March 4, 2020

#### Abstract

An equivalent definition of entropic Ricci curvature on discrete spaces was given in terms of the global gradient estimate in [1, Theorem 3.1]. With a particular choice of the density function $\rho$, we obtain a localized gradient estimate, which in turns allow us to apply the same technique as in [4] to derive a Bonnet-Myers type diameter bound for graphs with positive entropic Ricci curvature. However, the case of the hypercubes indicates that the bound may be not optimal (where $\theta$ is chosen to be logarithmic mean by default). If $\theta$ is arithmetic mean, the Bakry-Émery criterion can be recovered and the diameter bound is optimal as it can be attained by the hypercubes.

## 1 Introduction

The notion of entropic Ricci curvature on discrete spaces (i.e., Markov chains, or graphs) was introduced by Erbar and Maas [2] inspired by work of Sturm [10] and Lott and Villani [6] which describes the lower bound of Ricci curvature via the displacement convexity of the entropy functional. Equivalent definitions of Entropic curvature are also given in terms of Bochner's inequality [2] and in terms of gradient estimates [1]. Detailed notations and definitions are given in Section 2 and proofs are presented in Section 3,

Definition 1.1 (Entropic curvature). An irreducible and reversible Markov kernel $Q$ on a finite discrete space $X$ (with a steady state $\pi$ ) has entropic curvature at least $\kappa \in \mathbb{R}$, written as $\operatorname{Ric}(Q) \geq \kappa$, if and only if the entropy functional $\mathcal{H}$ satisfies the following $\kappa$-convexity inequality:

$$
\begin{equation*}
\mathcal{H}\left(\rho_{t}\right) \leq(1-t) \mathcal{H}\left(\rho_{0}\right)+t \mathcal{H}\left(\rho_{1}\right)-\frac{\kappa}{2} t(1-t) \mathcal{W}\left(\rho_{0}, \rho_{1}\right)^{2} \tag{1.1}
\end{equation*}
$$

for every constant speed geodesic $\left(\rho_{t}\right)_{t \in[0,1]}$ in the (modified) $L^{2}$-Wasserstein space of probabaility densities $(\mathscr{D}(X), \mathcal{W})$.

Theorem 1.1 (Equivalent definitions). For a finite set $X$ equipped with an irreducible and reversible Markov kernel $Q$ (and the steady state $\pi$ ), the following properties are equivalent:
(1) $\operatorname{Ric}(Q) \geq \kappa$;
(2) Bochner's inequality holds for all $\rho \in \mathscr{D}(X)$ and $f \in C(X)$ :

$$
\begin{equation*}
\mathcal{B}(\rho, f) \geq \kappa \mathcal{A}(\rho, f), \tag{1.2}
\end{equation*}
$$

where

$$
\mathcal{A}(\rho, f):=\langle\hat{\rho} \cdot \nabla f, \nabla f\rangle_{\pi}
$$

and

$$
\mathcal{B}(\rho, f):=\frac{1}{2}\langle\hat{\Delta} \rho \cdot \nabla f, \nabla f\rangle_{\pi}-\langle\hat{\rho} \cdot \nabla f, \nabla \Delta f\rangle_{\pi},
$$

where

$$
\begin{aligned}
\hat{\rho}(x, y) & :=\theta(\rho(x), \rho(y)), \\
\hat{\Delta} \rho & :=\partial_{1} \theta(\rho(x), \rho(y)) \Delta \rho(x)+\partial_{2} \theta(\rho(x), \rho(y)) \Delta \rho(y),
\end{aligned}
$$

and $\theta$ is a logarithmic mean: $\theta(a, b)=\frac{a-b}{\log a-\log b}$;
(3) Global gradient estimate holds for all $\rho \in \mathscr{D}(X)$ and $f \in C(X)$ and $t \geq 0$,

$$
\left|\nabla P_{t} f\right|_{\rho}^{2} \leq e^{-2 \kappa t}|\nabla f|_{P_{t} \rho}^{2},
$$

or more explicitly
$\frac{1}{2} \sum_{u, v}\left(P_{t} f(v)-P_{t} f(u)\right)^{2} \hat{\rho}(u, v) Q(u, v) \pi(u) \leq e^{-2 \kappa t} \frac{1}{2} \sum_{u, v}(f(v)-f(u))^{2} \widehat{P_{t} \rho}(u, v) Q(u, v) \pi(u)$
where $P_{t}=e^{t \Delta}$ denotes the heat semigroup.
The contribution of this paper is to follow ideas from [1] to derive a similar local gradient estimate, and to apply the same technique as in [4] to prove a Bonnet-Myers type diameter bound on the underlying graph $X$ (when $Q$ is a simple random walk) in the case of a positive lower bound of entropic curvature.

Theorem 1.2 (Local gradient estimate). If $\operatorname{Ric}(Q) \geq \kappa$, then for all $x \in X$ and $f \in C(X)$ and all $\varepsilon \geq 0$ we have

$$
\begin{equation*}
\Gamma\left(P_{t} f\right)(x) \pi(x) \leq \frac{e^{-2 \kappa t}}{2 \theta(1, \varepsilon)}\left[P_{t} \Gamma(f)(x) \pi(x)+\varepsilon \sum_{y \in N(x)} P_{t} \Gamma(f)(y) \pi(y)\right] . \tag{1.4}
\end{equation*}
$$

where $\Gamma(f)(x):=\sum_{y}(f(y)-f(x))^{2} Q(x, y)$.
Theorem 1.3 (Diameter bound). Let $Q$ represent a simple random walk on $X$ with strictly positive entropic Ricci curvature $\operatorname{Ric}(Q) \geq \kappa>0$. Then the diameter is bounded from above by $\operatorname{diam}(X) \leq \frac{2}{\kappa} \sqrt{\frac{D \log D}{D-1}}$ where $D$ is the maximal (vertex) degree.
Remark 1.4. It is known that the entropic curvature of (a simple random walk on) the discrete hypercube $\mathcal{Q}^{n}$ is $\frac{2}{n}$ (see [2, Example 5.7]). Therefore, in view of the hypercubes, the bound in Theorem 1.3 is not optimal:

$$
n=\operatorname{diam}\left(\mathcal{Q}^{n}\right) \leq n \sqrt{\frac{n}{n-1} \log n} .
$$

However, if we replace the logarithmic mean by the arithmetic mean for $\theta$ in Bochner's fomula (1.2) and inequality (1.3), the local gradient estimate in Theorem 1.2 would imply (by taking $\varepsilon=0$ ) the Bakry-Émery curvature criterion $C D(\kappa, \infty): \Gamma\left(P_{t} f\right)(x) \leq$ $e^{-2 \kappa t} P_{t} \Gamma(f)(x)$ in the sense of [3, Corollary 3.3]. This implication has already been mentioned in the survey [8]. Consequently, we obtain a diameter bound: $\operatorname{diam}(X) \leq \frac{2}{\kappa}$, which is sharp and the equality is attained if and only if $X$ is a hypercube $\mathcal{Q}^{n}$ (for details see [4] and [5]).

## 2 Setup and notations

### 2.1 Notions associated to a discrete Markov chain

We start with a Markov chain $(X, Q)$, where $X$ is a finite set and $Q: X \times X \rightarrow \mathbb{R}^{+} \cup\{0\}$ is a Markov kernel $Q$, i.e. $\sum_{y \in X} Q(x, y)=1$ for all $x \in X$. Furthermore, we assume that $Q$ is irreducible and reversible, which implies that there exists a unique stationary probability measure $\pi$ on $X$ satisfying $\sum_{x \in X} \pi(x)=1$ and the detail balanced equations:

$$
Q(x, y) \pi(x)=Q(y, x) \pi(y) \quad \forall x, y \in X
$$

The set of probability densities (with respect to $\pi$ ) is defined as

$$
\mathscr{D}(X):=\left\{\rho: X \rightarrow \mathbb{R}^{+} \cup\{0\} \mid \sum_{x \in X} \pi(x) \rho(x)=1\right\}
$$

The entropy functional, defined on $\mathscr{D}(X)$, is given by

$$
\mathcal{H}(\rho):=\sum_{x \in X} \rho(x) \log \rho(x) \pi(x)
$$

The discrete gradient $\nabla: C(X) \rightarrow C(X \times X)$, discrete divergence $\nabla \cdot: C(X \times X) \rightarrow C(X)$, and laplacian $\Delta:=\nabla \cdot \nabla$ are defined as follows:

Definition 2.1. For all $f, g \in C(X)$ and $U, V \in C(X \times X)$,

$$
\begin{aligned}
\nabla f(x, y) & :=f(y)-f(x) \\
\nabla \cdot V(x) & :=\frac{1}{2} \sum_{y \in X}(V(x, y)-V(y, x)) Q(x, y) \\
\Delta f(x) & :=\sum_{y \in X}(f(y)-f(x)) Q(x, y)
\end{aligned}
$$

The inner products are defined as

$$
\begin{aligned}
\langle f, g\rangle_{\pi} & :=\sum_{x \in X} f(x) g(x) \pi(x) \\
\langle U, V\rangle_{\pi} & :=\frac{1}{2} \sum_{x, y \in X} U(x, y) V(x, y) Q(x, y) \pi(x)
\end{aligned}
$$

and for all $\rho \in \mathscr{D}(X)$,

$$
\langle U, V\rangle_{\rho}:=\langle\hat{\rho} \cdot U, V\rangle_{\pi}=\frac{1}{2} \sum_{x, y \in X} U(x, y) V(x, y) \hat{\rho}(x, y) Q(x, y) \pi(x),
$$

where $\hat{\rho}(x, y):=\theta(\rho(x), \rho(y))$ and $\theta$ is a suitable mean satisfying Assumption 2.1 in [2]. By default, $\theta$ is chosen to be the logarithmic mean: $\theta(a, b)=\frac{a-b}{\log a-\log b}$.
Furthermore, we already introduced

$$
\begin{aligned}
\mathcal{A}(\rho, f) & :=|\nabla f|_{\rho}^{2}=\langle\hat{\rho} \cdot \nabla f, \nabla f\rangle_{\pi}, \\
\mathcal{B}(\rho, f) & :=\frac{1}{2}\langle\hat{\Delta} \rho \cdot \nabla f, \nabla f\rangle_{\pi}-\langle\hat{\rho} \cdot \nabla f, \nabla \Delta f\rangle_{\pi},
\end{aligned}
$$

where $\hat{\Delta} \rho:=\partial_{1} \theta(\rho(x), \rho(y)) \Delta \rho(x)+\partial_{2} \theta(\rho(x), \rho(y)) \Delta \rho(y)$.
Definition 2.2 (Discrete transport metric). For $\bar{\rho}_{0}, \bar{\rho}_{1} \in \mathscr{D}(X)$,

$$
\mathcal{W}\left(\bar{\rho}_{0}, \bar{\rho}_{1}\right):=\inf \left\{\int_{0}^{1} \mathcal{A}\left(\rho_{t}, f_{t}\right) \mathrm{d} t \mid\left(\rho_{t}, f_{t}\right) \in C E\left(\bar{\rho}_{0}, \bar{\rho}_{1}\right)\right\}^{\frac{1}{2}},
$$

where the infimum is taken over the set $C E\left(\rho_{0}, \rho_{1}\right)$ which consists of all sufficiently regular curves $\left(\rho_{t}\right)_{t \in[0,1]}$ on $\mathscr{D}(X)$ and $\left(f_{t}\right)_{t \in[0,1]}$ on $C(X)$ which satisfy the continuity equation $\partial_{t} \rho_{t}+\nabla \cdot\left(\hat{\rho}_{t} \nabla f_{t}\right)=0$ and $\rho_{0}=\bar{\rho}_{0}, \rho_{1}=\bar{\rho}_{1}$. It was shown that $\mathcal{W}$ is a metric on $\mathscr{D}(X)$. We refer to [2, 7 ] for further details. Note that this notion of the $\mathcal{W}$-metric is relevant in Definition 1.1 of entropic curvature.

### 2.2 Graph theoretical notions

The kernel $Q$ induces a graph structure on $X$ by assigning an edge $x \sim y$ if and only if $Q(x, y)>0$. Note that the graph is connected and undirected, due to irreducibility and reversibility of $Q$, respectively. For a vertex $x \in X$, denote $N(x):=\{y \in X \mid x \sim y\}$ the set of neighbors of $x$, and $d_{x}:=|N(x)|$ the degree of $x$, and $D:=\max _{x \in X} d_{x}$ the maximal degree. The graph is equipped with the usual combinatorial distance function $d$ where $d(x, y)$ is the length of shortest path(s) between $x$ and $y$, and the diameter of the graph is defined as $\operatorname{diam}(X)=\max _{x, y \in X} d(x, y)$. In this note, we restrict $Q$ to be a simple random walk, which is given by $Q(x, y)=\frac{1}{d_{x}}$ for all $y \in N(x)$, and $\pi(x)=d_{x} /\left(\sum_{v \in X} d_{v}\right)$.

## 3 Proofs

Proof of Theorem 1.1, Equivalence (1) $\Leftrightarrow(2)$ was stated in [2, Theorem 4.5] under the assumption that $\theta$ is the logarithmic mean. Equivalence (2) $\Leftrightarrow(3)$ was stated in [1, Theorem 3.1], regardless of the choice of a 'suitable' mean for $\theta$.

## Proof of Theorem 1.2 ,

The proof follows ideas of [1, Corollary 3.4]. Note that the inequality (1.3) is homogeneous in $\rho$. Therefore, we can drop the requirement that $\rho$ is a probability density: $\sum_{x} \rho(x) \pi(x)=$

1. We localize inequality (1.3) by choosing $\rho=\mathbf{1}_{x}+\varepsilon \sum_{y \in N(x)} \mathbf{1}_{y}$ for a fixed $x \in V$ and a parameter $\varepsilon \in[0, \infty)$.
In particular we know that $\hat{\rho}(x, y)=\hat{\rho}(y, x)=\theta(1, \varepsilon)$ for all $y \in N(x)$. The left-hand-side of (1.3) has the following lower bound

$$
\begin{equation*}
L . H . S . \geq \sum_{y \in N(x)}\left(P_{t} f(y)-P_{t} f(x)\right)^{2} \theta(1, \varepsilon) Q(x, y) \pi(x)=\theta(1, \varepsilon) \cdot \Gamma\left(P_{t} f\right)(x) \pi(x) \tag{3.1}
\end{equation*}
$$

On the other hand, we have the following bound on the right-hand-side of (1.3) by

$$
\begin{align*}
\text { R.H.S. } & \leq e^{-2 \kappa t} \frac{1}{2} \sum_{u, v}(f(v)-f(u))^{2} \frac{P_{t} \rho(u)+P_{t} \rho(v)}{2} Q(u, v) \pi(u) \\
& =e^{-2 \kappa t} \frac{1}{2} \sum_{u, v}(f(v)-f(u))^{2} P_{t} \rho(u) Q(u, v) \pi(u) \tag{3.2}
\end{align*}
$$

due to $\theta(s, t) \leq(s+t) / 2$ and symmetry from interchanging $u$ and $v$.
We now apply the heat kernel $p_{t}(\cdot, \cdot)$ given by $P_{t} g(u)=\sum_{z} p_{t}(u, z) g(z) \pi(z)$ for every function $g$. With our chosen $\rho$, we obtain $P_{t} \rho(u)=p_{t}(u, x) \rho(x) \pi(x)+\varepsilon \sum_{y \in N(x)} p_{t}(u, y) \rho(y) \pi(y)$, which we substitute into (3.2) and use the symmetry of heat kernel: $p_{t}(u, v)=p_{t}(v, u)$ to derive

$$
\begin{align*}
& \text { R.H.S. } \leq \frac{e^{-2 \kappa t}}{2}\left[\pi(x) \sum_{u} p_{t}(u, x) \pi(u) \sum_{v}(f(v)-f(u))^{2} Q(u, v)+\right. \\
&\left.\varepsilon \sum_{y \in N(x)} \pi(y) \sum_{u} p_{t}(u, y) \pi(u)\left(\sum_{v}(f(v)-f(u))^{2} Q(u, v)\right)\right] \\
&= \frac{e^{-2 \kappa t}}{2}\left[\pi(x) P_{t} \Gamma(f)(x)+\varepsilon \sum_{y \in N(x)} \pi(y) P_{t} \Gamma(f)(y)\right] \tag{3.3}
\end{align*}
$$

The desired inequality then follows from (3.1) and (3.3).
For the underlying graph $X$ with $Q$ representing a simple random walk, we have the following corollary as an immediate consequence of Theorem 1.2 ,

Corollary 3.1. Let $Q$ represent a simple random walk on $X$ with entropic Ricci curvature $\operatorname{Ric}(Q) \geq \kappa$. Then we have the following gradient estimate:

$$
\begin{equation*}
\Gamma\left(P_{t} f\right)(x) \leq c \cdot e^{-2 \kappa t}\left\|P_{t} \Gamma(f)\right\|_{\infty} \tag{3.4}
\end{equation*}
$$

where $c:=\frac{D \log D}{D-1}$ and $D$ is the maximal degree.
Proof of Corollary 3.1. Theorem 1.2 implies that $\Gamma\left(P_{t} f\right)(x) \leq c_{\varepsilon, x} \cdot e^{-2 \kappa t}\left\|P_{t} \Gamma(f)\right\|_{\infty}$. where $c_{\varepsilon, x}:=\frac{1+\varepsilon \sum_{y \in N(x)} \frac{d_{y}}{d_{x}}}{2 \theta(1, \varepsilon)} \leq \frac{1+\varepsilon D}{2 \theta(1, \varepsilon)}$. In particular when $\varepsilon=\frac{1}{D}$, we have $c_{\varepsilon, x} \leq c$.
Finally, we present the proof of the diameter bound in the case of strictly positive entropic curvature.

## Proof of Theorem 1.3.

The proof follows ideas of [4, Theorem 2.1]. Consider a particular choice of function $f \in C(X)$ given by $f(x)=d\left(x, x_{0}\right)$ for an arbitrary reference point $x_{0} \in X$. Since $f$ is a Lipschitz function with constant 1, it follows that $\Gamma(f)(x)=\sum_{y \in N(x)} \frac{1}{d_{x}}(f(y)-f(x))^{2} \leq 1$ for all $x \in X$, i.e., $\|\Gamma(f)\|_{\infty} \leq 1$, which then implies $\left\|P_{t} \Gamma(f)\right\|_{\infty} \leq\|\Gamma(f)\|_{\infty} \leq 1$.
Moreover, Cauchy-Schwartz and inequality (3.4) give

$$
\begin{equation*}
\left|\Delta P_{t} f(x)\right|^{2} \leq \frac{1}{d_{x}} \sum_{y \in N(x)}\left(P_{t} f(y)-P_{t} f(x)\right)^{2}=\Gamma\left(P_{t} f\right)(x) \leq e^{-2 \kappa t} c\left\|P_{t} \Gamma(f)\right\|_{\infty} \leq c e^{-2 \kappa t} .( \tag{3.5}
\end{equation*}
$$

From the fundamental theorem of calculus and the definition of $P_{t}$, we then obtain

$$
\left|f(x)-P_{T} f(x)\right| \leq \int_{0}^{T}\left|\frac{\partial}{\partial t} P_{t} f(x)\right| d t=\int_{0}^{T}\left|\Delta P_{t} f(x)\right| d t \leq \int_{0}^{T} \sqrt{c} e^{-\kappa t} d t \leq \frac{\sqrt{c}}{\kappa}
$$

which holds true for all $T>0$.
Moreover, the chain of inequalities in (3.5) implies that $\left|P_{t} f(y)-P_{t} f(x)\right|^{2} \leq d_{x} \cdot c e^{-2 \kappa t} \rightarrow 0$ as $t \rightarrow \infty$ for all neighbors $y \sim x$. Therefore, $\left|P_{t} f(y)-P_{t} f(x)\right| \rightarrow 0$ as $t \rightarrow \infty$ for an arbitrary pair of $x, y$ (by considering a connected path from $x$ to $y$ ).
Passing to the limit $T \rightarrow \infty$, we can conclude from triangle inequality that
$\mathrm{d}\left(x, x_{0}\right)=\left|f(x)-f\left(x_{0}\right)\right| \leq\left|f(x)-P_{T} f(x)\right|+\left|f\left(x_{0}\right)-P_{T} f\left(x_{0}\right)\right|+\left|P_{T} f(x)-P_{T} f\left(x_{0}\right)\right| \leq \frac{2 \sqrt{c}}{\kappa}$.
Since $x, x_{0}$ are arbitrary, we obtain the desired diameter bound.
