Abstract

Buch and Rimányi proved a formula for a specialization of double Grothendieck polynomials based on the Yang-Baxter equation related to the degenerate Hecke algebra. A geometric proof was found by Yong and Woo by constructing a Gröbner basis for the Kazhdan-Lusztig ideals. In this note, we give an elementary proof for this formula by using only divided difference operators.

1 Introduction

Let S_n denote the symmetric group of permutations of $\{1, 2, \dots, n\}$. For a permutation $w \in S_n$, the double Grothendieck polynomial $\mathfrak{G}_w(x; y)$ introduced by Lascoux and Schützenberger [12] is the polynomial representative of the class of the Schubert variety for w in the equivariant K -theory of the flag manifold. Write a permutation $v \in S_n$ in one-line notation, that is, write $v = v(1)v(2) \cdots v(n)$. The specialization

$$\mathfrak{G}_w(y_v; y) := \mathfrak{G}_w(y_{v(1)}, \dots, y_{v(n)}; y) \quad (1.1)$$

of $\mathfrak{G}_w(x; y)$ obtained by replacing x_i with $y_{v(i)}$ gives the restriction of this class to the fixed point corresponding to v . Buch and Rimányi [4] proved a formula for $\mathfrak{G}_w(y_v; y)$ based on the Yang-Baxter equation related to the degenerate Hecke algebra. Buch and Rimányi [4] also pointed out various important applications of this formula. By constructing a Gröbner basis for the Kazhdan-Lusztig ideals, Yong and Woo [15] found a geometric explanation for the Buch-Rimányi formula.

In this note, we give an elementary proof of the Buch-Rimányi formula by using only divided difference operators. As observed by Buch and Rimányi [4, Corollary 2.3], the classical pipe dream (or, RC-graph) formula of $\mathfrak{G}_w(x; y)$ (see for example [10, Corollary 5.4], [13, Theorem 6.3]) can be directly obtained from the specialization $\mathfrak{G}_w(y_v; y)$. Hence our approach implies that the pipe dream formula for double Grothendieck polynomials can be derived directly from divided difference operators.

2 The Buch-Rimányi formula

Fix a nonnegative integer n . For $1 \leq i < j \leq n$, let t_{ij} denote the transposition (i, j) in S_n . So, if $w \in S_n$, then wt_{ij} is the permutation obtained from w by interchanging $w(i)$ and $w(j)$, while $t_{ij}w$ is obtained from w by interchanging the values i and j . For example, for $w = 2143$, we have $wt_{13} = 4123$ and $t_{13}w = 2341$. Write s_i for the adjacent transposition $(i, i+1)$. Each permutation can be written as a product of adjacent transpositions. The length $\ell(w)$ of a permutation w is the minimum k such that $w = s_{i_1}s_{i_2}\cdots s_{i_k}$, and in this case, $(s_{i_1}, s_{i_2}, \dots, s_{i_k})$ is called a reduced word of w . It is well known that the length $\ell(w)$ is equal to the number of pairs (i, j) such that $i < j$ and $w(i) > w(j)$:

$$\ell(w) = \#\{(i, j): 1 \leq i < j \leq n, w(i) > w(j)\}.$$

Hence, it is clear that $\ell(ws_i) = \ell(w) + 1$ if and only if $w(i) < w(i+1)$, while $\ell(ws_i) = \ell(w) - 1$ if and only if $w(i) > w(i+1)$.

Let $\mathbb{Z}[x^\pm, y^\pm]$ denote the ring of Laurent polynomials in the $2n$ commuting indeterminates $x_1, \dots, x_n, y_1, \dots, y_n$. For a Laurent polynomial $f(x, y) \in \mathbb{Z}[x^\pm, y^\pm]$, the divided difference operator ∂_i acting on $f(x, y)$ is defined by

$$\partial_i f = (f - s_i f)/(x_i - x_{i+1}),$$

where $s_i f$ is obtained from f by interchanging x_i and x_{i+1} . It is easy to check that $\partial_i f$ is still a Laurent polynomial. Let $w_0 = n \cdots 21$ be the longest permutation in S_n . Set

$$\mathfrak{G}_{w_0}(x; y) = \prod_{i+j \leq n} \left(1 - \frac{y_j}{x_i}\right). \quad (2.1)$$

For $w \neq w_0$, choose an adjacent transposition s_i such that $\ell(ws_i) = \ell(w) + 1$. Let $\pi_i = \partial_i x_i$ and define

$$\mathfrak{G}_w(x; y) = \pi_i \mathfrak{G}_{ws_i}(x; y) = \frac{x_i \mathfrak{G}_{ws_i}(x; y) - x_{i+1} \mathfrak{G}_{ws_i}(\dots, x_{i+1}, x_i, \dots; y)}{x_i - x_{i+1}}. \quad (2.2)$$

The above definition is independent of the choice of s_i since the operators π_i satisfy the Coxeter relations: $\pi_i \pi_j = \pi_j \pi_i$ for $|i - j| > 1$, and $\pi_i \pi_{i+1} \pi_i = \pi_{i+1} \pi_i \pi_{i+1}$, see for example [14, (2.14)].

We remark that there are other equivalent definitions for double Grothendieck polynomials. The definition adopted here implies that $\mathfrak{G}_w(x; y)$ are Laurent polynomials. The double Grothendieck polynomials $\mathfrak{L}_w^{(-1)}(y; x)$ defined in [5] are legitimate polynomials, which can be obtained from $\mathfrak{G}_w(x; y)$ by replacing x_i and y_i respectively with $\frac{1}{1-x_i}$ and $1 - y_i$. It should also be noticed that $\mathfrak{G}_w(x^{-1}; y^{-1})$ are the double Grothendieck polynomials used in [9], and $\mathfrak{G}_w(x^{-1}; y)$ are the double Grothendieck polynomials appearing in [10]. It is worth mentioning that the double Schubert polynomial $\mathfrak{S}_w(x; y)$ is the lowest degree homogeneous component of $\mathfrak{L}_w^{(-1)}(y; x)$, see [1, 2, 6, 7, 11] for combinatorial constructions of Schubert polynomials.

To describe the Buch-Rimányi formula, consider the left-justified array Δ_n with $n-i$ squares in row i . Let $w = w(1)w(2)\cdots w(n) \in S_n$. For $1 \leq i \leq n$, let

$$I(w, i) = \{w(j): j > i, w(j) < w(i)\}$$

be the set of entries in w that are smaller than $w(i)$ but appear to the right of $w(i)$. Set $c(w, i) = |I(w, i)|$. It is clear that $0 \leq c(w, i) \leq n - i$. Let $D(w)$ be the subset of Δ_n consisting of the first $c(w, i)$ squares in the i -th row of Δ_n , where $1 \leq i \leq n$. Note that $D(w)$ corresponds to the bottom RC-graph of w , as defined by Bergeron and Billey [1]. Assume that the values in $I(w, i)$ are

$$w(j_1) < w(j_2) < \cdots < w(j_{c(w,i)}).$$

For a square $B \in D(w)$ in row i and column k , equip B with the weight

$$\text{wt}(B) = 1 - \frac{y_{w(j_k)}}{y_{w(i)}},$$

see Figure 2.1 for an illustration.

Figure 2.1: Weights of squares of $D(w)$ for $w = 2157634$.

Given a subset D of $D(w)$, one can generate a word, denoted $\text{word}(D)$, as follows. Label the square of $D(w)$ in row i and column k by the simple transposition s_{i+k-1} , see Figure 2.2 for an illustration. Then $\text{word}(D)$ is obtained by reading off the labels of the squares in D

Figure 2.2: Labels of the squares of $D(w)$ for $w = 2157634$.

along the rows from top to bottom and right to left. For example, for the diagram $D = D(w)$ in Figure 2.2, we have

$$\text{word}(D) = (s_1, s_4, s_3, s_6, s_5, s_4, s_6, s_5).$$

A word $(s_{i_1}, s_{i_2}, \dots, s_{i_m})$ is called a Hecke word of a permutation u of length m if

$$(((s_{i_1} * s_{i_2}) * s_{i_3}) * \dots) * s_{i_m} = u,$$

where, for a permutation w , we define $w * s_i$ to be w if $\ell(ws_i) < \ell(w)$ and ws_i otherwise. For example, (s_1, s_2, s_1, s_2) is a Hecke word of $u = 321$ of length 4 since

$$((s_1 * s_2) * s_1) * s_2 = ((s_1 s_2) * s_1) * s_2 = (s_1 s_2 s_1) * s_2 = s_1 s_2 s_1 = 321.$$

We note in passing that the operation $*$ can be extended to an associative operation on the whole S_n ; this latter operation is the multiplication in the Hecke algebra associated to S_n at $q = 0$, see [8, Chapter 7.4]. Hence $*$ satisfies the associative property. This means that the set of permutations in S_n forms a monoid structure (0-Hecke monoid) under the operation $*$.

Write $\text{Hecke}(D) = u$ if $\text{word}(D)$ is a Hecke word of a permutation u . Notice that a Hecke word of u of length $\ell(u)$ is a reduced word of u . Note that for any $w \in S_n$, the word $\text{word}(D(w))$ is a reduced word of w , and therefore, if we multiply the letters of $\text{word}(D(w))$ using either the $*$ product or the usual product of S_n , then we get w . That is, $\text{Hecke}(D(w)) = w$.

For any $u, v \in S_n$, let

$$\mathcal{H}(u, v) = \{D \subseteq D(v) \mid \text{Hecke}(D) = u\}.$$

For a subset D of $D(v)$, let

$$\text{wt}(D) = \prod_{B \in D} \text{wt}(B). \tag{2.3}$$

Theorem 2.1 (Buch-Rimányi [4, Theorem 2.1]). *For permutations $u, v \in S_n$, we have*

$$\mathfrak{G}_u(y_v; y) = \sum_{D \in \mathcal{H}(u, v)} (-1)^{|D| - \ell(u)} \text{wt}(D), \tag{2.4}$$

where empty sums are interpreted as 0.

We remark that in [4], formula (2.4) is described in terms of the notation $C(\mathfrak{D}_v)$ and FK-graphs for u with respect to \mathfrak{D}_v . With the notation in this note, $D(v)$ can be obtained from $C(\mathfrak{D}_v)$ by first reflecting along the main diagonal and then left-justifying the crossing positions. This operation also establishes a weight preserving bijection between the set $\mathcal{H}(u, v)$ and the set of FK-graphs for u with respect to \mathfrak{D}_v .

3 Elementary proof of Theorem 2.1

We need several lemmas which follow directly from the definition of $\mathfrak{G}_w(x; y)$.

Lemma 3.1. *Let $v = v' s_i$ and $\ell(v) > \ell(v')$. If $\ell(us_i) < \ell(u)$, then*

$$\mathfrak{G}_u(y_v; y) = \frac{y_{v'(i)}}{y_{v'(i+1)}} \mathfrak{G}_u(y_{v'}; y) + \left(1 - \frac{y_{v'(i)}}{y_{v'(i+1)}}\right) \mathfrak{G}_{us_i}(y_{v'}; y). \tag{3.1}$$

Proof. Applying (2.2) to $w = us_i$ and substituting x_j with $y_{v'(j)}$, we have

$$\mathfrak{G}_{us_i}(y_{v'}; y) = \frac{y_{v'(i)} \mathfrak{G}_u(y_{v'}; y) - y_{v'(i+1)} \mathfrak{G}_u(y_v; y)}{y_{v'(i)} - y_{v'(i+1)}},$$

which is equivalent to (3.1). ■

Lemma 3.2. *Let $v = v's_i$. If $\ell(us_i) > \ell(u)$, then*

$$\mathfrak{G}_u(y_v; y) = \mathfrak{G}_u(y_{v'}; y). \quad (3.2)$$

Proof. Applying (2.2) to $w = u$ and substituting x_j with $y_{v(j)}$ and $y_{v'(j)}$ respectively, we see that

$$\begin{aligned} \mathfrak{G}_u(y_v; y) &= \frac{y_{v(i)} \mathfrak{G}_{us_i}(y_v; y) - y_{v(i+1)} \mathfrak{G}_{us_i}(y_{v'}; y)}{y_{v(i)} - y_{v(i+1)}}, \\ \mathfrak{G}_u(y_{v'}; y) &= \frac{y_{v'(i)} \mathfrak{G}_{us_i}(y_{v'}; y) - y_{v'(i+1)} \mathfrak{G}_{us_i}(y_v; y)}{y_{v'(i)} - y_{v'(i+1)}}, \end{aligned}$$

which, together with the fact that $v(i) = v'(i+1)$ and $v(i+1) = v'(i)$, implies (3.2). ■

Let \leq denote the (strong) Bruhat order on permutations of S_n . Recall that the Bruhat order is the closure of the following covering relation: For $u, v \in S_n$, we say that v covers u if there exists a transposition t_{ij} such that $v = ut_{ij}$ and $\ell(v) = \ell(u) + 1$. The following lemma is known, see [4, Corollary 2.4] and the references therein.

Lemma 3.3. *We have $\mathfrak{G}_u(y_v; y) = 0$ whenever $u \not\leq v$ in the Bruhat order.*

Proof. The idea in the proof of [11, (2.22)] for double Schubert polynomials applies to double Grothendieck polynomials, and we include a proof here for the reader's convenience. Use descending induction on $\ell(u)$. The initial case is $u = w_0$. Since $u \not\leq v$, we have $v \neq w_0$. It is easily checked from (2.1) that $\mathfrak{G}_{w_0}(y_v; y) = 0$.

We now consider the case $u \neq w_0$. Choose a position i such that $u(i) < u(i+1)$. Note that $u < us_i$. Since $u \not\leq v$, we must have $us_i \not\leq v$. We further claim that $us_i \not\leq vs_i$. This can be seen as follows. We have either $vs_i < v$ or $v < vs_i$ (depending on which of $\ell(vs_i)$ and $\ell(v)$ is larger). If $vs_i < v$, then it is clear that $us_i \not\leq vs_i$ since otherwise there would hold $u \leq v$. It remains to verify the case $v < vs_i$. Suppose to the contrary that $us_i \leq vs_i$. Then $u < vs_i$. Since $vs_i > v$ and $us_i > u$, applying the Lifting Property (see [3, Proposition 2.2.7]) to u^{-1} and $(vs_i)^{-1}$, we obtain that $u \leq v$, leading to a contradiction. Now, by the definition in (2.2) and by the induction hypothesis,

$$\mathfrak{G}_u(y_v; y) = \frac{y_{v(i)} \mathfrak{G}_{us_i}(y_v; y) - y_{v(i+1)} \mathfrak{G}_{us_i}(y_{vs_i}; y)}{y_{v(i)} - y_{v(i+1)}} = 0,$$

as desired. ■

Lemma 3.4. *Let $u \in S_n$ and $u' = us_i$ for some i such that $\ell(us_i) < \ell(u)$. Then,*

$$\mathfrak{G}_u(y_u; y) = \left(1 - \frac{y_{u(i+1)}}{y_{u(i)}}\right) \mathfrak{G}_{u'}(y_{u'}; y).$$

Proof. Apply Lemma 3.1 to $v = u$ and $v' = u'$. The first addend on the right side vanishes due to Lemma 3.3. ■

Lemma 3.5 (Buch-Rimányi [4, Corollary 2.6]). *For each $u \in S_n$, we have*

$$\mathfrak{G}_u(y_u; y) = \prod_{\substack{i < j \\ u(i) > u(j)}} \left(1 - \frac{y_{u(j)}}{y_{u(i)}} \right).$$

Proof. Make descending induction on $\ell(u)$. The induction base for $u = w_0$ is a restatement of (2.1). Assume that $u \neq w_0$. Then there exists some $1 \leq k < n$ such that $\ell(us_k) > \ell(u)$. Let $u' = us_k$. It is easy to see that the set

$$\{(u'(i), u'(j)) \mid i < j, u'(i) > u'(j)\}$$

is the union of the two disjoint sets

$$\{(u(i), u(j)) \mid i < j, u(i) > u(j)\} \cup \{(u(k), u(k+1))\}.$$

The proof follows by induction together with Lemma 3.4. ■

Proof of Theorem 2.1. The proof is by induction on $\ell(v)$. Let us first consider the case $\ell(v) = 0$, that is, v is the identity permutation e . If $u = e$, then it follows from Lemma 3.5 (applied to $u = e$) that $\mathfrak{G}_e(y_e; y) = 1$. If $u \neq e$, then Lemma 3.3 forces that $\mathfrak{G}_u(y_e; y) = 0$. So (2.4) holds for $\ell(v) = 0$.

Assume now that $\ell(v) > 0$. Let s_r be the last descent of v , that is, r is the largest index such that $v(r) > v(r+1)$. Write $v = v's_r$. Clearly, the bottom row of $D(v)$ lies in row r of Δ_n . The leftmost square in the bottom row of $D(v)$, denoted B_0 , has weight

$$\text{wt}(B_0) = 1 - \frac{y_{v(r+1)}}{y_{v(r)}} = 1 - \frac{y_{v'(r)}}{y_{v'(r+1)}}.$$

Let $u = u's_r$. There are two cases.

Case 1. s_r is a descent of u . By Lemma 3.1 and by induction hypothesis, we have

$$\begin{aligned} \mathfrak{G}_u(y_v; y) &= \frac{y_{v'(r)}}{y_{v'(r+1)}} \mathfrak{G}_u(y_{v'}; y) + \left(1 - \frac{y_{v'(r)}}{y_{v'(r+1)}} \right) \mathfrak{G}_{u'}(y_{v'}; y) \\ &= (1 - \text{wt}(B_0)) \sum_{D \in \mathcal{H}(u, v')} (-1)^{|D| - \ell(u)} \text{wt}(D) + \text{wt}(B_0) \sum_{D \in \mathcal{H}(u', v')} (-1)^{|D| - \ell(u')} \text{wt}(D) \\ &= \sum_{D \in \mathcal{H}(u, v')} (-1)^{|D| - \ell(u)} \text{wt}(D) - \text{wt}(B_0) \sum_{D \in \mathcal{H}(u, v')} (-1)^{|D| - \ell(u)} \text{wt}(D) \\ &\quad + \text{wt}(B_0) \sum_{D \in \mathcal{H}(u', v')} (-1)^{|D| - \ell(u')} \text{wt}(D). \end{aligned} \tag{3.3}$$

To proceed, note that there is an obvious bijection ϕ between $D(v')$ and $D(v) \setminus \{B_0\}$. Since s_r is the last descent of v , we have $c(v', r) = 0$, $c(v', r+1) = c(v, r) - 1$, and $c(v', i) = c(v, i)$

for $i \neq r, r+1$. Let $B \in D(v')$. If B lies above row r , then set $\phi(B) = B$. Assume that B lies in row $r+1$ and column j , then let $\phi(B)$ be the square of $D(v) \setminus \{B_0\}$ in row r and column $j+1$. By construction, B and $\phi(B)$ are labeled by the same simple transposition. Moreover, it is easy to see that ϕ preserves the weight and words, namely, $\text{wt}(B) = \text{wt}(\phi(B))$ and $\text{word}(\phi(D)) = \text{word}(D)$ for all $D \subseteq D(v')$. Thus $\text{Hecke}(\phi(D)) = \text{Hecke}(D)$ for all $D \subseteq D(v')$.

We claim that $\mathcal{H}(u, v)$ is the disjoint union of the following sets:

$$\begin{aligned} S_1 &= \{\phi(D) : D \in \mathcal{H}(u, v')\}, \\ S_2 &= \{\phi(D) \cup \{B_0\} : D \in \mathcal{H}(u, v')\}, \\ S_3 &= \{\phi(D) \cup \{B_0\} : D \in \mathcal{H}(u', v')\}. \end{aligned}$$

This can be easily seen as follows. Keep in mind that B_0 is labeled by s_r . Let $D \in \mathcal{H}(u, v)$. If $B_0 \notin D$, then $D \in S_1$. If $B_0 \in D$, then $\text{word}(D)$ is obtained from $\text{word}(D \setminus \{B_0\})$ by appending the letter s_r at the end, and thus we have $\text{Hecke}(D) = \text{Hecke}(D \setminus \{B_0\}) * s_r$, and therefore either $\text{Hecke}(D \setminus \{B_0\}) = u$ or $\text{Hecke}(D \setminus \{B_0\}) = u'$. Hence either $D \in S_2$ or $D \in S_3$. Conversely, any $D \in S_1 \cup S_2 \cup S_3$ belongs to $\mathcal{H}(u, v)$, since $u * s_r = u' * s_r = u$. By the above claim and in view of (3.3), we obtain that

$$\mathfrak{G}_u(y_v; y) = \sum_{D \in S_1 \cup S_2 \cup S_3} (-1)^{|D| - \ell(u)} \text{wt}(D) = \sum_{D \in \mathcal{H}(u, v)} (-1)^{|D| - \ell(u)} \text{wt}(D).$$

Case 2. s_r is not a descent of u . Let $D \in \mathcal{H}(u, v)$. We claim that $B_0 \notin D$. Suppose otherwise that $B_0 \in D$. Consider $D' = D \setminus \{B_0\}$. If s_r is a descent of $\text{Hecke}(D')$, then $\text{Hecke}(D) = \text{Hecke}(D')$, while if s_r is not a descent of $\text{Hecke}(D')$, then $\text{Hecke}(D) = \text{Hecke}(D') s_r$. In both cases, s_r is a descent of $u = \text{Hecke}(D)$, leading to a contradiction. Therefore, we see that $\mathcal{H}(u, v) = \{\phi(D) \mid D \in \mathcal{H}(u, v')\}$. By Lemma 3.2 and by induction hypothesis,

$$\mathfrak{G}_u(y_v; y) = \mathfrak{G}_u(y_{v'}; y) = \sum_{D \in \mathcal{H}(u, v')} (-1)^{|D| - \ell(u)} \text{wt}(D) = \sum_{D \in \mathcal{H}(u, v)} (-1)^{|D| - \ell(u)} \text{wt}(D).$$

This completes the proof. ■
