Device-to-Device Communication Facilitating Full-Duplex Cooperative Relaying Using Non-Orthogonal Multiple Access

Mohammed Belal Uddin, Md. Fazlul Kader, *Senior Member, IEEE* and Soo Young Shin, *Senior Member, IEEE*

Abstract—This letter presents a device-to-device (D2D) enabling cellular full-duplex (FD) cooperative protocol using nonorthogonal multiple access (NOMA), where an FD relay assists in relaying NOMA far user's signal and transmits a D2D receiver's signal simultaneously. The ergodic capacity, outage probability, and diversity order of the proposed protocol are theoretically investigated under the realistic assumption of imperfect self and known interference cancellation. The Outcome of the investigation demonstrates the performance gain of the suggested protocol over conventional FD cooperative NOMA system.

Index Terms—Non-orthogonal multiple access, ergodic sum capacity, full-duplex, device-to-device communication.

I. INTRODUCTION

 $\bf\Gamma$ ON-ORTHOGONAL multiple access (NOMA) enables a transmitter to transmit multiple signals concurrently to multiple receivers having distinguished channel quality. NOMA is also combinable with other technical features like cooperative communication, device-to-device (D2D) communication, half/full duplex relaying, etc. Hence, it is considered as one of the promising radio access technologies for future wireless communication [\[1\]](#page-3-0), [\[2\]](#page-3-1). NOMA adopted full-duplex relay (FDR) aided cooperative communication (FDCC) can efficiently enhance spectral efficiency, ergodic capacity (EC), and signal reliability [\[3\]](#page-3-2). An FDR either can be a dedicated relay [\[3\]](#page-3-2) or a relay-like user [\[4\]](#page-3-3). In order to increase the outage performance of a far user, a simple FDCC protocol was considered [\[4\]](#page-3-3) wherein a NOMA near user relayed the signal to a far user. In [\[5\]](#page-3-4), a non-cooperative NOMA protocol consisting of a pair of cellular users and a pair of D2D users in a cell was devised and impact of interference from a D2D transmitter on cellular user's performance was investigated. An FDCC system was analyzed in [\[6\]](#page-3-5), where a dedicated FDR was used to transmit signal to a far user. Outage probability (OP) and ergodic sum capacity (ESC) were shown higher than the existing corresponding half-duplex cooperative relaying system. Focusing on achieving better spectral efficiency than [\[6\]](#page-3-5), an integrated D2D and cellular communication protocol is proposed in this letter. A succinct description of the contribution of this work is summarized as: (i) A D2D facilitating and an FDR assisted cooperative NOMA (termed as DFC-NOMA) protocol is proposed, where an FDR relays the far user's signal

BS D¹ Self-interference U1 U2 U3 Data link Interference link

Fig. 1. Proposed network model.

and acts as a D2D transmitter as well. (ii) A closed-form and an asymptotic (Asm.) expressions of each user's EC, OP, and system's ESC are analyzed over Rayleigh fading channel. The diversity order (DO) of each user is also investigated. (iii) Finally, performance gain of the proposed DFC-NOMA over conventional full-duplex cooperative NOMA (FC-NOMA) [\[6\]](#page-3-5) is shown by theoretical analysis and justified by simulation.

II. SYSTEM MODEL AND PROTOCOL DESCRIPTION

As shown in Fig. [1,](#page-0-0) a downlink DFC-NOMA is considered that consists of a base station (BS), two cellular users U_1 (near user) and U_3 (far user), one full-duplex relay acting user (U_2) for conveying signal to U_3 from BS, and a D2D user (D_1) . Due to the blockage and hindrance to signal propagation, BS-to- U_3 link is considered unavailable [\[6\]](#page-3-5) and the remaining links of the system are available. In [\[6\]](#page-3-5), the relay retransmits the decoded symbol only to far user. Contrarily, in the proposed DFC-NOMA, U_2 (acting as a relay) retransmits the decoded symbol to U_3 and its own symbol to D_1 at the same time, by exploiting NOMA. The channel coefficient experiences Rayleigh fading between two nodes *i* and *j* will be complex Gaussian random variable with zero mean and variance λ_{ij} that can be denoted by $h_{ij} \sim \mathcal{CN}(0, \lambda_{ij})$; $i, j \in \{BS, U_1, U_2, U_3,$ D_1 , and *i* \neq *j*. Hence, the channel gain $g_{ij} = |h_{ij}|^2$ will be the exponentially distributed random variable with scale parameter of $\lambda_{i,j}$ [\[3\]](#page-3-2). Subscripts *b*, 1, 2, 3, and *d* are respectively used for BS, U_1 , U_2 , U_3 , and D_1 . Each node excluding U_2 is equipped with single antenna. As U_2 operates in full-duplex mode, it is equipped with one transmit and one receive antennas. So, due to the simultaneous transmission and reception of signals, the relay suffers from a self-interference (SI) that can be subsided by applying multi-stage SI cancellation technique [\[7\]](#page-3-6). In practice, SI can not be removed perfectly. Therefore, imperfect SI cancellation is considered that causes residual SI at relay which is symbolized by $\tilde{h}_{22} \sim \mathcal{CN}(0, \zeta_1 \lambda_{22})$ with zero mean and $\zeta_1 \lambda_{22}$ variance. Hence, the channel gain of residual SI at U_2 is $\tilde{g}_{22} = |\tilde{h}_{22}|^2$. The variable ς_1 limiting as $0 \le \varsigma_1 \le 1$ specifies the effect of remaining SI. Devices are assumed to be located in such a way that the channel gains can be considered

as $g_{b2} \ll g_{b1}$ and $g_{23} \ll g_{2d}$. At any instant of time (*t*-th slot), the BS transmits a composite downlink NOMA signal $s_c[t]$ $\mu = \sqrt{\theta_1 p_b} s_1[t] + \sqrt{\theta_3 p_b} s_3[t]$ where s₁ information is intended to reach U_1 directly and s_3 information is intended to be reached to U₃ via the help of U₂. Parameters p_b , θ_1 , and θ_3 refer to the total transmit power of BS, associated power allocation factor with s_1 , and associated power allocation factor with s₃, respectively, where $\theta_1 + \theta_3 = 1$ and $\theta_1 < \theta_3$ is maintained due to the channel gain difference between BSto- U_1 and BS-to- U_2 as stated earlier. The relay U_2 decodes *s*³ at the direct phase and retransmits this decoded symbol along with it's own signal s_2 with a processing delay $v \ge 1$ at cooperative phase. According to the property of downlink NOMA, this transmit signal can be written as $s_r[t - v] =$ $\overline{\theta_2 p_u} s_2[t - v] + \sqrt{\theta_3' p_u} s_3[t - v]$, where $\theta_2 + \theta_3' = 1$, θ_2 < θ'_3 , p_u is the total transmit power of U₂, θ_2 and θ'_3 are the allocated power with *s*² and *s*³ informations, respectively. After receiving the transmitted signal from BS, relay decodes the information s_3 by treating s_1 as noise and the related signalto-interference-plus-noise ratio (SINR) at U_2 is given by

$$
\gamma_{b2}^{s_3} = \frac{\theta_3 \rho_{b} g_{b2}}{\theta_1 \rho_{b} g_{b2} + \rho_{u} \tilde{g}_{22} + 1},\tag{1}
$$

where $\rho_b = \frac{p_b}{\sigma^2}$ $\frac{p_b}{\sigma_2^2}$ and $\rho_u = \frac{p_u}{\sigma_2^2}$ $\frac{p_u}{\sigma_z^2}$ respectively represent the transmit SNR of BS and U₂; σ_2^2 is the variance of additive white Gaussian noise (AWGN) at U2. Let, AWGN at all receivers are identical. So, the variance of AWGN will be equal for all receivers. When the near user U_1 receives the transmitted signal from BS, it also gets the composite signal from U_2 as interference. During the self-signal decoding U_1 decodes U₃'s signal *s*₃ first and then performs successive interference cancellation (SIC) to obtain it's own signal *s*1. So, the information s_3 in interference signal from U_2 is known to U_1 and can remove it by applying known interference cancellation technique. But U_1 can not remove s_2 from interference signal as this is unknown to U_1 . Therefore, by considering imperfect cancellation of known interference s_3 and no cancellation of unknown interference $s₂$, the channel coefficient of interference link from U_2 to U_1 can be modeled as $\tilde{h}_{21} \sim \mathcal{CN}(0, \zeta_2 \theta_2 \lambda_{21} + \zeta_3 \theta_3' \lambda_{21})$, where the parameters ζ_2 (=1) and ζ_3 ($0 \leq \zeta_3 \leq 1$) refer level of residual interference. Accordingly, the received SINRs related to informations *s*³ and s_1 at U_1 are respectively obtained as

$$
\gamma_{b1}^{s_3} = \frac{\theta_3 \rho_{b} g_{b1}}{\theta_1 \rho_{b} g_{b1} + \rho_{u} \tilde{g}_{21} + 1},\tag{2}
$$

$$
\gamma_{b1}^{s_1} = \frac{\theta_1 \rho_{b} g_{b1}}{\rho_{u} \tilde{g}_{21} + 1},\tag{3}
$$

where $\tilde{g}_{21} = |\tilde{h}_{21}|^2$. At the cooperative phase, the far/weak user U_3 receives the signal transmitted from U_2 and decodes it's information s_3 by treating s_2 as noise. So, the related SINR for s_3 at U_3 is given by

$$
\gamma_{23}^{s_3} = \frac{\theta_3' \rho_{u} g_{23}}{\theta_2 \rho_{u} g_{23} + 1}.
$$
 (4)

D2D user D_1 also receives the transmitted signal from U_2 at cooperative phase. First, D_1 needs to decode s_3 by treating s_2 as noise. Then after performing SIC process, it decodes it's

own information s_2 . Hence, SINRs related to s_3 and s_2 at D_1 can be respectively expressed as

$$
\gamma_{2d}^{s_3} = \frac{\theta_3' \rho_u g_{2d}}{\theta_2 \rho_u g_{2d} + 1},\tag{5}
$$

$$
\gamma_{2d}^{s_2} = \theta_2 \rho_u g_{2d}.\tag{6}
$$

Using [\(3\)](#page-1-0) and [\(6\)](#page-1-1), the achievable rate of U_1 and D_1 are respectively written by

$$
C_1 = \log_2\left(1 + \gamma_{b1}^{s_1}\right),\tag{7}
$$

$$
C_d = \log_2\left(1 + \gamma_{2d}^{s_2}\right). \tag{8}
$$

Moreover, the achievable rate of U_3 can be obtained by using [\(1\)](#page-1-2), [\(2\)](#page-1-3), [\(4\)](#page-1-4), and [\(5\)](#page-1-5) as

$$
C_3 = \log_2 \left(1 + \min \{ \gamma_{b2}^{s_3}, \gamma_{b1}^{s_3}, \gamma_{23}^{s_3}, \gamma_{2d}^{s_3} \} \right). \tag{9}
$$

Finally, the overall achievable capacity of the proposed DFC-NOMA can be calculated as

$$
C_{\rm cap.}^{\rm pro.} = C_1 + C_d + C_3. \tag{10}
$$

III. PERFORMANCE ANALYSIS

A. Capacity Analysis

1) Ergodic Capacity of U_1 : Let $Q \triangleq \frac{\theta_1 \rho_{b} g_{b1}}{\rho_{b} \tilde{g}_{b1} + 1}$ $\frac{\sigma_1 p_{b} g_{b1}}{\rho_u \tilde{g}_{21} + 1}$. Using the definition of cumulative distribution function (CDF), $F_Q(q)$ = $Pr{\frac{\theta_1 \rho_b g_{b1}}{\rho_u \tilde{g}_{21} + 1}} < q$, the CDF of Q can be derived as

$$
F_Q(q) = 1 - e^{-\frac{q}{\theta_1 \rho_b \lambda_{b1}}} \left(1 + \frac{\rho_u (g_2 \theta_2 + g_3 \theta_3') \lambda_{21} q}{\theta_1 \rho_b \lambda_{b1}} \right)^{-1}.
$$
 (11)

Considering $\alpha = \frac{1}{\theta_1 \theta_2}$ $\frac{1}{\theta_1 \rho_b \lambda_{b1}}$, $\beta = \rho_u (g_2 \theta_2 + g_3 \theta'_3) \lambda_{21}$, and apply-ing [\(11\)](#page-1-6) to [\(7\)](#page-1-7), the closed-form solution of U_1 's EC can be calculated as

$$
\bar{C}_1 = \frac{1}{\ln 2} \int_0^\infty \frac{1 - F_Q(q)}{1 + q} dq = \frac{1}{\ln 2} \int_0^\infty \frac{1}{(1 + q)(1 + \alpha \beta q)} e^{-\alpha q} dq
$$

$$
= \frac{\log_2 e}{1 - \alpha \beta} \left[e^{\frac{1}{\beta}} \text{Ei}\left(-\frac{1}{\beta}\right) - e^{\alpha} \text{Ei}\left(-\alpha\right) \right],\tag{12}
$$

where Ei(*y*) = $\int_{-\infty}^{y}$ *e a* $\frac{a}{a}$ *da* expresses the exponential integral function [\[8\]](#page-3-7). In case of $\rho_b \to \infty$ and $\rho_u \to \infty$, Ei(-*x*) $\approx E_c +$ ln(*x*) [\[8\]](#page-3-7) and $e^x \approx 1 + x$ can be applied to derive the asymptotic EC of U_1 as follows.

$$
\bar{C}_1^{\infty} = \frac{\log_2 e}{1 - \alpha \beta} \left[\left(1 + \frac{1}{\beta} \right) \left\{ E_c - \ln(\beta) \right\} - (1 + \alpha) \left\{ E_c + \ln(\alpha) \right\} \right],
$$
\n(13)

where E_c represents the Euler constant.

*2) Ergodic Capacity of D*₁: Assuming $T \triangleq \gamma_{2d}^{s_2} = \theta_2 \rho_u g_{2d}$, the CDF $F_T(t)$ can be obtained as

$$
F_T(t) = 1 - e^{-\frac{t}{A_d}}.\t(14)
$$

where $A_d = \theta_2 \rho_u \lambda_{2d}$. Using [\(8\)](#page-1-8) and [\(14\)](#page-1-9), the EC of D₁ is written as

$$
\bar{C}_d = -\frac{1}{\ln 2} \int_0^\infty \frac{1}{(1+t)} e^{-\frac{t}{A_d}} dt = -\frac{1}{\ln 2} e^{\frac{1}{A_d}} \text{Ei}\left(-\frac{1}{A_d}\right). \tag{15}
$$

By following similar way as applied for \bar{C}_1^{∞} , the asymptotic EC of D_1 also can be obtained as follows.

$$
\bar{C}_d^{\infty} = \log_2\left(\frac{1}{e}\right)\left(1 + \frac{1}{A_d}\right)\left\{E_c + \ln\left(\frac{1}{A_d}\right)\right\}.
$$
 (16)

3) Ergodic Capacity of U₃: Let $X \triangleq \frac{\theta_3 p_b g_{b2}}{\theta_1 p_b g_{b2} + \theta_0 \hat{g}}$ $\frac{\sigma_3 p_{b}g_{b2}}{\theta_1 \rho_{b}g_{b2} + \rho_u \tilde{g}_{22} + 1},$ $Y \triangleq \frac{\theta_3 \rho_{b}g_{b1}}{\theta_1 \rho_{b2}g_{b1} + \rho_{c}g_{c1}}$ $\frac{\theta_3 \rho_{b}g_{b1}}{\theta_1 \rho_{b}g_{b1}+\rho_{u}\tilde{g}_{21}+1},\ Z \triangleq \frac{\theta_3'\rho_{u}g_{23}}{\theta_2\rho_{u}g_{23}+1}$ $\frac{\theta_3^{\prime} \rho_{\mu} g_{23}}{\theta_2 \rho_{\mu} g_{23}+1}$, $W \triangleq \frac{\theta_3^{\prime} \rho_{\mu} g_{2d}}{\theta_2 \rho_{\mu} g_{2d}+1}$ $\frac{\theta_3' \rho_u g_{2d}}{\theta_2 \rho_u g_{2d}+1}$, and $R \triangleq$ $\min(X, Y, Z, W)$. The CDF of *X*, *Y*, *Z*, and *W* are respectively calculated as

$$
F_X(x) = 1 - e^{-\frac{x}{(\theta_3 - \theta_1 x)\rho_b \lambda_{b2}}} \left(1 + \frac{\varsigma_1 \rho_u \lambda_{22} x}{(\theta_3 - \theta_1 x)\rho_b \lambda_{b2}} \right)^{-1}, (17)
$$

\n
$$
F_Y(y) = 1 - e^{-\frac{y}{(\theta_3 - \theta_1 y)\rho_b \lambda_{b1}}} \left(1 + \frac{\rho_u(\varsigma_2 \theta_2 + \varsigma_3 \theta_3') \lambda_{21} y}{(\theta_3 - \theta_1 y)\rho_b \lambda_{b1}} \right)^{-1}, (18)
$$

$$
F_Z(z) = 1 - e^{-\frac{z}{(\theta_3' - \theta_2 z)\rho_u \lambda_{23}}}, \qquad (19)
$$

$$
F_W(w) = 1 - e^{-\frac{w}{(\theta_3' - \theta_2 w)\rho_u \lambda_{2d}}}. \tag{20}
$$

Using [\(17\)](#page-2-0), [\(18\)](#page-2-1), [\(19\)](#page-2-2), and [\(20\)](#page-2-3), the CDF of *R* is written as

$$
F_R(r) = 1 - e^{-\frac{Dr}{(\theta_3 - \theta_1 r)} - \frac{Er}{(\theta_3' - \theta_2 r)}} \left[\frac{(\theta_3 - \theta_1 r)^2 \rho_b^2 \lambda_{b1} \lambda_{b2}}{\{A + Gr\} \{B + (\beta - J) r\}} \right],
$$
\n(21)

where $A = \theta_3 \rho_b \lambda_{b2}$, $B = \theta_3 \rho_b \lambda_{b1}$, $D = \frac{1}{\rho_b}$ $\frac{1}{2}$ $\frac{1}{\lambda_{b2}} + \frac{1}{\lambda_b}$ λ*b*1 $\Big), E =$ $\frac{1}{\rho_u}$ $\left(\frac{1}{\lambda_2}\right)$ $\frac{1}{\lambda_{23}} + \frac{1}{\lambda_{2}}$ λ2*d* \int , $G = \zeta_1 \rho_u \lambda_{22} - \theta_1 \rho_b \lambda_{b2}$, and $J = \theta_1 \rho_b \lambda_{b1}$. Putting in $\int_0^{\infty} \log_2(1+r) f_R(r) dr = \frac{1}{\ln 2} \int_0^{\infty} \frac{1-F_R(r)}{1+r} dr$, the EC of U_3 can be represented as

$$
\bar{C}_3 = \frac{1}{\ln 2} \int_0^\infty \frac{(\theta_3 - \theta_1 r)^2 \rho_b^2 \lambda_{b1} \lambda_{b2} e^{-\frac{Br}{(\theta_3 - \theta_1 r)} - \frac{Er}{(\theta_3' - \theta_2 r)}}}{(1 + r) \{A + (G - H) r\} \{B + (\beta - J) r\}} dr.
$$
\n(22)

However, the closed-form solution of [\(22\)](#page-2-4) is not tractable [\[6\]](#page-3-5). Rather, it can be evaluated through the numerical integration. To find out the asymptotic solution, consider $\rho_b = \rho_u =$ ρ , ρ $\rightarrow \infty$, $\theta_1 = \theta_2$, $\theta_3 = \theta'_3$, and $R \triangleq \min(X, Y, Z, W) \approx$ $\min\left(\frac{\theta_3}{\theta_1}\right)$ $\left(\frac{\theta_3}{\theta_1}, \frac{\theta_3 g_{b1}}{\theta_1 g_{b1}+\tilde{g}_{21}}\right) \approx \min\left(\frac{\theta_3}{\theta_1}\right)$ $\left(\frac{\theta_3}{\theta_1}, N\right)$ under perfect SI cancellation. Using $n = \frac{g_{b1}(\theta_3 - \theta_1 n)}{\tilde{g}_{21}}$ $\frac{\partial^2 \mathcal{B} - \theta_1 n}{\partial \tilde{g}_{21}}$, the CDF of *N* can be written as

$$
F_N(n) = \frac{n\beta}{\rho_u \lambda_{b1} \left(\theta_3 - \theta_1 n\right) + n\beta}.
$$
 (23)

Using (23) and following [\[3\]](#page-3-2), the asymptotic EC of U₃ can be derived as

$$
\bar{C}_{3}^{\infty} = \int_{\frac{\theta_{3}}{\theta_{1}}}^{\infty} \log_{2} \left(1 + \frac{\theta_{3}}{\theta_{1}} \right) f_{N}(n) \, dn + \int_{0}^{\frac{\theta_{3}}{\theta_{1}}} \log_{2} \left(1 + n \right) f_{N}(n) \, dn
$$
\n
$$
= \frac{1}{\ln 2} \int_{0}^{\frac{\theta_{3}}{\theta_{1}}} \frac{1 - F_{N}(n)}{1 + n} \, dn = \frac{1}{\ln 2} \int_{0}^{\frac{\theta_{3}}{\theta_{1}}} \frac{\chi - \psi n}{\left(\chi + n\right) \left(1 + n \right)} \, dn
$$
\n
$$
= \frac{\log_{2} e}{1 - \psi} \left\{ \psi \left(1 + \chi \right) \ln \left(\frac{\theta_{3}}{\theta_{1}} + \psi \right) - \left(\psi + \chi \right) \ln \left(\frac{\theta_{3}}{\theta_{1}} + 1 \right) \right\},\tag{24}
$$

where $\psi = \frac{\theta_3 \rho_u \lambda_{b1}}{\beta - \theta_1 \rho_u \lambda_{b1}}$ and $\chi = \frac{\theta_1 \rho_u \lambda_{b1}}{\beta - \theta_1 \rho_u \lambda_{b1}}$.

4) Ergodic Sum Capacity: By summing up [\(12\)](#page-1-10), [\(15\)](#page-1-11), [\(22\)](#page-2-4) and [\(13\)](#page-1-12), [\(16\)](#page-1-13), [\(24\)](#page-2-6), the exact and approximate ESC of the proposed system can be obtained, respectively.

B. Outage Probability and Diversity Order

*1) Outage Probability of U*1*:* Let R1, R3, R*^d* are the threshold data rates below which outage occurs for U_1 , U_3 , and D_1 , respectively. Outage will occur in U_1 either if it can not decode the information s_3 or if it decodes s_3 but fails to decode s_1 . So the OP of U₁ can be expressed as [\[6\]](#page-3-5)

$$
\mathscr{P}_{\mathscr{O},1} = 1 - \mathscr{P}\left(\log_2\left(1 + \gamma_{b1}^{s_3}\right) > R_3, \log_2\left(1 + \gamma_{b1}^{s_1}\right) > R_1\right),
$$
\n
$$
= 1 - \mathscr{P}\left(\varpi_{\mathsf{Pb}g_{b1}} > \rho_{u}\tilde{g}_{21} + 1, \frac{\theta_1}{\Lambda_1}\rho_{b}g_{b1} > \rho_{u}\tilde{g}_{21} + 1\right),\tag{25}
$$

where $\bar{\omega} = \frac{\theta_3 - \theta_1 \Lambda_3}{\Lambda_3}$ $\frac{-\theta_1 \Lambda_3}{\Lambda_3}$, $\Lambda_1 = 2^{R_1} - 1$, and $\Lambda_3 = 2^{R_3} - 1$. It is noted by analyzing [\(25\)](#page-2-7) that for $\Lambda_3 > \frac{\theta_3}{\theta_1}$ $\frac{\sigma_3}{\theta_1}$, the OP becomes $\mathscr{P}_{\mathscr{O},1} = 1$ and for $\Lambda_3 < \frac{\theta_3}{\theta_1}$ $\frac{\theta_3}{\theta_1}$, it takes the following form

$$
\mathscr{P}_{\mathscr{O},1} = 1 - e^{-\frac{1}{\varphi \rho_b \lambda_{b1}}} \left(\frac{\varphi \rho_b \lambda_{b1}}{\varphi \rho_b \lambda_{b1} + \beta} \right), \tag{26}
$$

where $\varphi = \min \left(\frac{\theta_3 - \theta_1 \Lambda_3}{\Lambda_3} \right)$ $\frac{\partial-\theta_1\Lambda_3}{\Lambda_3},\frac{\theta_1}{\Lambda_1}$.

2) *Outage Probability of* U_3 *:* If U_2 fails to decode s_3 or U_2 can decode but U_3 can not, then outage occurs in U_3 . Hence, the OP of U_3 can be calculated by

$$
\mathscr{P}_{\mathscr{O},3} = 1 - \mathscr{P}\left(\log_2\left(1 + \gamma_{b2}^{s_3}\right) > R_3, \log_2\left(1 + \gamma_{23}^{s_3}\right) > R_3\right),
$$
\n
$$
= 1 - \mathscr{P}\left(\varpi \rho_{b} g_{b2} > \rho_{u} \tilde{g}_{22} + 1, \, \aleph \rho_{u} g_{23} > \Lambda_3\right). \tag{27}
$$

where $\aleph = (\theta_3' - \theta_2 \Lambda_3)$. From [\(27\)](#page-2-8), if $\Lambda_3 > \frac{\theta_3}{\theta_1}$ $\frac{\theta_3}{\theta_1}$ and $\Lambda_3 > \frac{\theta_3}{\theta_2}$ exist, the OP becomes $\mathcal{P}_{\mathcal{O},3} = 1$, whereas for $\Lambda_3 < \frac{\theta_3}{\theta_1}$ $\frac{\sigma_3}{\theta_1}$, and $\Lambda_3 < \frac{\theta_3'}{\theta_2}$, it can be expressed as

$$
\mathscr{P}_{\mathscr{O},3} = 1 - e^{-\frac{\Lambda_3}{\aleph \rho_u \lambda_{23}} - \frac{1}{\varpi \rho_b \lambda_{b2}}} \frac{1}{1 + \frac{\varsigma_1 \lambda_{22} \rho_u}{\varpi \rho_b \lambda_{b2}}}.
$$
(28)

*3) Outage Probability of D*1*:* The D2D user will be in outage under two conditions; i.e., i. D_1 fails to decode U_3 's information and **ii**. D_1 decodes s_3 but fails to decode s_2 . So, the OP of D1 can be obtained as

$$
\mathscr{P}_{\mathscr{O},d} = 1 - \left(\frac{\theta_3' \rho_u g_{2d}}{\theta_2 \rho_u g_{2d} + 1} > \Lambda_3, \theta_2 \rho_u g_{2d} > \Lambda_d\right),\qquad(29)
$$

where $\Lambda_d = 2^{R_d} - 1$. For $\Lambda_3 > \frac{\theta'_3}{\theta_2}$, the OP becomes $\mathscr{P}_{\mathscr{O},d} = 1$. For $\Lambda_3 < \frac{\theta'_3}{\theta_2}$, $\mathscr{P}_{\mathscr{O},d}$ is given below

$$
\mathscr{P}_{\mathscr{O},d} = 1 - e^{-\frac{\Lambda_3}{\Re \rho_u \lambda_{2d}} - \frac{\Lambda_d}{\theta_2 \rho_u \lambda_{2d}}}.
$$
 (30)

4) High SNR approximation: Considering $\rho_b \rightarrow \infty$, and $\rho_u = \varepsilon \rho_b$, the OP of all users can be approximated in high SNR regime where ε is a relay transmit power controlling variable limiting as $0 < \varepsilon \le 1$ [\[6\]](#page-3-5). For two cases, i.e., imperfect and perfect SI as well as known interference cancellations (ICs), approximate OPs of U_1 , U_3 , and D_1 are respectively found as

$$
\mathscr{P}_{\mathscr{O},1}^{\infty} = \begin{cases} 1 - \left(1 + \frac{\beta}{\varphi \rho_b \lambda_{b1}}\right)^{-1} & \text{for} \quad 0 < \zeta_3 \le 1 \\ 1 - \left(1 + \frac{\varepsilon \zeta_2 \theta_2 \lambda_{21}}{\varphi \lambda_{b1}}\right)^{-1} & \text{for} \quad \zeta_3 = 0 \end{cases} \tag{31}
$$

$$
\mathscr{P}_{\mathscr{O},3}^{\infty} = \begin{cases} 1 - \left(1 + \frac{\varepsilon_{\mathsf{S1}} \lambda_{22}}{\varpi \lambda_{b2}}\right)^{-1} & \text{for} \quad 0 < \mathsf{S}_1 \le 1\\ \frac{\Lambda_3}{\aleph \rho_u \lambda_{23}} + \frac{1}{\varpi \rho_b \lambda_{b2}} & \text{for} \quad \mathsf{S}_1 = 0 \end{cases} \tag{32}
$$

Fig. 2. (a) Analytical justification of EC and ESC, (b) ESC comparison between DFC-NOMA and [\[6\]](#page-3-5).

$$
\mathscr{P}_{\mathscr{O},d}^{\infty} = \frac{\Lambda_3}{\aleph \rho_u \lambda_{2d}} + \frac{\Lambda_d}{\theta_2 \rho_u \lambda_{2d}}.
$$
 (33)

Due to the imperfect IC, OPs of U_1 and U_2 maintain constant values that create error floors (EFs) in the high SNR. Using $\lim_{\rho_b \to \infty} \frac{-\log \mathcal{P}_O}{\log \rho_b}$ $\frac{\log \mathcal{P}_O}{\log \rho_b}$ in [\(31\)](#page-2-9), [\(32\)](#page-2-10), and [\(33\)](#page-3-8), DOs of U₁, U₃, and D¹ under imperfect and perfect ICs are respectively found as

$$
\mathcal{D}_{\mathcal{O},1}^{\infty} = 0; \mathcal{D}_{\mathcal{O},3}^{\infty} = 0; \mathcal{D}_{\mathcal{O},d}^{\infty} = 1 \quad \text{for} \quad 0 < (g_1, g_3) \le 1,
$$

$$
\mathcal{D}_{\mathcal{O},1}^{\infty} = 0; \mathcal{D}_{\mathcal{O},3}^{\infty} = 1; \mathcal{D}_{\mathcal{O},d}^{\infty} = 1 \quad \text{for} \qquad g_1 = g_3 = 0. \quad (34)
$$

Unknown interference at U_1 makes it's DO zero for both perfect and imperfect ICs. Like $[6]$, U₃'s DO is unity under perfect IC and zero under imperfect IC. As there is no interference other than intended NOMA user interference on D_1 , its DO remains unity under both conditions.

IV. NUMERICAL RESULTS

All findings presented in this section are executed by considering $\rho_b = 2\rho_u$, $\lambda_{b1} = \lambda_{2d} = 1$, $\lambda_{b2} = \lambda_{21} = \lambda_{23} = 0.5$, and $\lambda_{22} = 0.3$. In each case, concordance between analytical (Anl.) and simulation (Sim.) plots verifies the accuracy of analyses. EC and ESC performances with respect to (w.r.t) ρ_b are evaluated in Fig. [2](#page-3-9) where $\theta_1 = \theta_2 = 0.05$ and $\theta_3 = \theta'_3 = 0.95$. ECs and ESC of the DFC-NOMA are shown under imperfect IC ($\zeta_1 = 0.08^2$, and $\zeta_3 = 0.1^2$) in [2\(](#page-3-9)a). EC and ESC increase linearly with the increase of ρ_b . Due to the large interference effect on SINRs of U_1 and U_3 , their ECs tend to saturate at high ρ_b . Contrarily, D_1 's EC maintains linear increment as a benefit of performing perfect SIC. Fig. [2\(](#page-3-9)b) displays the performance comparison between DFC-NOMA (pro.) and existing [\[6\]](#page-3-5) protocols for perfect $(\zeta_1 = \zeta_3 = 0)$, imperfect $(\zeta_1 = \zeta_3 = 0.5)$, and no interference $(\zeta_1 = \zeta_3 = 1)$ cancellations. Proposed protocol outperforms FC-NOMA [\[6\]](#page-3-5) in terms of ESC for all conditions.

Fig. [3\(](#page-3-10)a) shows the impact of changing θ_1 on ESC by letting $\theta_1 = \theta_2$ and $\theta_3 = \theta'_3$ for $\rho_b = 15$ and 35 dBs. In all θ_1 and

Fig. 3. (a) E-SC comparison w.r.t θ_1 between DFC-NOMA and [\[6\]](#page-3-5), (b) OP characteristic of each user with changing ρ_b , in DFC-NOMA.

both SNR values, DFC-NOMA poses noticeable ESC gain over [\[6\]](#page-3-5) under $\zeta_1 = 0.08^2$ and $\zeta_3 = 0.1^2$. In Fig. [3\(](#page-3-10)b), OPs of DFC-NOMA's individual users are presented w.r.t SNR under perfect IC and $R_1=R_3=R_d=1$. It is noticed that OPs decrease with the increase of ρ_b . OPs of U₃ and D₁ decrease linearly at high ρ_b , whereas U₁'s OP saturates due to the presence of interference that creates EF and lead DO to 0.

V. CONCLUSION

A D2D aided FDCC protocol using NOMA, i.e., DFC-NOMA has been proposed. Considering imperfect IC, the exact and asymptotic expressions of EC, E-SC, OP, and DO of the system have been analyzed over Rayleigh fading channel. By the cost of a slightly increased interference on a near user (U_1) than FC-NOMA [\[6\]](#page-3-5), DFC-NOMA facilitates simultaneous data transmission to a cellular and a D2D users that helps achieving higher capacity than FC-NOMA.
