

chosen above, let us then specify¹⁰

$$\mathcal{H} = \begin{pmatrix} \frac{1}{\alpha'} g & 0 \\ 0 & \alpha' g^{-1} \end{pmatrix}, \quad (7.22)$$

where g is the ordinary metric on M . Indeed, this choice of \mathcal{H} is positive definite. However, if we now perform a \mathbf{B} -transform (7.9) with an anti-symmetric matrix \mathbf{B}_{ij} given by the components of the the Kalb-Ramond field b as $\mathbf{B}_{ij} = \frac{1}{\alpha'} b_{ij}$, we find

$$\mathcal{H} \rightarrow \mathcal{H}' = \mathcal{O}_{\mathbf{B}}^{-T} \mathcal{H} \mathcal{O}_{\mathbf{B}}^{-1} = \begin{pmatrix} \frac{1}{\alpha'} (g - b g^{-1} b) & +b g^{-1} \\ -g^{-1} b & \alpha' g^{-1} \end{pmatrix}, \quad (7.23)$$

which is the generalised metric we defined already in (2.27). Let us mention that an arbitrary \mathbf{B} -transform is in general not an automorphism of the Courant bracket, and therefore changes the differentiable structure. Only when $db = 0$, the transformed and the original background are equivalent. However, for our purpose here of motivating the generalised metric locally this distinction is not important.

Generalised vielbein

We finally want to introduce a generalised vielbein basis for the generalised metric. To do so, we use a similar notation as in (2.23) and write for the components of the ordinary metric in a local basis $\{dx^i\} \in \Gamma(TM)$

$$g_{ij} = (e^T)_i^a \delta_{ab} e^b_j, \quad (7.24)$$

and the inverse of e^a_i is denoted again as \bar{e}^i_a . For the B -field we employ a similar notation, that is $b_{ij} = (e^T)_i^a b_{ab} e^b_j$. Using then $2D$ -dimensional indices I and A , the generalised vielbein $\mathcal{E}_I = \{\mathcal{E}^A_I\}$ with index structure

$$\mathcal{E} = \{\mathcal{E}^A_I\} = \begin{pmatrix} \mathcal{E}^a_i & \mathcal{E}^{ai} \\ \mathcal{E}_{ai} & \mathcal{E}_a^i \end{pmatrix} \quad (7.25)$$

can be defined via the relations

$$\eta = \mathcal{E}^T \begin{pmatrix} 0 & \mathbb{1} \\ \mathbb{1} & 0 \end{pmatrix} \mathcal{E}, \quad \mathcal{H} = \mathcal{E}^T \begin{pmatrix} \delta & 0 \\ 0 & \delta^{-1} \end{pmatrix} \mathcal{E}, \quad (7.26)$$

where matrix multiplication is understood. Note that the index-structure of the generalised metric is \mathcal{H}_{IJ} , for the Kronecker δ -symbol we use δ_{ab} and $\delta^{ab} \equiv (\delta^{-1})^{ab}$,

¹⁰This choice is well-motivated in the context of generalised Kähler geometry. For more details see for instance chapter 6 of [191].

and that the inverse of \mathcal{E} will be denoted by $\bar{\mathcal{E}}$. We can now solve (7.26) for the generalised vielbeins by introducing two sets of ordinary vielbein matrices $(e_{\pm})^a_i$ as $g_{ij} = (e_{\pm}^T)_i^a \delta_{ab} (e_{\pm})^b_j$. The subscripts \pm indicate to which of the two subspaces shown in (7.21) the vielbeins correspond to, and e_+ and e_- are related to each other by an $O(D, \mathbb{R})$ transformation acting on the flat index a which leaves the right-hand side of (7.24) invariant. The generalised vielbein can then be expressed as [43]

$$\mathcal{E} = \frac{1}{2\sqrt{\alpha'}} \begin{pmatrix} (e_+ + e_-)^a_i - \delta^{ab} (\bar{e}_+^T - \bar{e}_-^T)_b^m b_{mi} & \delta^{ab} \alpha' (\bar{e}_+^T - \bar{e}_-^T)_b^i \\ \delta_{ab} (e_+ - e_-)^b_i - (\bar{e}_+^T + \bar{e}_-^T)_a^m b_{mi} & \alpha' (\bar{e}_+^T + \bar{e}_-^T)_a^i \end{pmatrix}. \quad (7.27)$$

However, as for the usual frame-bundle the ordinary vielbeins take values in, also here there are transformations acting on \mathcal{E}_A which do not change the defining equations (7.26). Indeed, we see that

$$\mathcal{E}^A \rightarrow \mathcal{K}^A_B \mathcal{E}^B \quad (7.28)$$

with $\mathcal{K} \in O(D, D, \mathbb{R})$ leaves the first relation in (7.26) invariant. Though, the second relation is left invariant only by transformations $\mathcal{K} \in O(D, \mathbb{R}) \times O(D, \mathbb{R}) \subset O(D, D, \mathbb{R})$. In analogy to the usual frame bundle which defines an $O(D, \mathbb{R})$ structure, in the generalised-geometry situation we therefore have a $O(D, \mathbb{R}) \times O(D, \mathbb{R})$ structure. In particular, for the vielbein (7.27) the corresponding transformations are given by [43]

$$\mathcal{K} = \frac{1}{2} \begin{pmatrix} O_+ + O_- & (O_+ - O_-) \delta^{-1} \\ \delta(O_+ - O_-) & \delta(O_+ + O_-) \delta^{-1} \end{pmatrix}, \quad (O_{\pm})^a_b \in O(D, \mathbb{R}). \quad (7.29)$$

Using these transformations we can set for instance $e_+ = e_- = e$, which simplifies the generalised vielbein (7.27) to a convention often used in the literature

$$\mathcal{E} = \frac{1}{\sqrt{\alpha'}} \begin{pmatrix} e^a_i & 0 \\ -\bar{e}_a^m b_{mi} & \alpha' \bar{e}_a^i \end{pmatrix}. \quad (7.30)$$

7.2 Lie and Courant algebroids

The introduction of generalised geometry in the last section was done with an application to T-duality and non-geometric backgrounds in mind. In this section we want to explain the underlying mathematical structures in some more detail. For further discussions we refer to [191], and for a discussion in the physics literature for instance to [198, 199].

Lie algebroid

Let us start by introducing the concept of a Lie algebroid [200]. To specify a Lie algebroid one needs three pieces of information:

- a vector bundle E over a manifold M ,
- a bracket $[\cdot, \cdot]_E : E \times E \rightarrow E$, and
- a homomorphism $\rho : E \rightarrow TM$ called the anchor map.

Similar to the usual Lie bracket, we require the bracket $[\cdot, \cdot]_E$ to satisfy a Leibniz rule. Denoting functions by $f \in C^\infty(M)$ and sections of E by $s_i \in \Gamma(E)$, this reads

$$[s_1, fs_2]_E = f[s_1, s_2]_E + \rho(s_1)(f)s_2, \quad (7.31)$$

where $\rho(s_1)$ is a vector-field which acts on functions f as a derivation. If in addition the bracket $[\cdot, \cdot]_E$ satisfies a Jacobi identity

$$[s_1, [s_2, s_3]_E]_E = [[s_1, s_2]_E, s_3]_E + [s_2, [s_1, s_3]_E]_E, \quad (7.32)$$

then $(E, [\cdot, \cdot]_E, \rho)$ is called a Lie algebroid. (If the Jacobi identity is not satisfied, the resulting structure is called a quasi-Lie algebroid.) Therefore, roughly speaking, when replacing vector-fields and their Lie bracket $[\cdot, \cdot]_L$ by sections of E and the corresponding bracket $[\cdot, \cdot]_E$ one obtains a Lie algebroid. The relation between the brackets is established by the anchor ρ . Indeed, the requirement that ρ is a homomorphism implies that

$$\rho([s_1, s_2]_E) = [\rho(s_1), \rho(s_2)]_L, \quad s_{1,2} \in \Gamma(E). \quad (7.33)$$

Examples

Let us illustrate this construction with two examples.

- We start with considering the tangent-bundle $E = TM$ with the usual Lie bracket $[\cdot, \cdot]_E = [\cdot, \cdot]_L$. The anchor is chosen to be the identity map, i.e. $\rho = \text{id}$. Then, the conditions (7.31) and (7.32) reduce to the well-known properties of the Lie bracket, and (7.33) is trivially satisfied. Therefore, $E = (TM, [\cdot, \cdot]_L, \rho = \text{id})$ is indeed a Lie algebroid.
- As a second example, we consider a Poisson manifold (M, β) with Poisson tensor $\beta = \frac{1}{2} \beta^{ij} \partial_i \wedge \partial_j$, where $\{\partial_i\} \in \Gamma(TM)$ denotes again a local basis of vector-fields. A Lie algebroid is given by $E = (T^*M, [\cdot, \cdot]_{\text{KS}}, \rho = \beta^\sharp)$, in which the anchor β^\sharp is defined as

$$\beta^\sharp(dx^i) = \beta^{ij} \partial_j, \quad (7.34)$$

with $\{dx^i\} \in \Gamma(T^*M)$ the standard basis of one-forms dual to the vector-fields. The bracket $[\cdot, \cdot]_{\text{KS}}$ on T^*M is the Koszul-Schouten bracket, which for one-forms ξ and η is defined as

$$[\xi, \eta]_{\text{KS}} = \mathcal{L}_{\beta^\sharp(\xi)}\eta - \iota_{\beta^\sharp(\eta)}d\xi. \quad (7.35)$$

The conditions (7.31), (7.32) and (7.33) are satisfied, provided that β is a Poisson tensor, that is

$$\beta^{[i|m}\partial_m\beta^{j|k]} = 0. \quad (7.36)$$

Differential geometry

Using the bracket $[\cdot, \cdot]_E$ of a Lie algebroid E , one can define a corresponding differential $d_E : \Gamma(\wedge^k E^*) \rightarrow \Gamma(\wedge^{k+1} E^*)$ through the relation

$$\begin{aligned} (d_E \omega)(s_0, \dots, s_k) &= \sum_{i=0}^k (-1)^i \rho(s_i) \omega(s_0, \dots, \hat{s}_i, \dots, s_k) \\ &+ \sum_{i < j} (-1)^{i+j} \omega([s_i, s_j]_E, s_0, \dots, \hat{s}_i, \dots, \hat{s}_j, \dots, s_k), \end{aligned} \quad (7.37)$$

where $\omega \in \Gamma(\wedge^k E^*)$ with E^* the vector-space dual to E , $s_i \in \Gamma(E)$ and the hat stands for deleting the corresponding entry. One can show that this differential is nil-potent for a Lie algebroid. Furthermore, using this differential we can define a Lie derivative acting in the following way

$$\mathcal{L}_{s_1} s_2 = [s_1, s_2]_E, \quad \mathcal{L}_s \omega = \iota_s \circ d_E \omega + d_E \circ \iota_s \omega, \quad (7.38)$$

where $s, s_i \in \Gamma(E)$ and $\omega \in \Gamma(E^*)$. This Lie derivative satisfies the standard properties. Finally, a covariant derivative for a Lie algebroid E is a bilinear map $\nabla : \Gamma(E) \times \Gamma(E) \rightarrow \Gamma(E)$ which has the properties

$$\nabla_{f s_1} s_2 = f \nabla_{s_1} s_2, \quad \nabla_{s_1}(f s_2) = \rho(s_1)(f) s_2 + f \nabla_{s_1} s_2, \quad (7.39)$$

for $s_1, s_2 \in \Gamma(E)$ and $f \in \mathcal{C}^\infty(M)$. Using this covariant derivative and the Lie-algebroid bracket, one can now construct curvature and torsion tensors similarly to ordinary differential geometry as

$$\begin{aligned} R(s_1, s_2) s_3 &= [\nabla_{s_1}, \nabla_{s_2}] s_3 - \nabla_{[s_1, s_2]_E} s_3, \\ T(s_1, s_2) &= \nabla_{s_1} s_2 - \nabla_{s_2} s_1 - [s_1, s_2]_E, \end{aligned} \quad (7.40)$$

for $s_i \in \Gamma(E)$. For more details on these constructions we refer the reader for instance to [198, 199] and references therein.

Courant algebroid

Let us now turn to the mathematical structure relevant for generalised geometry, which is that of a Courant algebroid. It is a combination of a Lie algebroid with its dual into a Lie bi-algebroid [201,202]. To be more precise,

Let M be a manifold and $E \rightarrow M$ a vector-bundle over M together with a non-degenerate symmetric bilinear form $\langle \cdot, \cdot \rangle$, a skew-symmetric bracket $[\cdot, \cdot]_E$ on its sections $\Gamma(E)$ and a bundle map $\rho : E \rightarrow TM$. Then $(E, [\cdot, \cdot]_E, \langle \cdot, \cdot \rangle, \rho)$ is called a Courant algebroid if the following properties hold:

- For $s_1, s_2 \in \Gamma(E)$ one has $\rho([s_1, s_2]_E) = [\rho(s_1), \rho(s_2)]_E$.
- For $s_1, s_2 \in \Gamma(E)$ and $f \in \mathcal{C}^\infty(M)$ one has

$$[s_1, fs_2]_E = f[s_1, s_2]_E + \rho(s_1)(f)s_2 - \langle s_1, s_2 \rangle \mathfrak{D}f. \quad (7.41)$$

- For $f_1, f_2 \in \mathcal{C}^\infty(M)$ one has $\langle \mathfrak{D}f_1, \mathfrak{D}f_2 \rangle = 0$, which means that $\rho \circ \mathfrak{D} = 0$.
- For $s_0, s_1, s_2 \in \Gamma(E)$ one has

$$\begin{aligned} \rho(s_0)\langle s_1, s_2 \rangle &= \langle [s_0, s_1]_E + \mathfrak{D}\langle s_0, s_1 \rangle, s_2 \rangle \\ &\quad + \langle s_1, [s_0, s_2]_E + \mathfrak{D}\langle s_0, s_2 \rangle \rangle. \end{aligned} \quad (7.42)$$

- For $s_1, s_2, s_3 \in \Gamma(E)$ one has $\text{Jac}(s_1, s_2, s_3)_E = \mathfrak{D}\text{Nij}(s_1, s_2, s_3)_E$.

Here we used a definition of the Jacobiator $\text{Jac}(\cdot, \cdot, \cdot)_E$ and Nijenhuis tensor $\text{Nij}(\cdot, \cdot, \cdot)_E$ for a bracket $[\cdot, \cdot]_E$ similar to the ones in (7.14) and (7.15). In particular, we have defined

$$\begin{aligned} \text{Jac}(s_1, s_2, s_3)_E &= [[s_1, s_2]_E, s_3]_E + [[s_3, s_1]_E, s_2]_E + [[s_2, s_3]_E, s_1]_E, \\ \text{Nij}(s_1, s_2, s_3)_E &= \frac{1}{3} \left(\langle [s_1, s_2]_E, s_3 \rangle + \langle [s_3, s_1]_E, s_2 \rangle + \langle [s_2, s_3]_E, s_1 \rangle \right), \end{aligned} \quad (7.43)$$

and we defined a map $\mathfrak{D} : \mathcal{C}^\infty(M) \rightarrow \Gamma(E)$ through

$$\langle \mathfrak{D}f, s \rangle = \frac{1}{2} \rho(s)f. \quad (7.44)$$

If we now compare this definition to our discussion in section 7.1, we see that the generalised tangent-bundle (7.1) together with the bilinear pairing (7.6) and the Courant bracket (7.12) is a Courant algebroid, in which the anchor map ρ is the projection from E to TM . It then follows that the operator \mathfrak{D} is the exterior derivative d .

7.3 Buscher rules

In this section we discuss an application of the generalised-geometry framework to the Buscher rules considered in section 3. More concretely, we want to express the restrictions for performing T-duality in terms of generalised vectors on the generalised tangent-space.

Restrictions

Recall that the Buscher rules were derived by identifying a global symmetry of the world-sheet theory, gauging this symmetry, and integrating out the gauge field. In order for this to be possible, certain constraints on the background have to be satisfied. These are constraints for the existence of a global and a local symmetry, and we summarise the corresponding equations (3.42), (3.43) and (3.47) here as follows (we ignore the dilaton constraint)

$$\text{global symmetry} \quad \mathcal{L}_{k_\alpha} G = 0, \quad (7.45a)$$

$$\nu_{k_\alpha} H = dv_\alpha, \quad (7.45b)$$

$$\text{isometry algebra} \quad [k_\alpha, k_\beta]_{\text{L}} = f_{\alpha\beta}{}^\gamma k_\gamma, \quad (7.46)$$

$$\text{local symmetry} \quad \mathcal{L}_{k_{[\underline{\alpha}} v_{\underline{\beta}]}} = f_{\alpha\beta}{}^\gamma v_\gamma, \quad (7.47a)$$

$$3\nu_{k_{[\underline{\alpha}} f_{\underline{\beta}\underline{\gamma}]}}{}^\delta v_\delta = \nu_{k_\alpha} \nu_{k_\beta} \nu_{k_\gamma} H. \quad (7.47b)$$

Reformulation using the generalised Lie derivative

In order to describe the global-symmetry requirements (7.45), let us determine the generalised Lie derivative (7.20) of the generalised metric shown in (7.23). For a local basis on $TM \oplus T^*M$ of the form $\{dX^I\} = \{dx^i, \partial_i\}$, this Lie derivative is determined by computing

$$\mathcal{L}_X \mathcal{H} = \mathcal{L}_X \left(\mathcal{H}_{IJ} dX^I \vee dX^J \right). \quad (7.48)$$

If we choose for the generalised vector $X = x + \xi$ one finds that the components of (7.48) read [43]

$$(\mathcal{L}_X \mathcal{H})_{IJ} = \begin{pmatrix} \frac{1}{\alpha'} [(g+b)(\mathcal{L}_x g^{-1})(g-b) + [d\xi + \mathcal{L}_x(g+b)] g^{-1}(g-b)] & +b(\mathcal{L}_x g^{-1}) + [d\xi + \mathcal{L}_x b] g^{-1} \\ -(g+b) g^{-1} [d\xi - \mathcal{L}_x(g-b)] & \\ -(\mathcal{L}_x g^{-1}) b - g^{-1} [d\xi + \mathcal{L}_x b] & \alpha' \mathcal{L}_{k_\alpha} g^{-1} \end{pmatrix}. \quad (7.49)$$

In a similar way, one shows that $\mathcal{L}_X \eta = 0$ for all choices of generalised vectors X . Rewriting (7.45b) as $\mathcal{L}_{k_\alpha} B = d(v_\alpha + \iota_{k_\alpha} B)$ and defining

$$K_\alpha = k_\alpha - (v_\alpha + \iota_{k_\alpha} B), \quad (7.50)$$

we see that the global symmetry requirements can be stated using the generalised metric as

$$\mathcal{L}_{K_\alpha} \mathcal{H} = 0. \quad (7.51)$$

The generalised vectors K_α are then called generalised Killing vectors. Using (7.13), one can furthermore show that the isometry-algebra relation (7.46) and the local relations (7.47a) are encoded in the closure of the so-called H -twisted Courant bracket

$$[X, Y]_{\mathbb{C}}^H = [x, y]_{\mathbb{L}} + \mathcal{L}_x \chi - \mathcal{L}_y \xi - \frac{1}{2} d(\iota_x \chi - \iota_y \xi) + \iota_x \iota_y H \quad (7.52)$$

as

$$[K_\alpha, K_\beta]_{\mathbb{C}}^H = f_{\alpha\beta}{}^\gamma K_\gamma. \quad (7.53)$$

In addition, the remaining local symmetry relation (7.47b) is encoded in the vanishing of the Nijenhuis tensor (7.15) with respect to the twisted Courant bracket (7.52), that is [58]

$$\text{Nij}(K_\alpha, K_\beta, K_\gamma)_{\mathbb{C}}^H = 0. \quad (7.54)$$

To summarise, the constraints on performing a T-duality transformation using Buscher's approach can be expressed in the framework of generalised geometry as (7.50) being a generalised Killing vector with respect to the generalised metric, which is closed with respect to the H -twisted Courant bracket (7.52) and whose Nijenhuis tensor vanishes.

Remark

We remark that a particular solution to the constraint (7.47b) is given by requiring $\iota_{k(\bar{\alpha}v_{\bar{\beta}})} = 0$. This is what is often done in the literature, however, in general other solutions to (7.47b) may exist. Using the inner product (7.6), we can express $\iota_{k(\bar{\alpha}v_{\bar{\beta}})} = 0$ as

$$\langle K_\alpha, K_\beta \rangle = 0, \quad (7.55)$$

which is an isotropy condition. Together with (7.53), the generalised Killing vectors then define an isotropic and involutive sub-bundle of the generalised tangent-bundle. If this sub-bundle is in addition maximal, it defines a Dirac structure (cf. our discussion on page 107).

7.4 Fluxes

In this section we present a description of geometric as well as non-geometric fluxes within the framework of generalised geometry. We show how different flux-backgrounds can be generated by acting with $O(D, D)$ transformations on the generalised vielbeins; if these transformations are *not* automorphisms of the Courant bracket a different flux-background is obtained.

Generalised vielbein

In section 5.2 we have seen that the geometric flux can be defined via the exterior derivative of vielbein one-forms. Let us formalise this approach and introduce the connection one-form $\omega^a{}_b$ which satisfies Cartan's structure equations. (For a textbook introduction to this topic see for instance section 7.8 in [203].) In particular, choosing the torsion to be vanishing the connection one-form is specified by the relation

$$de^a + \omega^a{}_b \wedge e^b = 0, \quad \omega^a{}_b = \Gamma^a{}_{cb} e^c, \quad (7.56)$$

where $e^a = e^a{}_i dx^i$ is a basis of one-forms. As before, the $e^a{}_i$ are determined via $g_{ij} = (e^T)_i{}^a \delta_{ab} e^b{}_j$ and $\Gamma^a{}_{cb}$ are the Christoffel symbols for the vielbein-basis. The algebra of the vielbein vector-fields $\bar{e}_a = (\bar{e}^T)_a{}^i \partial_i$ is specified by structure constant $f_{ab}{}^c$ as

$$[\bar{e}_a, \bar{e}_b]_L = f_{ab}{}^c \bar{e}_c. \quad (7.57)$$

In case of vanishing torsion, we can express the structure constants as $f_{ab}{}^c = \Gamma^c{}_{ab} - \Gamma^c{}_{ba}$, and equation (7.56) can therefore be written as

$$de^a = -\frac{1}{2} f_{bc}{}^a e^b \wedge e^c. \quad (7.58)$$

With respect to the example of the geometric flux, we therefore see that this flux is alternatively encoded in the structure constants of the vielbein vector-field algebra (7.57).

We now apply a similar reasoning to the generalised vectors: we replace the ordinary vielbein vector-fields $\bar{e}_a = \{\bar{e}_a{}^i\}$ by the generalised vielbein vector-fields $\bar{\mathcal{E}}_A = \{\bar{\mathcal{E}}_A{}^I\}$ introduced in equation (7.25), and we replace the Lie bracket by the Courant bracket (7.12). In analogy to (7.57) we then define generalised structure constants $F_{AB}{}^C$ through

$$[\bar{\mathcal{E}}_A, \bar{\mathcal{E}}_B]_C = F_{AB}{}^C \bar{\mathcal{E}}_C. \quad (7.59)$$

Fluxes via $O(D, D)$ transformations

Let us now construct explicit examples for backgrounds with geometric and non-geometric fluxes. We start from a trivial generalised vielbein and act on them with non-constant $O(D, D)$ transformations. Such transformations are in general not symmetries of the Courant bracket and therefore change the corresponding background. However, this approach provides us with a technique to generate new flux backgrounds.

Our starting point is a locally-flat metric $g_{ij} = \alpha' \delta_{ij}$ and a vanishing Kalb-Ramond B -field. The generalised metric \mathcal{H} then takes a diagonal form, and the generalised vector-fields $\bar{\mathcal{E}}_A$ – which are the inverse-transpose of (7.25) – can be expressed as

$$(\bar{\mathcal{E}}_{(0)})_A{}^I = \begin{pmatrix} \delta_a^i & 0 \\ 0 & \delta^a_i \end{pmatrix}. \quad (7.60)$$

Employing a local basis $\{\partial_I\} = \{\partial_i, dx^i\}$ of the generalised tangent-space and defining $\bar{\mathcal{E}}_A = \bar{\mathcal{E}}_A{}^I \partial_I$, for the Courant bracket (7.12) of generalised vielbeins we find

$$\begin{aligned} [\bar{\mathcal{E}}_{(0)a}, \bar{\mathcal{E}}_{(0)b}]_C &= 0, \\ [\bar{\mathcal{E}}_{(0)a}, \bar{\mathcal{E}}_{(0)}{}^b]_C &= 0, \\ [\bar{\mathcal{E}}_{(0)}{}^a, \bar{\mathcal{E}}_{(0)}{}^b]_C &= 0. \end{aligned} \quad (7.61)$$

Next, we generate new backgrounds by applying $O(D, D)$ transformations \mathcal{O} to these generalised vectors, for which we have in matrix notation

$$\bar{\mathcal{E}}_{(\mathcal{O})} = \bar{\mathcal{E}}_{(0)} \mathcal{O}^T, \quad \mathcal{O} = \begin{pmatrix} A & B \\ C & D \end{pmatrix}. \quad (7.62)$$

Let us emphasise that these are in general non-constant transformations which are also not automorphisms of the Courant bracket. We discuss now four examples of $O(D, D)$ transformations acting on the generalised vector-field (7.60):

- We start with an **A**-transformation which was mentioned in equation (7.8). Choosing $A^i{}_j = \delta^i_b \hat{e}^b{}_j$ with $\hat{e}^a{}_i = e^a_i / \sqrt{\alpha'}$ non-trivial and dimension-less vielbein matrices, we obtain¹¹

$$(\bar{\mathcal{E}}_{(\text{A})})_A{}^I = \begin{pmatrix} \hat{e}_a^i & 0 \\ 0 & \hat{e}^a_i \end{pmatrix}. \quad (7.63)$$

¹¹We use dimension-less quantities in order to make the generalised vielbeins dimension-less, in accordance with our conventions in (7.26).

The Courant brackets between the generalised vectors then read

$$\begin{aligned}
[\bar{\mathcal{E}}_{(A)a}, \bar{\mathcal{E}}_{(A)b}]_C &= + \hat{f}_{ab}{}^c \bar{\mathcal{E}}_{(A)c}, \\
[\bar{\mathcal{E}}_{(A)a}, \bar{\mathcal{E}}_{(A)}{}^b]_C &= - \hat{f}_{ac}{}^b \bar{\mathcal{E}}_{(A)}{}^c, \\
[\bar{\mathcal{E}}_{(A)}{}^a, \bar{\mathcal{E}}_{(A)}{}^b]_C &= 0,
\end{aligned} \tag{7.64}$$

where $\hat{f}_{ab}{}^c$ are the structure constants of the dimension-less vielbein vector-fields \hat{e}_a defined as $[\hat{e}_a, \hat{e}_b]_L = f_{ab}{}^c \hat{e}_c$. We therefore see that an $O(D, D)$ transformation with non-trivial matrices A gives rise to a geometric flux.

- The next case we consider is a B -transformation (7.9) acting on the trivial generalised vielbeins (7.60). For $B_{ij} = \hat{b}_{ij}$ the (dimension-less) components of a non-trivial Kalb-Ramond field $b = \frac{\alpha'}{2} \hat{b}_{ij} dx^i \wedge dx^j$, we find

$$(\bar{\mathcal{E}}_{(B)})_A{}^I = \begin{pmatrix} \delta_a{}^i & -\delta_a{}^m \hat{b}_{mi} \\ 0 & \delta^a{}_i \end{pmatrix}. \tag{7.65}$$

The Courant bracket for the corresponding generalised vectors takes the form

$$\begin{aligned}
[\bar{\mathcal{E}}_{(B)a}, \bar{\mathcal{E}}_{(B)b}]_C &= - \hat{H}_{abc} \bar{\mathcal{E}}_{(B)}{}^c, \\
[\bar{\mathcal{E}}_{(B)a}, \bar{\mathcal{E}}_{(B)}{}^b]_C &= 0, \\
[\bar{\mathcal{E}}_{(B)}{}^a, \bar{\mathcal{E}}_{(B)}{}^b]_C &= 0,
\end{aligned} \tag{7.66}$$

where $\hat{H}_{abc} = \delta_a{}^i \delta_b{}^j \delta_c{}^k \hat{H}_{ijk}$ and $\hat{H}_{ijk} = 3 \partial_{[i} \hat{b}_{jk]}$ are the (dimension-less) components of the H -flux $H = db$. Here we see that a non-trivial B -transform can give rise to a non-trivial H -flux.

- Let us also discuss a β -transformation (7.10) acting again on the trivial generalised vielbeins (7.60). We find

$$(\bar{\mathcal{E}}_{(\beta)})_A{}^I = \begin{pmatrix} \delta_a{}^i & 0 \\ -\delta^a{}_m \beta^{mi} & \delta^a{}_i \end{pmatrix}, \tag{7.67}$$

where β^{ij} is an anti-symmetric matrix, and for the Courant brackets we obtain

$$\begin{aligned}
[\bar{\mathcal{E}}_{(\beta)a}, \bar{\mathcal{E}}_{(\beta)b}]_C &= 0, \\
[\bar{\mathcal{E}}_{(\beta)a}, \bar{\mathcal{E}}_{(\beta)}{}^b]_C &= - Q_a{}^{bc} \bar{\mathcal{E}}_{(\beta)c}, \\
[\bar{\mathcal{E}}_{(\beta)}{}^a, \bar{\mathcal{E}}_{(\beta)}{}^b]_C &= - Q_c{}^{ab} \bar{\mathcal{E}}_{(\beta)}{}^c + R^{abc} \bar{\mathcal{E}}_{(\beta)c}.
\end{aligned} \tag{7.68}$$

Here we defined the non-geometric Q - and R -flux as $Q_a{}^{bc} = \delta_a{}^i \delta_b{}^j \delta_c{}^k Q_i{}^{jk}$ and $R^{abc} = \delta_a{}^i \delta_b{}^j \delta_c{}^k R^{ijk}$ with

$$Q_i{}^{jk} = \partial_i \beta^{jk}, \quad R^{ijk} = 3 \beta^{[i|m} \partial_m \beta^{j]k} . \quad (7.69)$$

Let us point out that the expression for the R -flux is similar to equation (7.36) in the context of a Lie algebroid, and that a non-vanishing R -flux gives rise to a quasi-Lie algebroid.

- Finally, $O(D, D)$ -transformations $\mathcal{O}_{\pm i}$ defined in (7.11) act on the trivial generalised vielbeins (7.60) by interchanging vector-field and one-form components. Since the matrices $\mathcal{O}_{\pm i}$ are constant the resulting Courant brackets vanish, however, when $\mathcal{O}_{\pm i}$ acts on non-trivial vielbein matrices this changes. We come back to this point in section 7.5.

To summarise, when acting with non-trivial $O(D, D)$ transformations on the generalised vector-fields the corresponding Courant brackets are modified. This is expected since such transformations are in general not automorphisms of the Courant bracket, however, in this way we can generate backgrounds with non-vanishing geometric and non-geometric fluxes. In particular, A -transformations lead to a geometric flux, B -transformations give an H -flux, and β -transformations can generate Q - and R -fluxes. Using the notation (7.59), we see that the geometric and non-geometric fluxes are contained in $F_{AB}{}^C$, where the indices A, B, C can be upper or lower ones:

$$\begin{aligned} F_{abc} &= - \hat{H}_{abc} && H\text{-flux}, \\ F_{ab}{}^c &= + \hat{f}_{ab}{}^c && \text{geometric flux}, \\ F_a{}^{bc} &= - Q_a{}^{bc} && \text{non-geometric } Q\text{-flux}, \\ F^{abc} &= + R^{abc} && \text{non-geometric } R\text{-flux}. \end{aligned} \quad (7.70)$$

General form of fluxes

For completeness, let us also give a general expression for the fluxes. We start again from the trivial generalised vector-field (7.60) and apply to it a general $O(D, D)$ transformation of the form (7.62). The corresponding Courant brackets take the form (7.59). Expressing then the structure constants $F_{AB}{}^C$ using $\delta_A{}^I$ as $F_{ab}{}^c = \delta_a{}^i \delta_b{}^j F_{ij}{}^k \delta_k{}^c$, $F_{abc} = \delta_a{}^i \delta_b{}^j \delta_c{}^k F_{ijk}$ and so on, we find

$$\begin{aligned} F_{ijk} &= (A^T)_i{}^m \partial_m (A^T)_j{}^n C_{nk} - i \leftrightarrow j \\ &+ (A^T)_i{}^m \partial_m (C^T)_{jn} A^n{}_k - i \leftrightarrow j \\ &+ (A^T)_k{}^m \partial_m (A^T)_i{}^n C_{nj} \\ &+ (A^T)_k{}^m \partial_m (C^T)_{in} A^n{}_j, \end{aligned} \quad (7.71a)$$

$$\begin{aligned}
F_{ij}{}^k &= (A^T)_i{}^m \partial_m (A^T)_j{}^n D_n{}^k - i \leftrightarrow j \\
&+ (A^T)_i{}^m \partial_m (C^T)_{jn} B^{nk} - i \leftrightarrow j \\
&+ (B^T)^{km} \partial_m (A^T)_i{}^n C_{nj} \\
&+ (B^T)^{km} \partial_m (C^T)_{in} A^n{}_j,
\end{aligned} \tag{7.71b}$$

$$\begin{aligned}
F_i{}^{jk} &= (B^T)^{km} \partial_m (A^T)_i{}^n D_n{}^j - j \leftrightarrow k \\
&+ (B^T)^{km} \partial_m (C^T)_{in} B^{nj} - j \leftrightarrow k \\
&+ (A^T)_i{}^m \partial_m (B^T)^{jn} D_n{}^k \\
&+ (A^T)_i{}^m \partial_m (D^T)^j{}_n B^{nk},
\end{aligned} \tag{7.71c}$$

$$\begin{aligned}
F^{ijk} &= (B^T)^{im} \partial_m (B^T)^{jn} D_n{}^k - i \leftrightarrow j \\
&+ (B^T)^{im} \partial_m (D^T)^j{}_n B^{nk} - i \leftrightarrow j \\
&+ (B^T)^{km} \partial_m (B^T)^{in} D_n{}^j \\
&+ (B^T)^{km} \partial_m (D^T)^i{}_n B^{nj}.
\end{aligned} \tag{7.71d}$$

Example

Let us finally mention a particular example which is often discussed in the literature. We consider the generalised vielbein (7.30), which we can express as

$$\bar{\mathcal{E}}_A{}^I = \begin{pmatrix} \hat{e}_a{}^i & -\hat{e}_a{}^m \hat{b}_{mi} \\ 0 & \hat{e}^a{}_i \end{pmatrix} = \left[\bar{\mathcal{E}}_{(0)} \mathcal{O}_A^T \mathcal{O}_B^T \right]_A{}^I, \tag{7.72}$$

where $\bar{\mathcal{E}}_{(0)}$ has been defined in (7.60) and $\mathbf{A}^i{}_j = \delta^i_b \hat{e}^b{}_j$ and $\mathbf{B}_{ij} = \hat{b}_{ij}$ are given in terms of the dimension-less vielbein matrices and the Kalb-Ramond field. For the generalised vectors we then have

$$\bar{\mathcal{E}}_a = \hat{e}_a - \iota_{\hat{e}_a} \hat{b}, \quad \bar{\mathcal{E}}^a = \hat{e}^a, \tag{7.73}$$

and the Courant bracket (7.59) reads

$$\begin{aligned}
[\mathcal{E}_a, \mathcal{E}_b]_{\text{C}} &= + \hat{f}_{ab}{}^c \mathcal{E}_c - \hat{H}_{abc} \mathcal{E}^c, \\
[\mathcal{E}_a, \mathcal{E}^b]_{\text{C}} &= - \hat{f}_{ac}{}^b \mathcal{E}^c, \\
[\mathcal{E}^a, \mathcal{E}^b]_{\text{C}} &= 0.
\end{aligned} \tag{7.74}$$

The H -flux in the vielbein basis is given by $\hat{H}_{abc} = \hat{e}_a{}^i \hat{e}_b{}^j \hat{e}_c{}^k \hat{H}_{ijk}$. We therefore see that the generalised vielbein (7.73) encodes the H -flux as well as the geometric flux, as one would expect from (7.72).

7.5 T-duality

Let us now discuss T-duality transformations in the context of generalised geometry. These can be realised via $O(D) \times O(D)$ transformations of the form (7.28) acting on the generalised vielbein vector-fields.

$O(D) \times O(D)$ transformations

In section 7.4 we have considered $O(D, D)$ transformations acting on the generalised vector $\bar{\mathcal{E}}_A^I$ from the right, that is contracting the transformation matrix $\mathcal{O} \in O(D, D)$ with the index I . However, as noted in (7.28) we have an $O(D) \times O(D)$ structure, whose transformations act on the generalised vector from the left. Recalling the form of the transformations given in (7.29),

- we see that $O_+ = O_-$ corresponds to $O(D)$ transformations which rotate the generalised-vector components $\bar{\mathcal{E}}_a$ and $\bar{\mathcal{E}}^a$ in a similar way. The transformation of the corresponding Courant brackets is then worked out along similar lines as above.
- On the other hand, for $O_+ \neq O_-$ the $O(D) \times O(D)$ transformations mix the components $\bar{\mathcal{E}}_a$ and $\bar{\mathcal{E}}^a$. The corresponding Courant brackets are modified, in particular, the type of fluxes appearing on the right-hand side will in general change.

As a specific example for the second situation, let us consider two $D \times D$ matrices of the form

$$O_+ = \begin{pmatrix} +1 & & & \\ & +1 & & \\ & & \ddots & \\ & & & +1 \end{pmatrix}, \quad O_- = \begin{pmatrix} -1 & & & \\ & +1 & & \\ & & \ddots & \\ & & & +1 \end{pmatrix}, \quad (7.75)$$

which via (7.29) lead to a matrix \mathcal{K}_{+1} . The latter is an example of $\mathcal{K}_{\pm i}$, which we define as

$$\mathcal{K}_{\pm i} = \begin{pmatrix} \mathbb{1} - E_i & \pm E_i \\ \pm E_i & \mathbb{1} - E_i \end{pmatrix} \equiv \mathcal{O}_{\pm i}, \quad (7.76)$$

where E_i and $\mathcal{O}_{\pm i}$ were given around equation (7.11). Applying the transformation \mathcal{K}_{+1} induced by (7.75) to the generalised vector from the left, we interchange the first vector-field and one-form components

$$\bar{\mathcal{E}}_A \rightarrow \bar{\mathcal{E}}'_A = (\mathcal{K}_{+1})_A^B \bar{\mathcal{E}}_B = \begin{pmatrix} \delta_{11} \bar{\mathcal{E}}^1 \\ \bar{\mathcal{E}}_{\hat{a}} \\ \delta^{11} \bar{\mathcal{E}}_1 \\ \bar{\mathcal{E}}^{\hat{a}} \end{pmatrix}, \quad \hat{a} = 2, \dots, D. \quad (7.77)$$

Computing now the Courant bracket of the transformed generalised vector-fields, a similar interchange can be found. In particular, for (7.77) the index 1 of the various fluxes is raised or lowered according to the following mapping

$$\begin{aligned}
\hat{H}_{\hat{a}\hat{b}1} &\rightarrow -\hat{f}_{\hat{a}\hat{b}}{}^1, & \hat{f}_{\hat{a}\hat{b}}{}^1 &\rightarrow -\hat{H}_{\hat{a}\hat{b}1}, \\
\hat{f}_{\hat{a}1}{}^{\hat{b}} &\rightarrow -Q_{\hat{a}}{}^{1\hat{b}}, & Q_{\hat{a}}{}^{1\hat{b}} &\rightarrow -\hat{f}_{\hat{a}1}{}^{\hat{b}}, \\
Q_1{}^{\hat{a}\hat{b}} &\rightarrow -R^{1\hat{a}\hat{b}}, & R^{1\hat{a}\hat{b}} &\rightarrow -Q_1{}^{\hat{a}\hat{b}},
\end{aligned} \tag{7.78}$$

where $\hat{a}, \hat{b} = 2, \dots, D$ and where the other flux-components do not change. For transformations which are a combination of $\mathcal{K}_{\pm i}$ a similar exchange between upper- and lower-indices can be found. The behaviour of the fluxes shown in (7.78) is in agreement with our results from section 5, as well as with [121], where the same observation has been made in the context of supergravity. To summarise,

A T-duality transformation along the direction x^i can be realised by acting with $\mathcal{K}_{\pm i}$ on the generalised vector-field $\bar{\mathcal{E}}_A$ from the left. For the fluxes, a corresponding lower index i is raised and a corresponding upper index i is lowered.

$O(D, D)$ transformations

Let us now also relate the above results to $O(D, D)$ transformations acting on the generalised vectors from the right. Recall from (7.62) that a generalised vector can be expressed as $\bar{\mathcal{E}}_{(\mathcal{O})} = \bar{\mathcal{E}}_{(0)} \mathcal{O}^T$. Acting with a transformation $\mathcal{O}_{\pm i}$ from the right can be written as

$$\begin{aligned}
\bar{\mathcal{E}}_{(\mathcal{O})} &\rightarrow \bar{\mathcal{E}}'_{(\mathcal{O}')} = \bar{\mathcal{E}}_{(\mathcal{O})} \mathcal{O}_{\pm i}^T \\
&= \bar{\mathcal{E}}_{(0)} \mathcal{O}^T \mathcal{O}_{\pm i}^T \\
&= \mathcal{K}_{\pm i} \bar{\mathcal{E}}_{(0)} (\mathcal{O}_{\pm i}^{-1} \mathcal{O} \mathcal{O}_{\pm i})^T,
\end{aligned} \tag{7.79}$$

where the expression in parenthesis encodes the duality transformation of the metric and Kalb-Ramond field. We thus see that a $\mathcal{O}_{\pm i}$ transformation from the right leads to a transformation of the background quantities, and raises or lowers the position of the corresponding structure index.

Let us now note that transformations of the form $\bar{\mathcal{E}} \rightarrow \bar{\mathcal{E}}' = \bar{\mathcal{E}} \mathcal{O}_{\pm i}^T$ are in general not automorphisms of the Courant bracket. However, for backgrounds satisfying additional conditions – such as the T-duality requirements (7.45) – this can change [194]. Let us illustrate this observation with the example of the three-torus with H -flux discussed in section 5. Using (7.72), from the metric (5.1) and

the H -flux (5.2) we determine a generalised vector-field as

$$\bar{\mathcal{E}}_A{}^I = \left(\begin{array}{ccc|ccc} \frac{\sqrt{\alpha'}}{R_1} & 0 & 0 & 0 & -\frac{h}{2\pi} \frac{x^3}{R_1} & 0 \\ 0 & \frac{\sqrt{\alpha'}}{R_2} & 0 & +\frac{h}{2\pi} \frac{x^3}{R_2} & 0 & 0 \\ 0 & 0 & \frac{\sqrt{\alpha'}}{R_3} & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & \frac{R_1}{\sqrt{\alpha'}} & 0 & 0 \\ 0 & 0 & 0 & 0 & \frac{R_2}{\sqrt{\alpha'}} & 0 \\ 0 & 0 & 0 & 0 & 0 & \frac{R_3}{\sqrt{\alpha'}} \end{array} \right), \quad (7.80)$$

from which we can determine the only non-vanishing flux via the Courant brackets as $\hat{H}_{123} = \frac{h}{2\pi} \frac{1}{R_1 R_2 R_3}$ in accordance with (5.5). We now consider two types of $O(D, D)$ transformations:

- Let us first consider a matrix \mathcal{O}_{+1} acting on (7.80) from the right. This transformation leaves the Courant bracket between the generalised vectors (7.80) invariant, and hence the flux does not change. This can be understood from (7.79) by observing that \mathcal{O}_{+1} generates a T-duality transformation of the background along the direction x^1 , which is however un-done by \mathcal{K}_{+1} acting from the left.
- As a second type we consider a matrix \mathcal{O}_{+3} acting on (7.80) from the right. Note that since (7.80) depends explicitly on x^3 , this transformation is not an automorphism of the corresponding Courant bracket [194]. Indeed, the transformed flux reads $\hat{f}_{12}{}^3 = -\frac{h}{2\pi} \frac{R_3}{R_1 R_2}$. When comparing with (7.79), we see that \mathcal{O}_{+3} generates a T-duality transformation along the direction x^3 which maps $R_3 \rightarrow \alpha'/R_3$, and \mathcal{K}_{+3} maps the H -flux to a geometric flux.

To summarise, for the example of the three-torus with H -flux we have illustrated that T-duality transformations acting on the generalised vectors as $O(D, D)$ -transformations from the right leave the background invariant, provided that the conditions discussed in section 7.3 are satisfied. If the latter are not satisfied, the background changes.

7.6 Frame transformations

On page 110 we discussed the $O(D) \times O(D)$ structure of the generalised tangent-bundle. Let us now first consider a particular $O(D) \times O(D)$ transformation (7.29) which replaces the Kalb-Ramond B -field by a bivector-field β , and then construct an effective action for the transformed fields.

Change of frame

We start by recalling the generalised vielbein of a background with geometric and H -flux shown in equation (7.30) as

$$\mathcal{E} = \frac{1}{\sqrt{\alpha'}} \begin{pmatrix} e^a{}_i & 0 \\ -\bar{e}_a{}^m b_{mi} & \alpha' \bar{e}_a{}^i \end{pmatrix}, \quad (7.81)$$

and then we perform an $O(D) \times O(D)$ transformation (7.29) specified by the following two $O(D)$ matrices [43]

$$O_+ = \mathbb{1}, \quad O_- = (e - \delta^{-1} \bar{e}^T b) (e + \delta^{-1} \bar{e}^T b)^{-1}. \quad (7.82)$$

The transformed generalised vielbein then takes the following form

$$\mathcal{E}' = \frac{1}{\sqrt{\alpha'}} \begin{pmatrix} e'^a{}_i & -e'^a{}_m \beta^{mi} \\ 0 & \alpha' \bar{e}'_a{}^i \end{pmatrix}, \quad (7.83)$$

which is expressed in terms of a transformed vielbein $e'^a{}_i$ (with corresponding transformed metric g'_{ij}) and a bivector-field β^{ij} of the form

$$\begin{aligned} e' &= e g^{-1} (g - b), & g' &= (g + b) \quad g^{-1} (g - b), \\ \beta &= -(g - b)^{-1} \quad b \quad (g + b)^{-1}. \end{aligned} \quad (7.84)$$

Let us note that the expressions for the transformed metric and the bivector-field can also be encoded via the relation

$$(g - b)^{-1} = g'^{-1} - \beta. \quad (7.85)$$

Since the background can be specified in terms of a generalised vielbein, we see that locally the information is contained either in a metric and Kalb-Ramond field g and b – or equivalently in a different metric and a bivector-field g' and β .

Example

Even though locally one can always perform a change of frames from (g, b) to (g', β) , globally the transformation (7.82) may not be well-defined. Let us illustrate this situation with the example of the T-fold. Using our conventions from section 6.1, we recall the metric and B -field of the three-dimensional T-fold background as follows

$$g_{ij} = \begin{pmatrix} \frac{R_2^2}{\rho} & 0 & 0 \\ 0 & \frac{R_1^2}{\rho} & 0 \\ 0 & 0 & R_3^2 \end{pmatrix}, \quad b_{ij} = \frac{1}{\rho} \begin{pmatrix} 0 & -\frac{\alpha'}{2\pi} h x^3 & 0 \\ +\frac{\alpha'}{2\pi} h x^3 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad (7.86)$$

where $\rho = \frac{R_1^2 R_2^2}{\alpha'^2} + \left[\frac{h}{2\pi} x^3\right]^2$ and $h \in \mathbb{Z}$. The transformation (7.82) for this example takes the following explicit form

$$O_+ = \mathbf{1}, \quad O_- = \frac{1}{\rho} \begin{pmatrix} \frac{R_1^2 R_2^2}{\alpha'^2} - \left[\frac{h}{2\pi} x^3\right]^2 & +\frac{R_1 R_2}{\alpha'} \frac{h}{\pi} x^3 & 0 \\ -\frac{R_1 R_2}{\alpha'} \frac{h}{\pi} x^3 & \frac{R_1^2 R_2^2}{\alpha'^2} - \left[\frac{h}{2\pi} x^3\right]^2 & 0 \\ 0 & 0 & \rho \end{pmatrix}, \quad (7.87)$$

and the resulting metric and bivector-field is determined from (7.84) as

$$g'_{ij} = \begin{pmatrix} \frac{\alpha'}{R_1^2} & 0 & 0 \\ 0 & \frac{\alpha'}{R_2^2} & 0 \\ 0 & 0 & R_3^2 \end{pmatrix}, \quad \beta^{ij} = \begin{pmatrix} 0 & +\frac{hx^3}{2\pi\alpha'} & 0 \\ -\frac{hx^3}{2\pi\alpha'} & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}. \quad (7.88)$$

Note that these expressions are very similar to the metric and B -field of the three-torus with H -flux shown in equation (6.3). However, even though locally (7.88) takes a rather simple form, the T-fold background is nevertheless non-geometric. This can be seen by noting that the change of frame (7.87) is not well-defined under the identification $x^3 \rightarrow x^3 + 2\pi$, and hence the frame (7.88) is globally not well-defined [43]. This shows the globally non-geometric nature of the T-fold.

Effective action I – example

We now want to discuss how frame transformations change the effective description of the theory. In particular, let us recall the ten-dimensional string-theory action for the NS-NS sector in type II theories as

$$\mathcal{S} = \frac{1}{2\kappa^2} \int e^{-2\phi} \left[R \star 1 - \frac{1}{2} H \wedge \star H + 4d\phi \wedge \star d\phi \right], \quad (7.89)$$

where R denotes the Ricci scalar for the metric g , $H = db$ is the field strength of the Kalb-Ramond B -field, ϕ denotes the dilaton and \star is the ten-dimensional Hodge star-operator. We also note that the generalised vielbein shown in (7.81) contains information about the metric and B -field, which appear in the action (7.89). However, when performing the change of frames shown in (7.82) the degrees of freedom of g and b are re-packaged into a new metric g' and a bivector-field β . In view of (7.89), a natural question to ask is how an action for g' and β can be constructed. This program has been followed in the papers [204–208, 198, 209] and the resulting formulation has been called symplectic gravity or β -supergravity.

In order to address this question we first recall that (7.89) is invariant under diffeomorphisms $x^i \rightarrow x^i + \xi^i(x)$ and gauge transformations of the Kalb-Ramond

field. In particular, with ξ a vector-field and Λ a one-form, the metric and B -field transform as

$$\begin{aligned}\delta_\xi g &= \mathcal{L}_\xi g, & \delta_\Lambda g &= 0, \\ \delta_\xi b &= \mathcal{L}_\xi b, & \delta_\Lambda b &= d\Lambda,\end{aligned}\tag{7.90}$$

where \mathcal{L}_ξ denotes the usual Lie-derivative along the direction ξ . Now, when performing the change of frames (7.84), diffeomorphisms and gauge transformations of g and b become intertwined. Clearly, since g and b behave as ordinary tensors also g' and β will transform as expected under diffeomorphisms. However, under gauge transformations of b now both g' and β will transform, and these transformations have been called momentum- [204] or β -diffeomorphisms [207] in the literature.

The main task is now to construct an action for g' and β (and the dilaton ϕ), which is invariant under ordinary diffeomorphisms as well as β -diffeomorphisms. This has been investigated in the papers [204–206], where the explicit form of the action can be found. The latter is motivated from double field theory (see section 9.3 for a brief introduction to double field theory) and its explicit form is somewhat involved. We therefore do not recall it here but refer to the above-mentioned literature. However, we can comment on the appearance of non-geometric fluxes in this action. In particular, the analogue of the field strength for the Kalb-Ramond field, transforming covariantly under β -diffeomorphisms, is given by

$$\Theta_{ijk} = -g'_{im}g'_{jn}g'_{kl}(3\beta^{[m]p}\partial_p\beta^{nl}) + \mathcal{O}(\partial g') + \mathcal{O}(\partial\beta),\tag{7.91}$$

where the $\mathcal{O}(\partial g')$ and $\mathcal{O}(\partial\beta)$ terms can be made explicit. This expression contains the R -flux $R^{mnl} = 3\beta^{[m]p}\partial_p\beta^{nl}$ defined in equation (7.69), which shows that the transformed action is suitable for describing non-geometric flux-backgrounds. We also mention that questions concerning the equations of motion of the β -supergravity, its dimensional reduction and specific examples have been discussed in detail in [209].

Effective action II – Lie algebroid

The frame transformation (7.82) is only on particular example of an $O(D) \times O(D)$ transformation acting on the generalised vielbein (7.81). A framework which incorporates more general changes of frame [207, 208, 198] are Lie algebroids which we introduced in section 7.2. To explain this construction, we start from a general Lie algebroid $(E, [\cdot, \cdot]_E, \rho)$ and require the anchor $\rho : E \rightarrow TM$ to be invertible. We then consider the following additional structure:

- We equip the Lie algebroid E with a metric $\mathfrak{g} \in \Gamma(E^* \otimes_{\text{sym}} E^*)$, which is related to a Riemannian metric g on TM (appearing in (7.81)) through the

dual anchor $\rho^* : E^* \rightarrow T^*M$ as

$$g = (\otimes^2 \rho^*) \mathfrak{g}. \quad (7.92)$$

As briefly discussed on page 112, and more detailedly explained in [198], for the metric on E we can construct a corresponding differential geometry. The corresponding Ricci tensor $\text{Ric} \in \Gamma(E^* \otimes_{\text{sym}} E^*)$ on the Lie algebroid can be constructed explicitly and is related to the ordinary Ricci tensor $\text{Ric} \in \Gamma(T^*M \otimes_{\text{sym}} T^*M)$ via

$$\text{Ric} = (\otimes^2 \rho^*) \text{Ric}. \quad (7.93)$$

- Next, we turn to a Kalb-Ramond field $\mathfrak{b} \in \Gamma(\Lambda^2 E^*)$ on the Lie algebroid. It is related to the usual Kalb-Ramond field b via the dual anchor as

$$b = (\Lambda^2 \rho^*)(\mathfrak{b}). \quad (7.94)$$

Using the differential d_E on the Lie algebroid given in (7.37), we can define a corresponding field strength as

$$\Theta = d_E \mathfrak{b} \in \Gamma(\Lambda^3 E^*), \quad (7.95)$$

and due to d_E being nilpotent we see that Θ is invariant under Lie-algebroid gauge transformations

$$\mathfrak{b} \rightarrow \mathfrak{b} + d_E \mathfrak{a}, \quad \mathfrak{a} \in \Gamma(E^*). \quad (7.96)$$

In [198] these transformations have been called ρ -gauge transformations, and they are the analogue of the usual Kalb-Ramond B -field gauge transformations.

After having defined a metric and Kalb-Ramond field on the Lie algebroid, we can construct an action for \mathfrak{g} and \mathfrak{b} which is invariant under diffeomorphisms and ρ -gauge transformations. Including the dilaton, such an action is given by [198]

$$\mathcal{S} = \frac{1}{2\kappa^2} \int e^{-2\phi} |\rho^*| \left[\text{R} \star 1 - \frac{1}{2} \Theta \wedge \star \Theta + 4d_E \phi \wedge \star d_E \phi \right], \quad (7.97)$$

where R is the Ricci scalar constructed from the Ricci tensor Ric and the metric \mathfrak{g} on the Lie algebroid, the Hodge star-operator is defined with respect to the metric \mathfrak{g} , and Θ has been given in (7.95) in terms of the Lie algebroid differential d_E defined in (7.37). The determinant of the dual anchor ρ^* is denoted as $|\rho^*|$. This action is by construction invariant under diffeomorphisms and two-form gauge

transformations. Furthermore, using the anchor ρ we can for instance relate the Lie algebroid metric \mathfrak{g} to the ordinary metric g as shown in (7.92), and more generally show that (7.97) is equivalent to (7.89).

Let us finally connect our discussion here to the change of frames considered above. To do so, we have to specify the anchor and first note that the index structure of ρ is $\rho^i_{\mathfrak{a}}$, where i is an index on the tangent-space and \mathfrak{a} denotes a general index on the Lie algebroid (which can be upper or lower depending on the Lie algebroid E). The dual anchor is given by $\rho^* = \rho^{-T}$. For a given change of frames (7.29), specified in terms of two $O(D)$ -transformations O_+ and O_- , the anchor reads

$$\rho = \frac{1}{2} \bar{e} [O_+ e g^{-1} (g - b) + O_- e g^{-1} (g + b)] \mathbf{1}, \quad (7.98)$$

where e is the vielbein matrix corresponding to the metric g and the identity matrix $\mathbf{1}$ with index structure $\delta^i_{\mathfrak{a}}$ has been included to properly match the indices on E and TM . Now, for the example (7.82) the anchor takes the explicit form

$$\rho = \mathbf{1} - g^{-1} b = \mathbf{1} + \beta g', \quad (7.99)$$

but for instance also $\rho = \beta$ has been analysed [207, 208]. To summarise, given a $O(D) \times O(D)$ frame transformation of the generalised vielbein which mixes the metric and B -field, we can use the framework of Lie algebroids to construct a corresponding transformed effective action shown in (7.97). Further aspects of this action, such as its equations of motion, its extension to the Ramond-Ramond sector of type II string theory and its relation to double field theory, can be found in [207, 208, 198].

7.7 Bianchi identities

In this section we discuss Bianchi identities for the geometric and non-geometric fluxes introduced above. In the case of only H -flux, the Bianchi identity takes the well-known form $dH = 0$, however, if other fluxes are present this condition is modified.

Roytenberg algebra

Let us first summarise the Courant brackets between generalised vielbein vector-fields determined in (7.64), (7.66) and (7.68) as follows

$$\begin{aligned} [\bar{\mathcal{E}}_a, \bar{\mathcal{E}}_b]_{\mathbb{C}} &= + \hat{f}_{ab}{}^c \bar{\mathcal{E}}_c - \hat{H}_{abc} \bar{\mathcal{E}}^c, \\ [\bar{\mathcal{E}}_a, \bar{\mathcal{E}}^b]_{\mathbb{C}} &= - \hat{f}_{ac}{}^b \bar{\mathcal{E}}^c - Q_a{}^{bc} \bar{\mathcal{E}}_c, \\ [\bar{\mathcal{E}}^a, \bar{\mathcal{E}}^b]_{\mathbb{C}} &= - Q_c{}^{ab} \bar{\mathcal{E}}^c + R^{abc} \bar{\mathcal{E}}_c, \end{aligned} \quad (7.100)$$

where $\hat{f}_{ab}{}^c$ and \hat{H}_{abc} denote the dimension-less geometric and H -flux, and $Q_a{}^{bc}$ and R^{abc} denote the non-geometric Q - and R -flux. In the mathematical literature this algebra is also known as the Roytenberg algebra [202,210].¹² Using the conventions (7.70), the algebra (7.100) can be collectively written as in (7.59)

$$[\bar{\mathcal{E}}_A, \bar{\mathcal{E}}_B]_C = F_{AB}{}^C \bar{\mathcal{E}}_C. \quad (7.101)$$

Since the bracket for this algebra is the Courant bracket (7.12), we can demand that the Jacobi identity (7.16) is satisfied. In general, this will impose non-trivial restrictions on the various fluxes. In particular, starting from

$$0 = \text{Jac}(\bar{\mathcal{E}}_A, \bar{\mathcal{E}}_B, \bar{\mathcal{E}}_C)_C - d \text{Nij}(\bar{\mathcal{E}}_A, \bar{\mathcal{E}}_B, \bar{\mathcal{E}}_C)_C, \quad (7.102)$$

and assuming $F_{ABC} = F_{AB}{}^D \eta_{DC}$ to be completely anti-symmetric, we obtain

$$0 = D_{[A} F_{BCD]} - \frac{3}{4} F_{[AB}{}^M F_{M|CD]}. \quad (7.103)$$

The derivative $D_A = \rho(\bar{\mathcal{E}}_A)$ is the anchor-projection of the generalised vielbein vector-field $\bar{\mathcal{E}}_A$ (cf. section 7.2), in particular, for a generalised vector-field

$$\bar{\mathcal{E}}_A = \delta_A{}^I (\mathcal{O}^T)_I{}^J \partial_J, \quad \text{with} \quad \mathcal{O} = \begin{pmatrix} A & B \\ C & D \end{pmatrix}, \quad (7.104)$$

the derivative D_A is given by

$$D_a = \delta_a{}^i (A^T)_i{}^j \partial_j, \quad D^a = \delta^a{}_i (B^T)^{ij} \partial_j. \quad (7.105)$$

Bianchi identities

We can now work out the explicit form of the Bianchi identities (7.103) for the Roytenberg algebra (7.100). Using the conventions (7.70) for the fluxes and recalling that $H_{abc} = \delta_a{}^i \delta_b{}^j \delta_c{}^k H_{ijk}$, and so on, we have

$$\begin{aligned} 0 &= 2 D_{[a} \hat{H}_{bcd]} - 3 \hat{f}_{[ab}{}^m \hat{H}_{m|cd]}, \\ 0 &= 3 D_{[a} \hat{f}_{bc]}{}^d + D^d \hat{H}_{abc} - 3 \hat{f}_{[ab}{}^m \hat{f}_{m|c]}{}^d + 3 \hat{H}_{[ab|m} Q_{c]}{}^{md}, \\ 0 &= 2 D_{[a} Q_{b]}{}^{cd} - 2 D^{[c} \hat{f}_{ab]}{}^d - \hat{f}_{ab}{}^m Q_m{}^{cd} - 4 \hat{f}_{m[a}{}^{[c} Q_{b]}{}^{m|d]} - \hat{H}_{abm} R^{mcd}, \\ 0 &= D_a R^{abc} + 3 D^{[b} Q_a{}^{cd]} + 3 Q_a{}^{m[b} Q_m{}^{cd]} + 3 \hat{f}_{am}{}^{[b} R^{m|cd]}, \\ 0 &= 2 D^{[a} R^{bcd]} + 3 Q_m{}^{[ab} R^{m|cd]}, \end{aligned} \quad (7.106)$$

¹² In the context of gauged supergravities a similar structure has appeared [211], and for a discussion of this algebra from a world-sheet point of view see [212,213].

where for an easier distinction we underscored the indices which are anti-symmetrised. Let us make three remarks concerning these Bianchi identities:

- The relations (7.106) have appeared in the literature in various forms: for constant fluxes the derivatives D_a and D^a vanish and one finds the Bianchi identities of [121, 214, 215]. Using Lie algebroids similar expressions have appeared in [216], and in the context of double field theory the above Bianchi identities can be found for instance in the review [217]. The Bianchi identities can also be derived requiring a twisted differential to be nil-potent [121], which we discuss in the next section.
- It is also worth pointing out that when contracting all indices of the third relation in (7.106), one finds that $\hat{H}_{abc}R^{abc} = 0$. Applying this observation to a three-torus, we see that on \mathbb{T}^3 the H - and R -flux cannot be present simultaneously.
- For a discussion of Bianchi identities for geometric and non-geometric fluxes in the presence of NS-NS sources such as the NS5-brane, Kaluza-Klein monopole or 5_2^2 -brane see for instance [218, 219].

8 Flux compactifications

In this section we discuss non-geometric backgrounds from an effective field-theory point of view. We compactify type II superstring theory from ten to four dimensions on manifolds with $SU(3) \times SU(3)$ structure, include geometric as well as non-geometric fluxes, and investigate the resulting effective theory. We are particularly interested in how fluxes modify the effective four-dimensional theory. We also mention that reviews on (non-geometric) flux-compactifications can be found in [220–222, 124].

8.1 $SU(3) \times SU(3)$ structures

A suitable framework for discussing compactifications with non-geometric fluxes is that of $SU(3) \times SU(3)$ structures. In this section we give a brief review of the main concepts and ideas, but refer for more details to the original literature [223, 192, 224, 225, 43] or for instance to the lecture notes [226].

Pair of $SU(3)$ structures

We are interested in compactifications of type II string theory from ten to four dimensions. For the ten-dimensional space-time we make the following ansatz

$$\mathbb{M}^{3,1} \times \mathcal{M}, \quad (8.1)$$

where $\mathbb{M}^{3,1}$ is a four-dimensional space-time with Lorentz signature and \mathcal{M} is a compact six-dimensional Euclidean space. If we demand that $\mathcal{N} = 2$ supersymmetry is preserved in four dimensions, then the two ten-dimensional Majorana-Weyl spinors ϵ^A which parametrise the supersymmetry transformations in ten dimensions have to decompose as

$$\begin{aligned} \text{type IIA:} \quad \epsilon^1 &= \epsilon_+^1 \otimes \eta_+^1 + \epsilon_-^1 \otimes \eta_-^1, \\ \epsilon^2 &= \epsilon_+^2 \otimes \eta_-^2 + \epsilon_-^2 \otimes \eta_+^2, \end{aligned} \quad (8.2)$$

$$\text{type IIB:} \quad \epsilon^A = \epsilon_+^A \otimes \eta_-^A + \epsilon_-^A \otimes \eta_+^A,$$

with $A = 1, 2$. Here, ϵ_\pm^A are positive/negative chirality spinors in four dimensions and η_\pm^A are globally-defined and nowhere-vanishing spinors on the internal manifold \mathcal{M} . Due to the Majorana condition on ϵ^A in ten dimensions, ϵ_-^A and η_-^A are the charge conjugates of ϵ_+^A and η_+^A , respectively. The requirement of having two globally-defined and nowhere-vanishing spinors on \mathcal{M} implies that the structure group of the internal manifold has to be reduced to $SU(3)$ for each spinor, and

hence the internal manifold should admit a pair of $SU(3)$ structures. In the special case of a Calabi-Yau three-fold the two spinors are parallel everywhere, that is $\eta_+^1 = \eta_+^2$, and we have a single $SU(3)$ structure.

The two spinors η_{\pm}^A shown in (8.2) can be used to introduce two globally-defined real two-forms J_{ab}^A and two complex three-forms Ω_{abc}^A on the compact space. Using the usual anti-symmetrised product of γ -matrices along the compact six dimensions, we have

$$(J^A)_{ab} = i \eta_+^{A\dagger} \gamma_{ab} \eta_+^A, \quad (\Omega^A)_{abc} = -i \eta_-^{A\dagger} \gamma_{abc} \eta_+^A. \quad (8.3)$$

These expressions provide an alternative definition of a pair of $SU(3)$ structures, and they illustrate the general correspondence between almost complex structures J^A and Weyl spinors η_+^A .

$SU(3) \times SU(3)$ structure

It turns out that the two spinors η_{\pm}^A along the compact directions can be described conveniently using generalised geometry [190, 191, 227]. In particular, (η_+^1, η_+^2) transforms as a $Spin(D, D)$ spinor of the generalised tangent-bundle E introduced in section 7.1. For our case of interest the dimension is $D = 6$, and the basic $Spin(6, 6)$ spinor representations are Majorana-Weyl. The pair of $SU(3)$ structures can then be viewed as an $SU(3) \times SU(3)$ structure on E (provided the compatibility condition (8.15) discussed below is satisfied).

It turns out that for the generalised tangent-bundle the spinor bundle S is isomorphic to the bundle of forms $\wedge^*(T^*\mathcal{M})$ [190]. More concretely, the positive-helicity spin bundle S^+ is isomorphic to poly forms of even degree and the negative-helicity spin bundle S^- is isomorphic to odd forms

$$S^+ \simeq \bigwedge_{\text{even}} T^*\mathcal{M}, \quad S^- \simeq \bigwedge_{\text{odd}} T^*\mathcal{M}. \quad (8.4)$$

Let us make that more precise and consider the following two globally-defined spinors [228]

$$\Phi_{(0)}^+ = \eta_+^1 \otimes \bar{\eta}_+^2, \quad \Phi_{(0)}^- = \eta_+^1 \otimes \bar{\eta}_-^2, \quad (8.5)$$

where $\Phi_{(0)}^+ \in \Gamma(S^+)$ and $\Phi_{(0)}^- \in \Gamma(S^-)$. The product of the spinors η_{\pm}^A is defined using $n_D \times n_D$ anti-symmetrised γ -matrices as

$$\begin{aligned} \eta_+^1 \otimes \eta_+^2 &= \frac{1}{n_D} \sum_{p \in 2\mathbb{Z}} \frac{1}{p!} (\bar{\eta}_+^2 \gamma_{a_1 \dots a_p} \eta_+^1) \gamma^{a_p \dots a_1}, \\ \eta_+^1 \otimes \eta_-^2 &= \frac{1}{n_D} \sum_{p \in 2\mathbb{Z}+1} \frac{1}{p!} (\bar{\eta}_-^2 \gamma_{a_1 \dots a_p} \eta_+^1) \gamma^{a_p \dots a_1}. \end{aligned} \quad (8.6)$$

Using now the Clifford map we can relate these expressions to elements of $\wedge^*(T^*\mathcal{M})$ in the following way

$$\psi = \sum_k \frac{1}{k!} \omega_{m_1 \dots m_k}^{(k)} \gamma^{m_1 \dots m_k} \longleftrightarrow \omega = \sum_k \frac{1}{k!} \omega_{m_1 \dots m_k}^{(k)} dx^{m_1} \wedge \dots \wedge dx^{m_k}. \quad (8.7)$$

This shows that Φ^+ is an even multiform and Φ^- is an odd multiform, in agreement with (8.4). The degrees of freedom of the Kalb-Ramond B -field can be included in the above spinors as follows,

$$\Phi^+ = e^B \Phi_{(0)}^+, \quad \Phi^- = e^B \Phi_{(0)}^-, \quad (8.8)$$

where the exponential is understood as a series expansion and where the wedge product is left implicit.

Generalised spinors

Let us now briefly summarise some of the main formulas and concepts relevant for generalised spinors, which will be useful for our subsequent discussion.

- We denote a generalised spinor by Φ , a generalised vector will be written again as $X = (x, \xi)$ and $O(D, D)$ γ -matrices are denoted by Γ^M . The Clifford action of X on a generalised spinor is then given by

$$X \cdot \Phi = X_M \Gamma^M \Phi = (x^m \Gamma_m + \xi_m \Gamma^m) \Phi. \quad (8.9)$$

Alternatively, as pointed out above, Φ can be interpreted as a multi-form (for which we use the same symbol). The corresponding Clifford action is then realised by $\Gamma^m = dx^m \wedge$ and $\Gamma_m = \iota_{\partial_m}$ as follows

$$X \cdot \Phi = (\iota_x + \xi \wedge) \Phi. \quad (8.10)$$

Note that Γ^m and Γ_m satisfy a Clifford algebra, since the operators $dx^i \wedge$ and ι_{∂_i} satisfy

$$\{dx^i \wedge, dx^j \wedge\} = 0, \quad \{\iota_{\partial_i}, \iota_{\partial_j}\} = 0, \quad \{dx^i \wedge, \iota_{\partial_j}\} = \delta^i_j. \quad (8.11)$$

These relations can be combined into the Clifford algebra $\{\Gamma^M, \Gamma^N\} = \eta^{MN}$, where the metric η_{MN} has been defined in (7.7) which we recall for convenience as

$$\eta_{IJ} = \begin{pmatrix} 0 & \delta_i^j \\ \delta^i_j & 0 \end{pmatrix}. \quad (8.12)$$

- Let us also note that $O(D, D)$ transformations act on generalised spinors. For \mathbf{B} - and β -transformations one finds in particular

$$\begin{aligned}\Phi &\xrightarrow{\mathbf{B}\text{-transform}} \Phi' = e^{\mathbf{B}\wedge} \Phi, \\ \Phi &\xrightarrow{\beta\text{-transform}} \Phi' = e^{\beta\lrcorner} \Phi,\end{aligned}\tag{8.13}$$

where the exponential is understood again as an expansion and the action of β has been given below (7.10). The action of an \mathbf{A} -transform is somewhat more involved, and can be found for instance in section 2.3 of [191].

- The pairing for generalised spinors can be expressed using the Mukai pairing. The latter is defined as ¹³

$$\langle \Phi^{(1)}, \Phi^{(2)} \rangle = \sum_{p=0}^D (-1)^{\lfloor \frac{p+1}{2} \rfloor} \Phi_p^{(1)} \wedge \Phi_{D-p}^{(2)},\tag{8.14}$$

where $\lfloor a \rfloor$ denotes the integer part of some number a and where Φ_p denotes the p -form part of the multiform Φ . Note furthermore that the Mukai pairing is invariant under the action of $O(D, D)$.

- Let us also introduce the annihilator space of a spinor as $L_\Phi = \{X \in \Gamma(E) : X \cdot \Phi = 0\}$, where E is the generalised tangent bundle locally expressed as $E = T\mathcal{M} \oplus T^*\mathcal{M}$ (see our discussion around equation (7.1)). It is isotropic, and if L_Φ is of maximal dimension D the corresponding spinor is called pure. Alternatively, a pure spinor is annihilated by half of the Γ -matrices. Note that the spinors defined in (8.8) are pure spinors, and that any pure spinor can be represented as a wedge product of an exponentiated complex two-form with a complex k -form [191].

Pure spinors are in one-to-one correspondence with a generalised almost complex structure on the generalised tangent-space.

- Each of the pure spinors (8.8) defines an $SU(3)$ structure on the generalised tangent-space E . If these spinors are compatible, together they form an $SU(3) \times SU(3)$ structure. The requirements for compatibility are that $\dim(L_{\Phi^+} \cap L_{\Phi^-}) = 3$ and that Φ^+ and Φ^- have the same normalisation [191]. Using the Mukai pairing, these conditions can be written as [223, 225]

$$\begin{aligned}\langle \Phi^+, X \cdot \Phi^- \rangle &= \langle \bar{\Phi}^+, X \cdot \Phi^- \rangle = 0, & \forall X \in \Gamma(E), \\ \langle \Phi^+, \bar{\Phi}^+ \rangle &= \langle \Phi^-, \bar{\Phi}^- \rangle.\end{aligned}\tag{8.15}$$

¹³ In the literature one can also find a convention where instead of $(-1)^{\lfloor \frac{p+1}{2} \rfloor}$ one uses $(-1)^{\lfloor \frac{p}{2} \rfloor}$ in the Mukai pairing. This leads to some sign-differences in subsequent formulas.

Example: Calabi-Yau three-fold

Finally, let us come back to the example of a Calabi-Yau three-fold. In this case the spinors are parallel to each other everywhere, that is $\eta_+^1 = \eta_+^2 = \eta_+$. The pair of $SU(3)$ structures then reduces to a single $SU(3)$ structure, for which we have from (8.3)

$$J_{ab} = i \eta_+^\dagger \gamma_{ab} \eta_+, \quad \Omega_{abc} = -i \eta_-^\dagger \gamma_{abc} \eta_+. \quad (8.16)$$

The corresponding spinors, written as differential forms, then read

$$\Phi^+ = e^{B-iJ}, \quad \Phi^- = \Omega, \quad (8.17)$$

which are familiar expressions from Calabi-Yau compactifications. One can furthermore check that the compatibility conditions (8.15) are satisfied, using that $\Omega \wedge J = 0$ as well as the normalisation $\frac{i}{8} \Omega \wedge \bar{\Omega} = \frac{1}{3!} J^3$. We discuss the case of Calabi-Yau three-folds in more detail in section 8.3.

8.2 Four-dimensional supergravity

We are interested in the effective theory resulting from compactifications of type II string theory to four dimensions preserving some supersymmetry. In this section we therefore review some aspects of four-dimensional supergravity theories. We focus on $\mathcal{N} = 2$ or $\mathcal{N} = 1$ local supersymmetry, and for a reviews on this topic see for instance [229, 230] and for a textbook treatment see [231].

$\mathcal{N} = 2$ supergravity in $D = 4$

Let us start with $\mathcal{N} = 2$ supergravity in four dimensions. The relevant supergravity multiplets are the gravitational multiplet, vector-multiplet and hyper-multiplet, which are summarised in table 2. The scalar fields of these multiplets parametrise the vector- and hyper-multiplet moduli spaces, and due to supersymmetry the vector moduli space has to be a special Kähler manifold and the hyper-multiplet scalars span a quaternionic-Kähler manifold. For $\mathcal{N} = 2$ supersymmetry, they form a direct product

$$\mathcal{M}^{\text{scalar}} = \mathcal{M}_{\text{SK}}^{\text{vector}} \times \mathcal{M}_{\text{quaternionic}}^{\text{hyper}}. \quad (8.18)$$

Next, we turn to the supergravity action for the multiplets shown in table 2. The kinetic terms of the bosonic fields for the $\mathcal{N} = 2$ multiplets are determined as follows:

multiplet	bosonic fields	fermionic fields
gravity	metric $g_{\mu\nu}$, gravi-photon A_μ^0	2 gravitini
vector	vector A_μ^i , complex scalar z^i	2 gaugini
hyper	4 real scalars q^u	4 fermions

Table 2: Multiplets relevant for four-dimensional $\mathcal{N} = 2$ supergravity theories. The index $i = 1, \dots, n_V$ labels the vector-multiplets and $u = 1, \dots, 4n_H$ labels the real scalars of the hyper-multiplets. The total number of vector- and hyper-multiplets is denoted by n_V and n_H , respectively.

- The moduli space of the vector-multiplet scalars z^i is a Kähler manifold, and can therefore be described using a Kähler potential $\mathcal{K}(z, \bar{z})$. The corresponding Kähler metric is given by

$$\mathcal{G}_{i\bar{j}} = \partial_i \partial_{\bar{j}} \mathcal{K}, \quad \partial_i \equiv \frac{\partial}{\partial z^i}. \quad (8.19)$$

The metric for the hyper-multiplet scalars will be denoted by h_{uv} with $u, v = 1, \dots, 4n_H$. It describes a quaternionic-Kähler manifold, which is related to a triplet of almost complex structures J^x with $x = 1, 2, 3$ satisfying a quaternionic algebra. However, note that a quaternionic-Kähler manifold is not Kähler. We refer to [231] for more details on the geometry of such spaces. The Kähler metric (8.19) and the quaternionic-Kähler metric h_{uv} then determine the kinetic terms of the scalar fields in the action.

- For the kinetic terms of the vector-fields, we first note that the moduli space of the vector-multiplet scalars is special Kähler and therefore is equipped with an additional structure. In particular, the corresponding Kähler potential \mathcal{K} can be expressed using a holomorphic pre-potential \mathcal{F} .¹⁴ Introducing projective coordinates $Z^I = (Z^0, Z^i)$ for the vector-multiplet scalars via $z^i = Z^i/Z^0$, the Kähler potential is given by

$$\mathcal{K} = -\log [i(\bar{Z}^I \mathcal{F}_I - Z^I \bar{\mathcal{F}}_I)], \quad \mathcal{F}_I = \frac{\partial \mathcal{F}}{\partial Z^I}, \quad (8.20)$$

with $I = 0, \dots, n_V$. Since the Z^I are projective coordinates, Z^0 cancels out in all physically-relevant quantities. For convenience, one therefore often

¹⁴The notion of special Kähler geometry is more general than discussed here, and a pre-potential does not need to exist. However, in our subsequent discussion a pre-potential always exists.

chooses $Z^0 = 1$. Furthermore, in order to preserve $\mathcal{N} = 2$ supersymmetry the holomorphic pre-potential $\mathcal{F}(Z)$ has to be a homogeneous function of degree two. Using the pre-potential, one can construct a period matrix of the following form

$$\mathcal{N}_{IJ} = \overline{\mathcal{F}}_{IJ} + 2i \frac{\text{Im}(\mathcal{F}_{IM})Z^M \text{Im}(\mathcal{F}_{JN})Z^N}{Z^M \text{Im}(\mathcal{F}_{MN})Z^N}, \quad \mathcal{F}_{IJ} = \frac{\partial \mathcal{F}_I}{\partial Z^J}. \quad (8.21)$$

This matrix encodes the kinetic term for the combined gravi-photon and vector-multiplet vector-fields $A^I = (A^0, A^i)$.

- Finally, the kinetic term of the four-dimensional metric is given by the usual Einstein-Hilbert term in the action.

The bosonic part of the (ungauged) $\mathcal{N} = 2$ supergravity action in four dimensions can now be expressed using the above quantities. It takes the following general form¹⁵

$$\mathcal{S} = \frac{1}{2\kappa_4^2} \int \left[R \star 1 + \text{Im}(\mathcal{N}_{IJ}) F^I \wedge \star F^J - \text{Re}(\mathcal{N}_{IJ}) F^I \wedge F^J - 2\mathcal{G}_{i\bar{j}} dz^i \wedge \star d\bar{z}^j - h_{uv} dq^u \wedge \star dq^v \right], \quad (8.22)$$

where \star is the usual Hodge star-operator in four dimensions, κ_4^2 is the four-dimensional gravitational coupling constant and F^I denote the field strengths of the vector-fields A^I .

$\mathcal{N} = 2$ gauged supergravity in $D = 4$

It is possible to deform the $\mathcal{N} = 2$ supergravity theory to a gauged supergravity (for reviews see [232, 230]). More concretely, the scalar manifolds (8.18) described by the metrics (8.19) and h_{uv} can have isometries. These isometries usually extend to global symmetries of the supergravity action (8.22) and can be gauged.

The gauging procedure promotes the global symmetries to local ones using the vector-fields A^I . Let us assume that for infinitesimal transformation parameters $\epsilon^I \ll 1$ the Kähler metrics are invariant under

$$\delta z^i = \epsilon^I k_I^i, \quad \delta q^u = \epsilon^I k_I^u, \quad (8.23)$$

which implies that the vector-field components k_I^i and k_I^u correspond to Killing vectors $k_I = k_I^i \partial_{z^i} + k_I^u \partial_{q^u}$. These can in general be non-abelian with structure

¹⁵ Here we assume here that the pre-potential $\mathcal{F}(Z)$ is invariant under gauge transformations of the vector-fields A^I . If this is not the case, a Chern-Simons term has to be added to the action (8.22). See for instance [231] for more details.

constants $f_{IJ}{}^K$ determined through $[k_I, k_J]_L = f_{IJ}{}^K k_K$. Furthermore, since the Killing vectors k_I^i for the vector-multiplet scalars are holomorphic they can be expressed as

$$k_I^i = -i \mathcal{G}^{i\bar{j}} \partial_{\bar{j}} \mathcal{P}_I^0, \quad (8.24)$$

where $\mathcal{G}^{i\bar{j}}$ is the inverse of the Kähler metric (8.19) and where the real functions \mathcal{P}_I^0 are called moment maps. For the Killing vectors of the hyper-multiplet scalars a similar result can be obtained: using an appropriate covariant derivative ∇_u one finds that

$$\nabla_u \mathcal{P}_I^x = J_{uv}^x k_I^v, \quad (8.25)$$

where J^x with $x = 1, 2, 3$ is the triplet of complex structures mentioned above. There are further conditions and restrictions on the moment maps $\vec{\mathcal{P}}_I = \{\mathcal{P}_I^x\}$ which we do not discuss here, but which can be found for instance in [231].

Finally, when gauging the $\mathcal{N} = 2$ supergravity theory one essentially has to apply the following changes to the ungauged action shown in (8.22):

- One replaces the ordinary derivative for the scalar fields z^i and q^u by covariant derivatives

$$dz^i \rightarrow Dz^i = dz^i - k_I^i A^I, \quad dq^u \rightarrow Dq^u = dq^u - k_I^u A^I. \quad (8.26)$$

- The field strength of the gauge fields A^I is replaced in the following way

$$F^I \rightarrow \mathbf{F}^I = F^I - \frac{1}{2} f_{MN}{}^I A^M \wedge A^N. \quad (8.27)$$

- The gauging generates a scalar potential, which can be expressed using the Kähler potential \mathcal{K} , the moment maps $\vec{\mathcal{P}}_I$ and the Kähler covariant derivative $D_i \equiv \partial_i + \partial_i \mathcal{K}$ as

$$\begin{aligned} V = & e^{\mathcal{K}} \left(\mathcal{G}_{i\bar{j}} k_I^i k_J^{\bar{j}} + 4 h_{uv} k_I^u k_J^v \right) \bar{Z}^I Z^J \\ & + e^{\mathcal{K}} \left(\mathcal{G}^{i\bar{j}} D_i Z^I D_{\bar{j}} \bar{Z}^J - 3 Z^I \bar{Z}^J \right) \vec{\mathcal{P}}_I \cdot \vec{\mathcal{P}}_J. \end{aligned} \quad (8.28)$$

$\mathcal{N} = 1$ supergravity in $D = 4$

We now turn to the case of $\mathcal{N} = 1$ supergravity in four dimensions. The multiplets relevant for our subsequent discussion are the gravity multiplet, vector-multiplet and chiral multiplet, and their field content is summarised in table 3. For $\mathcal{N} = 1$ supergravity the moduli space parametrised by the complex scalar fields ϕ^α of the chiral multiplets is a Kähler manifold.

Let us now discuss the kinetic terms for the bosonic fields shown in table 3. They are characterised in the following way:

multiplet	bosonic fields	fermionic fields
gravity	metric $g_{\mu\nu}$	1 gravitino
vector	vector A_μ^i	1 gaugino
chiral	complex scalar ϕ^α	2 fermions

Table 3: Multiplets relevant for four-dimensional $\mathcal{N} = 1$ supergravity theories. The index $i = 1, \dots, n_V$ labels the vector-multiplets and $\alpha = 1, \dots, n_C$ labels chiral multiplets. The total numbers of vector- and chiral multiplets are denoted by n_V and n_C , respectively.

- Since the manifold of the complex scalar fields in the chiral multiplets is Kähler, its metric can be expressed using a Kähler potential \mathcal{K} similarly as in (8.19)

$$\mathcal{G}_{\alpha\bar{\beta}} = \partial_\alpha \partial_{\bar{\beta}} \mathcal{K}, \quad \partial_\alpha \equiv \frac{\partial}{\partial \phi^\alpha}. \quad (8.29)$$

This Kähler metric in turn determines the kinetic terms of the scalar fields in the action.

- The kinetic term of the vector-fields can be expressed in terms of a holomorphic function $f_{ij}(\phi)$. The real part of this function is symmetric in its indices and is required to be invertible. Note that this function can depend on the scalars ϕ^α .
- The kinetic term for the four-dimensional metric is again the Einstein-Hilbert term.

Next, we turn to the interactions. There are the following two sources of interaction terms in $\mathcal{N} = 1$ supergravity theories:

- Interactions of the ungauged theory are encoded in a superpotential $W(\phi)$, which is an arbitrary holomorphic function of the complex scalars.
- In a gauged theory, isometries of the scalar manifold have been promoted to local symmetries. Say that the moduli-space metric stays invariant under $\delta\phi^\alpha = \epsilon^i k_i^\alpha$ for $\epsilon^i \ll 1$, then k_i^α are holomorphic Killing vectors. The latter are determined again from real moment maps \mathcal{P}_i as $k_i^\alpha = -i \mathcal{G}^{\alpha\bar{\beta}} \partial_{\bar{\beta}} \mathcal{P}_i$, where

$\mathcal{G}_{\alpha\bar{\beta}}$ is the Kähler metric (8.29). Integrating this relation determines the moment maps as

$$\mathcal{P}_i = i(k_i^\alpha \partial_\alpha \mathcal{K} - \xi_i), \quad (8.30)$$

where the constants ξ_i are called Fayet-Iliopoulos parameters. For an $U(1)$ symmetry they can take arbitrary real values, whereas for non-abelian symmetries they are required to vanish [231]. We furthermore note that gauge invariance of the superpotential leads to the requirement that $k_i^\alpha D_\alpha W + i\mathcal{P}_i W = 0$, where $D_\alpha \equiv \partial_\alpha + \partial_\alpha \mathcal{K}$.

We can now write down the bosonic part of the $\mathcal{N} = 1$ supergravity action in four dimensions. It is given by

$$\mathcal{S} = \frac{1}{2\kappa_4^2} \int \left[R \star 1 - \text{Re}(f_{ij}) F^i \wedge \star F^j + \text{Im}(f_{ij}) F^I \wedge F^J - 2\mathcal{G}_{\alpha\bar{\beta}} d\phi^\alpha \wedge \star d\bar{\phi}^{\bar{\beta}} - (V_F + V_D) \star 1 \right], \quad (8.31)$$

where the scalar potential can be split into an F- and D-term contribution. The F-term scalar potential is expressed in terms of the superpotential and Kähler potential in the following way

$$V_F = e^{\mathcal{K}} \left(\mathcal{G}^{\alpha\bar{\beta}} D_\alpha W D_{\bar{\beta}} \bar{W} - 3|W|^2 \right), \quad (8.32)$$

where $\mathcal{G}^{\alpha\bar{\beta}}$ is the inverse of the Kähler metric of the scalar fields shown in (8.29). The Kähler-covariant derivative $D_\alpha W$ is given as above by

$$D_\alpha W = \partial_\alpha W + (\partial_\alpha \mathcal{K}) W, \quad (8.33)$$

and the D-term potential is expressed using the gauge kinetic function f_{ij} and the moment maps \mathcal{P}_i as follows

$$V_D = \frac{1}{2} [(\text{Re } f)^{-1}]^{ij} \mathcal{P}_i \mathcal{P}_j. \quad (8.34)$$

Summary

To summarise the discussion in this section, we recall that four-dimensional $\mathcal{N} = 2$ and $\mathcal{N} = 1$ supergravity theories are characterised by only a few quantities:

- For $\mathcal{N} = 2$ supergravity, a holomorphic pre-potential \mathcal{F} (if it exists) describes the vector-multiplet sector, and a quaternionic-Kähler metric h_{uv} describes the hyper-multiplets. In the gauged theory one additionally specifies local isometries by their Killing vectors, which in turn determine moment maps \mathcal{P}_I^0 and $\vec{\mathcal{P}}_I$.
- For the $\mathcal{N} = 1$ theory, a Kähler potential \mathcal{K} encodes the dynamics of the chiral multiplets, a holomorphic gauge-kinetic function f_{ij} describes the vector-multiplets, and a holomorphic superpotential W gives rise to an F-term potential. If the theory is gauged, Killing vectors specify the local symmetries which determine moment maps \mathcal{P}_i . The latter generate a D-term potential.

In the following sections we determine these quantities for Calabi-Yau compactifications with geometric and non-geometric fluxes.

8.3 Calabi-Yau manifolds

As a starting point for compactifications of type II string theory from ten to four dimensions, we consider Calabi-Yau three-folds and therefore want to briefly establish our notation for the latter. A Calabi-Yau n -fold is a compact Kähler manifold of complex dimension n with vanishing first Chern class. It comes with a holomorphic n -form Ω and a Kähler form J , which satisfy the following relations

$$d\Omega = 0, \quad dJ = 0, \quad \Omega \wedge J = 0. \quad (8.35)$$

We furthermore include a common normalisation condition for Calabi-Yau three-folds, which takes the form

$$\frac{i}{8} \Omega \wedge \bar{\Omega} = \frac{1}{3!} J^3. \quad (8.36)$$

The cohomology of a Calabi-Yau three-fold can be characterised in terms of the Hodge numbers $h^{p,q} = \dim H^{p,q}(\mathcal{M})$, which are the dimensions of the corresponding Dolbeault cohomology groups. The only non-vanishing Hodge numbers are

$$\begin{aligned} h^{0,0} = h^{3,3} = 1, & & h^{1,1} = h^{2,2}, \\ h^{3,0} = h^{0,3} = 1, & & h^{2,1} = h^{1,2}. \end{aligned} \quad (8.37)$$

Odd cohomology

Let us first discuss the third cohomology group $H^3(\mathcal{M})$ of a Calabi-Yau three-fold. We note that its dimension is $2h^{2,1} + 2$, and a symplectic basis for this group will be denoted by

$$\{\alpha_I, \beta^I\} \in H^3(\mathcal{M}), \quad I = 0, \dots, h^{2,1}. \quad (8.38)$$

This basis can be chosen such that the only non-vanishing pairings satisfy

$$\int_{\mathcal{M}} \alpha_I \wedge \beta^J = \delta_I^J. \quad (8.39)$$

The holomorphic three-form Ω of the Calabi-Yau three-fold can then be expanded in the basis (8.38) as [233]

$$\Omega = Z^I \alpha_I - \mathcal{F}_I \beta^I, \quad (8.40)$$

where the periods Z_I and \mathcal{F}_I are functions of the complex-structure moduli z^i with $i = 1, \dots, h^{2,1}$. Furthermore, the \mathcal{F}_I can be determined from a holomorphic pre-potential \mathcal{F} as $\mathcal{F}_I = \partial\mathcal{F}/\partial Z^I$. Using the corresponding period matrix \mathcal{N}_{IJ} defined in equation (8.21), one furthermore finds

$$\begin{aligned} \int_{\mathcal{M}} \alpha_I \wedge \star \alpha_J &= -(\text{Im}\mathcal{N})_{IJ} - [(\text{Re}\mathcal{N})(\text{Im}\mathcal{N})^{-1}(\text{Re}\mathcal{N})]_{IJ}, \\ \int_{\mathcal{M}} \alpha_I \wedge \star \beta^J &= -[(\text{Re}\mathcal{N})(\text{Im}\mathcal{N})^{-1}]_I^J, \\ \int_{\mathcal{M}} \beta^I \wedge \star \beta^J &= -[(\text{Im}\mathcal{N})^{-1}]^{IJ}, \end{aligned} \quad (8.41)$$

with \star denoting the six-dimensional Hodge star-operator on \mathcal{M} . For later purpose let us also define a $(2h^{2,1} + 2) \times (2h^{2,1} + 2)$ matrix as

$$\begin{aligned} \mathcal{M}^- &= \begin{pmatrix} \mathbf{1} & \text{Re}\mathcal{N} \\ 0 & \mathbf{1} \end{pmatrix} \begin{pmatrix} -\text{Im}\mathcal{N} & 0 \\ 0 & -\text{Im}\mathcal{N}^{-1} \end{pmatrix} \begin{pmatrix} \mathbf{1} & 0 \\ \text{Re}\mathcal{N} & \mathbf{1} \end{pmatrix} \\ &= \int_{\mathcal{M}} \begin{pmatrix} \alpha_\Lambda \wedge \star \alpha_\Sigma & \alpha_\Lambda \wedge \star \beta^\Sigma \\ \beta^\Lambda \wedge \star \alpha_\Sigma & \beta^\Lambda \wedge \star \beta^\Sigma \end{pmatrix}. \end{aligned} \quad (8.42)$$

Even cohomology

Turning now to the even cohomology, for the (1, 1)- and (2, 2)-part of a Calabi-Yau three-fold \mathcal{M} we introduce bases of the form

$$\begin{aligned} \{\omega_A\} &\in H^{1,1}(\mathcal{M}), \\ \{\sigma^A\} &\in H^{2,2}(\mathcal{M}), \end{aligned} \quad A = 1, \dots, h^{1,1}. \quad (8.43)$$

We can group these two- and four-forms together with the zero- and six-form on \mathcal{M} in the following way

$$\begin{aligned} \{\omega_A\} &= \{1, \omega_A\}, \\ \{\sigma^A\} &= \left\{ \frac{\sqrt{g}}{V} dx^6, \sigma^A \right\}, \end{aligned} \quad A = 0, \dots, h^{1,1}, \quad (8.44)$$

where $\mathcal{V} = \frac{1}{6} \int_{\mathcal{M}} J^3$ is the volume of \mathcal{M} . These two bases can be chosen such that

$$\int_{\mathcal{M}} \omega_A \wedge \sigma^B = \delta_A^B, \quad (8.45)$$

and the triple intersection numbers corresponding to the ω_A in (8.43) are given by

$$\kappa_{ABC} = \int_{\mathcal{M}} \omega_A \wedge \omega_B \wedge \omega_C. \quad (8.46)$$

The Kähler form J and the Kalb-Ramond field B can be expanded in the basis $\{\omega_A\}$ in the following way

$$J = t^A \omega_A, \quad B = b^A \omega_A, \quad (8.47)$$

which are then combined into a so-called complexified Kähler form \mathcal{J} as

$$\mathcal{J} = B - iJ = (b^A - it^A) \omega_A = \mathcal{J}^A \omega_A. \quad (8.48)$$

We also note that similarly to the complex-structure moduli space, also for the Kähler moduli of a Calabi-Yau three-fold one finds a special Kähler structure [233]. The corresponding pre-potential is given by

$$\mathcal{F} = \frac{1}{6} \frac{\kappa_{ABC} \mathfrak{J}^A \mathfrak{J}^B \mathfrak{J}^C}{\mathfrak{J}^0}, \quad (8.49)$$

where the triple intersection numbers have been defined in equation (8.46) and where we introduced projective coordinates \mathfrak{J}^A through $\mathcal{J}^A = \mathfrak{J}^A / \mathfrak{J}^0$. Using this pre-potential we can determine a matrix similar to (8.42). We will discuss this point in the following paragraph.

***B*-twisted Hodge star-operator**

Let us define a so-called *B*-twisted Hodge star-operator, which is needed in order to describe the dynamics of *B*-twisted pure spinors of the form (8.8). Following [227, 234, 225], we write

$$\star_B = e^{-B} \wedge \star \lambda e^{+B}, \quad (8.50)$$

where the projection operator λ acts on $2n$ -forms as $\lambda(\rho^{(2n)}) = (-1)^n \rho^{(2n)}$ and on $(2n - 1)$ -forms as $\lambda(\rho^{(2n-1)}) = (-1)^n \rho^{(2n-1)}$. For the Mukai pairings of the basis elements we then find for instance that

$$\begin{aligned} \langle \alpha_I, \star_B \alpha_J \rangle &= (\alpha_I \wedge e^{+B}) \wedge \star (\alpha_J \wedge e^{+B}), \\ \langle \omega_A, \star_B \omega_B \rangle &= -(\omega_A \wedge e^{+B}) \wedge \star (\omega_B \wedge e^{+B}), \end{aligned} \quad (8.51)$$

and similarly for the other combinations. We can then modify the matrix (8.42) in the following way

$$\mathcal{M}^- = + \int_{\mathcal{M}} \begin{pmatrix} \langle \alpha_\Lambda, \star_B \alpha_\Sigma \rangle & \langle \alpha_\Lambda, \star_B \beta^\Sigma \rangle \\ \langle \beta^\Lambda, \star_B \alpha_\Sigma \rangle & \langle \beta^\Lambda, \star_B \beta^\Sigma \rangle \end{pmatrix}. \quad (8.52)$$

The analogue of \mathcal{M}^- in (8.52) for the even cohomology takes a similar form. In particular, we have

$$\mathcal{M}^+ = - \int_{\mathcal{M}} \begin{pmatrix} \langle \omega_A, \star_B \omega_B \rangle & \langle \omega_A, \star_B \sigma^B \rangle \\ \langle \sigma^A, \star_B \omega_B \rangle & \langle \sigma^A, \star_B \sigma^B \rangle \end{pmatrix}. \quad (8.53)$$

Note that both \mathcal{M}^+ and \mathcal{M}^- are positive-definite matrices.

8.4 Calabi-Yau compactifications

In this section we briefly summarise the main features of type II string-theory compactifications on Calabi-Yau three-folds. This will serve as a starting point for compactifications with fluxes [235–242], which we consider in section 8.5. For a textbook treatment of Calabi-Yau compactifications see for instance [18], and in this section we focus on type IIB string theory for simplicity. Similar results are obtained for type IIA.

Type II string theory in ten dimensions

The massless field content of type IIB string theory is described by type IIB supergravity in ten dimensions, whose bosonic field content in the Neveu-Schwarz–Neveu-Schwarz (NS-NS) and Ramond–Ramond (R-R) sector is given by (see also our discussion in section 3.4)

$$\begin{aligned} g & \dots \text{ metric,} \\ B & \dots \text{ Kalb-Ramond field,} & C_p & \dots \text{ R-R } p\text{-form potential,} \\ \phi & \dots \text{ dilaton.} \end{aligned} \quad (8.54)$$

In type IIB string theory R-R p -form potentials of degree $p = 0, 2, 4$ are present, however, for our purposes the so-called democratic formulation [243] turns out to be more useful in which p -form potentials of degree $p = 0, 2, 4, 6, 8$ are considered. The corresponding field strengths are defined as

$$\tilde{F}_p = dC_{p-1} + H \wedge C_{p-3}, \quad (8.55)$$

where $H = dB$ is the field strength of the Kalb-Ramond field. In order to obtain the field content of type IIB supergravity, the following duality relations are imposed on the equations of motion

$$\tilde{F}_p = (-1)^{\frac{p+3}{2}} \star \tilde{F}_{10-p}. \quad (8.56)$$

For later convenience, we also note that the field strengths (8.55) can be encoded in a multiform \tilde{F} using a multiform potential \mathcal{C} in the following way

$$\tilde{F} = (d + H \wedge) \mathcal{C}, \quad \mathcal{C} = \sum_{p=0,2,4,6,8} C_p. \quad (8.57)$$

With $(2\kappa_{10}^2)^{-1} = 2\pi \ell_s^{-8}$ and ℓ_s the string length, the bosonic part of the democratic type IIB (pseudo-)action reads [243]

$$\mathcal{S}_{\text{IIB}} = \frac{1}{2\kappa_{10}^2} \int \left[e^{-2\phi} \left(R \star 1 + 4 d\phi \wedge \star d\phi - \frac{1}{2} H \wedge \star H \right) - \frac{1}{4} \sum_{p=1,3,5,7,9} \tilde{F}_p \wedge \star \tilde{F}_p \right]. \quad (8.58)$$

Compactification

We now compactify the ten-dimensional type IIB theory on a Calabi-Yau three-fold and determine the effective theory of the massless modes in four dimensions. This is done by expanding the ten-dimensional fields in the cohomology of the Calabi-Yau manifold introduced above and integrating over the compact space.

The massless degrees of freedom of the internal metric are encoded in the Kähler form J and the holomorphic three-form Ω . These are the Kähler moduli t^A and the complex structure moduli z^i . Furthermore, the Kalb-Ramond two-form can be expanded as in (8.47) for the internal part, and we note that a massless two-form in four dimensions is dual to a scalar. The dilaton provides an additional scalar degree of freedom. Thus, the massless field-content in four dimensions originating from the type IIB NS-NS sector is summarised as

$$\begin{array}{lll} \text{NS-NS sector:} & g_{MN} & \rightarrow g_{\mu\nu}, \quad t^A, \quad z^i, \\ & B_{MN} & \rightarrow B_{\mu\nu}, \quad b^A, \\ & \phi & \rightarrow \phi, \end{array} \quad (8.59)$$

where $\mu, \nu = 0, \dots, 3$ label the four-dimensional non-compact directions. For the Ramond-Ramond sector, the physical degrees of freedom are the ten-dimensional zero-, two-, and self-dual four-form. Expanding again in the cohomology basis of

multiplet	multiplicity	bosonic field content
gravity	1	$g_{\mu\nu}, (C_4)_\mu^0$
vector	$h^{2,1}$	$(C_4)_\mu^i, z^i$
hyper	1	$\phi, C_0, B_{\mu\nu}, (C_2)_{\mu\nu}$
hyper	$h^{1,1}$	$(C_4)_{\mu\nu}^A, (C_2)^A, t^A, B^A$

Table 4: Massless bosonic field content of type IIB string theory compactified on a Calabi-Yau three-fold. We have indicated how these fields are combined into massless multiplets of $\mathcal{N} = 2$ supergravity in four dimensions.

the Calabi-Yau three-fold, the massless degrees in four-dimensions are determined as

$$\begin{aligned}
& C_0 \quad \rightarrow \quad C_0, \\
\text{R-R sector:} \quad & C_2 \quad \rightarrow \quad (C_2)_{\mu\nu}, (C_2)^A, \\
& C_4 \quad \rightarrow \quad (C_4)_{\mu\nu}^A, (C_4)_\mu^I,
\end{aligned} \tag{8.60}$$

where a two-form in four dimensions is again dual to a scalar. Due to C_4 being self-dual, we only keep half of the degrees of freedom in C_4 . The massless field content can now be combined into massless $\mathcal{N} = 2$ supergravity multiplets, which is summarised in table 4.

Supergravity data and generalised spinors

The four-dimensional theory preserves $\mathcal{N} = 2$ supersymmetry. As we have seen in section 8.2, the corresponding supergravity data is encoded in a Kähler potential for the vector-multiplet scalar fields, a pre-potential \mathcal{F} for the vector-multiplet vectors, a quaternionic-Kähler metric for the hyper-multiplet scalars, and Killing pre-potentials \mathcal{P}^x describing possible gaugings. Let us now express (some of) these quantities using the pure spinors (8.17).

- The scalar fields of the vector-multiplets span a special-Kähler manifold. The geometry of this manifold is therefore described by a Kähler potential \mathcal{K}^- , which can be expressed using the pure spinor Φ^- given in (8.17) as [223,244]

$$\Phi^- = \Omega, \quad e^{-\mathcal{K}^-} = -i \int_{\mathcal{M}} \langle \Phi^-, \bar{\Phi}^- \rangle = -i \int_{\mathcal{M}} \Omega \wedge \bar{\Omega}, \tag{8.61}$$

where $\langle \cdot, \cdot \rangle$ denotes the Mukai pairing (8.14). From this Kähler potential the corresponding Kähler metric for the complex-structure moduli can be determined, similarly as in (8.19).

- For the vector-fields the kinetic terms are given by the period matrix (8.21), which is determined from Z^I and \mathcal{F}_I appearing in (8.40).
- For the hyper-multiplets we first recall that the scalar fields parametrise a quaternionic-Kähler manifold. However, this manifold contains a special Kähler manifold as a sub-manifold, which is parametrised by the NS-NS sector scalars. Using the pure spinor Φ^+ given in (8.17), the corresponding Kähler potential can be written as [223]

$$\Phi^+ = e^{B-iJ}, \quad e^{-\kappa^+} = +i \int_{\mathcal{M}} \langle \Phi^+, \bar{\Phi}^+ \rangle = \frac{4}{3} \int_{\mathcal{M}} J^3, \quad (8.62)$$

where the pairing between the pure spinors is again the Mukai pairing.

The scalar potential of the $\mathcal{N} = 2$ theory can be determined from the moment maps $\mathcal{P}^x = \bar{Z}^I \mathcal{P}_I^x$.¹⁶ For type IIB compactifications they can be written using the pure spinors and the Mukai pairing as [223]

$$\mathcal{P}^1 - i\mathcal{P}^2 \sim \int_{\mathcal{M}} \langle \Phi^-, d\Phi^+ \rangle, \quad (8.63a)$$

$$\mathcal{P}^3 \sim \int_{\mathcal{M}} \langle \Phi^-, \tilde{F} \rangle, \quad (8.63b)$$

where \tilde{F} is the combined field strength given in (8.57). The precise normalisation of the Killing pre-potentials is not important here but can be found for instance in [224]. However, for Calabi-Yau compactifications without fluxes it follows that B in Φ^+ is closed and hence $d\Phi^+ = 0$, and that the R-R fluxes \tilde{F} are set to zero. The moment maps (8.63) therefore vanish, and the four-dimensional theory is an ungauged $\mathcal{N} = 2$ supergravity.

8.5 Calabi-Yau compactifications with fluxes

In this section we discuss Calabi-Yau compactifications with geometric as well as non-geometric fluxes [239–242]. In the NS-NS sector, we generate these fluxes by performing non-trivial $O(D, D)$ transformations of the background, similarly as in section 7.4. In particular, we consider $O(D, D)$ transformations of the generalised

¹⁶ Gaugings of the vector-multiplet scalars z^i are not important for our discussion, and hence the Killing vectors k_J^i appearing in the potential (8.28) are set to zero.

spinors which in general will lead to non-vanishing moment maps (8.63). The resulting theory is then a gauged $\mathcal{N} = 2$ supergravity theory in four dimensions. In this section we illustrate the role played by non-geometric fluxes in the effective theory, and refer to the original literature [223–225] for a more detailed analysis.

NS-NS sector – examples

We implement an $O(D, D)$ transformation of the background via $O(D, D)$ transformations of the pure spinors Φ^+ and Φ^- . As we have mentioned before, $O(D, D)$ transformations leave the Mukai pairing (8.14) invariant, and hence the Kähler potentials (8.61) and (8.62) stay invariant. On the other hand, the interactions described via the Killing pre-potentials (8.63) will be modified. Let us discuss this point for two examples:

- First, we consider a non-trivial \mathbf{B} -transform of the pure spinors. According to (8.13) we take $\Phi^\pm \rightarrow e^{\mathbf{B}} \Phi^\pm$ with \mathbf{B} a two-form with field strength $H = d\mathbf{B}$. Using the invariance of the Mukai pairing, for (8.63a) this implies

$$\begin{aligned} \langle \Phi^-, d\Phi^+ \rangle &\rightarrow \langle e^{+\mathbf{B}} \Phi^-, d(e^{+\mathbf{B}} \Phi^+) \rangle \\ &= \langle \Phi^-, e^{-\mathbf{B}} d(e^{+\mathbf{B}} \Phi^+) \rangle \\ &= \langle \Phi^-, (d + H) \Phi^+ \rangle, \end{aligned} \quad (8.64)$$

where the exponentials are again understood as a series expansion and wedge products between differential forms are left implicit. Using that Φ^+ is closed, we therefore see that a non-trivial \mathbf{B} -transform generates an interaction term of the form

$$\mathcal{P}^1 - i\mathcal{P}^2 \sim \int_{\mathcal{M}} \Omega \wedge H. \quad (8.65)$$

- As a second example we consider a β -transform of the pure spinors. Following (8.13) we take $\Phi^\pm \rightarrow e^{\beta} \Phi^\pm$, where the contraction of the bivector-field is again left implicit (cf. below equation (7.10)). We then find that

$$\begin{aligned} \langle \Phi^-, d\Phi^+ \rangle &\rightarrow \langle e^{+\beta} \Phi^-, d(e^{+\beta} \Phi^+) \rangle \\ &= \langle \Phi^-, e^{-\beta} d(e^{+\beta} \Phi^+) \rangle \\ &= \langle \Phi^-, (D + Q - R) \Phi^+ \rangle, \end{aligned} \quad (8.66)$$

where we use the following notation

$$\begin{aligned} D &= dx^m \delta_m^n \partial_n - \iota_m \beta^{mn} \partial_n, \\ Q &= \frac{1}{2} Q_i{}^{jk} dx^i \wedge \iota_j \wedge \iota_k, & Q_i{}^{jk} &= \partial_i \beta^{jk}, \\ R &= \frac{1}{6} R^{ijk} \iota_i \wedge \iota_j \wedge \iota_k, & R^{ijk} &= 3\beta^{[i|m} \partial_m \beta^{j]k}. \end{aligned} \quad (8.67)$$

Details of this computation can be found in the appendix of [245]. The expressions for $Q_i{}^{jk}$ and R^{ijk} have appeared already in (7.69), where we identified them with the non-geometric Q - and R -flux, and the derivative D is related to the expressions shown in (7.105). A non-trivial β -transformation therefore generates a potential due to non-vanishing Q - and R -fluxes. Using the two-form \mathcal{J} defined in (8.48) which encodes the complexified Kähler moduli, we find in particular

$$\mathcal{P}^1 - i\mathcal{P}^2 \sim \int_{\mathcal{M}} \Omega \wedge \left[\frac{1}{2} Q \mathcal{J}^2 - \frac{1}{6} R \mathcal{J}^3 \right]. \quad (8.68)$$

Note that since \mathcal{J} is a $(1, 1)$ -form, $D e^{\mathcal{J}}$ in (8.66) cannot become a $(0, 3)$ -form and therefore $\Phi^- \wedge D \Phi^+ = 0$ on a Calabi-Yau three-fold.

NS-NS sector – general expression

We can now combine these two examples into a general expression including all types of fluxes. Using the Clifford action discussed on page 133, under a general $O(D, D)$ transformation we have

$$\langle \Phi^-, d\Phi^+ \rangle \rightarrow \langle \Phi^-, \mathcal{D}\Phi^+ \rangle, \quad (8.69)$$

where the generalised Dirac operator for the generalised spinor is given by

$$\mathcal{D} = \not{\nabla} = \nabla_A \Gamma^A, \quad \nabla_A = \rho(\bar{\mathcal{E}}_A) - \frac{1}{3!} F_{ABC} \Gamma^B \Gamma^C. \quad (8.70)$$

Here we use the same conventions as in section 7.4 and express the $O(D, D)$ γ -matrices $\Gamma^M = (dx^m \wedge, \iota_m)$ as $\Gamma^A = \delta^A_M \Gamma^M$, and the anchor-projection $\rho(\bar{\mathcal{E}}_A) = D_A$ of the generalised vielbein vector-field was discussed below (7.103). The spin-connection is expressed in terms of the fluxes $F_{ABC} = F_{AB}{}^D \eta_{DC}$ introduced in section 7.4.¹⁷ Using (7.105) as well as the conventions (7.70), one reproduces (8.64) and (8.66). In components, we can write (8.70) in the following way [121]

$$\mathcal{D} = D + H - F + Q - R, \quad (8.71)$$

where

$$\begin{aligned} D &= dx^i (A^T)_{i,j} \partial_j + \iota_i (B^T)^{ij} \partial_j, \\ H &= \frac{1}{6} H_{ijk} dx^i \wedge dx^j \wedge dx^k, \\ F &= \frac{1}{2} F_{ij}{}^k dx^i \wedge dx^j \wedge \iota_k, \\ Q &= \frac{1}{2} Q_i{}^{jk} dx^i \wedge \iota_j \wedge \iota_k, \\ R &= \frac{1}{6} R^{ijk} \iota_i \wedge \iota_j \wedge \iota_k. \end{aligned} \quad (8.72)$$

¹⁷We assume, similarly as in section 7.7, that the flux components F_{ABC} are completely anti-symmetric in their indices. This excludes terms of the form $F_{im}{}^m$ and $Q_m{}^{mi}$.

The flux-components H_{ijk} , $F_{ij}{}^k$, $Q_i{}^{jk}$ and R^{ijk} in a local basis have been defined in (7.71), which in turn are given by a choice of generalised vielbein. The generalised vielbein can be expressed in terms of an $O(D, D)$ matrix as in (7.62), which then determines D . We can now give the general form for (8.63a) using (8.71) as

$$\mathcal{P}^1 - i\mathcal{P}^2 \sim \int_{\mathcal{M}} \Omega \wedge \left[H - F \mathcal{J} + \frac{1}{2} Q \mathcal{J}^2 - \frac{1}{6} R \mathcal{J}^3 \right]. \quad (8.73)$$

To conclude, we see that deforming the background geometry by a non-trivial $O(D, D)$ transformation generates non-vanishing moment maps (8.63a). This implies that the four-dimensional theory becomes a gauged $\mathcal{N} = 2$ supergravity theory, in which the gaugings are determined by the geometric and non-geometric fluxes.

R-R sector

Let us next turn to the moment map \mathcal{P}^3 shown in (8.63b). Non-vanishing field strengths for R-R potentials C_p cannot be generated by an $O(D, D)$ transformation, so here we have to choose them by hand. We start again from the situation of vanishing NS-NS fluxes for which we have $\tilde{F} = d\mathcal{C}$. Performing a non-trivial B-transform of the pure spinors as well as of \mathcal{C} , we find

$$\begin{aligned} \langle \Phi^-, \tilde{F} \rangle &= \langle \Phi^-, d\mathcal{C} \rangle \rightarrow \langle e^{+\mathbf{B}} \Phi^-, d(e^{+\mathbf{B}} \mathcal{C}) \rangle \\ &= \langle \Phi^-, e^{-\mathbf{B}} d(e^{+\mathbf{B}} \mathcal{C}) \rangle \\ &= \langle \Phi^-, (d + H) \mathcal{C} \rangle, \end{aligned} \quad (8.74)$$

where $H = dB$. This suggests that $\tilde{F} = (d + H)\mathcal{C}$ should be identified as the R-R field strength in the case of non-vanishing H -flux, which agrees with the definition given already in (8.55). Using this example together with our results from the NS-NS sector, for a general $O(D, D)$ transformation of the background we are therefore led to the field strength

$$\tilde{F} = \mathcal{D}\mathcal{C}. \quad (8.75)$$

In the four-dimensional theory, this gives rise to a modification of the kinetic terms of the R-R sector scalars in the hyper-multiplets, which is expected from the general expression given in (8.26). We therefore see again that a non-trivial $O(D, D)$ transformation leads to geometric and non-geometric fluxes, which generates gaugings in the four-dimensional theory.

Cohomology

Let us also consider the action of (8.71) on the cohomology of the Calabi-Yau three-fold. The operator \mathcal{D} is often also called a twisted differential [121], and its action on the cohomology bases (8.38) and (8.44) can be parametrised as¹⁸ [224]

$$\begin{aligned}\mathcal{D}\alpha_I &\sim q_I^A \omega_A + f_{IA} \sigma^A, & \mathcal{D}\beta^I &\sim \tilde{q}^{IA} \omega_A + \tilde{f}^I{}_A \sigma^A, \\ \mathcal{D}\omega_A &\sim -\tilde{f}^I{}_A \alpha_I + f_{IA} \beta^I, & \mathcal{D}\sigma^A &\sim \tilde{q}^{IA} \alpha_I - q_I^A \beta^I.\end{aligned}\tag{8.76}$$

Here \sim denotes equality up to terms which vanish under the Mukai pairing (8.14) with any other basis element. Furthermore, f_{IA} and $\tilde{f}^I{}_A$ correspond to the geometric F -fluxes, while q_I^A and \tilde{q}^{IA} are the components of the non-geometric Q -fluxes. For the H - and R -flux we use the conventions

$$\begin{aligned}f_{I0} &= h_I, & \tilde{f}^I{}_0 &= \tilde{h}^I, \\ q_I^0 &= r_I, & \tilde{q}^{I0} &= \tilde{r}^I.\end{aligned}\tag{8.77}$$

Let us furthermore define a $(2h^{2,1} + 2) \times (2h^{1,1} + 2)$ matrix as follows

$$\mathcal{Q} = \begin{pmatrix} -\tilde{f}^I{}_A & \tilde{q}^{IA} \\ f_{IA} & -q_I^A \end{pmatrix},\tag{8.78}$$

as well as two symplectic structures \mathcal{S}_\pm as

$$\mathcal{S}_\pm = \begin{pmatrix} 0 & +\mathbb{1} \\ -\mathbb{1} & 0 \end{pmatrix},\tag{8.79}$$

where \mathcal{S}_+ is of dimensions $(2h^{1,1}+2) \times (2h^{1,1}+2)$ and \mathcal{S}_- is a matrix with dimensions $(2h^{2,1} + 2) \times (2h^{2,1} + 2)$. Defining finally $\tilde{\mathcal{Q}} = \mathcal{S}_- \mathcal{Q} \mathcal{S}_+^T$, we can write (8.76) more compactly as [224]

$$\mathcal{D} \begin{pmatrix} \omega_A \\ \sigma^A \end{pmatrix} \sim \mathcal{Q}^T \begin{pmatrix} \alpha_I \\ \beta^I \end{pmatrix}, \quad \mathcal{D} \begin{pmatrix} \alpha_I \\ \beta^I \end{pmatrix} \sim -\tilde{\mathcal{Q}} \begin{pmatrix} \omega_A \\ \sigma^A \end{pmatrix}.\tag{8.80}$$

¹⁸ For the action of \mathcal{D} on the cohomology a local basis on the tangent- and cotangent-space as in (8.71) is not suitable. Furthermore, the flux components are required to be constants in order to have elements in $H^{p,q}(\mathcal{M}, \mathbb{R})$.

Bianchi identities

Let us now come back to the twisted differential \mathcal{D} shown in (8.70), and determine its square. We find the following expression

$$\begin{aligned} \mathcal{D}^2 = \nabla^2 &= -\frac{1}{24} \left[D_{[M} F_{NOP]} - \frac{3}{4} F_{[MN}{}^R F_{R][OP]} \right] \Gamma^{MNOP} \\ &\quad - \frac{1}{8} D^M F_{MPQ} \Gamma^{PQ} \\ &\quad - \frac{1}{48} F^{MNO} F_{MNO}. \end{aligned} \tag{8.81}$$

Note that the first line is proportional to the Bianchi identity (7.103), whereas the third line can be obtained by suitable index contractions. These expressions have appeared in the literature before, see for instance [217] for the context of double field theory. Requiring then the extended Bianchi identities, that is including $D^M F_{MPQ} = 0$, to be satisfied gives $\mathcal{D}^2 = 0$.

We can also turn this reasoning around and require the twisted differential to be nil-potent, that is $\mathcal{D}^2 = 0$, leading to the Bianchi identities for the fluxes. For the action of the twisted differential on the cohomology shown in (8.80), this implies that [224]¹⁹

$$\mathcal{D}^2 = 0 \quad \longrightarrow \quad \begin{aligned} Q^T \cdot \mathcal{S}_- \cdot Q &= 0, \\ Q \cdot \mathcal{S}_+ \cdot Q^T &= 0. \end{aligned} \tag{8.82}$$

Furthermore, we can derive the Bianchi identity (in the absence of sources, see section 8.6 for their inclusion) for the R-R field strength shown in equation (8.75) as

$$\mathcal{D}\tilde{F} = 0. \tag{8.83}$$

However, there appears to be a slight mismatch between the Bianchi identities (8.82) computed from the action of \mathcal{D} on the cohomology and the Bianchi identities in a coordinate basis shown in (7.106). This issue has been studied in [246, 247] for toroidal examples, but to our knowledge is currently still under investigation.

Scalar potential

Given the action (8.80) of the twisted differential on the cohomology of the Calabi-Yau three-fold, we can now derive explicit expressions for the moment maps (8.63)

¹⁹In the presence of NS-NS sources such as the NS5-brane, KK-monopole or 5₂-brane the condition (8.82) is modified. See [218, 219] for details.

and determine the resulting scalar potential. To do so, we first expand the pure spinors Φ^+ and Φ^- of the Calabi-Yau three-fold in the bases (8.44) and (8.38) as

$$\begin{aligned}\Phi^+ &= (\omega_0 \ \omega_A \ \sigma^0 \ \sigma^A) \cdot \begin{pmatrix} 1 \\ \mathcal{J}^A \\ \frac{1}{6} \kappa_{ABC} \mathcal{J}^A \mathcal{J}^B \mathcal{J}^C \\ \frac{1}{2} \kappa_{ABC} \mathcal{J}^B \mathcal{J}^C \end{pmatrix}, \\ \Phi^- &= (\alpha_I \ \beta^I) \cdot \begin{pmatrix} X^I \\ -\mathcal{F}_I \end{pmatrix}.\end{aligned}\tag{8.84}$$

These expansions define a $(2h^{2,1} + 2)$ -dimensional vector V^+ and a $(2h^{2,1} + 2)$ -dimensional vector V^- as follows

$$V^+ = \begin{pmatrix} 1 \\ \mathcal{J}^A \\ \frac{1}{6} \kappa_{ABC} \mathcal{J}^A \mathcal{J}^B \mathcal{J}^C \\ \frac{1}{2} \kappa_{ABC} \mathcal{J}^B \mathcal{J}^C \end{pmatrix}, \quad V^- = \begin{pmatrix} X^I \\ -\mathcal{F}_I \end{pmatrix}.\tag{8.85}$$

For the Ramond-Ramond sector we expand the \tilde{F} -flux and the potentials \mathcal{C} along the Calabi-Yau manifold \mathcal{M} in a similar way

$$\begin{aligned}\mathcal{C}|_{\mathcal{M}} &= (\omega_0 \ \omega_A \ \sigma^0 \ \sigma^A) \cdot \begin{pmatrix} (C_0) \\ (C_2)^A \\ C_6 \\ (C_4)_A \end{pmatrix}, \\ \tilde{F}|_{\mathcal{M}} &= (\alpha_I \ \beta^I) \cdot \begin{pmatrix} (F_3)^I \\ -(F_3)_I \end{pmatrix},\end{aligned}\tag{8.86}$$

which defines two vectors as

$$\mathbf{C} = \begin{pmatrix} (C_0) \\ (C_2)^A \\ C_6 \\ (C_4)_A \end{pmatrix}, \quad \mathbf{F} = \begin{pmatrix} (F_3)^I \\ -(F_3)_I \end{pmatrix}.\tag{8.87}$$

Here, C_6 denotes the component of the R-R six-form potential along the compact manifold. Using these definitions, we can evaluate the moment maps \mathcal{P}^x discussed above, and use the general expression (8.28) to evaluate the scalar potential. Using

the definition of the matrices \mathcal{M}^+ and \mathcal{M}^- given in (8.53) and (8.52) we find

$$\begin{aligned}
V = & \frac{1}{2}(\mathbb{F}^T + \mathbb{C}^T \cdot \mathcal{Q}^T) \cdot \mathcal{M}^- \cdot (\mathbb{F} + \mathcal{Q} \cdot \mathbb{C}) \\
& + \frac{e^{-2\phi}}{2} V^{+T} \cdot \mathcal{Q}^T \cdot \mathcal{M}^- \cdot \mathcal{Q} \cdot \bar{V}^+ \\
& + \frac{e^{-2\phi}}{2} V^{-T} \cdot \tilde{\mathcal{Q}} \cdot \mathcal{M}^+ \cdot \tilde{\mathcal{Q}}^T \cdot \bar{V}^- \\
& - \frac{e^{-2\phi}}{4\mathcal{V}} V^{-T} \cdot \mathcal{S}_- \cdot \mathcal{Q} \cdot (V^+ \times \bar{V}^{+T} + \bar{V}^+ \times V^{+T}) \cdot \mathcal{Q}^T \cdot \mathcal{S}_-^T \cdot \bar{V}^-,
\end{aligned} \tag{8.88}$$

where \mathcal{V} is the overall volume of the Calabi-Yau three-fold and where \cdot denotes matrix multiplication while \times stands for the ordinary product of scalars. This expression agrees with the scalar potential of $\mathcal{N} = 2$ gauged supergravity found in [248] (after going to Einstein frame). In the context of $SU(3) \times SU(3)$ structure compactifications this potential has appeared for instance in [249], and in the context of double field theory it has been derived in [250].

Mirror symmetry

With the help of the scalar potential (8.88), we can also illustrate mirror symmetry [3]. This is a well-established duality between compactifications of type IIA and type IIB string theory on Calabi-Yau three-folds, which essentially interchanges the even and odd cohomology groups. In the scalar potential this is realised by interchanging the $+$ and $-$ labels of the vectors V^+ and V^- , and by exchanging the fluxes as

$$\mathcal{Q} \longrightarrow \tilde{\mathcal{Q}}^T. \tag{8.89}$$

For the R-R sector one finds that the fluxes between type IIB and type IIA are interchanged. Working out how the components of \mathcal{Q} transform under mirror symmetry, we see that some of the geometric and non-geometric fluxes are mapped as follows [224]

$$\begin{aligned}
f & \longrightarrow -f^T, & \tilde{f} & \longrightarrow q^T, \\
\tilde{q} & \longrightarrow -\tilde{q}^T, & q & \longrightarrow \tilde{f}^T.
\end{aligned} \tag{8.90}$$

Therefore, when compactifying string theory on a Calabi-Yau three-fold for instance with geometric H -flux, the mirror dual will in general be a Calabi-Yau compactification with non-geometric R -flux. This shows that non-geometric fluxes are a natural part of string-theory compactifications, which are connected via mirror symmetry to geometric fluxes.

Remark

We also briefly mention partial supersymmetry breaking from $\mathcal{N} = 2$ to $\mathcal{N} = 1$ in four-dimensions, for which non-geometric fluxes play an important role. In the series of papers [251–254] it was studied how partial supersymmetry breaking can be realised in string-theory compactifications. It turns out that for partially-broken Minkowski vacua one needs at least two gauged isometries, which can be generated by at least two entries in the flux matrix (8.78) – out of which one has to be a non-geometric flux.²⁰ This observation has been employed in [256,257] to determine the back-reaction of non-geometric fluxes on Calabi-Yau three-fold compactifications. The back-reacted solutions are asymmetric Gepner models, which are related to non-geometric constructions previously studied in [174,258].

8.6 Calabi-Yau orientifolds with fluxes

In string theory one is often interested in $\mathcal{N} = 1$ supergravity theories in four dimensions, which can be obtained from $\mathcal{N} = 2$ compactifications by performing an orientifold projection [259,260]. In this section we want to determine the scalar potential of the four-dimensional $\mathcal{N} = 1$ theory corresponding to the orientifold-projected version of (8.88), and for a full analysis we refer to [234,261].

Orientifold projection

We focus again on type IIB string theory and perform an orientifold projection of the form $\Omega_{\mathbb{P}}(-1)^{F_L}\sigma$. Here, $\Omega_{\mathbb{P}}$ denotes the world-sheet parity operator, F_L is the left-moving fermion number (cf. page 56), and σ is a holomorphic involution on the compact space \mathcal{M} . We choose the action of σ^* on the Kähler and holomorphic three-form as

$$\sigma^*J = +J, \quad \sigma^*\Omega = -\Omega. \quad (8.91)$$

The fixed loci of this involution on \mathcal{M} are zero- and four-dimensional which – taking into account that σ leaves the four-dimensional space invariant – gives rise to orientifold three- and seven-planes.²¹ The orientifold projection gives rise to a

²⁰ More concretely, one needs both electric and magnetic gaugings with one of them corresponding to a non-geometric flux. We did not introduce a distinction between electric and magnetic gaugings in this section, but schematically an electric gauging is done with a gauge field whose field strength appears in the action explicitly. A magnetic gauging on the other hand is done with a gauge field corresponding to the dual field strength and which does not explicitly appear in the action. A formalism to deal with such gaugings in a systematic way has been developed in [255].

²¹If σ^* leaves Ω invariant, one obtains O5- and O9-planes. The analysis done in this section for this situation can be found in [234].

splitting of the cohomology groups into even and odd eigenspaces of σ^* as follows

$$H^{p,q}(\mathcal{M}) = H_+^{p,q}(\mathcal{M}) \oplus H_-^{p,q}(\mathcal{M}), \quad (8.92)$$

and the corresponding Hodge numbers will be denoted by $h_{\pm}^{p,q} = \dim H_{\pm}^{p,q}(\mathcal{M})$. According to (8.92) they satisfy $h^{p,q} = h_+^{p,q} + h_-^{p,q}$. One can furthermore determine the following relations [259]

$$\begin{aligned} h_{\pm}^{1,1} &= h_{\pm}^{2,2}, & h_+^{3,0} &= h_+^{0,3} = 0, & h_+^{0,0} &= h_+^{3,3} = 1, \\ h_{\pm}^{2,1} &= h_{\pm}^{1,2}, & h_-^{3,0} &= h_-^{0,3} = 1, & h_-^{0,0} &= h_-^{3,3} = 0. \end{aligned} \quad (8.93)$$

Turning to the world-sheet parity operator and the left-moving fermion number, one finds that their action on the ten-dimensional bosonic fields is given by

$$\begin{aligned} \Omega_{\text{P}}(-1)^{F_L} g &= +g, & \Omega_{\text{P}}(-1)^{F_L} B &= -B, \\ \Omega_{\text{P}}(-1)^{F_L} \phi &= +\phi, & \Omega_{\text{P}}(-1)^{F_L} C_p &= (-1)^{\frac{p}{2}} C_p. \end{aligned} \quad (8.94)$$

For the H -flux and the \tilde{F}_3 -form flux one can infer their transformation behaviour from (8.94), and for the geometric and non-geometric fluxes one chooses [121, 250]

$$\begin{aligned} \Omega_{\text{P}}(-1)^{F_L} H &= -H, \\ \Omega_{\text{P}}(-1)^{F_L} F &= +F, & \Omega_{\text{P}}(-1)^{F_L} \tilde{F}_3 &= -\tilde{F}_3, \\ \Omega_{\text{P}}(-1)^{F_L} Q &= -Q, \\ \Omega_{\text{P}}(-1)^{F_L} R &= +R. \end{aligned} \quad (8.95)$$

Massless spectrum

The massless spectrum of the theory compactified on a Calabi-Yau orientifold can be determined as before by expanding the ten-dimensional fields into elements of the appropriate cohomology groups and integrating over the compact space. Only fields invariant under the orientifold projection are kept, which means for instance that we consider

$$J \in H_+^{1,1}(\mathcal{X}), \quad \Omega \in H_-^3(\mathcal{X}), \quad B|_{\mathcal{M}} \in H_-^{1,1}(\mathcal{X}), \quad (8.96)$$

where $B|_{\mathcal{M}}$ denotes the restriction of the Kalb-Ramond field to the compact space. For the R-R potentials similar results apply, depending on the degree of C_p . The resulting spectrum is summarised in table 5, where we indicated the index running over the σ^* -odd cohomology by a hat, that is

$$\begin{aligned} i &= 1, \dots, h_+^{2,1}, & A &= 1, \dots, h_+^{1,1}, \\ \hat{i} &= 1, \dots, h_-^{2,1}, & \hat{A} &= 1, \dots, h_-^{1,1}. \end{aligned} \quad (8.97)$$

multiplet	multiplicity	bosonic field content
gravity	1	$g_{\mu\nu}$
vector	$h_+^{2,1}$	$(C_4)_\mu^i$
chiral	$h_-^{2,1}$	$z^{\hat{i}}$
chiral	1	τ
chiral	$h_+^{1,1}$	T_A
chiral	$h_-^{1,1}$	$G^{\hat{A}}$

Table 5: Massless bosonic field content of type IIB string theory compactified on a Calabi-Yau orientifold with O3- and O7-planes in four dimensions.

The complex-structure moduli $z^{\hat{i}}$ in table 5 originate from the projection of the $\mathcal{N} = 2$ moduli (8.40) by keeping only the odd cohomology expansion coefficients. The remaining scalar fields τ , T_A and $G^{\hat{A}}$ are a combination of the R-R potentials C_p , the Kalb-Ramond field B , the dilaton ϕ and the Kähler moduli t^A . We specify their precise form below.

Generalised spinors and $\mathcal{N} = 1$ supergravity data

Similar to the $\mathcal{N} = 2$ situation, one can encode the properties of the $\mathcal{N} = 1$ theory in terms of generalised spinors. To do so, let us define the following quantities [234]

$$\begin{aligned}\Phi^+ &= e^{-\phi} e^{B-iJ}, & \Phi_c^+ &= e^B \mathcal{C}_{\text{mod}} + i \text{Re} \Phi^+, \\ \Phi^- &= \Omega, & & \end{aligned} \quad (8.98)$$

where the sum over all R-R potential C_p defined in (8.57) has been separated into a flux contribution and a moduli contribution as $\mathcal{C} = \mathcal{C}_{\text{flux}} + \mathcal{C}_{\text{mod}}$. The scalar fields τ , T_A and $G^{\hat{A}}$ shown in table 5 can be determined by expanding Φ_c^+ as follows

$$\Phi_c^+ = \tau + G^{\hat{A}} \omega_{\hat{A}} + T_A \sigma^A, \quad (8.99)$$

where we employed the basis of (1, 1)- and (2, 2)-forms introduced in (8.43). Let us now discuss the $\mathcal{N} = 1$ supergravity data of these theories:

- Since these scalar fields are part of chiral multiplets of a $\mathcal{N} = 1$ supergravity theory in four dimensions, the metrics of their scalar manifolds are Kähler. The corresponding Kähler potentials can be expressed using (8.98) in the

following way [234, 225]

$$\begin{aligned}\mathcal{K}^+ &= -2 \log \left[+i \int_{\mathcal{M}} \langle \Phi^+, \bar{\Phi}^+ \rangle \right] = -\log \left[-\frac{i}{2} (\tau - \bar{\tau}) \right] - 2 \log [8 \hat{\mathcal{V}}], \\ \mathcal{K}^- &= -\log \left[-i \int_{\mathcal{M}} \langle \Phi^-, \bar{\Phi}^- \rangle \right] = -\log \left[-i \int_{\mathcal{M}} \Omega \wedge \bar{\Omega} \right],\end{aligned}\tag{8.100}$$

where $\hat{\mathcal{V}} = e^{-\frac{3}{2}\phi} \frac{1}{6} \int J^3$ denotes the volume of \mathcal{M} in Einstein frame. Note that \mathcal{K}^- is the projection of the $\mathcal{N} = 2$ result given in (8.61), whereas \mathcal{K}^+ differs from (8.62) by a factor of two and the dilaton dependence. Furthermore, these expressions agree with the standard results for the Kähler potential of Calabi-Yau orientifold compactifications [259].

- Turning now to the interactions, the superpotential W of the $\mathcal{N} = 1$ supergravity theory is given by a suitable combination of the moment maps (8.63) of the $\mathcal{N} = 2$ theory, subject to the orientifold projection. In the absence of H -flux, one finds [234, 225]

$$W = \int_{\mathcal{M}} \langle \Phi^-, \tilde{F} + d\Phi_c^+ \rangle.\tag{8.101}$$

where the field strength of the R-R potentials $\tilde{F} = d\mathcal{C}_{\text{flux}}$ contains only terms invariant under the orientifold projection and where we employed the Mukai pairing (8.14).

- Note that in W only the real part of the generalised spinor Φ^+ appears. The imaginary part contributes to the $\mathcal{N} = 1$ D-term potential, which takes the form (see for instance [225, 250])

$$V_D \sim \int_{\mathcal{M}} \langle d\text{Im}\Phi^+, \star d\text{Im}\Phi^+ \rangle,\tag{8.102}$$

where \star denotes the Hodge star-operator on \mathcal{M} and where we employed again the Mukai pairing (8.14). Note that $d\text{Im}\Phi^+$ is part of the σ^* -even cohomology.

However, recall that the D-term potential arises from gaugings of the chiral-multiplet scalars using the vector-fields. From the spectrum of the $\mathcal{N} = 1$ theory shown in table 5 we see that only vector-fields $(C_4)_\mu^i$ with index $i = 1, \dots, h_+^{2,1}$ are present. Other vector-field components of C_4 are either projected out through the orientifold projection, or are removed due to the

self-duality of C_4 . In the scalar potential (8.102) we therefore have to restrict $d\text{Im}\Phi^+$ to those parts proportional to $\{\alpha_i\} \in H_+^{2,1}(\mathcal{M})$. This situation changes when considering magnetic gaugings of the isometries, which we do not discuss here.

For the case of a Calabi-Yau orientifold without fluxes, we note that Φ^+ is closed and that \tilde{F} is vanishing. This implies that the scalar F- and D-term potentials vanish, and that the four-dimensional theory is an ungauged $\mathcal{N} = 1$ supergravity.

Deformations I – F-term potential

Similarly as in section 8.5, we now want to deform the Calabi-Yau orientifold background by performing non-trivial $O(D, D)$ transformations of the generalised spinors Φ^\pm and of the R-R potentials \mathcal{C} . Let us start by considering a non-trivial B-transform acting as $\Phi^\pm \rightarrow e^{\text{B}}\Phi^\pm$ and as $\mathcal{C} \rightarrow e^{\text{B}}\mathcal{C}$. For the superpotential (8.101) this means that

$$\begin{aligned} \langle \Phi^-, d\mathcal{C}_{\text{flux}} + d\Phi_c^+ \rangle &\rightarrow \langle e^{+\text{B}}\Phi^-, d(e^{+\text{B}}\mathcal{C}_{\text{flux}}) + d(e^{\text{B}}\Phi_c^+) \rangle \\ &= \langle \Phi^-, e^{-\text{B}}d(e^{+\text{B}}\mathcal{C}_{\text{flux}}) + e^{-\text{B}}d(e^{\text{B}}\Phi_c^+) \rangle \quad (8.103) \\ &= \langle \Phi^-, (d + H)\mathcal{C}_{\text{flux}} + (d + H)\Phi_c^+ \rangle, \end{aligned}$$

where $H = dB$. This suggests that in the case of non-vanishing H -flux we should identify the R-R field strength as $\tilde{F} = (d + H)\mathcal{C}_{\text{flux}}$, which agrees again with our definition already given in (8.55). Using this example as well as our results from section 8.5, for a background originating from a general $O(D, D)$ transformation the superpotential should be given by [121, 262, 123]

$$W = \int_{\mathcal{M}} \langle \Phi^-, \tilde{F} + \mathcal{D}\Phi_c^+ \rangle, \quad (8.104)$$

where $\tilde{F} = \mathcal{D}\mathcal{C}_{\text{flux}}$ and where \mathcal{D} has been given in (8.71). Due to $\Phi^- = \Omega$ being part of the orientifold-odd cohomology, in the superpotential only the orientifold-odd part of $\tilde{F} + \mathcal{D}\Phi_c^+$ contributes. Explicitly, the superpotential reads

$$W = \int_{\mathcal{M}} \Omega \wedge \left(\tilde{F}_3 + \tau H - F\omega_{\hat{A}}G^{\hat{A}} + Q\sigma^A T_A \right). \quad (8.105)$$

Note that the first two terms are the familiar Gukov-Vafa-Witten superpotential [263], whereas the remaining terms provide the generalisation for all types of fluxes. Furthermore, we point out that the R -flux does not contribute to the superpotential.

Deformations II – D-term potential

A similar analysis can be performed for the D-term potential (8.102). We replace the exterior derivative in $d\text{Im}\Phi^+$ by the twisted differential \mathcal{D} , and we use the matrix \mathcal{M}^- defined in (8.53) to write

$$V_D = \frac{1}{2} \left[(\text{Im}\mathcal{N})^{-1} \right]^{ij} (\mathcal{D}\text{Im}\Phi^+)_i (\mathcal{D}\text{Im}\Phi^+)_j. \quad (8.106)$$

Here, only the even part of the third cohomology contributes which is again related to the self-duality condition to be imposed on the R-R four-form potential. We can then determine explicitly [250]

$$(\mathcal{D}\text{Im}\Phi^+)_i = e^{-\phi} \left[-\frac{1}{6} R J^3 + \frac{1}{2} R (B^2 J) - Q (B J) + F J \right]_i, \quad (8.107)$$

where the index i labels the corresponding component of the orientifold-even third cohomology. We also note that the flux-components appearing in the superpotential (8.104) do not appear in (8.107) and vice versa. In particular, the H -flux does not contribute to the D-term potential.

Localised sources I – tadpole conditions

When performing the orientifold projection described above, in string theory new localised sources are introduced. These are orientifold planes, and the choice (8.91) gives rise to orientifold three- and seven-planes which fill out four-dimensional space-time and wrap zero- and four-dimensional sub-manifolds in the compactification space \mathcal{M} . These O-planes are non-dynamical objects, however, they couple to the Ramond-Ramond potentials C_p . In the democratic formulation of type II supergravity [243] the resulting equations of motion/Bianchi identities (8.83) of the $\mathcal{N} = 2$ theory are therefore modified to

$$\mathcal{D}\tilde{F} = \text{sources}. \quad (8.108)$$

In order to solve such Bianchi identities one typically has to introduce D-branes as additional local sources, and the integrated Bianchi identities are known as tadpole cancellation conditions. In the context of non-geometric fluxes this question has been discussed in [261, 264–266].

Let us make this more precise: Dp -branes and orientifold Op -planes are hypersurfaces in ten-dimensional space-time. The corresponding world-volume actions contain Chern-Simons couplings to the R-R potentials C_q which read (for reviews

see e.g. [222, 267])

$$\begin{aligned}
\mathcal{S}_{Dp} &\supset - \mu_p \int_{\Gamma} \text{ch}(\mathcal{F}) \wedge \sqrt{\frac{\hat{\mathcal{A}}(\mathcal{R}_T)}{\hat{\mathcal{A}}(\mathcal{R}_N)}} \wedge \bigoplus_q \varphi^* C_q, \\
\mathcal{S}_{Op} &\supset -Q_p \mu_p \int_{\Gamma} \sqrt{\frac{\mathcal{L}(\mathcal{R}_T/4)}{\mathcal{L}(\mathcal{R}_N/4)}} \wedge \bigoplus_q \varphi^* C_q.
\end{aligned} \tag{8.109}$$

These expressions require some further clarification and explanation:

- The D-branes and O-planes wrap sub-manifolds Γ of the ten-dimensional space-time and are therefore localised. In (8.109) φ^* denotes the pull-back from ten dimensions to Γ .
- The expressions \mathcal{R}_T and \mathcal{R}_N stand for the restrictions of the curvature two-form \mathcal{R} to the tangent and normal bundle of Γ . We have furthermore employed the Chern character $\text{ch}(\mathcal{F})$ of the open-string field strength \mathcal{F} (cf. our discussion on page 28) as well as the $\hat{\mathcal{A}}$ -genus and the Hirzebruch polynomial \mathcal{L} . The definitions of these quantities can be found for instance in [203], and we note that the square-roots in (8.109) can be expanded as $(1 + 4\text{-form} + 8\text{-form} + \dots)$.
- The tension of the D-branes and O-planes μ_p and the charge of the O-planes Q_p are given by $\mu_p = 2\pi/l_s^{p+1}$ and $Q_p = -2^{p-4}$. In particular, (mutually supersymmetric) D-branes and O-planes have opposite charges.
- We are using the democratic formulation of type IIA/B supergravity in which all odd/even R-R potentials C_q appear in the action. In order to connect to ordinary type II supergravity, one imposes self-duality constraints for the R-R field strengths \tilde{F}_q of the form $\tilde{F}_q \sim \star \tilde{F}_{10-q}$ on the equations of motion. This means in particular that equations of motion for the potentials of the form $d \star \tilde{F} + \dots = 0$ can equivalently be expressed as Bianchi identities $d\tilde{F} + \dots = 0$ (see [243] for more details).

After having introduced the D-brane and O-plane actions involving the R-R potentials C_q , we can now determine the Bianchi identities for the R-R field strengths. We do this by first computing the equations of motion for the R-R potentials C_q , and then using the above-mentioned duality to obtain the Bianchi identities. The action from which we want to determine the equations of motion reads schematically

$$\mathcal{S} = \mathcal{S}_{\text{type II}} + \sum_{Dp} \mathcal{S}_{Dp} + \sum_{Op} \mathcal{S}_{Op}, \tag{8.110}$$

where the sums are over all D-branes and O-planes present in the background. In particular, the D-brane sum includes the orientifold images. In the absence of NS-NS fluxes, we determine from the equations of motion the following Bianchi identities (see e.g. [268] for an explicit computation)

$$d\tilde{F}_q = \sum_{Dp} \mathcal{Q}_{Dp} + \sum_{Op} \mathcal{Q}_{Op} \Big|_{q+1}. \quad (8.111)$$

The charges \mathcal{Q} are multi-forms and we have restricted them to their $(q+1)$ -form part. With $[\Gamma]$ denoting the Poincaré dual to the cycle Γ wrapped by the D-brane or O-plane,²² the \mathcal{Q} are defined as [269, 270]

$$\mathcal{Q}_{Dp} = \text{ch}(\mathcal{F}) \wedge \sqrt{\frac{\hat{\mathcal{A}}(\mathcal{R}_T)}{\hat{\mathcal{A}}(\mathcal{R}_N)}} \wedge [\Gamma_{Dp}], \quad \mathcal{Q}_{Op} = Q_p \sqrt{\frac{\mathcal{L}(\mathcal{R}_T/4)}{\mathcal{L}(\mathcal{R}_N/4)}} \wedge [\Gamma_{Op}]. \quad (8.112)$$

So far we have assumed that the NS-NS fluxes are vanishing. However, for non-vanishing H -flux we find from the type II supergravity action (8.58) that the left-hand side of (8.111) should be replaced by $(d + H \wedge) \tilde{F}$. Furthermore, for non-vanishing geometric fluxes F and non-geometric Q - and R -fluxes we have argued in section 8.5 that the Bianchi identity should involve the twisted differential \mathcal{D} (see equation (8.83)). In the presence of NS-NS fluxes and localised sources, the Bianchi identity (8.111) therefore becomes

$$\mathcal{D}\tilde{F} = \sum_{Dp} \mathcal{Q}_{Dp} + \sum_{Op} \mathcal{Q}_{Op}. \quad (8.113)$$

Finally, when integrating these Bianchi identities over the transversal space one finds the tadpole-cancellation conditions.

Localised sources II – Freed-Witten anomaly

D-branes in flux-backgrounds furthermore have to satisfy the Freed-Witten anomaly cancellation condition [125]. In the case of only H -flux this means that H restricted to the D-brane has to be exact, which reads in formulas

$$[H] \Big|_{D\text{-brane}} = 0. \quad (8.114)$$

²²For instance, when considering space-times of the form $\mathbb{R}^{3,1} \times \mathcal{M}$ with \mathcal{M} a compact six-dimensional space and Dp -branes filling $\mathbb{R}^{3,1}$, Γ_{D3} is point-like in \mathcal{M} and $[\Gamma_{D3}] \in H^6(\mathcal{M})$ is a six-form in \mathcal{M} , Γ_{D5} wraps a two-cycle in \mathcal{M} and $[\Gamma_{D5}] \in H^4(\mathcal{M})$ is a four-form in \mathcal{M} and Γ_{D7} wraps a four-cycle in \mathcal{M} and $[\Gamma_{D7}] \in H^2(\mathcal{M})$ is a two-form in \mathcal{M} .

Here $[H] \in H^3$ denotes the cohomology class of the H -flux. For general fluxes it has been argued that the Freed-Witten condition can be expressed as [271, 262, 265, 271–273, 215, 266]

$$\mathcal{D}[\Gamma_{Dp}] = 0, \quad (8.115)$$

where $[\Gamma_{Dp}]$ denotes again the Poincaré dual of the cycle Γ_{Dp} wrapped by the D-brane. In (8.115) we assumed that the open-string gauge flux \mathcal{F} vanishes, but the natural generalisation to non-trivial \mathcal{F} can be expressed using the charges (8.112) as [266]

$$\mathcal{D}Q_{Dp} = 0. \quad (8.116)$$

8.7 Scherk-Schwarz reductions

In our discussion above we have studied how geometric and non-geometric fluxes of a higher-dimensional theory affect the lower-dimensional one. In particular, we have interpreted fluxes as operators acting on the cohomology of the compactification space – as shown in equation (8.76) – which gave rise to a gauged supergravity theory. However, as we have argued in section 6, fluxes can also be considered as encoding the non-triviality of torus fibrations. We now want to describe compactifications of type II string theory on such backgrounds, which fall into the class of (generalised) Scherk-Schwarz reductions [126, 127]. In regard to non-geometric backgrounds, these have been investigated for instance in the papers [129, 141, 130, 274, 131, 275, 276].

General idea I

Let us start by reviewing the main idea of Scherk-Schwarz compactifications in the present context, following in parts [129, 130]. We consider a gravity theory in $D+1$ dimensions together with a number of scalar fields $\Phi(\hat{x})$. The latter are assumed to take values in a coset space G/K , where G is typically a non-compact group with maximal compact subgroup K . In this case the scalar fields can be combined into a vielbein matrix $\mathcal{V}(\hat{x})$, transforming under global transformations $g \in G$ and local transformations $k(\hat{x}) \in K$ as $\mathcal{V} \rightarrow k(\hat{x})\mathcal{V}g$. Restricting to real matrices \mathcal{V} , the action for the combined system (invariant under the above transformations) reads

$$\hat{\mathcal{S}} = \frac{1}{2\hat{\kappa}^2} \int \left[\hat{R} \star 1 + \frac{1}{2} \text{Tr}(d\mathcal{V}^{-1} \wedge \star d\mathcal{V}) \right], \quad (8.117)$$

where \hat{R} is the Ricci scalar in $D+1$ dimensions and \star denotes the corresponding Hodge star-operator. Note that the scalar potential for this theory vanishes and hence the scalar fields $\Phi(\hat{x})$ contained in $\mathcal{V}(\hat{x})$ are massless.

We now want to reduce this theory on a circle, over which \mathcal{V} is non-trivially fibred. We therefore split the $(D + 1)$ -dimensional coordinates as $\hat{x}^I \rightarrow (x^\mu, y)$ with $\mu = 0, \dots, D - 1$ and identify $y \sim y + 2\pi$ which gives rise to a circle. For $\mathcal{V}(\hat{x})$ we consider the ansatz

$$\mathcal{V}(\hat{x}) = \mathbf{V}(x) \exp\left[\frac{\mathbf{m}y}{2\pi}\right], \quad (8.118)$$

where $\mathbf{m} = \log M$ is the Lie-algebra element corresponding to a monodromy matrix $M \in G$. This ensures that the theory is well-defined under $y \rightarrow y + 2\pi$, since $\mathcal{V}(x, y + 2\pi) = \mathcal{V}(x, y)M$ is a symmetry of the $(D + 1)$ -dimensional action. We can then perform a dimensional reduction of (8.117) on the circle: the (y, y) -component of the $(D + 1)$ -dimensional metric becomes a scalar field $\phi(x)$ in the D -dimensional theory, and the off-diagonal (x, y) -components of the metric give rise to a D -dimensional gauge field A . After going to Einstein frame, we arrive at the following D -dimensional theory

$$\begin{aligned} \mathcal{S} = \frac{1}{2\kappa^2} \int \left[R \star 1 - \frac{1}{2} d\phi \wedge \star d\phi - e^{-\gamma\phi} F \wedge \star F \right. \\ \left. + \frac{1}{2} \text{Tr}(DV^{-1} \wedge \star DV) - V \star 1 \right], \end{aligned} \quad (8.119)$$

where $\kappa^2 = \hat{\kappa}^2/2\pi$ is the D -dimensional coupling constant, $F = dA$ denotes the field strength of the gauge field A , γ is a positive constant satisfying $\gamma^2 = 2\frac{D-1}{D-2}$ and the gauge-covariant derivative of \mathbf{V} reads $D\mathbf{V} = d\mathbf{V} + A\mathbf{V}\frac{\mathbf{m}}{2\pi}$. The scalar potential is non-zero and takes the form

$$V = \frac{1}{8\pi^2} e^{\gamma\phi} \text{Tr}(\mathbf{m}^2). \quad (8.120)$$

We thus see that in D dimensions a potential V is generated by the Lie-algebra element \mathbf{m} corresponding to the monodromy M . The ansatz (8.118) therefore gives rise to a non-trivial potential [127].

General idea II

For our subsequent discussion we are interested in a slightly different setting. In particular, we want to consider a kinetic term in the $(D + 1)$ -dimensional theory given by

$$\hat{\mathcal{S}} \supset \frac{1}{2\hat{\kappa}^2} \int \frac{1}{2} \text{Tr}(d\mathcal{H}^{-1} \wedge \star d\mathcal{H}), \quad \mathcal{H} = \mathcal{V}^T \eta \mathcal{V}, \quad (8.121)$$

where \mathcal{H} is a non-degenerate real symmetric matrix. In this ansatz the matrix η is a constant metric invariant under the local K -transformations specified above.

Under global transformations $g \in G$ the field \mathcal{H} transforms as $\mathcal{H} \rightarrow g^T \mathcal{H} g$, under which (8.121) is invariant. Upon dimensional reduction with the ansatz (8.118) for \mathcal{V} , the D -dimensional action contains in addition to the first line in (8.119) the terms

$$\mathcal{S} \supset \frac{1}{2\kappa^2} \int \left[\text{Tr} \left(DV^{-1} \wedge \star DV - (V^T \eta V)^{-1} DV^T \eta \wedge \star DV \right) - V \star 1 \right], \quad (8.122)$$

where again $DV = dV + AV \frac{\mathbf{m}}{2\pi}$ and where the scalar potential V is given by [129]

$$V = \frac{1}{4\pi^2} e^{\gamma\phi} \text{Tr} \left[\mathbf{m}^2 + (V^T \eta V)^{-1} \mathbf{m}^T V^T \eta V \mathbf{m} \right]. \quad (8.123)$$

Note that this potential depends on the scalar fields $\Phi(x)$ implicitly via the reduced vielbein matrix $V(x)$, and that V will in general generate a mass-term for these scalars.

Let us now study the properties of this potential in some more detail. First, we note that we can rewrite the scalar potential in the following way

$$V = \frac{1}{8\pi^2} e^{\gamma\phi} \text{Tr} \left[(\tilde{\mathbf{m}} + \eta^{-1} \tilde{\mathbf{m}}^T \eta)^2 \right], \quad \tilde{\mathbf{m}} = V \mathbf{m} V^{-1}, \quad (8.124)$$

in which $\tilde{\mathbf{m}}$ depends on the moduli fields $\Phi(x)$. Since above $\mathcal{V}(\hat{x})$ was assumed to be real, the potential has an absolute minimum $V = 0$ which is reached either for $\phi \rightarrow -\infty$ or for [129]

$$\eta \tilde{\mathbf{m}} + \tilde{\mathbf{m}}^T \eta = 0. \quad (8.125)$$

The situation described by (8.125) is more interesting as it fixes (some of) the moduli fields $\Phi(x)$. From the minimum-condition (8.125) we see that $r = \eta \tilde{\mathbf{m}}_0$ is a generator of rotations since it satisfies $r^T = -r$, where the subscript indicates that we are at the minimum of the potential. We can then determine from $\mathbf{m} = V_0^{-1} \eta^{-1} r V_0$ the monodromy matrix $M = V_0^{-1} \exp(\eta^{-1} r) V_0$, and we can show that in the minimum the matrix \mathcal{H} in (8.121) is given by $\mathcal{H}_0 = V_0^T \eta V_0$. This implies now that at the minimum of the scalar potential, \mathcal{H}_0 is invariant under the monodromy group generated by \mathbf{m} , that is

$$M^T \mathcal{H}_0 M = \mathcal{H}_0, \quad (8.126)$$

and hence such a critical point of the potential is a fixed point under the monodromy group [129]. We finally remark the following:

- The minimum-condition (8.125) can also be expressed in terms of the full matrix \mathcal{H} and the un-dressed Lie-algebra element \mathbf{m} as

$$\mathcal{H} \mathbf{m} + \mathbf{m}^T \mathcal{H} = 0. \quad (8.127)$$

In fact, the kinetic term (8.122) as well as the scalar potential (8.123) can be formulated entirely in terms of $\mathcal{H}(\hat{x}) = \exp[\mathbf{m}^T y / 2\pi] H(x) \exp[\mathbf{m} y / 2\pi]$.

- For complex Lie-algebra elements \mathbf{m} , one has to use $\mathcal{H} = \mathcal{V}^\dagger \eta \mathcal{V}$ instead of the expression given in (8.121). The minimum condition (8.127) then for instance becomes $\mathcal{H} \mathbf{m} + \mathbf{m}^\dagger \mathcal{H} = 0$.

\mathbb{T}^2 -fibrations

Let us now connect our present analysis to our discussion in section 6. In particular, we want to describe the effective theory obtained by compactifying string theory on \mathbb{T}^2 -fibrations over a circle. We do this in two steps:

1. First, we perform a Kaluza-Klein reduction of string theory on a two-torus from $D + 3$ to $D + 1$ dimensions.
2. In a second step we perform a Scherk-Schwarz reduction of the $(D + 1)$ -dimensional theory on a circle from $D + 1$ to D dimensions.

Let us therefore recall from equation (6.22) that the metric of a two-torus and the Kalb-Ramond B -field can be parametrised in terms of two complex scalar fields in the following way

$$G_{\mathbf{ab}} = \alpha' \frac{\rho_2}{\tau_2} \begin{pmatrix} \tau_1^2 + \tau_2^2 & \tau_1 \\ \tau_1 & 1 \end{pmatrix}, \quad B_{\mathbf{ab}} = \alpha' \begin{pmatrix} 0 & +\rho_1 \\ -\rho_1 & 0 \end{pmatrix}, \quad (8.128)$$

where $\mathbf{a}, \mathbf{b} = 1, 2$, $\tau = \tau_1 + i\tau_2$ is the complex-structure modulus and $\rho = \rho_1 + i\rho_2$ denotes the complexified Kähler modulus. Now, when compactifying a $(D + 3)$ -dimensional theory on a two-torus with metric and B -field (8.128), we obtain a $(D + 1)$ -dimensional theory which contains the kinetic terms of the moduli as

$$\hat{\mathcal{S}}_{\mathbb{T}^2} \supset \frac{1}{2\hat{\kappa}^2} \int \left[\frac{2}{\tau_2^2} d\tau \wedge \star d\bar{\tau} + \frac{2}{\rho_2^2} d\rho \wedge \star d\bar{\rho} \right]. \quad (8.129)$$

Using then the generalised metric \mathcal{H} defined in (2.27), we can bring (8.129) into the form

$$\hat{\mathcal{S}}_{\mathbb{T}^2} \supset \frac{1}{2\hat{\kappa}^2} \int \frac{1}{2} \text{Tr} (d\mathcal{H}^{-1} \wedge \star d\mathcal{H}), \quad (8.130)$$

which agrees precisely with the general expression shown in equation (8.121). Next, we perform a Scherk-Schwarz compactification of this $(D + 1)$ -dimensional theory on a circle to D dimensions. To do so, we note that (8.130) is in general invariant under global $GL(2D, \mathbb{R})$ transformations acting on \mathcal{H} . However, as we discussed in section 2.3, in string theory this is broken to $O(D, D, \mathbb{Z})$. Following the Scherk-Schwarz procedure discussed above, we now choose a vielbein \mathcal{V} as in (8.118) with

for instance

$$V = \sqrt{\frac{\rho_2}{\tau_2}} \left(\begin{array}{cc|cc} \tau_2 & 0 & 0 & 0 \\ \tau_1 & 1 & 0 & 0 \\ \hline -\frac{\rho_1}{\rho_2} \tau_1 & -\frac{\rho_1}{\rho_2} & \frac{1}{\rho_2} & -\frac{\tau_1}{\rho_2} \\ +\frac{\rho_1}{\rho_2} \tau_2 & 0 & 0 & +\frac{\tau_2}{\rho_2} \end{array} \right), \quad \mathfrak{m} \in \mathfrak{so}(D, D), \quad (8.131)$$

and η is taken as the four-by-four identity matrix. The potential in the D -dimensional theory has been determined in (8.124), and it has a global minimum if the twisting \mathfrak{m} satisfies (8.125) – or in terms of \mathcal{H} – (8.127).

Examples

Let us now discuss some examples for Scherk-Schwarz reductions of \mathbb{T}^2 -fibrations over the circle. We recall from equation (6.18) that the corresponding $O(2, 2, \mathbb{Z})$ duality group splits into two $SL(2, \mathbb{Z})$ factors acting on τ and ρ and two \mathbb{Z}_2 factors. Since the latter are not connected to the identity, we are not able to describe them in the present approach. However, for $SL(2, \mathbb{Z})$ this is possible, and the corresponding monodromies M can be of parabolic, elliptic or hyperbolic type [129, 130] (see also our discussion on page 83). We discuss these situations in turn:

- First, for parabolic monodromies in τ or in ρ the condition (8.125) cannot be satisfied and hence the potential has no minimum [129]. Let us illustrate this result with the examples of the three-torus with H -flux, the twisted three-torus and the three-torus T-fold discussed in section (6.1). We note that the Lie algebra elements \mathfrak{m} corresponding to (6.4), (6.7) and (6.10) are given by

$$\mathfrak{m}_B = \left(\begin{array}{cc|cc} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ \hline 0 & +h & 0 & 0 \\ -h & 0 & 0 & 0 \end{array} \right), \quad \mathfrak{m}_A = \left(\begin{array}{cc|cc} 0 & +h & 0 & 0 \\ 0 & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & 0 \\ 0 & 0 & -h & 0 \end{array} \right), \quad (8.132)$$

$$\mathfrak{m}_\beta = \left(\begin{array}{cc|cc} 0 & 0 & 0 & +h \\ 0 & 0 & -h & 0 \\ \hline 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{array} \right),$$

respectively. Each of these elements satisfies the minimum condition (8.127) (with \mathcal{H} computed from (8.128) according to (2.27)) only in some degeneration limit where for instance $\rho_2 \rightarrow \infty$ or $|\tau|^2 \rightarrow 0$. For finite values of the

moduli the Scherk-Schwarz potential (8.124) has no minimum. This shows that the family of three-tori with H -flux, geometric flux and Q -flux provides only toy-models.

- For elliptic monodromies we mentioned on page 84 that these are of finite orders six, four and three. In all of these cases the minimum-condition (8.127) has a finite solution, and hence the scalar potential has a minimum [129]. An overview on the Lie-algebra generators \mathfrak{m} together with stabilised values of τ and ρ for some combinations of monodromies can be found in table 6.
- For hyperbolic monodromies the analysis is rather involved. However, one can show that the scalar potential (8.124) does not have a minimum specified by (8.127) [129]. Simple examples for hyperbolic monodromies in τ are of the form (with $N \in \mathbb{Z}$ and $|N| > 2$)

$$\tau \rightarrow N - \frac{1}{\tau}, \quad M = \left(\begin{array}{cc|cc} N & +1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & +1 \\ 0 & 0 & -1 & N \end{array} \right). \quad (8.133)$$

Asymmetric orbifolds

As we have argued above, if the scalar potential (8.124) has a minimum characterised by (8.127), then at the minimum the monodromy M leaves the generalised metric invariant, that is

$$M^{-T} \mathcal{H}_0 M^{-1} = \mathcal{H}_0. \quad (8.134)$$

In other words, at this fixed point the background specified by a metric and B -field is invariant under M . However, this does not imply that the action of the monodromy group on the fibre-coordinates X^a is trivial. More concretely, as explained in more detail in [129], if a discrete symmetry is gauged – which is the case in our situation – one should think of the resulting space as an orbifold construction.²³ To illustrate this point let us recall from section 2.3 that under transformations of the form (2.31) the left- and right-moving coordinates in the lattice basis transform as (2.39). In particular, we have for

$$M = \begin{pmatrix} A & B \\ C & D \end{pmatrix}, \quad \Omega_{\pm} = A \pm \frac{1}{\alpha'} B (g \pm b), \quad (8.135)$$

²³ Orbifolds are manifolds subject to identifications under a discrete symmetry group. For instance, the circle S^1 can be seen as the freely-acting orbifold $S^1 = \mathbb{R}/\mathbb{Z}$ where \mathbb{Z} denotes the identification of points $x \sim x + 2\pi$. However, more general orbifold groups are possible, which do not need to be freely acting. For more information on orbifold constructions in string theory see for instance the original papers [12, 13] or for instance [277].

τ -monodromy	ρ -monodromy	generator \mathbf{m}	minimum of potential
elliptic 4	\emptyset	$\mathbf{m} = \frac{\pi}{2} \begin{pmatrix} 0 & +1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & +1 \\ 0 & 0 & -1 & 0 \end{pmatrix}$	$\tau = +i$
elliptic 6	\emptyset	$\mathbf{m} = \frac{\pi}{3\sqrt{3}} \begin{pmatrix} +1 & -2 & 0 & 0 \\ +2 & -1 & 0 & 0 \\ 0 & 0 & -1 & -2 \\ 0 & 0 & +2 & +1 \end{pmatrix}$	$\tau = \frac{-1+i\sqrt{3}}{2}$
\emptyset	elliptic 4	$\mathbf{m} = \frac{\pi}{2} \begin{pmatrix} 0 & 0 & 0 & +1 \\ 0 & 0 & -1 & 0 \\ 0 & +1 & 0 & 0 \\ -1 & 0 & 0 & 0 \end{pmatrix}$	$\rho = +i$
\emptyset	elliptic 6	$\mathbf{m} = \frac{2\pi}{3\sqrt{3}} \begin{pmatrix} -1 & 0 & 0 & +2 \\ 0 & -1 & -2 & 0 \\ 0 & +2 & +1 & 0 \\ -2 & 0 & 0 & +1 \end{pmatrix}$	$\rho = \frac{-1+i\sqrt{3}}{2}$
elliptic 4	elliptic 4	$\mathbf{m} = \frac{i\pi}{2} \begin{pmatrix} +1 & 0 & +1 & 0 \\ 0 & +1 & 0 & +1 \\ +1 & 0 & +1 & 0 \\ 0 & +1 & 0 & +1 \end{pmatrix}$	$\tau = +i$ $\rho = +i$
elliptic 4	elliptic 6	$\mathbf{m} = \frac{\pi}{6} \begin{pmatrix} +\frac{2}{\sqrt{3}} & -3 & 0 & -\frac{4}{\sqrt{3}} \\ 3 & +\frac{2}{\sqrt{3}} & +\frac{4}{\sqrt{3}} & 0 \\ 0 & -\frac{4}{\sqrt{3}} & -\frac{2}{\sqrt{3}} & -3 \\ +\frac{4}{\sqrt{3}} & 0 & 3 & -\frac{2}{\sqrt{3}} \end{pmatrix}$	$\tau = +i$ $\rho = \frac{-1+i\sqrt{3}}{2}$
elliptic 6	elliptic 4	$\mathbf{m} = \frac{\pi}{6} \begin{pmatrix} +\frac{2}{\sqrt{3}} & -\frac{4}{\sqrt{3}} & 0 & +3 \\ +\frac{4}{\sqrt{3}} & -\frac{2}{\sqrt{3}} & -3 & 0 \\ 0 & 3 & -\frac{2}{\sqrt{3}} & -\frac{4}{\sqrt{3}} \\ -3 & 0 & +\frac{4}{\sqrt{3}} & +\frac{2}{\sqrt{3}} \end{pmatrix}$	$\tau = \frac{-1+i\sqrt{3}}{2}$ $\rho = +i$

Table 6: Overview of Lie-algebra generators \mathbf{m} and values of τ and ρ satisfying the corresponding minimum condition (8.127) for some combinations of elliptic monodromies. Note that in the case of elliptic monodromies of orders four in τ and σ the Lie-algebra element \mathbf{m} is complex valued, and hence the minimum condition reads $\mathcal{H}\mathbf{m} + \mathbf{m}^\dagger\mathcal{H} = 0$.

that the coordinates transform as (cf. equation (2.39))

$$X_R^i \rightarrow (\Omega_-)^i_j X_R^j, \quad X_L^i \rightarrow (\Omega_+)^i_j X_L^j. \quad (8.136)$$

Now, for the sub-block B in M non-zero, we see that the left- and right-moving coordinates transform in general differently. The corresponding orbifold is therefore an asymmetric orbifold, in which the group acts differently in the left- and right-moving sectors.

As an example, let us consider the situation of elliptic monodromies of order four and six in τ and ρ , respectively (cf. table 6). The corresponding monodromy element $M \in G$ takes the form

$$M = \left(\begin{array}{cc|cc} 0 & +1 & +1 & 0 \\ -1 & 0 & 0 & +1 \\ \hline +1 & 0 & 0 & 0 \\ 0 & +1 & 0 & 0 \end{array} \right), \quad (8.137)$$

and at the minimum $(\tau_0, \rho_0) = (+i, \frac{-1+i\sqrt{3}}{2})$ the left- and right-moving coordinates (in the lattice basis) transform under M as

$$\begin{aligned} X_L^a &\rightarrow \begin{pmatrix} \cos \phi_L & + \sin \phi_L \\ - \sin \phi_L & \cos \phi_L \end{pmatrix}_b^a X_L^b, & \phi_L &= \frac{\pi}{6}, \\ X_R^a &\rightarrow \begin{pmatrix} \cos \phi_R & + \sin \phi_R \\ - \sin \phi_R & \cos \phi_R \end{pmatrix}_b^a X_R^b, & \phi_R &= \frac{5\pi}{6}, \end{aligned} \quad (8.138)$$

with $\mathbf{a}, \mathbf{b} = 1, 2$ labelling the coordinates of the \mathbb{T}^2 . Note that this action is of order twelve, and that the action on the left- and right-moving sector is indeed different.

Remarks

We close this section on generalised Scherk-Schwarz reductions with the following remarks:

- Our discussion was focused on the bosonic sector of the theory. When considering superstring theory, space-time fermions have to be included and in this case Scherk-Schwarz reductions generically break supersymmetry [126]. For a discussion of this result in the present context see for instance [129, 278].
- The Scherk-Schwarz compactifications discussed above lead to theories in which some of the symmetries are gauged. This can be seen for instance from

comparing the kinetic terms of the scalars in (8.122) with gauge-covariant derivative

$$DV = dV + AV \frac{\mathbf{m}}{2\pi}, \quad (8.139)$$

with the general expression (8.26) of gauged supergravity theories. The gauging parameter is related to the matrix \mathbf{m} , and in regard to our discussion in sections 8.5 and 8.6 we note that \mathbf{m} encodes the geometric and non-geometric fluxes of the higher-dimensional theory [279].

For Scherk-Schwarz reductions on n -dimensional tori \mathbb{T}^n from $D + n$ to D dimensions, the $(D + n)$ -dimensional metric gives rise to n gauge fields in D dimensions. In this case there are n monodromy generators \mathbf{m} , which in general are non-commuting.

- A discussion of the relation between asymmetric orbifolds at the fixed point of a monodromy and non-geometric backgrounds from a world-sheet perspective can be found in [280, 281] as well as in [282–284], and we discuss this point in some more detail in section 10.2.

8.8 Validity of solutions

In the sections above we have argued that non-geometric fluxes are a natural part of string theory. In particular, at the level of the *theory* we have seen that

1. non-geometric fluxes naturally combine into a twisted differential and can be described using the framework of $SU(3) \times SU(3)$ structures.
2. We have also illustrated how non-geometric backgrounds can be incorporated into generalised Scherk-Schwarz reductions, in which monodromies around compact directions can contain T-duality transformations.

In this section we now want to discuss *solutions* to theories with non-geometric features, in particular their validity from an effective-field-theory point of view.²⁴

Flux compactifications I – perturbing the background

One way to approach compactifications of string theory on Calabi-Yau manifolds with fluxes, is to start from a Calabi-Yau background without fluxes. Such configurations solve the string-equations of motion (3.31) and have a vanishing scalar potential. In a second step one perturbs these backgrounds by including fluxes,

²⁴We consider a *theory* to give rise to a set of equations of motion, and *solutions* to a theory are solutions to the equations of motion.

which in turn generates a potential. If these perturbations are small one can expect that minima of the potential correspond to small deformations of the Calabi-Yau background, which include the back-reaction of the fluxes on the geometry.

The quantity which encodes the perturbation generated by the fluxes is the flux density. Indeed, for the case of H -flux we see that the β -functionals (3.31) contain for instance a term $H_{ijk}G^{ii'}G^{jj'}G^{kk'}H_{i'j'k'}$ which is the flux-density squared. Let us illustrate this point for the example of the three-torus introduced in section 5. For a rectangular three-torus with radii R_1, R_2, R_3 the densities of the H -flux H_{123} , geometric flux f_{23} ¹, Q -flux Q_3 ¹² and R -flux R^{123} read, respectively,

$$\begin{aligned}
H\text{-flux density:} & \quad \frac{h}{2\pi} \frac{\alpha'}{R_1 R_2 R_3}, \\
f\text{-flux density:} & \quad \frac{f}{2\pi} \frac{R_1}{R_2 R_3}, \\
Q\text{-flux density:} & \quad \frac{q}{2\pi} \frac{R_1 R_2}{\alpha' R_3}, \\
R\text{-flux density:} & \quad \frac{r}{2\pi} \frac{R_1 R_2 R_3}{\alpha'^2},
\end{aligned} \tag{8.140}$$

where $h, f, q, r \in \mathbb{Z}$. From (8.140) we see that in certain parameter regimes of the radii the flux-densities can be made small, however, not all densities can be made small at the same time. Let us consider two cases:

- In the scaling limit $R_1 \sim \sqrt{\alpha'}L$, $R_2 \sim \sqrt{\alpha'}L$, $R_3 \sim \sqrt{\alpha'}L^3$ with $L \gg 1$, the densities of the H -, f - and Q -flux become small whereas the R -flux density becomes large. The requirement of small perturbations can therefore be realised only for the first three fluxes but not for the R -flux. On the other hand, we note that due to the Bianchi identities (7.106) – in particular $H_{ijk}R^{ijk} = 0$ – a simultaneous presence of H - and R -flux on the three-torus is excluded.
- As a second case let us also consider the scaling limit $R_1 \sim \sqrt{\alpha'}/L^3$, $R_2 \sim \sqrt{\alpha'}L$, $R_3 \sim \sqrt{\alpha'}L$ with $L \gg 1$. Here the f -, Q - and R -flux densities become small whereas the H -flux density becomes large. However, again the Bianchi identities for the fluxes do not allow for an H - and R -flux to be simultaneously present on a three-torus.

It is expected (but to our knowledge not investigated in detail) that this observation is a general feature: the Bianchi identities for the fluxes ensure that a scaling limit can be found in which all of the allowed flux-densities become small.

Flux compactifications II – validity of approximation

However, for backgrounds with non-geometric fluxes one generically faces the following issues:

- In string theory the length-scales of the compactification space (such as the radii of the three-torus) cannot be chosen by hand. They correspond to moduli fields which have to be stabilised dynamically, and one has to ensure that in a specific model the stabilised values of these fields indeed lead to small flux-densities.
- Furthermore, even though the flux-densities may be made small, in the presence of non-geometric fluxes typically some of the length-scales of the compactification space become small. For instance, in the second example above we have $R_1 \ll \sqrt{\alpha'}$. This implies that in general the supergravity approximation breaks down and that string-theoretical effects have to be taken into account. Hence, naively such solutions are not trustworthy which is a generic problem of non-geometric backgrounds.

These issues have to be addressed in order for a particular solution to be reliable. We want to point out however that these are questions concerning the solutions of the theory – at the level of the theory we have argued that non-geometric fluxes are a natural part of string theory.

Scherk-Schwarz reductions

For the Scherk-Schwarz reductions discussed in section 8.7 the situation is slightly different. To illustrate this point, let us first recall that for ordinary Kaluza-Klein reductions of a scalar field $\phi(x, y)$ on a circle of radius R , one expands $\phi(x, y)$ in eigenfunctions of the Laplace operator on the circle as

$$\phi(x, y) = \sum_{n \in \mathbb{Z}} \phi_n(x) e^{i \frac{ny}{R}}. \quad (8.141)$$

Here x^μ denotes D -dimensional coordinates and $y \sim y + 2\pi R$ parametrises the circle. The mass of the Kaluza-Klein modes $\phi_n(x)$ in D dimensions can be determined from the Klein-Gordon equation as $m_n^2 = (n/R)^2$ (see for instance [18] for a textbook treatment). In string theory, we are now interested in the following limits:

1. We want to decouple the massive Kaluza-Klein modes $\phi_n(x)$ with $n \neq 0$ and make them heavier than some observable energy-scale $m_{\text{obs}} \sim 1/L_{\text{obs}}$, where L_{obs} is some minimal observable length-scale. This implies that $R \ll L_{\text{obs}}$ and hence the compact dimension is not observed in experiments.

2. However, in the supergravity approximation employed for Kaluza-Klein reductions of string theory, we also want to decouple higher string-excitations. We therefore require in addition that $\sqrt{\alpha'} \ll R$.

Let us now come to our discussion of string-theory compactifications on \mathbb{T}^2 -fibrations over a circle on page 166. We have split this procedure into two steps: 1) we performed an ordinary Kaluza-Klein compactification on \mathbb{T}^2 and kept only the massless modes, and 2) we performed a Scherk-Schwarz reduction of these massless modes on a circle. When determining the minima of the resulting scalar potential (for elliptic monodromies), we observed that they correspond to fixed points of the monodromy group. More concretely,

- from for instance table 6 we see that typical values for the stabilised Kähler and complex-structure moduli of the \mathbb{T}^2 satisfy $|\tau| \sim \mathcal{O}(1)$ and $|\rho| \sim \mathcal{O}(1)$. This means that the length-scales $R_{\mathbb{T}^2}$ of the \mathbb{T}^2 are of order of the string length, i.e. $R_{\mathbb{T}^2} \sim \sqrt{\alpha'}$. Such values however violate our second requirement from above $\sqrt{\alpha'} \ll R_{\mathbb{T}^2}$, and therefore string-effects have to be taken into account in order for these solutions to be reliable.
- On the other hand, at the minimum of the potential the theory has an orbifold description. For such orbifolds of \mathbb{T}^2 a CFT description exists [129], which includes all higher string-modes (at the perturbative level). At the minimum we therefore have a string-theoretical description and can trust this solution.

These examples of non-geometric Scherk-Schwarz reductions indicate, that finding reliable non-geometric solutions is rather a technical problem of controlling string-theory corrections and not a conceptual problem.

8.9 Applications

We have seen that when compactifying string theory on backgrounds with (non-geometric) fluxes, a potential for the moduli fields is generated in the lower-dimensional theory. This potential provides mechanisms to give masses to the moduli, to realise inflation and to construct solutions with a positive cosmological constant.

Moduli stabilisation

For compactifications of string theory from ten to say four dimensions, the degrees of freedom of the metric, dilaton and p -form potentials along the compact directions appear as scalar and vector fields in the four-dimensional theory. The massive excitations can be ignored below a certain cut-off scale (typically

the m_{obs} mentioned above), however, the massless excitations contribute to the lower-dimensional spectrum. These massless scalar fields are called moduli and parametrise deformations of the compactification background. For the example of Calabi-Yau compactifications discussed in section 8.4, the massless fields have been summarised in table 4.

From a phenomenological point of view, the presence of massless particles during the early universe can modify the abundances of hydrogen and helium and thereby destroy the very successful predictions of big bang nucleosynthesis. Massless scalar fields (apart from the Higgs field) furthermore give rise to fifth forces, which are highly constrained by experiment. Moduli fields should therefore acquire a mass, which is known as moduli stabilisation (for reviews see for instance [220, 222]). Moduli can be stabilised by generating a scalar potential for them and – as we have seen in the above sections – fluxes achieve this requirement. Let us briefly discuss moduli stabilisation for type IIB and type IIA orientifold compactifications:

- As we explained in section 8.6, for type IIB orientifolds with O3-/O7-planes the superpotential (8.105) contains couplings between the H -flux and the axio-dilaton τ , between the geometric F -flux and the moduli $G^{\hat{A}}$ and between the non-geometric Q -flux and the Kähler moduli T_A . If all fluxes compatible with the Bianchi identities are non-vanishing, generically all moduli fields appear in the scalar potential and will receive a mass in the four-dimensional theory.

Let us emphasise that this is an interesting result: for vanishing Q -flux the Kähler moduli do not appear in the superpotential W and therefore remain massless at the perturbative level. On the other hand, non-perturbative corrections to W coming from D-brane instantons or gaugino condensates can generate a dependence of the superpotential on the Kähler moduli, which leads to the KKLT [285] or large-volume [286] scenarios. In these approaches the Kähler moduli are stabilised through non-perturbative effects, whereas the Q -flux allows to stabilise Kähler moduli perturbatively.

- For type IIB orientifolds with O5-/O7-planes the situation is slightly different [234]. The four-dimensional complex scalar fields take a different form as compared to type IIB with O3-/O7-planes, but in the superpotential the Kähler moduli couple to the geometric F -flux, the analogues of the $G^{\hat{A}}$ -moduli couple to the non-geometric Q -flux and the axio-dilaton couples to the non-geometric R -flux [262].
- For type IIA orientifolds the fixed loci of the orientifold projection are O6-planes. In this setting the NS-NS fluxes couple to the complex-structure

moduli, as expected from mirror symmetry. For more details we refer the reader to [234].

Let us now give an overview of string-theory constructions with non-geometric fluxes, where moduli have been stabilised.

- On toroidal compactification backgrounds moduli stabilisation using non-geometric fluxes has been studied in [121, 287, 262, 123]. In particular, systematic studies of allowed flux combinations and resulting solutions can be found in [273, 264, 288, 289, 265, 290, 291].
- On more general Calabi-Yau or $SU(3)$ -structure backgrounds moduli stabilisation using non-geometric fluxes has been studied for instance in [261, 292, 266]. In [261] it was argued that non-geometric flux-vacua in a parametrically-controlled regime can be constructed.

Inflation

There are strong experimental indications that our universe underwent a period of inflation in which it expanded rapidly (see for instance [293] for a review). In order to realise inflation a non-trivial potential for a scalar field has to be generated, which satisfies certain slow-roll conditions. We do not want to go into further details here, but only mention that background fluxes can give rise to such potentials. Using non-geometric fluxes, this has been studied for instance in [294–297].

De Sitter vacua

In [298] a no-go theorem has been formulated which – under certain conditions – forbids vacua with a positive cosmological constant. In particular, string theory with usual geometric fluxes does not allow for de Sitter vacua. However, non-geometric fluxes violate the assumptions of [298] and are therefore believed to circumvent the no-go theorem.

Explicit constructions of de Sitter vacua using non-geometric fluxes can be found for instance in the papers [299, 288, 289, 300, 290, 301–303, 295, 304, 297, 305]. However, as we have mentioned in section 8.8, typically the validity of such solutions is difficult to show. This may be in accordance with the very recent de Sitter conjectures [306, 307], which exclude meta-stable de Sitter vacua in any theory of quantum gravity.

8.10 Summary

Let us close our discussion of type II string-theory compactifications with a brief summary of the main points discussed in this section:

- In section 8.2 we have reviewed some basic results of $\mathcal{N} = 2$ and $\mathcal{N} = 1$ supergravity theories in four dimensions. We found that these theories are characterised by only a few quantities.

For $\mathcal{N} = 2$ theories these are a Kähler potential \mathcal{K} (often with a corresponding pre-potential \mathcal{F}) which describes vector-multiplets, and a quaternionic-Kähler metric h_{uv} describing hyper-multiplets. For Calabi-Yau compactifications the latter contains a Kähler sub-manifold, which is described again by a Kähler potential. A scalar potential is generated by moment maps \mathcal{P} , which correspond to gaugings of vector- and hyper-multiplet isometries.

For the $\mathcal{N} = 1$ theory the vector-multiplets are characterised in terms of a holomorphic gauge kinetic function f , and the chiral multiplets are described by a Kähler potential \mathcal{K} . A scalar potential is generated by a holomorphic superpotential W as well as by gaugings of isometries.

- In section 8.4 we then compactified type IIB string theory on a Calabi-Yau three-fold (without fluxes). The resulting theory is a $\mathcal{N} = 2$ supergravity in four dimensions. The relevant supergravity quantities of this theory, such as the Kähler potential and the moment maps, can be expressed using the framework of generalised geometry. In particular, two generalised spinors Φ^\pm determine two Kähler potentials \mathcal{K}^\pm and the moment maps \mathcal{P} .
- In section 8.5 we then discussed how non-trivial $O(D, D)$ transformations can generate geometric as well as geometric fluxes. The effect of these transformations is encoded in a so-called twisted differential \mathcal{D} , which contains the various fluxes. These fluxes give rise to gaugings in the $\mathcal{N} = 2$ theory.

We furthermore mentioned mirror symmetry, which is a symmetry between type IIB and type IIA compactifications that exchanges geometric and non-geometric flux-components. This shows that non-geometric fluxes are an integral part of flux compactifications.

- In section 8.6 we discussed the orientifold projection of type IIB compactifications from $\mathcal{N} = 2$ to $\mathcal{N} = 1$ theories. Here, the gaugings of the $\mathcal{N} = 2$ theory are split into an F-term contribution contained in the generalisation of the Gukov-Vafa-Witten superpotential, and a D-term potential.
- In section 8.7 we studied generalised Scherk-Schwarz reductions. This analysis connects to our discussion of torus fibrations in section 6, and we have

described how the scalar potential of such compactifications can be obtained. The properties of the minimum have been analysed and we observed that, if the minimum exists, it is in general described by asymmetric orbifold constructions.

- In section 8.8 we have discussed the validity of non-geometric solutions. We have recalled that non-geometric fluxes are a natural part of string theory, however, non-geometric solutions (i.e. minima of the potential) typically violate the supergravity approximation. They are therefore naively not reliable. On the other hand, for certain non-geometric Scherk-Schwarz reductions the minimum of the potential has a CFT description and such solutions can therefore be trusted.
- In section 8.9 we gave an overview on applications of non-geometric fluxes to moduli stabilisation, realising inflation and constructing de Sitter vacua in string theory.

9 Doubled geometry

In this section we give an introduction to doubled geometry [16, 308, 309]. In this approach to T-duality and non-geometric backgrounds, a world-sheet action invariant under the duality group $O(D, D, \mathbb{Z})$ is constructed. In section 9.1 we motivate such two-dimensional theories from the example of toroidal compactifications, and in section 9.2 we give a more general derivation following [309]. In section 9.3 we comment on a target-space approach to a doubled geometry, called double field theory [310–312].

9.1 Toroidal compactifications

We start this section by introducing doubled geometry through the example of toroidal compactifications with constant Kalb-Ramond field. We work with a world-sheet theory with flat world-sheet metric of Lorentzian signature, and we follow the original papers [16, 309] where further details can be found.

Doubled coordinates

Let us recall from page 22 that on a D -dimensional torus with constant Kalb-Ramond field the T-duality group acts as $O(D, D, \mathbb{Z})$ transformations. Using the formulas (2.39) and (2.35), for the left- and right-moving target-space coordinates X_L^i and X_R^i this means that they transform as

$$\begin{aligned} \begin{pmatrix} \tilde{X}_L \\ +\frac{1}{\alpha'}(\tilde{g} + \tilde{b})\tilde{X}_L \end{pmatrix} &= \begin{pmatrix} A & B \\ C & D \end{pmatrix} \begin{pmatrix} X_L \\ +\frac{1}{\alpha'}(g + b)X_L \end{pmatrix}, \\ \begin{pmatrix} \tilde{X}_R \\ -\frac{1}{\alpha'}(\tilde{g} - \tilde{b})\tilde{X}_R \end{pmatrix} &= \begin{pmatrix} A & B \\ C & D \end{pmatrix} \begin{pmatrix} X_R \\ -\frac{1}{\alpha'}(g - b)X_R \end{pmatrix}, \end{aligned} \tag{9.1}$$

where the $O(D, D, \mathbb{Z})$ transformation is parametrised in terms of $D \times D$ matrices A, B, C, D as in (2.32). Here and in the following matrix multiplication is understood. Next, as we explained around equation (2.55), a T-duality transformation along all D directions of the torus corresponds to a transformation parametrised by the $O(D, D, \mathbb{Z})$ matrix

$$\mathcal{O}_+ = \begin{pmatrix} 0 & \delta^{-1} \\ \delta & 0 \end{pmatrix}, \tag{9.2}$$

where for notational convenience we chose the positive sign. From (9.1) we can then infer that the fully-dualised coordinates take the form

$$\tilde{X}^i = \tilde{X}_L^i + \tilde{X}_R^i = \left[\frac{1}{\alpha'} \delta^{-1} (g + b) X_L - \frac{1}{\alpha'} \delta^{-1} (g - b) X_R \right]^i, \tag{9.3}$$

with $i = 1, \dots, D$. Motivated by this result, we define an additional set of coordinates as

$$\hat{X}_i = \frac{1}{\alpha'}(g+b)_{ij}X_L^j - \frac{1}{\alpha'}(g-b)_{ij}X_R^j, \quad (9.4)$$

which together with the original coordinates $X^i = X_L^i + X_R^i$ transform under $O(D, D, \mathbb{Z})$ in the following way (cf. equation (9.1))

$$\begin{pmatrix} \tilde{X}^i \\ \hat{X}_i \end{pmatrix} = \begin{pmatrix} A^i_j & B^{ij} \\ C_{ij} & D_i^j \end{pmatrix} \begin{pmatrix} X^j \\ \hat{X}_j \end{pmatrix}. \quad (9.5)$$

It is then convenient to introduce a set of doubled coordinates \mathbb{X}^I with $I = 1, \dots, 2D$ and their transformation under $\mathcal{O} \in O(D, D, \mathbb{Z})$ as

$$\mathbb{X}^I = \begin{pmatrix} X^i \\ \hat{X}_i \end{pmatrix} = \begin{pmatrix} X_L^i + X_R^i \\ \frac{1}{\alpha'}(g+b)_{ij}X_L^j - \frac{1}{\alpha'}(g-b)_{ij}X_R^j \end{pmatrix} \quad (9.6)$$

$$\tilde{\mathbb{X}}^I = \mathcal{O}^I_J \mathbb{X}^J. \quad (9.7)$$

The definition of the coordinates \mathbb{X}^I can also be motivated by considering the tachyon vertex operator for the closed string compactified on a torus. (For an introduction to vertex operators in two-dimensional CFTs see for instance [1].) Denoting normal ordering by $:\dots:$ and recalling the form of the left- and right-moving momenta from (2.22), we have

$$\begin{aligned} \mathcal{V} &= :\exp\left(ip_L \cdot X_L + ip_R \cdot X_R\right): \\ &= :\exp\left(\frac{1}{2}m_i[X_L + X_R]^i + \frac{1}{2}n^i\left[\frac{1}{\alpha'}(g+b)X_L - \frac{1}{\alpha'}(g-b)X_R\right]_i\right): \\ &= :\exp\left(\frac{1}{2}m_i\mathbb{X}^i + \frac{1}{2}n^i\mathbb{X}_i\right):, \end{aligned} \quad (9.8)$$

where $m_i, n^i \in \mathbb{Z}$ are the momentum and winding numbers. Note that this expression is invariant under $O(D, D, \mathbb{Z})$ transformations of the form (2.29) provided that \mathbb{X}^I transforms as in (9.7). We also mention that X^i are the coordinates conjugate to the momentum numbers m_i , while the dual coordinates \hat{X}_i are dual to the winding numbers n^i . The \hat{X}_i are therefore also called winding coordinates.

Constraint

From the definition of the doubled coordinates \mathbb{X}^I shown in (9.6) we see that X^i and \hat{X}_i contain similar information. We can make this more precise by separating

the left- and right-moving sectors through the following relations

$$\begin{aligned}\eta^{-1}\mathcal{H}\partial_+\mathbb{X} &= \partial_+\mathbb{X}, \\ \eta^{-1}\mathcal{H}\partial_-\mathbb{X} &= -\partial_-\mathbb{X},\end{aligned}\tag{9.9}$$

where matrix multiplication is understood and where η and the generalised metric \mathcal{H} were given in (2.27). We furthermore employed that the metric and B -field are constant as well as that $X_L^i \equiv X_L^i(\sigma^+)$ and $X_R^i \equiv X_R^i(\sigma^-)$ with $\sigma^\pm = \tau \pm \sigma$. Using the Hodge star-operator on a two-dimensional flat world-sheet with Lorentzian signature we have $\star d\sigma^\pm = \pm d\sigma^\pm$, which allows us to express (9.9) as

$$d\mathbb{X} = \eta^{-1}\mathcal{H} \star d\mathbb{X}.\tag{9.10}$$

Consistency of this constraint requires that $(\eta^{-1}\mathcal{H})^2 = \mathbb{1}$, which is indeed satisfied for the generalised metric \mathcal{H} . To conclude, we see that the doubled coordinates \mathbb{X}^I have to satisfy a self-duality relation.

World-sheet action

We have seen above that the doubled coordinates \mathbb{X}^I transform covariantly under the duality group $O(D, D, \mathbb{Z})$, and we now want to construct a world-sheet action which is invariant under such duality transformations. A natural guess is the following expression [16]

$$\mathcal{S} = -\frac{1}{4\pi} \int_{\Sigma} \left[\frac{1}{2} \mathcal{H}_{IJ} d\mathbb{X}^I \wedge \star d\mathbb{X}^J + \Omega_{IJ} d\mathbb{X}^I \wedge d\mathbb{X}^J \right],\tag{9.11}$$

where \mathcal{H} denotes again the generalised metric (2.27). The topological term corresponding to an anti-symmetric matrix Ω_{IJ} has been introduced for later use and does not affect the dynamics. The $2D$ components of \mathbb{X}^I appearing in (9.11) are considered to be independent fields, which are however subject to the duality condition (9.10) to be imposed on the equations of motion. The action (9.11) is then invariant under the following $O(D, D, \mathbb{Z})$ transformations

$$\mathbb{X} \rightarrow \mathcal{O}\mathbb{X}, \quad \mathcal{H} \rightarrow \mathcal{O}^{-T}\mathcal{H}\mathcal{O}^{-1}, \quad \Omega \rightarrow \mathcal{O}^{-T}\Omega\mathcal{O}^{-1},\tag{9.12}$$

which agrees with the transformation behaviour of the coordinates \mathbb{X}^I shown in (9.7) and with that of the generalised metric given in (2.31).

Turning now to the equations of motion for the doubled action (9.11), we see that they take the form

$$d(\mathcal{H}_{IJ} \star d\mathbb{X}^J) = 0.\tag{9.13}$$

When imposing the constraint (9.10) they are automatically satisfied, which means that the dynamics is governed by the constraint.

Equivalence with the standard formulation

We now want to show that the doubled world-sheet action (9.11) is equivalent to the standard formulation (2.1) [309]. We follow an approach similar to our discussion of the Buscher rules in section 3, and first expand (9.11) as follows

$$\mathcal{S} = -\frac{1}{4\pi} \int_{\Sigma} \left[\begin{aligned} & \frac{1}{2} \frac{1}{\alpha'} g_{ij} dX^i \wedge \star dX^j \\ & + \frac{1}{2} \alpha' g^{ij} (d\hat{X} - \frac{1}{\alpha'} b dX)_i \wedge \star (d\hat{X} - \frac{1}{\alpha'} b dX)_j \\ & + d\hat{X}_i \wedge dX^i \end{aligned} \right], \quad (9.14)$$

where we made a specific choice for the matrix Ω_{IJ} . This action has a number of global symmetries, for instance it is invariant under $\hat{X}_i \rightarrow \hat{X}_i + \epsilon_i$ for $\epsilon_i = \text{const.}$ In a second step we make this global symmetry local by introducing one-form world-sheet gauge fields C_i . This leads to the gauged action

$$\hat{\mathcal{S}} = -\frac{1}{4\pi} \int_{\Sigma} \left[\begin{aligned} & \frac{1}{2} \frac{1}{\alpha'} g_{ij} dX^i \wedge \star dX^j \\ & + \frac{1}{2} \alpha' g^{ij} (d\hat{X} + C - \frac{1}{\alpha'} b dX)_i \wedge \star (d\hat{X} + C - \frac{1}{\alpha'} b dX)_j \\ & + (d\hat{X} + C)_i \wedge dX^i \end{aligned} \right], \quad (9.15)$$

which, since g_{ij} and b_{ij} are assumed to be constant, is invariant under the local transformations

$$\hat{X}_i \rightarrow \hat{X}_i + \epsilon_i, \quad C_i \rightarrow C_i - d\epsilon_i, \quad (9.16)$$

for ϵ_i depending on the world-sheet coordinates. The last step for showing the equivalence with the standard formulation is to integrate out the gauge fields C_i . The solutions to the equations of motion for the latter are determined as

$$C_i = -d\hat{X}_i - \frac{1}{\alpha'} g_{ij} \star dX^j + \frac{1}{\alpha'} b_{ij} dX^j, \quad (9.17)$$

and using them in (9.15) gives the standard expression (2.1) (up to the dilaton contribution to be discussed below)

$$\check{\mathcal{S}} = -\frac{1}{4\pi\alpha'} \int_{\Sigma} \left[g_{ij} dX^i \wedge \star dX^j - b_{ij} dX^i \wedge dX^j \right]. \quad (9.18)$$

This shows that the doubled world-sheet action (9.11) is equivalent to the usual string-theory action.

Polarisation and T-duality

In the doubled world-sheet action (9.11) the $2D$ coordinates \mathbb{X}^I are considered to be independent of each other. From the identification (2.20) we know already that the ordinary coordinates X^i parametrise a D -dimensional torus \mathbb{T}^D , but using the mode expansion (2.21) we can similarly determine an identification for the dual coordinates \hat{X}_i . Together they read

$$\begin{aligned} X^i &\sim X^i + 2\pi n^i, & n^i &\in \mathbb{Z}, \\ \hat{X}_i &\sim \hat{X}_i + 2\pi m_i, & m_i &\in \mathbb{Z}, \end{aligned} \tag{9.19}$$

where n^i and m_i denote the momentum and winding numbers of the closed string. We therefore see that the doubled coordinates \mathbb{X}^I parametrise a $2D$ -dimensional doubled torus $\mathbb{T}^{2D} = \mathbb{T}^D \times \hat{\mathbb{T}}^D$.

From the doubled-geometry perspective the coordinates \mathbb{X}^i and \mathbb{X}_i are on equal footing. The identification of $\mathbb{X}^i = X^i$ with the physical coordinates and $\mathbb{X}_i = \hat{X}_i$ with the dual ones introduced in (9.6) is arbitrary, and we can equally-well take another D -dimensional subset of \mathbb{X}^I to represent the physical space. This freedom of choice is related to $O(D, D, \mathbb{Z})$ transformations, which we can make more precise by considering a projector $\Pi^I{}_J$ separating the physical from the dual coordinates as

$$X^I = \begin{pmatrix} X^i \\ \hat{X}_i \end{pmatrix} = \begin{pmatrix} \Pi^i{}_J \mathbb{X}^J \\ \hat{\Pi}_i{}_J \mathbb{X}^J \end{pmatrix} = \Pi^I{}_J \mathbb{X}^J. \tag{9.20}$$

In our conventions (9.6) the projector has been chosen as the identity. Let us also note that the projector has to be consistent with the boundary conditions (9.19), which means the entries of the matrix $\Pi^I{}_J$ have to be integers. A T-duality transformation can now be interpreted in two ways:

- It is either an active $O(D, D, \mathbb{Z})$ transformation acting on the doubled coordinates \mathbb{X}^I and the generalised metric \mathcal{H}_{IJ} . This changes the background encoded in \mathcal{H}_{IJ} while keeping the projector $\Pi^I{}_J$ fixed.
- Alternatively, a duality transformation can be seen as a passive transformation which only acts on the projector $\Pi^I{}_J$. This changes the identification of the physical subspace inside the doubled torus \mathbb{T}^{2D} . This point is illustrated in figures 11.

Remarks

Let us close this section with the following remarks on doubled geometry.

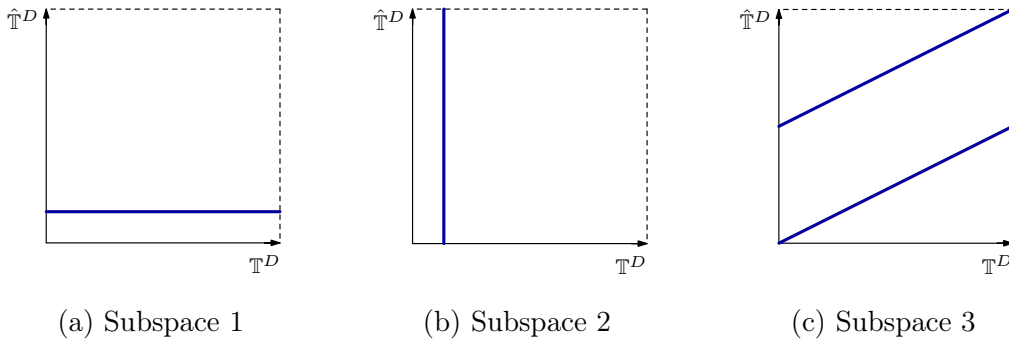

Figure 11: Illustration of how a D -dimensional physical subspace inside the $2D$ -dimensional doubled space $\mathbb{T}^D \times \hat{\mathbb{T}}^D$ can be identified. In figure 11a the projector $\Pi^I{}_J$ selects the ordinary space \mathbb{T}^D , in figure 11b the fully T-dual space $\hat{\mathbb{T}}^D$ is chosen, and in figure 11c a linear combination of both is chosen.

- We note that when imposing the constraint (9.10) directly on (9.11) the doubled action vanishes. This is familiar from theories with odd self-dual forms, such as the five-form field strength of type IIB string theory. The constraint has to be imposed on the equations of motion, and the action (9.11) therefore is only a pseudo-action.
- Determining a general D -dimensional background from the doubled geometry can also be achieved via a gauging procedure, similar as on page 182. One considers a global symmetry

$$\mathbb{X}^I \rightarrow \mathbb{X}^I + \epsilon^\alpha k_\alpha^I, \quad (9.21)$$

with $\alpha = 1, \dots, D$, where the D vectors k_α^I are required to be linearly-independent and parametrise which global symmetries are gauged. After constructing the gauged action by introducing gauge fields and integrating the gauge fields out, one obtains the action in which the directions corresponding to k_α have been removed. Note that this procedure is similar to our discussion of the Buscher rules in section 3, except that no Lagrange multipliers are introduced.

9.2 Torus fibrations

We now extend the formalism of the previous section from toroidal compactifications to non-trivial torus fibrations over some base-manifold. We mainly follow the original papers [16, 309], to which we refer for further details.

The setting

Let us start by specifying the setting we are working in. Similarly as in section 6, we consider D -dimensional torus fibrations with n -dimensional fibres \mathbb{T}^n over a $(D - n)$ -dimensional base-manifold \mathcal{B} . However, in order to be compatible with the notation in [309] we change our convention to the following

$$\begin{array}{llll} \text{coordinates on } \mathbb{T}^n & X^i & \text{with} & i = 1, \dots, n, \\ \text{coordinates on } \mathcal{B} & Y^m & \text{with} & m = 1, \dots, D - n. \end{array} \quad (9.22)$$

Choosing suitable coordinates on the torus fibre, the metric for such torus fibrations can be brought into the following form

$$G = \frac{1}{2} g_{mn} dY^m \vee dY^n + \frac{1}{2} g_{ij} P^i \vee P^j, \quad (9.23)$$

where P^i are globally-defined one-forms

$$P^i = dX^i + A^i. \quad (9.24)$$

The $A^i = A^i_m(Y) dY^m$ can be interpreted as connection one-forms, whose field strength will be denoted by $F^i = dA^i$. This data encodes the non-triviality of the fibration of the metric. Furthermore, the components g_{mn} and g_{ij} are independent of X^i . For the Kalb-Ramond field we use the same basis $\{dY^m, P^i\}$ of the cotangent-space to express B as

$$B = \frac{1}{2} b_{mn} dY^m \wedge dY^n - \alpha' P^i \wedge \hat{A}_i + \frac{1}{2} b_{ij} P^i \wedge P^j, \quad (9.25)$$

where $\hat{A}_i = \hat{A}_{im}(Y) dY^m$ are one-forms on the base-manifold \mathcal{B} . The components b_{mn} and b_{ij} are again required to be independent of X^i .

Let us then note that the Kalb-Ramond B -field does not need to be globally-defined but can have a non-vanishing field strength $H = dB \neq 0$. This implies in particular that the \hat{A}_i are in general not globally-defined, similarly as the A^i . In fact, the \hat{A}_i can be interpreted as connection one-forms on a dual bundle [16, 309] for which we denote the corresponding field strength by $\hat{F}_i = d\hat{A}_i$. This data encodes the non-triviality of the fibration related to the B -field. By introducing coordinates \hat{X}_i on a dual torus fibre $\hat{\mathbb{T}}^n$, we can then define globally-defined one-forms for a dual torus fibration as

$$\hat{P}_i = d\hat{X}_i + \hat{A}_i. \quad (9.26)$$

The doubled action

Motivated by these observations, let us consider general doubled coordinates \mathbb{X}^I on a doubled torus-fibre \mathbb{T}^{2n} together with corresponding doubled connections \mathcal{A}^I . We then introduce globally-defined one-forms as

$$\mathcal{P}^I = d\mathbb{X}^I + \mathcal{A}^I, \quad I = 1, \dots, 2n. \quad (9.27)$$

A metric on the doubled torus fibre will be denoted by \mathcal{H}_{IJ} , and we required it to be independent of \mathbb{X} as well as to satisfy $(\eta^{-1}\mathcal{H})^2 = \mathbb{1}$ with η_{IJ} the $O(n, n, \mathbb{Z})$ invariant metric. The corresponding doubled world-sheet action takes the form [309]

$$\begin{aligned} \mathcal{S} = -\frac{1}{4\pi} \int_{\Sigma} \left[\frac{1}{2} \mathcal{H}_{IJ} \mathcal{P}^I \wedge \star \mathcal{P}^J + \eta_{IJ} \mathcal{P}^I \wedge \mathcal{A}^J \right. \\ \left. + \Omega_{IJ} d\mathbb{X}^I \wedge d\mathbb{X}^J + \frac{1}{\alpha'} \mathcal{L}(Y) \right], \end{aligned} \quad (9.28)$$

where \mathcal{P}^I , \mathcal{A}^I and $d\mathbb{X}^I$ denote the pull-backs of the corresponding target-space quantities to the world-sheet Σ . We use the same symbols for the world-sheet and target-space quantities, but the distinction should be clear from the context. The term in (9.28) containing Ω_{IJ} is topological and is needed for showing the equivalence with the standard formulation. The Lagrangian for the base-manifold is given by

$$\mathcal{L}(Y) = g_{mn} dY^m \wedge \star dY^n - b_{mn} dY^m \wedge dY^n + \alpha' \Omega_{IJ} \mathcal{A}^I \wedge \mathcal{A}^J. \quad (9.29)$$

The theory is furthermore subject to the constraint

$$\mathcal{P} = \eta^{-1} \mathcal{H} \star \mathcal{P}, \quad (9.30)$$

and with $\mathcal{F}^I = d\mathcal{A}^I$ the field strength of \mathcal{A}^I the equations of motion are obtained as

$$d \star (\mathcal{H}_{IJ} \mathcal{P}^J) = \eta_{IJ} \mathcal{F}^J. \quad (9.31)$$

Note that the latter can be expressed also as $d \star (\eta^{-1} \mathcal{H} \mathcal{P} - \star \mathcal{P}) = 0$, and hence the constraint implies the equations of motion.

The action (9.28) is invariant under the following $GL(2n, \mathbb{R})$ transformations acting on the coordinates and metrics

$$\begin{aligned} \mathcal{P} &\rightarrow \mathcal{O} \mathcal{P}, & \mathcal{H} &\rightarrow \mathcal{O}^{-T} \mathcal{H} \mathcal{O}^{-1}, \\ \mathcal{A} &\rightarrow \mathcal{O} \mathcal{A}, & \Omega &\rightarrow \mathcal{O}^{-T} \Omega \mathcal{O}^{-1}, \end{aligned} \quad (9.32)$$

which is however broken to $GL(2n, \mathbb{Z})$ by the boundary conditions of the doubled torus \mathbb{T}^{2n} imposed on \mathbb{X}^I . Furthermore, the constraint (9.30) breaks $GL(2n, \mathbb{Z})$ to $O(n, n, \mathbb{Z})$ which shows that the action (9.28) is invariant under T-duality transformations.

Equivalence with the standard formulation

The equivalence with the standard formulation is again shown using a gauging procedure, similarly as in section 9.1. To do so, we first have to choose a polarisation $\Pi^I{}_J$ specifying which of the coordinates \mathbb{X}^I correspond to the physical space. In particular, we define

$$\begin{aligned} X^I &= \begin{pmatrix} X^i \\ \hat{X}_i \end{pmatrix} = \begin{pmatrix} \Pi^i{}_J \mathbb{X}^J \\ \Pi_{iJ} \mathbb{X}^J \end{pmatrix} = \Pi^I{}_J \mathbb{X}^J, \\ P^I &= \begin{pmatrix} P^i \\ \hat{P}_i \end{pmatrix} = \begin{pmatrix} \Pi^i{}_J \mathcal{P}^J \\ \Pi_{iJ} \mathcal{P}^J \end{pmatrix} = \Pi^I{}_J \mathcal{P}^J, \\ A^I &= \begin{pmatrix} A^i \\ \hat{A}_i \end{pmatrix} = \begin{pmatrix} \Pi^i{}_J \mathcal{A}^J \\ \Pi_{iJ} \mathcal{A}^J \end{pmatrix} = \Pi^I{}_J \mathcal{A}^J. \end{aligned} \quad (9.33)$$

Using this polarisation, we can identify \mathcal{H} as the generalised metric (2.27), and we take $\Omega_{IJ} = \frac{1}{2} \begin{pmatrix} 0 & -1 \\ +1 & 0 \end{pmatrix}$. The doubled action (9.28) can then be written as

$$\begin{aligned} \mathcal{S} = -\frac{1}{4\pi} \int_{\Sigma} \Big[& \frac{1}{2} \frac{1}{\alpha'} g_{ij} P^i \wedge \star P^j + \frac{1}{2} \alpha' g^{ij} (\hat{P} - \frac{1}{\alpha'} bP)_i \wedge \star (\hat{P} - \frac{1}{\alpha'} bP)_j \\ & + (P^i \wedge \hat{A}_i + \hat{P}_i \wedge A^i) + d\hat{X}_i \wedge dX^i \\ & + \frac{1}{\alpha'} \mathcal{L}(Y) \Big]. \end{aligned} \quad (9.34)$$

Since g_{ij} and b_{ij} do not depend on \mathbb{X} , this action is invariant under transformations of the form $\hat{X}_i \rightarrow \hat{X}_i + \epsilon_i$ for $\epsilon_i = \text{const}$. Similarly as on page 182, this global symmetry can be made local by introducing gauge fields C_i and replacing $\hat{P}_i \rightarrow \hat{P}_i + C_i$ as well as $d\hat{X}_i \rightarrow d\hat{X}_i + C_i$ in the action (9.34). The equations of motion for the gauge fields C_i are solved by

$$C_i = -\hat{P}_i - \frac{1}{\alpha'} g_{ij} \star P^j + \frac{1}{\alpha'} b_{ij} P^j, \quad (9.35)$$

which when inserted into the gauged action gives

$$\begin{aligned} \tilde{\mathcal{S}} = -\frac{1}{4\pi\alpha'} \int_{\Sigma} \Big[& g_{mn} dY^m \wedge dY^n + g_{ij} P^i \wedge P^j \\ & - b_{mn} dY^m \wedge dY^n + 2\alpha' P^i \wedge \hat{A}_i - b_{ij} P^i \wedge P^j \Big]. \end{aligned} \quad (9.36)$$

Comparing now with the metric and B -field shown in (9.23) and (9.25), we see that this is the ordinary string-theory action for the D -dimensional torus fibration considered in this section. We have therefore established the equivalence of the doubled action with the standard formulation [309].

Non-geometric backgrounds – T-folds

The doubled formalism provides a suitable framework to describe non-geometric backgrounds. Let us recall that according to our characterisation 3 on page 9, for non-geometric backgrounds the transition functions between local patches are duality transformations. These spaces are also called T-folds [16]. More concretely, as discussed in section 6, for torus fibrations with fibre \mathbb{T}^n the monodromy group along non-contractible loops in the base-manifold is contained in $O(n, n, \mathbb{Z})$. For geometric backgrounds the monodromy belongs to the geometric subgroup, while for non-geometric backgrounds the monodromy is a proper duality transformation.

Let us now compare the description of non-geometric backgrounds in section 6 to our present discussion:

- In the approach of section 6, we have constructed non-geometric backgrounds whose transition functions are duality transformations. In this case the action is not invariant when changing from one local patch to another.
- In the doubled formalism on the other hand, the world-sheet action is invariant under $O(n, n, \mathbb{Z}) \subset GL(2n, \mathbb{Z})$ transformations and duality transformations are diffeomorphisms for the doubled space. Thus, non-geometric backgrounds in doubled geometry actually have a geometric description, and the action is invariant when changing between local patches.

The non-geometric nature of this background arises because it is not possible to find a globally-consistent choice of a physical subspace \mathbb{T}^n inside the doubled torus \mathbb{T}^{2n} .

Dilaton

The dilaton has not been included in the above discussion. However, following [309], we can add a term of the form

$$-\frac{1}{4\pi} \int_{\Sigma} \mathbf{R} \Phi \star 1 \tag{9.37}$$

to the doubled action (9.28), where \mathbf{R} is the Ricci scalar of the world-sheet metric and $\Phi = \Phi(Y)$ denotes the doubled dilaton. Note that since Φ is independent of \mathbb{X} , (9.37) is invariant under $O(n, n, \mathbb{Z})$ transformations.

Now, when relating the doubled action to the standard formulation by integrating out a local symmetry, there is a one-loop effect when performing the path-integral [313, 314]. This implies that the doubled dilaton Φ in (9.37) gets an additional contribution, so that the physical dilaton ϕ takes the form

$$\phi = \Phi - \frac{1}{4} \log(\det G_{ij}), \tag{9.38}$$

where G_{ij} denotes the metric on the physical space shown in (9.23). Under duality transformations, ϕ then transforms in the standard way (3.30).

9.3 Double field theory

In this section we briefly discuss double field theory (DFT) [310–312], which is a target-space formulation manifestly invariant under $O(D, D, \mathbb{Z})$ transformations. A detailed discussion of DFT is beyond the scope of this work, for which we want to refer the reader to the reviews [315–317]. Here we only point out relations with doubled geometry and the relevance of DFT for non-geometric backgrounds.

Doubled world-sheet actions

In section 9.1 we have illustrated that a world-sheet theory with doubled coordinates is subject to a self-duality constraint. Theories with self-dual odd forms are difficult to deal with, since when the constraint is imposed at the level of the action the latter vanishes. Examples for such theories are type IIB string theory with a self-dual five-form field strength, the world-volume theory of M5-branes with a self-dual three-form field strength and the above-mentioned doubled world-sheet theory with a self-dual one-form. In all these cases it turns out to be difficult to quantise the theory.

Let us now be somewhat more precise concerning the doubled world-sheet formalism. The approach of Hull [16] discussed in this section, involving both coordinates X^i and \hat{X}_i , has previously appeared in a similar form in [318] and is related to the approaches in [319, 320]. The important question is, however, how the self-duality constraint (9.30) is imposed:

- If the constraint is implemented using the non-covariant formalism of [321], then the doubled-geometry formulation of [16] is closely related to that of Tseytlin [313, 314]. In this formulation manifest Lorentz invariance of the two-dimensional world-sheet theory is lost, which makes it difficult to compute for instance the β -functionals.
- One can impose additional constraints to restore Lorentz invariance for the action by Tseytlin [322, 323], which however complicates the computation of the Weyl anomaly. Other approaches are that of twisted double-tori which can be found in [324], or by following the Pasti-Sorokin-Tonin procedure [325] which has been discussed in [109].
- When imposing an additional gauge symmetry for the doubled action, one can obtain the Tseytlin model as a particular gauge choice [326, 327]. This approach is based on [328].

- When following the approach to self-dual forms by Siegel [329], one is led to a formulation similar to that of [330].
- In Hull's formalism [16,309] the constraint is imposed through a gauging procedure as discussed above. Here a particular polarisation separating physical from dual coordinates has to be chosen by hand, but it is argued that this method is suitable for quantising the theory.

More proposals for such actions can be found in the literature, which are all classically-equivalent to the ordinary string-theory action. However, it is usually difficult to quantise these actions.

Double field theory

In string theory, the vanishing of the β -functionals (3.31) is interpreted as the equations of motion of an effective target-space theory. For the doubled world-sheet theories one can try to follow a similar reasoning, and the corresponding one-loop β -functionals have been computed for instance in [331, 332] and [327]. However, these have technical difficulties concerning the validity of a perturbative α' -expansion or they do not reproduce the equations of motion expected from a doubled target-space theory, respectively.

On the other hand, in [310] a target-space theory has been constructed using closed-string field theory which is manifestly invariant under $O(D, D)$ transformations. This formulation is expected to be a target-space description of the doubled world-sheet action (or a variant thereof), for which a number of indications have been collected. The current status in the literature is, however, that this question has not yet been completely settled.

Basics of DFT

We now want to give a brief introduction to double field theory, which is defined on a space with a doubled number of target-space dimensions. Similarly to what we have seen for the world-sheet action, in DFT the ordinary coordinates X^i are supplemented by dual coordinates \hat{X}_i (also called winding coordinates). These are combined into double coordinates $X^I = (X^i, \hat{X}_i)$, with $i = 1, \dots, D$ and $I = 1, \dots, 2D$. Relevant quantities for double field theory are the $O(D, D)$ invariant metric η_{IJ} and the generalised metric \mathcal{H}_{IJ} shown in (2.27). We recall them here as

$$\mathcal{H} = \begin{pmatrix} \frac{1}{\alpha'}(g - bg^{-1}b) & +bg^{-1} \\ -g^{-1}b & \alpha'g^{-1} \end{pmatrix}, \quad \eta = \begin{pmatrix} 0 & \mathbf{1} \\ \mathbf{1} & 0 \end{pmatrix}. \quad (9.39)$$

For these expressions we can introduce vielbein matrices $\mathcal{E}^A{}_I$ as in (7.26). In particular, we have

$$\eta = \mathcal{E}^T \eta \mathcal{E}, \quad \mathcal{H} = \mathcal{E}^T \mathcal{S} \mathcal{E}, \quad (9.40)$$

where the $2D \times 2D$ matrix \mathcal{S} is given by the following expression in the generalised vielbein basis

$$\mathcal{S}_{AB} = \begin{pmatrix} \delta & 0 \\ 0 & \delta^{-1} \end{pmatrix}. \quad (9.41)$$

Here we restrict the doubling of the coordinates to say a compact part of the space-time such that the time direction is not doubled. This can however also be extended to the full space-time. An action for double field theory can be determined by invoking the following symmetries:

- First, one requires the action to be invariant under local diffeomorphisms of the doubled coordinates X^I , that is $(X^i, \hat{X}_i) \rightarrow (X^i + \xi^i(X), \hat{X}_i + \hat{\xi}_i(X))$.
- Second, the action should be invariant under a global $O(D, D)$ symmetry. It has been realised that for manifest $O(D, D)$ invariance and for closure of the algebra of infinitesimal diffeomorphisms, one has to impose the so-called strong constraint

$$\partial_i A \hat{\partial}^i B + \hat{\partial}^i A \partial_i B = 0, \quad (9.42)$$

where $\hat{\partial}^i$ denotes the derivative with respect to the winding coordinate \hat{X}_i . The quantities A and B in (9.42) can be any function or matrix.

We note that there exist two formulations of a DFT action, which differ by terms that are either total derivatives or are vanishing due to the strong constraint (9.42).

Flux-formulation of DFT

For our purposes it is convenient to use the flux formulation of double field theory, which has been developed in [333–335] and is, as has been shown in [336], related to earlier work of Siegel [337, 338]. In a frame with flat indices, the action is given by

$$\begin{aligned} \mathcal{S}_{\text{DFT}} = & \frac{1}{2\kappa_{10}^2} \int d^{2D} X e^{-2d} \left[\right. \\ & \mathcal{F}_{ABC} \mathcal{F}_{A'B'C'} \left(\frac{1}{4} \mathcal{S}^{AA'} \eta^{BB'} \eta^{CC'} - \frac{1}{12} \mathcal{S}^{AA'} \mathcal{S}^{BB'} \mathcal{S}^{CC'} - \frac{1}{6} \eta^{AA'} \eta^{BB'} \eta^{CC'} \right) \\ & \left. + \mathcal{F}_A \mathcal{F}_{A'} \left(\eta^{AA'} - \mathcal{S}^{AA'} \right) \right], \quad (9.43) \end{aligned}$$

where we used $d^{2D}X \equiv d^D X \wedge d^D \hat{X}$. The definition of e^{-2d} contains the ordinary dilaton ϕ and the determinant of the metric g_{ij} , and reads $\exp(-2d) = \sqrt{|g|} \exp(-2\phi)$. The objects \mathcal{F}_A are expressed as

$$\mathcal{F}_A = \Omega^B{}_{BA} + 2\bar{\mathcal{E}}_A{}^I \partial_I d, \quad (9.44)$$

with $\bar{\mathcal{E}}_A{}^I$ the inverse of the vielbeins $\mathcal{E}^A{}_I$, ∂_I denoting the derivative with respect to the doubled coordinates X^I , and Ω_{ABC} being the generalised Weitzenböck connection

$$\Omega_{ABC} = \bar{\mathcal{E}}_A{}^I (\partial_I \bar{\mathcal{E}}_B{}^J) \mathcal{E}_{JC}. \quad (9.45)$$

Note that the frame-index of $\mathcal{E}_I{}^A$ has been lowered using η_{AB} . The three-index object \mathcal{F}_{ABC} appearing in (9.43) is the anti-symmetrisation of Ω_{ABC} , that is

$$\mathcal{F}_{ABC} = 3\Omega_{[ABC]}. \quad (9.46)$$

(Non-)geometric fluxes

Since the three-index fluxes (9.46) have upper and lower indices, it is natural to identify (the vacuum expectation value of) \mathcal{F}_{ABC} with the H -flux, geometric flux, non-geometric Q - and non-geometric R -flux as

$$\mathcal{F}_{abc} = H_{abc}, \quad \mathcal{F}_{ab}{}^c = F_{ab}{}^c, \quad \mathcal{F}_a{}^{bc} = Q_a{}^{bc}, \quad \mathcal{F}^{abc} = R^{abc}. \quad (9.47)$$

Double-field theory therefore includes geometric and non-geometric fluxes on equal footing. Furthermore, the fluxes have to satisfy consistency conditions of the form [217]

$$\begin{aligned} 0 &= \mathcal{D}_{[A} \mathcal{F}_{BCD]} - \frac{3}{4} \mathcal{F}_{[AB}{}^M \mathcal{F}_{M|CD]}, \\ 0 &= \mathcal{D}^M \mathcal{F}_{MAB} + 2\mathcal{D}_{[A} \mathcal{F}_{B]} - \mathcal{F}^M \mathcal{F}_{MAB}, \end{aligned} \quad (9.48)$$

where $\mathcal{D}_A = \bar{\mathcal{E}}_A{}^I \partial_I$. These expressions are similar in form to the Bianchi identities discussed around equation (8.81).

However, even though the DFT fluxes (9.46) are similar to the fluxes in generalised geometry (cf. for instance (7.71)), there are important differences. In particular, in double field theory the generalised vielbeins $\bar{\mathcal{E}}$ can depend not only on the ordinary coordinates X^i but also on the dual winding coordinates \hat{X}_i . Let us illustrate this for the following DFT vielbein

$$\bar{\mathcal{E}}_A{}^I = \begin{pmatrix} \delta_a{}^i & -\delta_a{}^m b_{mi} \\ 0 & \delta^a{}_i \end{pmatrix}, \quad (9.49)$$

in which $b_{ij} \equiv b_{ij}(X, \hat{X})$ can depend on both types of coordinates. The corresponding non-vanishing fluxes (in the coordinates basis) are then determined as follows

$$\begin{aligned}
\text{double field theory} \quad & \mathcal{F}_{ijk} = -3\partial_{[i} b_{jk]} + 3b_{[im} \hat{\partial}^m b_{jk]}, \\
& \mathcal{F}_{ij}{}^k = -\hat{\partial}^k b_{ij}, \\
\text{generalised geometry} \quad & \mathcal{F}_{ijk} = -3\partial_{[i} b_{jk]},
\end{aligned} \tag{9.50}$$

where $\hat{\partial}^i$ denotes the derivative with respect to \hat{X}^i , and where included the generalised-geometry result from equation (7.65). We therefore see that in double field theory there is an additional contribution to the fluxes coming from the dual winding coordinates.

Remarks

We close this section with the following remarks:

- Ignoring how the DFT fluxes are realised in terms of vielbein matrices and considering only the expectation values of \mathcal{F}_{ABC} , it has been shown in [250] that DFT compactified on Calabi-Yau three-folds leads to the scalar potential (8.88) of four-dimensional $\mathcal{N} = 2$ gauged supergravity. (Here the supersymmetric extension of bosonic DFT to type IIB has been considered.) Similarly, for compactifications of DFT on toroidal backgrounds with fluxes the scalar potential of four-dimensional $\mathcal{N} = 4$ supergravity has been obtained [334]. These results show that double field theory correctly reproduces the scalar potential expected from flux compactifications.
- Double field theory is subject to the strong constraint (9.42). This constraint can be solved for instance by setting to zero all winding-coordinate dependencies, which for (9.50) implies that the DFT expressions agree with the generalised-geometry fluxes.

However, the strong constraint can also be solved by eliminating a linear combination of coordinates X^i and \hat{X}_i . In generalised geometry this corresponds to choosing a different anchor projection for the Courant algebroid.

- Double field theory is a rich subject with many applications. It is beyond the scope of this work to go into more detail, and we have therefore only illustrated the appearance of non-geometric fluxes. The point we want to emphasise is that from a DFT point of view, non-geometric fluxes are on equal footing with ordinary geometric fluxes.

- The generalised metric \mathcal{H}_{IJ} and the $O(D, D)$ invariant metric η_{IJ} shown in (9.39) satisfy the following two relations

$$\mathcal{H}^T = \mathcal{H}, \quad \mathcal{H}^T \eta^{-1} \mathcal{H} = \eta. \quad (9.51)$$

Taking these now as defining relations for two arbitrary $2D \times 2D$ matrices, in [339] the corresponding geometries have been classified. Such geometries are in general non-Riemannian and have been called doubled-yet-gauged space-times [340].

10 Non-commutative and non-associative structures

We now discuss non-commutative and non-associative structures in string theory. We explain how a non-commutative or non-associative behaviour of closed-string coordinates is related to non-geometric fluxes, how such backgrounds can be obtained by applying T-duality transformations, and how asymmetric orbifolds provide concrete realisations thereof. A review of these topics with focus on the underlying mathematical structures can be found in [341].

10.1 Non-associativity for closed strings

In this section we start our discussion by recalling non-commutativity for the open string, and then discuss a similar reasoning for the closed string. For latter we will see a non-associative structure, which we describe using a tri-product.

Open strings

Let us start with non-commutativity in the open-string sector. The world-sheet action describing open strings has a form similar to (2.1), with the difference that the two-dimensional world-sheet Σ has a non-trivial boundary $\partial\Sigma \neq \emptyset$. Using the same conventions as in section 2 we have

$$\begin{aligned} \mathcal{S} = & -\frac{1}{4\pi\alpha'} \int_{\Sigma} \left[G_{\mu\nu} dX^{\mu} \wedge \star dX^{\nu} - B_{\mu\nu} dX^{\mu} \wedge dX^{\nu} + \alpha' R \phi \star 1 \right] \\ & -\frac{1}{2\pi\alpha'} \int_{\partial\Sigma} \left[a_{\mu} dX^{\mu} + \alpha' k(s) \phi ds \right], \end{aligned} \quad (10.1)$$

where the open-string $U(1)$ gauge field $a = a_{\mu} dX^{\mu}$ is understood to be restricted to the boundary $\partial\Sigma$. Coordinates on the world-sheet are denoted by $\sigma^{\alpha} = \{\sigma^0, \sigma^1\}$, and t^{α} and n^{α} are unit vectors tangential and normal to the boundary, respectively. The extrinsic curvature of the boundary is expressed as $k = t^{\alpha} t^{\beta} \nabla_{\alpha} n_{\beta}$, the coordinate on the boundary $\partial\Sigma$ is denoted by s , and we have $dX^{\mu}|_{\partial\Sigma} = t^{\alpha} \partial_{\alpha} X^{\mu} ds$. The gauge-invariant open-string field strength is a combination of the field strength $F = da$ for a and the Kalb-Ramond field B , and can be expressed as²⁵

$$\mathcal{F} = F - B. \quad (10.2)$$

As boundary condition we can impose Dirichlet boundary conditions of the form $\delta X^{\mu}|_{\partial\Sigma} = 0$ or Neumann boundary conditions. Denoting the tangential and normal

²⁵In this section we choose a different normalisation of $F = da$ as compared to equation (2.65).

part of dX^μ on the boundary by $(dX^\mu)_{\text{tan}} \equiv t^\alpha \partial_\alpha X^\mu ds|_{\partial\Sigma}$ and $(dX^\mu)_{\text{norm}} \equiv n^\alpha \partial_\alpha X^\mu ds|_{\partial\Sigma}$ we can summarise these boundary conditions as

$$\begin{aligned} \text{Dirichlet} \quad & 0 = (dX^\mu)_{\text{tan}}, \\ \text{Neumann} \quad & 0 = (dX^\mu)_{\text{norm}} + \mathcal{F}^\mu{}_\nu (dX^\nu)_{\text{tan}} + \alpha' k(s) G^{\mu\nu} \partial_\nu \phi ds \Big|_{\partial\Sigma}, \end{aligned} \quad (10.3)$$

where the index of \mathcal{F} has been raised with the inverse of $G_{\mu\nu}$. Finally, a Dp-brane is characterised by Neumann boundary conditions along the target-space time direction X^0 and along p spatial directions. The remaining target-space directions are of Dirichlet type.

Non-commutativity

Restricting now to a flat target space with $G_{\mu\nu} = \eta_{\mu\nu}$, constant Kalb-Ramond field $B_{\mu\nu}$, constant dilaton ϕ and constant open-string field strength $F_{\mu\nu}$, one can determine the mode expansion of the open-string fields $X^\mu(\sigma^\alpha)$. In particular, for Neumann boundary conditions we have

$$\begin{aligned} X^\mu(\tau, \sigma) = & x_0^\mu + \frac{2\pi\alpha'}{\ell_s} (p^\mu \tau - \mathcal{F}^\mu{}_\nu p^\nu \sigma) \\ & + i\sqrt{2\alpha'} \sum_{n \neq 0} \frac{1}{n} e^{-i\frac{n\pi\tau}{\ell_s}} \left[\alpha_n^\mu \cos\left(\frac{n\pi\sigma}{\ell_s}\right) - i\mathcal{F}^\mu{}_\nu \alpha_n^\nu \sin\left(\frac{n\pi\sigma}{\ell_s}\right) \right], \end{aligned} \quad (10.4)$$

where we normalised the world-sheet direction normal to the boundary as $0 \leq \sigma \leq \ell_s$, and where the world-sheet time coordinate τ is tangential to the boundary. As carried out in [342], the commutation relations for the modes appearing in (10.4) can be obtained via canonical quantisation. Using these relations, the equal-time commutator on the D-brane is evaluated as

$$[X^\mu(\tau, 0), X^\nu(\tau, 0)] = -[X^\mu(\tau, \ell_s), X^\nu(\tau, \ell_s)] = 2\pi i \alpha' (M^{-1} \mathcal{F})^{\mu\nu}, \quad (10.5)$$

where $\sigma = 0, \ell_s$ corresponds to the two endpoints of the open string on the D-brane. The matrix M is defined as $M_{\mu\nu} = \eta_{\mu\nu} - \mathcal{F}_\mu{}^\rho \mathcal{F}_{\rho\nu}$. The relations (10.5) show that the endpoints of the open string do not commute, and hence we find a non-commutative structure in the open-string sector. Their low-energy limit can be described via a non-commutative gauge theory [343], and for a review of such theories see for instance [344].

The Moyal-Weyl product for open strings

Another way to detect the non-commutative nature of the above setting is to consider the two-point function of two fields $X^\mu(\tau, \sigma)$. Going to an Euclidean

world-sheet via a Wick rotation $\tau \rightarrow i\tau$ and introducing a complex coordinate $z = \exp(\tau + i\sigma)$, the two-point function of two open-string coordinates $X^\mu(z)$ inserted on the boundary takes the form [345–347, 343]

$$\langle X^\mu(\mathbf{z}_1) X^\nu(\mathbf{z}_2) \rangle = -\alpha' \mathbf{G}^{\mu\nu} \log(\mathbf{z}_1 - \mathbf{z}_2)^2 + \frac{i}{2} \theta^{\mu\nu} \epsilon(\mathbf{z}_1 - \mathbf{z}_2), \quad (10.6)$$

where $\mathbf{z} = \text{Re}(z)$ denotes the real part of the complex world-sheet coordinate z . The matrix $\mathbf{G}^{\mu\nu}$ is symmetric and can be interpreted as the (inverse of the) effective metric seen by the open string, and $\theta^{\mu\nu}$ is anti-symmetric and proportional to the two-form flux \mathcal{F} . They are determined as the symmetric and the anti-symmetric part of the inverse of $G - \mathcal{F}$ as

$$\left[(G - \mathcal{F})^{-1} \right]^{\mu\nu} = \mathbf{G}^{\mu\nu} + \frac{1}{2\pi\alpha'} \theta^{\mu\nu}. \quad (10.7)$$

The function $\epsilon(\mathbf{z})$ is defined as

$$\epsilon(\mathbf{z}) = \begin{cases} +1 & \mathbf{z} \geq 0, \\ -1 & \mathbf{z} < 0, \end{cases} \quad (10.8)$$

and it is the appearance of the jump given by $\epsilon(\mathbf{z}_1 - \mathbf{z}_2)$ in (10.6) which leads to non-commutativity of the open-string coordinates on the D-brane. The latter has also been discussed for instance in [348–351].

Next, we recall the form of an open-string vertex operator inserted at the boundary of an open-string disc diagram. Employing the short-hand notation $p \cdot X = p_\mu X^\mu$ and denoting normal-ordered products by $:\dots:$, such a tachyon vertex operator can be written as (for an introduction to conformal-field-theory techniques see for instance [1])

$$\mathcal{V}(\mathbf{z}; p) = : \exp(i p \cdot X(\mathbf{z})) : . \quad (10.9)$$

A correlation function of two such vertex operators in a background with non-vanishing \mathcal{F} -flux is found to be

$$\langle \mathcal{V}_1 \mathcal{V}_2 \rangle = \exp \left[i (p_1)_\mu \theta^{\mu\nu} (p_2)_\nu \epsilon(\mathbf{z}_1 - \mathbf{z}_2) \right] \times \langle \mathcal{V}_1 \mathcal{V}_2 \rangle_{\theta=0}, \quad (10.10)$$

where $\theta = 0$ denotes the result of the two-point function for vanishing flux. The effect of the flux \mathcal{F} encoded in θ is a phase factor due to the non-commutative nature of the theory. This behaviour gives rise to the Moyal-Weyl star-product between functions f_1 and f_2

$$(f_1 \star f_2)(x) := \exp \left[i \theta^{\mu\nu} \partial_\mu^{x_1} \partial_\nu^{x_2} \right] f_1(x_1) f_2(x_2) \Big|_{x_1=x_2=x}, \quad (10.11)$$

which correctly reproduces the phase appearing in (10.10). Therefore, by evaluating correlation functions of vertex operators in open-string theory, it is possible to derive the Moyal-Weyl product.

(a) World-sheet disc diagram.

(b) World-sheet sphere diagram.

Figure 12: Open-string disc diagram with the insertion of two open-string vertex operators on the boundary, and closed-string sphere diagram with the insertion of three closed-string vertex operators.

Non-associativity

We now want to perform a computation analogous to the open-string case for the closed string. We are guided by the following observation:

- For the open string, the non-commutativity arises because two operators inserted at the boundary of a world-sheet diagram (cf. figure 12a) do not commute. This non-commutativity is controlled by a two-form flux \mathcal{F} .
- For the closed string, operators are inserted on a world-sheet without boundary (cf. figure 12b). Here, one cannot define an ordering between two points – however, for three-points we can define an orientation. We therefore expect that for the closed string an object involving three closed-string fields is relevant, which in turn should correspond to a three-form flux.

To make the latter point more precise, we consider the equal-time Jacobiator of three closed-string fields defined as [352]

$$[X^\mu, X^\nu, X^\rho] := \lim_{\sigma_i \rightarrow \sigma} [[X^\mu(\tau, \sigma_1), X^\nu(\tau, \sigma_2)], X^\rho(\tau, \sigma_3)] + \text{cyclic}. \quad (10.12)$$

Note that if this bracket is non-vanishing we have a non-associative structure, and we expect this three-bracket to be related to a three-form flux – such as the H -flux, geometric flux, or the non-geometric Q - or R -fluxes.

This strategy has been followed in [352], where the equal-time Jacobiator (10.12) has been determined for the $SU(2)$ Wess-Zumino-Witten model (introduced around equation (3.71)). This model is described by an action of the form (3.39), and corresponds to a string moving on a three-sphere S^3 with H -flux, where the radius of S^3 is related to the flux such that the string equations of motion (3.31)

are satisfied to all orders in sigma-model perturbation theory. For this background, the three-bracket (10.12) was found to be [352]

$$[X^\mu, X^\nu, X^\rho] = \epsilon \theta^{\mu\nu\rho}, \quad (10.13)$$

where $\theta^{\mu\nu\rho}$ is completely anti-symmetric in its indices and encodes the three-form flux. The parameter ϵ turns out to be $\epsilon = 0$ for the H -flux background and $\epsilon = 1$ for the background one obtains after three T-dualities. Hence, for such backgrounds the closed string shows not only a non-commutative but a non-associative behaviour.

Tri-product

Similarly to the open string, for the closed string the non-associativity can be encoded in a product of functions. This has been analysed in [353] using conformal field theory techniques, where correlation functions of tachyon vertex operators have been computed for a background with H -flux (in a perturbative expansion). Let us be more precise and state the definition of a closed-string tachyon vertex operator as

$$\mathcal{V}(z, \bar{z}; p) = : \exp(ip_L \cdot \mathcal{X}_L + ip_R \cdot \mathcal{X}_R) :, \quad (10.14)$$

where $p_{L,R}^\mu$ are the left- and right-moving momenta. The coordinates $\mathcal{X}_{L,R}^\mu$ are the left- and right-moving coordinates of the closed string, including linear corrections due to the H -flux. The complex coordinate on the world-sheet is denoted by z . For the three-tachyon amplitude one then finds [353]

$$\langle \mathcal{V}_1 \mathcal{V}_2 \mathcal{V}_3 \rangle^\pm = \exp \left[-i \theta^{\mu\nu\rho} (p_1)_\mu (p_2)_\nu (p_3)_\rho \left[\mathcal{L}\left(\frac{z_{12}}{z_{13}}\right) \pm \mathcal{L}\left(\frac{\bar{z}_{12}}{\bar{z}_{13}}\right) \right] \right] \times \langle \mathcal{V}_1 \mathcal{V}_2 \mathcal{V}_3 \rangle_{\theta=0}, \quad (10.15)$$

where we emphasise that the exponential has been determined only up to linear order in θ . The notation employed for the world-sheet coordinates is $z_{ij} = z_i - z_j$, where z_i corresponds to the world-sheet coordinate of the closed-string vertex operator $\mathcal{V}_i(z_i, \bar{z}_i; p_i)$. The function $\mathcal{L}(z)$ is expressed in terms of the Rogers dilogarithm $L(z)$, which in turn is defined in terms of the usual dilogarithm $\text{Li}_2(z)$ as follows

$$\begin{aligned} \mathcal{L}(z) &= L(z) + L\left(1 - \frac{1}{z}\right) + L\left(\frac{1}{1-z}\right), \\ L(z) &= \text{Li}_2(z) + \frac{1}{2} \log(z) \log(1-z). \end{aligned} \quad (10.16)$$

The correlation function (10.15) can be determined reliably only for the H -flux background (corresponding to the $-$ sign) and a background resulting after three

T-dualities (corresponding to the + sign). The latter is identified with an R -flux background.

Let us now study the behaviour of (10.15) under permutations of the vertex operators \mathcal{V}_i . Using properties of the function $\mathcal{L}(z)$ and denoting by the + sign again the R -flux background and by $-$ the H -flux background, one finds

$$\langle \mathcal{V}_{\sigma(1)} \mathcal{V}_{\sigma(2)} \mathcal{V}_{\sigma(3)} \rangle^\pm = \exp \left[i \left(\frac{1 \pm 1}{2} \right) \eta_\sigma \pi^2 \theta^{\mu\nu\rho} (p_1)_\mu (p_2)_\nu (p_3)_\rho \right] \langle \mathcal{V}_1 \mathcal{V}_2 \mathcal{V}_3 \rangle^\pm, \quad (10.17)$$

where $\eta_\sigma = 1$ for an odd permutation and $\eta_\sigma = 0$ for an even one. Thus, for the R -flux background a non-trivial phase may appear which in [353] has been established up to linear order in the flux. The phase in (10.17) suggests the definition of a three-product of functions $f(x)$ in the following way

$$(f_1 \Delta f_2 \Delta f_3)(x) := \exp \left(\frac{\pi^2}{2} \theta^{\mu\nu\rho} \partial_\mu^{x_1} \partial_\nu^{x_2} \partial_\rho^{x_3} \right) f_1(x_1) f_2(x_2) f_3(x_3) \Big|_{x_1=x_2=x_3=x}. \quad (10.18)$$

The three-bracket (10.13) can then be re-derived as the completely anti-symmetrised sum of three-products (up to an overall constant) as

$$[X^\mu, X^\nu, X^\rho] = \sum_{\sigma \in P^3} \text{sign}(\sigma) x^{\sigma(\mu)} \Delta x^{\sigma(\nu)} \Delta x^{\sigma(\rho)} = 3\pi^2 \theta^{\mu\nu\rho}, \quad (10.19)$$

where P^3 denotes the permutation group of three elements. Let us recall that this three-bracket was defined as the Jacobi-identity of the coordinates, which can only be non-zero if the space is non-commutative and non-associative.

Remarks

Let us close this section with remarks on the tachyon correlation function and on the tri-product (10.18):

- In CFT correlation functions operators are understood to be radially ordered and so changing the order of operators should not change the form of the amplitude. This is known as crossing symmetry which is one of the defining properties of a CFT. In the case of the R -flux background, this is reconciled with (10.17) by applying momentum conservation as

$$\theta^{\mu\nu\rho} (p_1)_\mu (p_2)_\nu (p_3)_\rho = 0 \quad \text{for} \quad p_1 + p_2 + p_3 = 0. \quad (10.20)$$

Therefore, scattering amplitudes of three tachyons do not receive any corrections at linear order in θ both for the H - and R -flux. (This is analogous to the situation in non-commutative open-string theory, where the two-point function (10.10) does not receive any corrections.) The non-associative behaviour for the closed string should therefore be understood as an off-shell property of the theory (see also [354]).

- In the above analysis the flux $\theta^{\mu\nu\rho}$ was assumed to be constant. For a discussion with a non-constant flux in the context of double field theory see [355].
- Using Courant algebroids and regarding closed strings as boundary excitations of more fundamental membrane degrees of freedom, a non-associative star-product has been proposed in [356]. This product can be related to the tri-product introduced in (10.18), which has been established at linear order in the flux in [356] and at all orders in [354] (including extensions towards a non-associative differential geometry). This star-product was also obtained via deformation quantisation of twisted Poisson manifolds in [356], but can also be found by integrating higher Lie-algebra structures [357]. We also note that membrane sigma-models have been used to study non-geometric fluxes [358] and properties of double field theory [359].
- In relation to the open string, we note that the result of a two-form flux inducing non-commutativity of brane coordinates is completely general, and has also been studied for codimension one branes in the $SU(2)$ WZW model [360]. However, due to a background H -flux in this case, it turns out that the obtained structure is not only non-commutative but also non-associative [360–362].
- Using a non-associative star-product, one can try to construct a corresponding non-associative theory of differential geometry and a non-associative theory of gravity. This idea has been proposed in [352], and further been developed in [363–366].
- Properties of non-associative star-products have been studied from a more mathematical point of view also in [367, 368] and [369].

10.2 Non-commutativity for closed strings

In this section, we discuss the non-commutative behaviour of the closed string in the context of torus fibrations. In particular, we consider parabolic and elliptic \mathbb{T}^2 -fibrations over a circle and perform T-duality transformations. It turns out that the T-dual configurations can be interpreted as asymmetric orbifolds, for which the closed-string coordinates do not commute.

Main idea

Let us consider a setting similar to the one in section 6, where we considered n -dimensional torus fibrations over a base-manifold. Assuming that the non-triviality of the fibration is small in a certain parameter regime (for instance a monodromy

around a large cycle in the base), we can quantise the closed string on the fibre perturbatively. In this regime the equation of motion for the fibre-coordinates $X^a(\tau, \sigma)$ reads (cf. equation (2.4))

$$0 = \partial_+ \partial_- X^a(\tau, \sigma) + \mathcal{O}(\Theta), \quad \mathbf{a} = 1, \dots, n, \quad (10.21)$$

where $\Theta \ll 1$ encodes the non-triviality of the fibration. For the geometric-flux background discussed in section 5.2, this parameter would be related to the flux-density shown in (5.12). As discussed for instance in [353], the solution to this equation of motion can then be split into left- and right-moving part similarly as in (2.5)

$$X^a(\tau, \sigma) = X_L^a(\tau + \sigma) + X_R^a(\tau - \sigma). \quad (10.22)$$

In general, the commutation relations of the left- and right-moving modes will take the following form [282]

$$[X_L^a, X_L^b] = \frac{i}{2} \Theta_1^{ab}, \quad [X_L^a, X_R^b] = 0, \quad [X_R^a, X_R^b] = \frac{i}{2} \Theta_2^{ab}, \quad (10.23)$$

where $\Theta_{1,2}^{ab}$ are anti-symmetric in their indices and encode the non-triviality of the fibration. Now, for a purely geometric background – such as the twisted torus with geometric flux – one finds that $\Theta_1^{ab} = -\Theta_2^{ab} = \Theta^{ab}$, and hence the fibre-coordinates commute

$$[X^a, X^b] = [X_L^a + X_R^a, X_L^b + X_R^b] = \frac{i}{2} (\Theta^{ab} - \Theta^{ab}) = 0. \quad (10.24)$$

Let us now perform T-duality transformations for the above situation fibre-wise. As discussed in the case of a single T-duality in section 2.2, for the left- and right-moving coordinates this implies that the sign of the right-moving coordinate is changed

$$(X_L^{\hat{a}}, X_R^{\hat{a}}) \longrightarrow (+X_L^{\hat{a}}, -X_R^{\hat{a}}). \quad (10.25)$$

Here, \hat{a} denotes the direction along which a T-duality transformation has been performed, and in the following the dual coordinate will be denoted by $\tilde{X}^{\hat{a}} = X_L^{\hat{a}} - X_R^{\hat{a}}$. Coming back to the commutation relation (10.24), we can now compute for instance [282]

$$[\tilde{X}^{\hat{a}}, X^b] = [X_L^{\hat{a}} - X_R^{\hat{a}}, X_L^b + X_R^b] = \frac{i}{2} (\Theta^{\hat{a}b} + \Theta^{\hat{a}b}) = i\Theta^{\hat{a}b}. \quad (10.26)$$

This means that after one T-duality for a purely geometric background the coordinates for the dual background do not need to commute anymore, and in general one obtains a non-commutative geometry.

Examples I – parabolic \mathbb{T}^2 -fibrations over S^1

The main idea outlined above has been proposed in [282] for \mathbb{T}^2 -fibrations over a circle, and has been checked more systematically in [370]. In order to discuss these results, let us denote coordinates in the fibre torus by X^1 and X^2 , and the coordinate in the base will be denoted by X^3

$$\begin{array}{ll} \text{fibre } \mathbb{T}^2 & \left\{ \begin{array}{l} X^1 \\ X^2 \end{array} \right. \\ \text{base } S^1 & X^3 \end{array} \quad (10.27)$$

The metric and Kalb-Ramond B -field can be parametrised similarly as in (6.2), and the fibre-components can be expressed using the complexified Kähler and complex-structure moduli ρ and τ as in (6.22). Let us then recall from section 6.2 that the three-torus with H -flux, the twisted torus with geometric flux and the T-fold with non-geometric Q -flux can be characterised by the following monodromies

$$\begin{array}{ll} \mathbb{T}^3 \text{ with } H\text{-flux} & \tau \rightarrow \tau, \quad \rho \rightarrow \rho + h, \\ \text{twisted torus with } f\text{-flux} & \tau \rightarrow \frac{\tau}{-f\tau + 1}, \quad \rho \rightarrow \rho, \\ \text{T-fold with } Q\text{-flux} & \tau \rightarrow \tau, \quad \rho \rightarrow \frac{\rho}{-q\rho + 1}, \end{array} \quad (10.28)$$

when going around the base-circle as $X^3 \rightarrow X^3 + 2\pi$. In this list, $h, f, q \in \mathbb{Z}$ denote the flux-quantum for the H -, geometric and Q -flux, and we note that these monodromies are all of parabolic type (cf. page 83).

In [282, 283, 370] the commutation relations between the fibre-coordinates X^1 and X^2 have been determined for all three backgrounds mentioned above. In particular, for a sector of the theory in which the base-coordinate X^3 has winding-number N^3 the equal-time commutator in the limit of coincident world-sheet space coordinates takes the form

$$\begin{array}{ll} \mathbb{T}^3 \text{ with } H\text{-flux} & [X^1(\tau, \sigma), X^2(\tau, \sigma')] \xrightarrow{\sigma' \rightarrow \sigma} 0, \\ \text{twisted torus with } f\text{-flux} & [X^1(\tau, \sigma), X^2(\tau, \sigma')] \xrightarrow{\sigma' \rightarrow \sigma} 0, \\ \text{T-fold with } Q\text{-flux} & [X^1(\tau, \sigma), X^2(\tau, \sigma')] \xrightarrow{\sigma' \rightarrow \sigma} -\frac{i}{2} \frac{\pi^2}{3} N^3 q. \end{array} \quad (10.29)$$

Hence, in this limit, the commutator of two fibre-coordinates of the T-fold is non-vanishing, indicating a non-commutative behaviour. Furthermore, the right-hand side of this commutator is proportional to the winding number N^3 which can also

be expressed as $N^3 = \oint dX^3$. Denoting then the constant Q -flux by $q = Q_3^{12}$ we can express the commutator for the T-fold as [206]

$$[X^1(\tau, \sigma), X^2(\tau, \sigma')]_{\text{T-fold}} \xrightarrow{\sigma' \rightarrow \sigma} -\frac{i\pi^2}{6} \oint Q_3^{12} dX^3. \quad (10.30)$$

It has furthermore been proposed that this expression also holds for flux backgrounds in which the Q -flux depends on the target-space coordinates.

Examples II – elliptic \mathbb{T}^2 -fibrations over S^1

Another class of examples are \mathbb{T}^2 -fibrations with elliptic monodromies, as opposed to the parabolic ones of the previous paragraph. As mentioned in section 8.7, elliptic monodromies have fixed points which have an orbifold description (see footnote 23). Let us consider for instance a background with vanishing Kalb-Ramond field and elliptic monodromy

$$\tau \rightarrow -\frac{1}{\tau}. \quad (10.31)$$

If we denote two lattice vectors generating the two-torus by $\omega_1, \omega_2 \in \mathbb{C}$, the complex structure is given by $\tau = \omega_2/\omega_1$. The monodromy (10.31) can then be represented by for instance $\omega_1 \rightarrow \omega_2$ and $\omega_2 \rightarrow -\omega_1$, which for the coordinates of the \mathbb{T}^2 -fibre shown in (10.27) implies

$$\begin{pmatrix} X^1 \\ X^2 \end{pmatrix} \rightarrow \begin{pmatrix} +X^2 \\ -X^1 \end{pmatrix}. \quad (10.32)$$

This \mathbb{Z}_4 -action can be conveniently expressed in terms of a complex target-space coordinate $Z = \frac{1}{\sqrt{2}}(X^1 + iX^2)$, for which one finds that

$$Z \rightarrow e^{-\frac{2\pi i}{4}} Z. \quad (10.33)$$

Similarly as above, the mode expansion of the world-sheet field $Z(\tau, \sigma)$ can be determined which respects this orbifold action. However, when taking into account the non-trivial fibration of the \mathbb{T}^2 -fibre over the base-circle, such an expansion can only be written down at lowest order in the twisting of the fibre. Following [282, 283], one finds that

$$\begin{aligned} Z_L(\tau + \sigma) &= i\sqrt{\frac{\alpha'}{2}} \sum_{n \in \mathbb{Z}} \frac{1}{n - \theta} \alpha_{n-\theta} e^{-\frac{2\pi i}{\ell_s}(n-\theta)(\tau+\sigma)}, \\ Z_R(\tau - \sigma) &= i\sqrt{\frac{\alpha'}{2}} \sum_{n \in \mathbb{Z}} \frac{1}{n + \theta} \tilde{\alpha}_{n+\theta} e^{-\frac{2\pi i}{\ell_s}(n+\theta)(\tau-\sigma)}, \end{aligned} \quad (10.34)$$

where $\theta = -fN^3$ with $f \in \frac{1}{4} + \mathbb{Z}$ and N^3 labelling the winding-sector of the base-coordinate X^3 . Similar expressions are obtained for the complex-conjugate coordinate $\bar{Z}(\tau, \sigma)$, and the commutation relations for the oscillator modes are found to be $[\alpha_{m-\theta}, \bar{\alpha}_{n-\theta}] = (m - \theta)\delta_{m,n}$. Using these expressions, the following equal-time commutators are computed

$$\begin{aligned} [Z_L(\tau + \sigma), \bar{Z}_L(\tau + \sigma')] &= - [Z_R(\tau - \sigma), \bar{Z}_R(\tau - \sigma')] = \frac{1}{2}\Theta(\sigma - \sigma'; \theta), \\ [Z_L(\tau + \sigma), \bar{Z}_R(\tau - \sigma')] &= [Z_R(\tau - \sigma), \bar{Z}_L(\tau + \sigma')] = 0. \end{aligned} \quad (10.35)$$

The function $\Theta(\sigma - \sigma'; \theta)$ depends on the difference of the world-sheet space coordinates σ and σ' , and its explicit form can be found [283]. However, here we are only interested in the limit

$$\Theta(\theta) = \lim_{\sigma' \rightarrow \sigma} \Theta(\sigma - \sigma'; \theta) = \begin{cases} -2\pi \cot(\pi\theta) & \text{for } \theta \notin \mathbb{Z}, \\ 0 & \text{for } \theta \in \mathbb{Z}. \end{cases} \quad (10.36)$$

From these expressions one finds that the target-space coordinates for an elliptic monodromy commute and that therefore the background is geometric

$$[Z, \bar{Z}] = 0 \quad \Longleftrightarrow \quad [X^1, X^2] = 0. \quad (10.37)$$

Let us next perform a T-duality transformation along say the direction X^1 , which implies that similarly as in (10.25) we change the sign of the right-moving modes. This means that $Z_R \rightarrow -\bar{Z}_R$, which then leads to the equal time commutator $[Z(\tau, \sigma), \bar{Z}(\tau, \sigma')] \xrightarrow{\sigma' \rightarrow \sigma} \Theta(\theta)$. Using the real target-space fields, this corresponds to [282]

$$[\tilde{X}^1(\tau, \sigma), X^2(\tau, \sigma')] \xrightarrow{\sigma' \rightarrow \sigma} i\Theta(\theta). \quad (10.38)$$

Hence, after a T-duality transformation a background with non-commuting coordinates is obtained. The commutation relations of the T-dual background are the same as for an orbifold with the following orbifold action

$$\begin{pmatrix} X_L^1 \\ X_L^2 \end{pmatrix} \rightarrow \begin{pmatrix} +X_L^2 \\ -X_L^1 \end{pmatrix}, \quad \begin{pmatrix} X_R^1 \\ X_R^2 \end{pmatrix} \rightarrow \begin{pmatrix} -X_R^2 \\ +X_R^1 \end{pmatrix}, \quad (10.39)$$

which in terms of the complex coordinate Z is expressed as

$$Z_L \rightarrow e^{-\frac{2\pi i}{4}} Z_L, \quad Z_R \rightarrow e^{+\frac{2\pi i}{4}} Z_R. \quad (10.40)$$

Note that the transformation behaviour is asymmetric between the left- and right-moving sectors, and hence it is called an asymmetric orbifold [14, 15]. We furthermore observe that the mapping (10.39) can be understood using $O(D, D)$ -transformations. Recalling from page 22 how the left- and right-moving coordinates behave under the duality group $O(D, D)$, we can infer that for the above background (with vanishing Kalb-Ramond field) the corresponding $O(2, 2, \mathbb{Z})$ matrix can be chosen as

$$\mathcal{O} = \begin{pmatrix} 0 & 0 & 0 & +1 \\ 0 & 0 & -1 & 0 \\ 0 & +1 & 0 & 0 \\ -1 & 0 & 0 & 0 \end{pmatrix}. \quad (10.41)$$

This transformation does not belong to the geometric subgroup of $O(2, 2, \mathbb{Z})$, and hence the dual background is non-geometric. We therefore see in this example that a T-duality transformation applied to a symmetric orbifold compactification leads to an asymmetric one, which can then be interpreted as a non-geometric background.

Remarks

Let us close this section with the following remarks and comments:

- It is worth emphasising that similar to the discussion in section 10.1, the analysis is done at lowest order in the fluxes. In particular, the non-triviality of the fibration has been taken into account only at linear order, which made it possible to obtain explicit mode expansions and compute the commutators. This approach is justified since in the β -functionals (3.31) the flux only appears at quadratic order [353]. At higher orders in the flux the above analysis becomes more involved.
- The equal-time commutators of the target-space coordinates discussed in (10.29) and (10.38) depend in general on the world-sheet coordinate σ . Hence, from a target-space point of view such a commutator is not well-defined. However, in the limit $\sigma' \rightarrow \sigma$ this dependence vanishes, and a target-space interpretation is possible.
- Additional examples for elliptic monodromies and their T-dual asymmetric orbifolds can be found in [283]. In particular, \mathbb{T}^5 -fibrations over a circle with freely-acting asymmetric orbifold actions are analysed. In [284] this analysis has been extended to include more general cases, and an explicit relation between asymmetric orbifolds and the effective gauged supergravity theory

has been given. Other examples for asymmetric orbifolds and their relation to non-geometric backgrounds can be found for instance in [129, 134, 141, 280, 371].

- In an approach similar to [282], the non-commutative behaviour of the string coordinates has been derived by computing Dirac brackets for doubled-geometry world-sheet theory in [372].

10.3 Phase-space algebra

The above results for the commutation relations of closed-string coordinates can be generalised. In this section we discuss such a generalisation as a twisted Poisson structure.

Point-particle in a magnetic field

Before coming to the non-associativity corresponding to the R -flux, it is worth pointing out that a point-particle in the background of a magnetic field also leads to a non-associative behaviour. Denoting by x^i the coordinates and by p_i the corresponding momenta, the phase-space algebra takes the form

$$[x^i, x^j] = 0, \quad [x^i, p_j] = i\delta^i_j, \quad [p_i, p_j] = ie\epsilon_{ijk}B^k, \quad (10.42)$$

where ϵ_{ijk} denotes the Levi-Civita tensor, e is the electric charge of the point-particle and B^k contains the magnetic field. For this algebra the Jacobiator of the momenta is computed as [373, 374]

$$[p_i, p_j, p_k] := [[p_i, p_j], p_k] + \text{cyclic} = -e\epsilon_{ijk}\nabla_m B^m, \quad (10.43)$$

which in general is non-vanishing and which shows the non-associative behaviour of the setting. Furthermore, from Maxwell's equations we know that for a magnetic monopole one has $\nabla_m B^m = 4\pi\rho$, where ρ denotes the charge distribution of the monopole.

Considering now the finite translation operator $U(a) = \exp(i\vec{a} \cdot \vec{p})$ along a distance \vec{a} , we can determine the associator of three such operators as

$$(U(a)U(b))U(c) = \exp\left[-ie\Phi(a, b, c)\right]U(a)(U(b)U(c)), \quad (10.44)$$

where $\Phi(a, b, c) = \frac{1}{6}\epsilon_{ijk}a^ib^jc^k\nabla_m B^m$ denotes the magnetic flux through the tetrahedron spanned by the three vectors \vec{a} , \vec{b} and \vec{c} . Using Gauss law, this is the magnetic charge $4\pi m$ inside the tetrahedron. We also note that the non-associative phase in (10.44) vanishes if $em \in \frac{1}{2}\mathbb{Z}$, which is Dirac's quantisation condition of the electric charge in the presence of a magnetic monopole. Hence, the non-associative behaviour is related to a violation of the Dirac quantisation condition.

***R*-flux algebra**

Let us now turn to the string-theory setting. We recall the commutator of two target-space coordinates for the T-fold background shown in (10.29), and note that the right-hand side is proportional to the winding number of the field X^3 parametrising the circle in the base. Even though this direction is not an isometry, one can perform a T-duality transformation along the base-circle in an abstract way. As mentioned for instance in equation (2.14), such a transformation is expected to interchange the winding with the momentum number and hence on the right-hand side of the T-dual commutator the momentum appears. This now motivates the following *R*-flux phase-space algebra [282]

$$[x^i, x^j] = i R^{ijk} p_k, \quad [x^i, p_j] = i \delta^i_j, \quad [p_i, p_j] = 0, \quad (10.45)$$

where p_i are again the momenta conjugate to the positions x^i , and where R^{ijk} denotes the *R*-flux obtained after T-dualising the *Q*-flux. These relations arise from a twisted Poisson structure on the phase space [375, 356], and one can determine the Jacobiator (10.13) as

$$[x^i, x^j, x^k] := [[x^i, x^j], x^k] + \text{cyclic} = 3R^{ijk}, \quad (10.46)$$

showing that the phase-space algebra (10.45) is non-associative. Furthermore, we note that in [357] the Jacobiator (10.46) has been identified as a three-cocycle in Lie algebra cohomology.

Remarks

Let us close this section with the following remarks:

- In order to construct a Hilbert space for a quantised theory, one usually requires associativity. However, this requirement is not necessary and one can in fact construct a non-associative form of quantum mechanics [376–378]. An investigation of the point-particle in a magnetic field from a quantum-mechanical point of view can be found in [379], and for a more formal analysis see [380].
- The *R*-flux algebra (10.45), and more generally non-commutative and non-associative structures originating from non-geometric fluxes, have been discussed in the context of matrix models in [381].
- A realisation of the *R*-flux algebra in M-theory based on octonions has been first discussed in [382]. In [383] a higher three-algebra structure expected to govern the non-geometric M2-brane phase space has been proposed, which has been embedded into a covariant description in [384] and related to exceptional field theory in [385].

10.4 Topological T-duality

In this section we discuss how non-commutative and non-associative structures arise when studying T-duality transformations from a mathematical point of view.

Topology change from T-duality

We have already seen that under T-duality the topology can change [76, 60]. For instance, the three-torus with H -flux can be seen as a trivially-fibred circle over \mathbb{T}^2 while its T-dual – the twisted torus – can be seen as a non-trivially fibred circle over \mathbb{T}^2 . In order to formalise this observation, let us consider a circle bundle over some base-manifold \mathcal{B}

$$\begin{array}{ccc} S^1 & \hookrightarrow & \mathcal{M} \\ & & \downarrow \pi \\ & & \mathcal{B} \end{array} \quad (10.47)$$

where $\pi : \mathcal{M} \rightarrow \mathcal{B}$ denotes the projection from the fibre to a point in the base. The non-triviality of the fibration is encoded in the first Chern class $c_1(\mathcal{M}) \in H^2(\mathcal{B}, \mathbb{Z})$, which is a two-form in the cohomology of the base-manifold. (For a textbook introduction to these concepts see for instance [203].) Next, we denote the vector-field along the S^1 -fibre by k , and we perform a T-duality transformation along the fibre. One then finds that [60]

$$c_1(\mathcal{M}) \xleftarrow{\text{T-duality}} \iota_k H, \quad (10.48)$$

where $\iota_k H$ denotes the contraction of the H -flux $H \in H^3(\mathcal{M}, \mathbb{Z})$ with the vector-field k . Hence, under T-duality the two-form corresponding to the first Chern class is exchanged with a two-form constructed from the H -flux. For the example of the three-sphere with H -flux we discussed this point in section 3.2.

In order to describe T-duality in this way, it is convenient to introduce the following structure. Denoting by a tilde the T-dual background and by $\times_{\mathcal{B}}$ the fibre-wise product over the base-manifold \mathcal{B} , one has

$$\begin{array}{ccc} & \mathcal{M} \times_{\mathcal{B}} \widetilde{\mathcal{M}} & \\ p \swarrow & & \searrow \tilde{p} \\ \mathcal{M} & & \widetilde{\mathcal{M}} \\ \pi \searrow & & \swarrow \tilde{\pi} \\ & \mathcal{B} & \end{array} \quad (10.49)$$

where $\mathcal{M} \times_{\mathcal{B}} \widetilde{\mathcal{M}}$ is also called the correspondence space and $\pi, \tilde{\pi}, p$ and \tilde{p} denote various projections. For the bundle \mathcal{M} one can define a twisted cohomology $H^\bullet(\mathcal{M}, H)$, where the nil-potent operator is given by $d + H \wedge$ similarly as in section 8.5. As shown in [60], T-duality for a circle bundle can now be seen as an isomorphism

$$T_* : H^\bullet(\mathcal{M}, H) \rightarrow H^{\bullet+1}(\widetilde{\mathcal{M}}, \widetilde{H}) \quad (10.50)$$

where the superscript $+1$ denotes a shift in the degree of the cohomology group. This isomorphism can be understood by first lifting $H^\bullet(\mathcal{M}, H)$ to the correspondence space using p^* , then performing a transformation on the correspondence space, and finally projecting down to $H^\bullet(\widetilde{\mathcal{M}}, \widetilde{H})$ using \tilde{p}_* . We also note that in order to describe T-duality for the Ramond-Ramond sector one has to use twisted K-theory, for which one obtains a similar isomorphism.

Torus fibrations

One can now generalise the above discussion to n -dimensional (principal) torus fibrations \mathcal{M} over a base-manifold \mathcal{B} . To do so, let us first split the H -flux into fibre- and base-components in the following way

$$H = H_0 + H_1 \wedge b_1 + H_2 \wedge b_2 + H_3 \wedge b_3, \quad (10.51)$$

where H_p is a $(p - 3)$ -form along the torus-fibre and b_q is a q -form on the base-manifold \mathcal{B} (this notation is chosen for comparison with [386]). Furthermore, H is required to be closed with respect to the exterior derivative. We can now distinguish the following cases:

- For $H_0 = 0$ and $H_1 = 0$ we have a situation similar as above [387]. The first Chern class of the \mathbb{T}^n -fibre can be interpreted as a vector-valued two-form on the base-manifold $c_1^{\mathbf{a}}(\mathcal{M})$, where the index $\mathbf{a} = 1, \dots, n$ labels the circles in $\mathbb{T}^n = S^1 \times \dots \times S^1$. For this situation there is a uniquely-determined T-dual background, where under T-duality along a fibre direction i the first Chern class $c_1^i(\mathcal{M})$ and the two-form $\iota_{\partial_i} H$ are interchanged.
- For $H_0 = 0$ and $H_1 \neq 0$ the situation is different [388, 389]. A T-duality transformation along two directions supported by the H -flux results in a field of non-commutative tori over the base-manifold \mathcal{B} . The T-dual is not unique, however, it does not affect its K-theory.
- Finally, for $H_0 \neq 0$ and if $H = H_0$ the T-dual is a field of non-associative tori over the base [386]. The T-dual is again not unique, but it does not affect its K-theory. If furthermore also $H_1 \neq 0$ then one obtains a combination of non-commutative and non-associative tori.

Let us remark that a possible connection between the non-commutative torus and the T-fold background has been investigated in [390], and that the non-associative torus has been studied using D-branes in [391].

Non-commutative torus

Let us now provide some explanation for a non-commutative and non-associative torus. Roughly speaking, a topological space can be characterised in terms of the algebra of functions on this space (cf. Gelfand-Naimark theorem). A commutative algebra of functions corresponds to a commutative space – while a non-commutative or non-associative algebra corresponds to a non-commutative or non-associative space.

Let us now consider the non-commutative torus. To do so, we start from an ordinary two-torus \mathbb{T}^2 with plane-waves $U_1 = e^{2\pi i x_1}$ and $U_2 = e^{2\pi i x_2}$ where $x_{1,2} \in [0, 1]$. Functions $f \in C^\infty(\mathbb{T}^2)$ on \mathbb{T}^2 can be expressed using a Fourier expansion as

$$f = \sum_{(m,n) \in \mathbb{Z}^2} a_{m,n} U_1^m U_2^n, \quad (10.52)$$

where $a_{m,n}$ are complex-valued Schwartz-functions and U_1^m denotes the m 'th power of U_1 . The algebra of functions on \mathbb{T}^2 is commutative. Next, we promote $x_{1,2}$ to operators $\hat{x}_{1,2}$ which satisfy

$$[\hat{x}_1, \hat{x}_2] = \frac{\theta}{2\pi i}, \quad \theta \in \mathbb{R}. \quad (10.53)$$

Using the Baker-Campbell-Hausdorff formula, this implies for the corresponding plane-waves $\hat{U}_{1,2}$ that

$$\hat{U}_1 \hat{U}_2 = e^{2\pi i \theta} \hat{U}_2 \hat{U}_1, \quad (10.54)$$

which characterises the non-commutative torus. Functions \hat{f} can now be expanded similarly as in (10.52), which now satisfy a non-commutative algebra. Coming now back to our discussion of T-duality, for a duality transformation along two directions the two-form H_1 in (10.51) corresponds to the parameter θ in (10.53) and (10.54) on the dual side and controls the non-commutativity.

Remark

We close this section with two remarks:

- The non-associative torus is similar to the non-commutative torus, where however the algebra of functions is non-associative. The technical details of this construction can be found in [386].

- The description of T-duality as an isomorphism between H -twisted cohomologies can also be formulated as an isomorphism of Courant algebroids. A discussion of this result can be found in [392].

11 Summary

In this work we gave an overview of non-geometric backgrounds in string theory. These are spaces which cannot be described in terms of Riemannian geometry, but which are well-defined in string theory. For instance, transition functions between local charts do not need to belong to symmetry transformations of the action such as diffeomorphisms or gauge transformations, but can contain T-duality transformations.

Non-geometric backgrounds are an integral part of string theory: they can be characterised in terms of non-geometric fluxes which fit naturally into the framework of $SU(3) \times SU(3)$ structure compactifications and which complete mirror symmetry for Calabi-Yau compactifications; and non-geometric torus fibrations are needed for heterotic–F-theory duality. On the other hand, constructing explicit non-geometric solutions of string theory is difficult as typically supergravity approximations break down. However, solutions for certain non-geometric torus fibrations are provided by asymmetric orbifolds, for which a CFT description exists. Non-geometric backgrounds belong to the string-theory landscape and understanding them is crucial for understanding the space of string-theory solutions. But also at a more practical level such backgrounds are important: they lead to scalar potentials in lower-dimensional theories and can therefore be used to construct models of particle physics and cosmology in string theory. Furthermore, non-geometry can give rise to non-commutative and non-associative structures relevant for theories of quantum gravity.

The material discussed in this review can be organised into three (sometimes overlapping) topics: non-geometric spaces and their explicit realisation, non-geometric fluxes and their effect on string-theory compactifications, and non-commutative and non-associative structures. We summarise them in some more detail in the following.

Non-geometric spaces

In the introduction we have mentioned on page 9 that non-geometric spaces are configurations which do not allow for a geometric interpretation.

- Non-geometric spaces have been discussed in the context of torus fibrations in section 6. As illustrated for instance in figure 6, for these constructions the monodromy group acting on a n -dimensional torus fibre is given by $O(n, n, \mathbb{Z})$, which is the T-duality group identified in section 2. This group contains symmetry transformations such as diffeomorphisms and gauge transformations as well as proper duality transformations.
- The prime example for non-geometric spaces is the three-torus with H -flux

with its T-dual backgrounds, which have been studied in detail in section 5. Other explicit examples are the compactified NS5-brane together with the Kaluza-Klein monopole and 5_2^2 -brane which have been considered in section 6.4, and the \mathbb{T}^2 -fibrations discussed in sections 6.2 and 6.3.

- A framework to discuss such non-geometric spaces is that of doubled geometry reviewed in section 9. Here one doubles the dimensions of the fibre, which allows for a geometric description of non-geometric spaces.

Non-geometric fluxes

To the backgrounds mentioned above one can often associate geometric as well as non-geometric fluxes. This has been made explicit for the example of the three-torus with H -flux discussed in section 5.

- The H -flux encodes the non-triviality of the Kalb-Ramond B -field, and the geometric flux (related to the first Chern class of torus fibrations) encodes the non-triviality of the geometry. Both belong to the geometric fluxes. The non-geometric Q - and R -fluxes arise from applying T-duality transformations.
- For more general backgrounds, fluxes can be defined in the framework of generalised geometry discussed in section 7. In particular, the Courant bracket of generalised vielbeins determines these fluxes.
- In section 8 we have analysed how non-geometric fluxes modify the effective four-dimensional theory corresponding to Calabi-Yau compactifications: fluxes lead to a gauging of $\mathcal{N} = 2$ and $\mathcal{N} = 1$ supergravity theories in four dimensions, which in turn induces a scalar potential. Explicit examples in the context of Scherk-Schwarz reductions have been discussed in section 8.7. We have furthermore seen that non-geometric fluxes appear on equal footing with geometric fluxes and that they are needed for mirror symmetry.

Non-commutative and non-associative structures

In section 10 we have illustrated how non-geometric backgrounds give rise to non-commutative and non-associative structures.

- Non-associativity for the closed string due to non-geometric R -flux has been discussed in section 10.1. Such a behaviour can be detected by computing correlation functions of vertex operators, which in turn leads to a non-associative tri-product.

- In a slightly different approach, non-commutativity for closed strings has been studied in section 10.2 by quantising the closed string for torus fibrations. After performing T-duality transformations this leads to non-vanishing commutators between target-space coordinates parametrised by the Q -flux. These constructions correspond to asymmetric orbifolds.
- In section 10.4 non-commutative and non-associative structures originating from topological T-duality have been discussed.

Topics not covered

In this review we gave a pedagogical introduction to non-geometric backgrounds in string theory. While providing an overview on many aspects of such spaces, it was not possible to discuss each of those topics in detail and some topics had to be omitted:

- We have discussed (collective) abelian T-duality transformations and we commented on non-abelian T-duality starting on page 49. For a more detailed discussion of the latter we refer the reader for instance to [62, 36, 37, 63–66, 45, 67], and we mention that non-abelian T-duality has been employed as a solution-generating technique for instance in [72–74].
- Certain (non-abelian) T-duality transformations can be related to integrable deformations of supergravity backgrounds. This has been investigated in [393, 71, 394–397]. Relations to non-commutative geometries and non-geometric backgrounds have been addressed for instance in [398, 399, 108].
- A world-sheet formulation which incorporates non-geometric fluxes has been proposed in [212, 213]. The Courant bracket (encoding geometric as well as non-geometric fluxes, cf. section 7) has been derived from the usual sigma model in [400], and a description of R -fluxes from a membrane sigma-model point of view can be found in [356].
- In section 8.9 we gave an overview on non-geometric string-theory solutions in view of moduli stabilisation, realising inflation and constructing de Sitter vacua. We did not construct explicit models in this review, but on page 176 referred to the existing literature.
- In section 9.3 we gave a brief introduction to double field theory and explained its relevance in regard to non-geometric fluxes, however, a more thorough discussion is beyond the scope of this work. For more details we refer to the existing review articles [315–317]. The extension of the T-duality covariant formulation given by DFT to a U-duality covariant framework is

called exceptional field theory. Review articles for these formulations can be found in [160–162].

- In this review we have focused on bosonic string theory and on type II superstring theory. But non-geometric backgrounds also appear for the heterotic string as studied in [176–178, 132, 179, 180]. In the context of M-theory non-geometric fluxes have been discussed for instance in [401, 382, 384, 385].

Acknowledgements

The author is grateful for many helpful and interesting discussions during the preparation of this work with D. Andriot, D. Berman, R. Blumenhagen, I. Brunner, G. Cavalcanti, A. Chatzistavrakidis, G. Dall'Agata, L. Ferro, S. Groot-Nibbelink, M. Haack, R. Helling, C. Hull, L. Jonke, D. Junghans, E. Kiritsis, S. Krippendorf, V. Kupriyanov, M. Larfors, D. Lüst, S. Massai, E. Malek, C. Mayrhofer, J. McOrist, A. Orta, F. Rudolph, C. Schmidt-Colinet, R. Szabo, V. Vall Camell, T. van Riet and M. Zagermann. For very useful comments on the manuscript he thanks A. Chatzistavrakidis, F. Cordonier-Tello, H. Erbin, D. Klaewer, D. Osten and M. Syväri, and he thanks his collaborators with whom he has worked on many aspects of non-geometric backgrounds over the last years: I. Bakas, P. Betzler, R. Blumenhagen, F. Cordonier-Tello, A. Deser, A. Font, M. Fuchs, D. Herschmann, D. Lüst, F. Rennecke, C. Schmid, Y. Sekiguchi, V. Vall Camell and F. Wolf.

The author is partially supported through a Maria-Weber-Grant of the Hans Böckler Foundation, and he is grateful to the Mainz Institute for Theoretical Physics (MITP) for its hospitality and its partial support during the completion of this work. He also thanks the Lorentz Institute for Theoretical Physics in Leiden for its hospitality.
