Estimate the exponential convergence rate of f-ergodicity via spectral gap

Xianping Guo[∗](#page-0-0) Zhong-Wei Liao[†](#page-0-1) ,

Abstract This paper studies the f -ergodicity and its exponential convergence rate for continuous-time Markov chain. Assume f is square integrable, for reversible Markov chain, it is proved that the exponential convergence of f -ergodicity holds if and only if the spectral gap of the generator is positive. Moreover, the convergence rate is equal to the spectral gap. For irreversible case, the positivity of spectral gap remains a sufficient condition of f-ergodicity. The effectiveness of these results are illustrated by some typical examples.

Keywords Spectral gap; f-ergodicity; Markov chain; h-transform.

MSC(2010) 60J25, 60J27

1 Introduction and main results

In this paper, we study the rate of convergence to equilibrium of continuous-time Markov chain. Assume $(X_t)_{t\geq0}$ is a positive recurrent Markov chain defined on a countable state space E with stationary distribution π . Denote by $Q = (q_{ij})$ and $P_t(i, j)$ the Q-matrix and the corresponding Markov semigroup. For any measurable function $f: E \to [1,\infty)$, the f-norm of signed measure μ is defined as $\|\mu\|_f :=$ $\sup_{|g| \leq f} |\mu(g)|$. When f is a constant function, the f-norm is nothing but the total variation norm. The main objective is the f -ergodicity of P_t , which means that for all $i \in E$, we have

$$
\lim_{t \to \infty} r(t) \| P_t(i, \cdot) - \pi \|_f = 0,\tag{1}
$$

where f satisfies $\pi(f) < \infty$ and $r(t)$ is a positive function being used to describe the convergence rate. For example, the exponential convergence means $r(t) = e^{\varepsilon t}$, $\varepsilon > 0$. Refer to [\[13,](#page-10-0) Chapter 14] or [\[16\]](#page-10-1) for more details about the terminology and notations.

For $f \equiv 1$, [\(1\)](#page-0-2) depicts the long time behavior of Markov semigroup in total variation norm. There are many approaches in the quantitative research, refer to [\[4\]](#page-10-2), [\[5\]](#page-10-3), [\[8\]](#page-10-4) and [\[11\]](#page-10-5). For example, one of the efficient instrument popularized by Meyn and Tweedie is the drift condition (or Foster-Lyapunov control conditions), which implies the exponential convergence, see [\[8\]](#page-10-4) or [\[13\]](#page-10-0). Another useful tool is functional inequalities. Assume the semigroup P_t is reversible with respect to π , which means $\pi_i P_t(i,j) = \pi_j P_t(j,i)$, for all $i, j \in E$ and $t \geq 0$ (equivalently, $\pi_i q_{ij} = \pi_j q_{ji}$). The Poincaré inequality is defined as

$$
C_{\text{PI}} \text{Var}_{\pi}(g) \leqslant (-Qg, g), \qquad g \in L^2(\pi), \tag{2}
$$

[∗]School of Mathematics, Sun Yat-Sen University, China. E-mail: mcsgxp@mail.sysu.edu.cn

[†]South China Research Center for Applied Mathematics and Interdisciplinary Studies, South China Normal University, China. E-mail: zhwliao@hotmail.com

where C_{PI} is denotes as the optimal constant and (\cdot, \cdot) is the inner product in $L^2(\pi)$. This inequality is also referred to spectral gap inequality, since the spectral gap of Q can be redefined as the optimal constant of the Poincaré inequality:

$$
gap(Q) = inf{(-Qg, g) : \pi(g) = 0 \text{ and } ||g||_{L^2(\pi)} = 1}.
$$

Corresponding to the spectral gap is the exponential ergodicity in $L^2(\pi)$:

$$
||P_t g - \pi(g)||_{L^2(\pi)} \leq e^{-C_{\text{PI}}t} ||g - \pi(g)||_{L^2(\pi)}, \qquad g \in L^2(\pi).
$$

According to Cauchy-Schwarz inequality, the Poincaré inequality implies the exponential convergence in total variation distance. There is a great deal of publications in this field, see for instance $[2]$, $[6]$, $[10]$ and references within. In addition, the relationship between the Mayn-Tweedie approach and the functional inequality approach has been discussed in [\[1\]](#page-9-0). Generalizations of functional inequalities have been studied by several authors, here we refer to $\lbrack 3\rbrack$, $\lbrack 12\rbrack$ and $\lbrack 15\rbrack$ for related results on weak Poincaré inequalities and weak logarithmic Sobolev inequalities.

For $f \geq 1$ and $r \equiv 1$ in [\(1\)](#page-0-2), that is the f-ergodicity introduced in [\[13,](#page-10-0) Chapter 14], but without consideration the convergence rate. What we concern is the case $f \geq 1$ and $r(t) = e^{-\varepsilon t}$, in other words, the semigroup P_t is said to have exponential f-ergodicity if there exists constants $\varepsilon > 0$ and $C(i, f) > 0$ such that

$$
||P_t(i, \cdot) - \pi||_f \leq C(i, f)e^{-\varepsilon t}, \qquad \forall i \in E, \ t \geq 0.
$$
 (3)

The maximal parameter ε_{max} is called the exponential convergence rate of f-ergodicity. Our objectives in this paper are the criterion of f -ergodicity and the estimation of the convergence rate in [\(3\)](#page-1-0) .

Researches surrounding f-ergodicity is applied in the theory of controlled Markov models (Markov decision processes) in [\[9\]](#page-10-12). Specifically, it ensures the existence of average optimal policies in the unbounded rewards model. Hence, the explicit criterion of f-ergodicity is the original motive of this thesis. Following the Meyn-Tweedie approach, Douc et al. [\[7\]](#page-10-13) give a general form of drift condition, which is depend on the notion of "petite set".

The main tool we use is the functional inequality. We review the conditions of f in [\(1\)](#page-0-2). The condition " $f \ge 1$ " ensures that the f-ergodicity of P_t implies the original ergodicity. However, it is not essential because it can be replaced by " $f \geq \delta$ " for any $\delta > 0$. The condition " $\pi(f) < \infty$ " is necessary, otherwise [\(1\)](#page-0-2) might be not welldefine. Furthermore, when $f \in L^2(\pi)$, the exponential rate of f-ergodicity ε_{max} can be estimated by the spectral gap of generator, which is our main result. Different from the drift conditions given in [\[11\]](#page-10-5) and [\[13\]](#page-10-0), we introduce a new equivalent condition of f -ergodicity. The principal tools are Poincaré inequality and h -transform, which will be given in Section 3.

Theorem 1.1. *Assume* $f \in L^2(\pi)$ *and* P_t *is reversible. Then* P_t *has exponential* f-ergodicity if and only if the spectral gap of Q -matrix $\text{gap}(Q) > 0$. More*over, the convergence rate satisfies* $\varepsilon_{\text{max}} = \text{gap}(Q)$ *, and constant of* [\(3\)](#page-1-0) is $C(i, f) =$ $\pi (f^2)^{1/2} (\pi_i^{-1} - 1)^{1/2}.$

Since $(X_t)_{t\geq0}$ is positive recurrent, the stationary distribution π satisfies $\pi_i > 0$, $\forall i \in E$. Hence $C(i, f) < \infty$, $\forall i \in E$. For irreversible case, the above-mentioned equivalence will be false. However, the spectral gap condition is still a sufficient condition of f-ergodicity.

Proposition 1.2. *Assume* $\pi(f^2) < \infty$. If the semigroup P_t is irreversible, then $\text{gap}(Q) > 0$ *implies the exponential f-ergodicity of* P_t .

In Section 2, we will give some examples to illustrate the effectiveness of Theorem [1.1.](#page-1-1) The h-transformation will introduced in Section 3, and then we give the proof of Theorem [1.1](#page-1-1) by this method.

2 Examples

As previous mentioned, one of the practical criterion is the drift condition (cf. [\[11\]](#page-10-5)). In practical applications, this criterion is easy to verify, although the invariant measure is unknown. However, the next example show that the drift condition can not give a exact estimation of the convergence rate ε_{max} .

Example 2.1. Take $E = \mathbb{Z}_+$. Let $\pi_i > 0$, ($\forall i \in E$) be an arbitrary distribution on E and the Q-matrix defined as: $q_{ij} = \pi_j$ for $j \neq i$; $q_{ii} = -\sum_{j \neq i} q_{ij}$. Consider the f-ergodicity with f satisfying $f_0 = 1$, $f_i \equiv \beta > 1$, $\forall i \geq 1$. Theorem [1.1](#page-1-1) gives the convergence rate as

$$
\varepsilon_{\text{max}} = 1
$$
 and $C(i, f) = [\pi_0 + \beta^2 (1 - \pi_0)]^{1/2} \left(\frac{1}{\pi_i} - 1\right)^{1/2}$.

Proof. By the definition of Q-matrix, we have $\pi Q = 0$ and $\pi_i q_{ij} = \pi_j q_{ji}$, which means Q-matrix is reversible respect to the stationary distribution π . For any $g \in L^2(\pi)$ we have

$$
(-Q(g), g) = \sum_{j} \pi_{j} g_{j} \left(\sum_{k} q_{jk} (g_{k} - g_{j}) \right) = \pi(g)^{2} - \pi(g^{2}) = \text{Var}_{\pi}(g).
$$

Hence $\text{gap}(Q) = 1$. Since $f \in L^2(\pi)$, using Theorem [1.1,](#page-1-1) we obtain

$$
\varepsilon_{\text{max}} = 1,
$$
 $C(i, f) = [\pi_0 + \beta^2 (1 - \pi_0)]^{1/2} \left(\frac{1}{\pi_i} - 1\right)^{1/2}.$

This gives the exact description of ε_{max} and $C(i, f)$.

If we use the drift condition given in [\[11,](#page-10-5) Theorem 2.2], we need to solve the equation

$$
Qf(i) \leqslant -cf(i) + b\mathbb{1}_{\{0\}}(i), \qquad \forall i \in E.
$$

For $x \neq 0$, it implies that $c \leq 1 - \beta^{-1}\pi(f) = \pi_0(1 - \beta^{-1}) < 1$. For $x = 0$, we have $b \ge \beta(1 - \pi_0) + (\pi_0 + c - 1)$. Hence the drift condition shows the f-ergodicity holds with convergence rate $c \in (0, \pi_0(1 - \beta^{-1}))$. with convergence rate $c \in (0, \pi_0(1 - \beta^{-1})).$ \Box

For the irreversible case, the equivalence in Theorem [1.1](#page-1-1) is erroneous. The following example show that there is some difference between gap(Q) and ε_{max} .

Example 2.2. (irreversible case) Let $E = \{0, 1, 2\}$ and f satisfying $f_i \in [1, \infty)$, $i = 1, 2, 3$. Consider the process with Q -matrix

$$
Q = \left(\begin{array}{rrr} -1/2 & 1/2 & 0 \\ 0 & -1 & 1 \\ 1 & 0 & -1 \end{array} \right).
$$

Then the process has f-ergodicity with convergence rate $5/4 > \text{gap}(Q) = 1$.

Proof. By $\pi Q = 0$, we have $\pi_0 = 1/2$, $\pi_1 = \pi_2 = 1/4$. In this irreversible situation, we adopt the Q-matrix by the symmetrizing procedure. Let $\hat{q}_{ij} = \pi_j q_{ji}/\pi_i$ and $\bar{q}_{ij} = (q_{ij} + \hat{q}_{ij})/2$, then we have

$$
\hat{Q} = \begin{pmatrix} -1/2 & 0 & 1/2 \\ 1 & -1 & 0 \\ 0 & 1 & -1 \end{pmatrix}, \qquad \bar{Q} = \begin{pmatrix} -1/2 & 1/4 & 1/4 \\ 1/2 & -1 & 1/2 \\ 1/2 & 1/2 & -1 \end{pmatrix}
$$

The matrix \overline{Q} is symmetry with respect to π and it is easy to calculate that gap(\overline{Q}) = $\text{gap}(Q) = 1 > 0$. Hence, by Proposition [1.2,](#page-2-0) we obtain the f-ergodicity of this Qprocess and $\varepsilon_{\text{max}} \geq 1$. However, we can not get the exact value of the convergence rate from Proposition [1.2.](#page-2-0)

Fortunately, the convergence rate of f-ergodicity could be calculated directly. Firstly, the eigenvalues of Q are

$$
\lambda_0 = 0
$$
, $\lambda_1 = -\frac{5}{4} + \frac{\sqrt{7}i}{4}$, $\lambda_2 = -\frac{5}{4} - \frac{\sqrt{7}i}{4}$.

By the representation $P_t = U \Lambda_t U^{-1}$, where U is a matrix whose column vectors are the eigenvectors, Λ_t is a diagonal matrix $\Lambda_t = \text{diag}(\exp(\lambda_i t))$, then

$$
P_t = e^{-5/4t} R_t + \begin{pmatrix} 1/2 & 1/4 & 1/4 \ 1/2 & 1/4 & 1/4 \ 1/2 & 1/4 & 1/4 \end{pmatrix}.
$$

where

$$
R_t = \frac{\sin(\sqrt{7}t)}{\sqrt{7}} \begin{pmatrix} -1/2 & 1/2 & 0 \\ 0 & -1 & 1 \\ 1 & 0 & -1 \end{pmatrix}
$$

+
$$
\begin{pmatrix} \cos(\sqrt{7}t) + \frac{5\sin(\sqrt{7}t)}{\sqrt{7}} \end{pmatrix} \begin{pmatrix} 1/2 & -1/4 & -1/4 \\ -1/2 & 3/4 & -1/4 \\ -1/2 & -1/4 & 3/4 \end{pmatrix}
$$

By the representation of P_t and (6) , we can calculate the convergence rate immediately

$$
||P_t(x,\cdot) - \pi||_f = \sum_{i=0}^2 |f_i(p_t(x,i) - \pi_i)| = e^{-5/4t} \left| \sum_{i=0}^2 f_i R_t(x,i) \right|.
$$

The convergence rate of f-ergodicity is $5/4$ which is bigger than gap(Q). \Box

3 The proofs

The h-transform (or Doob's h-transform) is an useful transformation in probability or potential theory. For instance, in [\[14\]](#page-10-14), the principal eigenvalue of diffusion operators have been carefully handled by the h-transform and applied to multi-dimensional case. Refer to [\[2,](#page-10-6) Chapter 1] for more details.

Let P_t be a Markov semigroup with stationary measure π and $f \in L^2(\pi)$ be a strictly positive measurable function. Define a new semigroup as

$$
P_t^f(g) = \frac{1}{f} P_t(fg), \qquad \forall g \in L^2(\pi), \ t \geq 0.
$$

Similarly, the h-transform of Q-matrix and stationary distribution π are

$$
Q^{f}(g)(i) = \frac{1}{f(i)} \sum_{j \in E} q_{ij} f(j)g(j), \quad \pi^{f}(g)(i) := \frac{1}{f(i)} \sum_{j \in E} \pi_{j} f(j)g(j), \quad \forall g \in L^{2}(\pi).
$$

When P_t is reversible, it is easy to show that P_t^f is reversible with respect to measure $\nu_i := f^2(i)\pi_i$. Moreover, the semigroup P_t^f has similar properties with P_t .

Lemma 3.1. Let P_t be a reversible Markov semigroup with respect to π , define P_t^f , π^f and ν as mentioned above. For any function $g_1, g_2 \in L^2(\nu)$ we have:

- (1) Semigroup property: $P_{t+s}^f = P_t^f P_s^f, \quad \forall t, s \geq 0;$
- (2) Conjugacy: $(P_t^f g_1, g_2)_{\nu} = (g_1, P_t^f g_2)_{\nu}$; $(\pi^f (g_1), g_2)_{\nu} = (g_1, \pi^f (g_2))_{\nu}$;
- (3) $\pi^f\left(P_t^fg_1\right) = P_t^f\left(\pi^f(g_1)\right) = \pi^f(g_1).$

The proof of Lemma [3.1](#page-4-0) is easy and straightforward. It should be noted that the P_t^f is not a Markov semigroup though its properties are similar to P_t , and ν is not a probability measure. In order to ensure ν to be a finite measure, we need the condition $f \in L^2(\pi)$.

This section is devoted to prove an equivalence of the exponential f-ergodicity and the exponential convergence of the semigroup P_t^f . We will start with reversible case. The irreversible case can be reduced to the symmetric one, which will be discussed shortly in the end this section.

Definition 3.2. The semigroup P_t^f converges exponentially in the $L^2(\nu)$ -norm if *there is a constant* $\sigma > 0$ *such that*

$$
\left\| P_t^f g - \pi^f(g) \right\|_{L^2(\nu)} \leq \|g - \pi^f(g)\|_{L^2(\nu)} e^{-\sigma t}, \quad \forall t \geq 0, \ g \in L^2(\nu). \tag{4}
$$

The largest σ is denoted by σ_{max} , which is called the $L^2(\nu)$ -exponential convergence *rate.*

It is known that the exponential ergodicity rate in total variation norm (when $f \equiv 1$) is given by the spectral gap of the Q-matrix, refer to [\[6\]](#page-10-7). Hence, it is natural to consider the relationship of f-ergodicity and the spectral gap of Q^f . Firstly, we give this equivalence between the convergence of P_t^f and the f-ergodicity, which is inspired by the h-transform and $[6,$ Theorem 9.15].

Theorem 3.3. Assume that $\pi(f^2) < \infty$ and P_t is reversible. Then P_t satisfies $exponential$ f -ergodicity if and only if the semigroup P_t^f converges exponentially in *the* $L^2(\nu)$ -norm. Moreover, we have $\varepsilon_{\text{max}} = \sigma_{\text{max}}$.

To begin with, we give some short lemmas about the operator norm of P_t^f .

Lemma 3.4. Let P_t be a reversible semigroup. Define P_t^f , π^f and ν as mentioned *above, then we have*

$$
\left\| P_t^f - \pi^f \right\|_{L^{\infty}(\nu) \to L^2(\nu)}^2 = \left\| P_{2t}^f - \pi^f \right\|_{L^{\infty}(\nu) \to L^1(\nu)}.
$$

Proof. For any $g \in L^{\infty}(\nu)$, by the semigroup property and conjugacy of P_t^f in Lemma [3.1,](#page-4-0) we have

$$
\left\| \left(P_t^f - \pi^f \right) g \right\|_{L^2(\nu)}^2 = \left(g, \left(P_t^f - \pi^f \right)^2 g \right)_{\nu} = \left(g, \left(P_{2t}^f - \pi^f \right) g \right)_{\nu}
$$

$$
\leqslant \|g\|_{L^{\infty}(\nu)} \left\| \left(P_{2t}^{f} - \pi^{f} \right) g \right\|_{L^{1}(\nu)} \leqslant \|g\|_{L^{\infty}(\nu)}^{2} \left\| P_{2t}^{f} - \pi^{f} \right\|_{L^{\infty}(\nu) \to L^{1}(\nu)}.
$$

The last inequality gives $\left\| P_t^f - \pi^f \right\|$ 2 $\left\| P_{2t}^f - \pi^f \right\|_{L^{\infty}(\nu) \to L^1(\nu)}.$ The inverse inequality is obvious by the conjugacy of P_t^f , details as below

$$
\|P_{2t}^{f} - \pi^{f}\|_{L^{\infty}(\nu) \to L^{1}(\nu)} \le \|P_{t}^{f} - \pi^{f}\|_{L^{\infty}(\nu) \to L^{2}(\nu)} \|P_{t}^{f} - \pi^{f}\|_{L^{2}(\nu) \to L^{1}(\nu)}
$$

\n
$$
= \|P_{t}^{f} - \pi^{f}\|_{L^{\infty}(\nu) \to L^{2}(\nu)} \|P_{t}^{f} - \pi^{f}\|_{L^{\infty}(\nu) \to L^{2}(\nu)} \|_{L^{\infty}(\nu) \to L^{2}(\nu)}
$$

\n
$$
= \|P_{t}^{f} - \pi^{f}\|_{L^{\infty}(\nu) \to L^{2}(\nu)}^{2},
$$

here $(P_t^f - \pi^f)^*$ is the dual of $P_t^f - \pi^f$ with respect to $(\cdot, \cdot)_\nu$. \Box

The next lemma is about the relationship between the operator norm of P_t^f and the f-ergodicity.

Lemma 3.5. *Under the same conditions of Lemma [3.4,](#page-4-1) we have*

$$
\left\| P_t^f - \pi^f \right\|_{L^\infty(\nu) \to L^1(\nu)} \leqslant \sum_{i \in E} \pi_i f(i) \left\| P_t(i, \cdot) - \pi \right\|_f. \tag{5}
$$

Proof. For any $g \in L^{\infty}(\nu)$, we have $g/||g||_{L^{\infty}(\nu)} \leq 1$. Directly calculating, we have

$$
\sum_{i \in E} \pi_i f(i) \| P_t(i, \cdot) - \pi \|_f = \sum_{i \in E} \pi_i f(i) \sup_{|\varphi| \le f} |(P_t - \pi) (\varphi)(i)|
$$

\n
$$
= \sum_{i \in E} \pi_i f^2(i) \sup_{|\varphi|/f \le 1} \left| \left(P_t^f - \pi^f \right) \left(\frac{\varphi}{f} \right)(i) \right|
$$

\n
$$
= \sum_{i \in E} \pi_i f^2(i) \sup_{|\varphi^*| \le 1} \left| \left(P_t^f - \pi^f \right) (\varphi^*)(i) \right| \qquad \text{(where } \varphi^* := \varphi/f \text{)}
$$

\n
$$
\ge \sum_{i \in E} \pi_i f^2(i) \left| \left(P_t^f - \pi^f \right) \left(\frac{g}{\|g\|_{L^\infty(\nu)}} \right)(i) \right| = \frac{\left\| \left(P_t^f - \pi^f \right) g \right\|_{L^1(\nu)}}{\|g\|_{L^\infty(\nu)}}.
$$

That implies

$$
\left\| P_t^f - \pi^f \right\|_{L^{\infty}(\nu) \to L^1(\nu)} = \sup_{g \in L^{\infty}(\nu)} \frac{\left\| \left(P_t^f - \pi^f \right) g \right\|_{L^1(\nu)}}{\|g\|_{L^{\infty}(\nu)}}
$$

$$
\leqslant \sum_{i \in E} \pi_i f(i) \left\| P_t(i, \cdot) - \pi \right\|_f.
$$

By Hahn decomposition theorem, every signed measure ν has a unique decomposition into a difference $\nu = \nu^+ - \nu^-$ of two positive measures ν^+ and ν^- , then the total variation norm of ν is given simply by

$$
\|\nu\|_{\text{var}} = \sup_{|g| \le 1} |\nu(g)| = \sum_{i \in E} |\nu_i|,
$$

where $|\nu| := \nu^+ + \nu^-$. Therefore, for any positive function f,

$$
\|\nu\|_{f} = \sup_{|g| \le f} |\nu(g)| = \sup_{|g|/f \le 1} \left| \nu \left[f\left(\frac{g}{f}\right) \right] \right| = \sum_{i \in E} f(i) |\nu_{i}|.
$$
 (6)

Furthermore, we have following lemma.

Lemma 3.6. *For any probability measure* μ *, define* $h_i = \mu_i / \pi_i$ *. Then we have*

$$
\|\mu P_t - \pi\|_f = \|f(P_t^*(h) - 1)\|_{L^1(\pi)},
$$

where P_t^* *is the dual semigroup of* P_t *, which means* $P_t^*(i,j) := P_t(j,i)\pi_j/\pi_i$ *. If* P_t *is reversible respect to* π *, we have* $P_t^* = P_t$ *.*

Proof. The proof is straightforward. By the Hahn decomposition, we have

$$
\|\mu P_t - \pi\|_f = \sum_{i \in E} f(i) |(\mu P_t)(i) - \pi_i| = \sum_{i \in E} f(i) \left| \sum_{j \in E} \mu_j P_t(j, i) - \pi_i \right|
$$

=
$$
\sum_{i \in E} f(i) \left| \sum_{j \in E} h_j \pi_j P_t(j, i) - \pi_i \right| = \sum_{i \in E} f(i) \left| \sum_{j \in E} h_j \pi_i P_t^*(i, j) - \pi_i \right|
$$

=
$$
\sum_{i \in E} \pi_i f(i) |P_t^*(h)(i) - 1|.
$$

Having these preparations at hand, we are ready to prove the main results.

Proof of Theorem [3.3.](#page-4-2) (i). We consider the sufficiency of Theorem [3.3.](#page-4-2) Assume P_t satisfies exponential f-ergodicity, which means that there exists constants $\varepsilon_{\text{max}} > 0$ and $C(i, f) > 0$ such that [\(3\)](#page-1-0) holds. Firstly, we give a direct proof under a technical condition:

$$
\pi(fC(\cdot,f)) = \sum_{i \in E} \pi_i f(i)C(i,f) < \infty. \tag{7}
$$

 \mathbf{I}

 $\overline{1}$

By Lemma [3.4,](#page-4-1) Lemma [3.5](#page-5-0) and [\(7\)](#page-6-1), we have

$$
\left\| P_t^f - \pi^f \right\|_{L^{\infty}(\nu) \to L^2(\nu)}^2 = \left\| P_{2t}^f - \pi^f \right\|_{L^{\infty}(\nu) \to L^1(\nu)} \le \sum_{i \in E} \pi_i f(i) \left\| P_{2t}(i, \cdot) - \pi \right\|_f \le \pi (fC(\cdot, f)) e^{-2\varepsilon_{\text{max}}t}.
$$

Hence, for any g satisfies $g \in L^{\infty}(\nu)$ and $\nu(g^2) = 1$, we have

$$
\left\| \left(P_t^f - \pi^f \right) g \right\|_{L^2(\nu)}^2 \leq \pi (fC(\cdot, f)) \left\| g \right\|_{L^\infty(\nu)}^2 e^{-2\varepsilon_{\text{max}} t}.
$$

The constant $\pi(fC(\cdot,f)) ||g||^2_{L^{\infty}(\nu)}$ in the last line can be removed, which is in-spired by [\[17\]](#page-10-15). For every g with $\pi(fg) = 0$ and $\nu(g^2) = 1$, using [\[17,](#page-10-15) Lemma 2.2] and the spectral representation theorem, we have

$$
\left\| P_t^f g \right\|_{L^2(\nu)}^2 = \left\| P_t(fg) \right\|_{L^2(\pi)}^2 = \int_0^\infty e^{-2\alpha t} \mathrm{d} \left(E_\alpha(fg), fg \right)
$$

$$
\geqslant \left[\int_0^\infty e^{-2\alpha s} d\left(E_\alpha(fg), fg \right) \right]^{t/s} \quad (\forall s \leqslant t, \text{ by Jensen's inequality})
$$

= $||P_s(fg)||_{L^2(\pi)}^{2t/s} = ||P_s^f g||_{L^2(\nu)}^{2t/s},$

where E_{α} is the spectral measure of the generator with respect to α . Thus,

$$
\left\|P_s^f g\right\|_{L^2(\nu)}^2 \leqslant \left[\pi(fC(\cdot,f))\|g\|_{L^\infty(\nu)}^2\right]^{s/t} e^{-2\varepsilon_{\text{max}}s}.
$$

Letting $t \to \infty$, we obtain

 $\ddot{}$

$$
||P_s^f g||^2_{L^2(\nu)} \le e^{-2\varepsilon_{\max} s}
$$
, $g \in L^{\infty}(\nu)$, $||g||_{L^2(\nu)} = 1$, $\pi(fg) = 0$.

Finally, since $L^{\infty}(\nu)$ is dense in $L^{2}(\nu)$, we have $\varepsilon_{\max} \leq \sigma_{\max}$, which means the semigroup P_t^f converges exponentially in the $L^2(\nu)$ -norm.

(ii). The next step, we show that the technical assumption [\(7\)](#page-6-1) could be removed. Since $f \geq 1$, the exponential f-ergodicity of P_t implies its exponential ergodicity:

$$
\|P_t(i,\cdot)-\pi\|_{\text{var}}\leqslant C(i)e^{-\varepsilon' t},\qquad \forall t\geqslant 0,\ i\in E.
$$

Moreover, by [\[6,](#page-10-7) Theorem 4.43] and references therein, the constant $C(i)$ satisfies $C(i) \in L^1(\pi)$. If f is bounded, the ergodicity of P_t ensures that the f-ergodicity holds. To be specific, let $f(i) \leq b, \forall i \in E$, then we have

$$
\|P_t(i, \cdot) - \pi\|_f = \sup_{|g| \leq f} |(P_t(i, \cdot) - \pi)g| \leq \sup_{|g| \leq b} |(P_t(i, \cdot) - \pi)g|
$$

=
$$
\sup_{|g|/b \leq 1} b |(P_t(i, \cdot) - \pi)(g/b)| = b \|P_t(i, \cdot) - \pi\|_{var},
$$

which means the exponential f-ergodicity holds with constant $C(i, f) = bC(i)$. Then, the conclusion holds by the method we used in the proof (i).

If the assumption [\(7\)](#page-6-1) is invalid, we can define bounded functions as $f_N := f \wedge N$, $N \in \mathbb{N}^+$. Based on the above discussion, we have

$$
\left\| \left(P_t^{f_N} - \pi^{f_N} \right) g \right\|_{L^2(\nu)}^2 \leqslant e^{-2t\varepsilon_{\max}}, \qquad \|g\|_{L^2(\nu)} = 1.
$$

Note that the right hand side of last inequality is independent of N. By dominated convergence theorem, we obtain the exponential convergence of the semigroup P_t^f in the $L^2(\nu)$ -norm by letting $N \to \infty$.

(iii). Finally, we prove the necessity of Theorem [3.3.](#page-4-2) Assume $f \in L^2(\pi)$ and P_t is reversibility. If P_t^f converges exponentially in the $L^2(\nu)$ -norm with $\sigma_{\max} > 0$, for any $0 < s \leq t$, we have

$$
||P_s P_{t-s}(i, \cdot) - \pi||_f = \left|| f \left[P_{t-s} \left(\frac{P_s(i, \cdot)}{\pi} - 1 \right) \right] \right||_{L^1(\pi)}
$$
 (by Lemma 3.6)

$$
= \sum_{j \in E} \pi_j f(j) \left| \sum_{k \in E} P_{t-s}(j, k) \left(\frac{P_s(i, k)}{\pi_k} - 1 \right) \right|
$$

$$
= \sum_{j \in E} \pi_j f^2(j) \left| \sum_{k \in E} \frac{1}{f(j)} P_{t-s}(j, k) f(k) \left(\frac{1}{f(k)} \frac{P_s(i, k)}{\pi_k} - \frac{1}{f(k)} \right) \right|
$$

$$
= \sum_{j \in E} \pi_j f^2(j) \left| P_{t-s}^f \left(\frac{1}{f(\cdot)} \frac{P_s(i, \cdot)}{\pi} - \frac{1}{f(\cdot)} \right) (j) \right|
$$

=
$$
\left\| P_{t-s}^f \left(h_s(i, \cdot) \right) \right\|_{L^1(\nu)}
$$

$$
\leq \left\| P_{t-s}^f \left(h_s(i, \cdot) \right) \right\|_{L^2(\nu)} \pi \left(f^2 \right)^{1/2},
$$

The last step is Cauchy-Schwarz inequality and $h_s(i, \cdot)$ is defined as

$$
h_s(i,j) = \frac{1}{f(j)} \frac{P_s(i,j)}{\pi_j} - \frac{1}{f(j)}.
$$
\n(8)

For any $i \in E$ and $s > 0$, we have $\pi^f(h_s(i, \cdot)) = 0$. By the exponential convergence of P_t^f we have

$$
\left\| P_{t-s}^{f}(h_s(i, \cdot)) \right\|_{L^2(\nu)} \leq e^{-\sigma_{\max}(t-s)} \left\| h_s(i, \cdot) \right\|_{L^2(\nu)},
$$

where

$$
||h_s(i, \cdot)||_{L^2(\nu)}^2 = \sum_{j \in E} \pi_j f^2(j) \left(\frac{1}{f(j)} \frac{P_s(i,j)}{\pi_j} - \frac{1}{f(j)} \right)^2
$$

=
$$
\sum_{j \in E} \left(\frac{P_s(i,j)}{\pi_j} \right)^2 \pi_j - 1
$$

=
$$
\frac{P_{2s}(i,i)}{\pi_i} - 1,
$$

the last step depends on the reversibility of P_t . Hence, we obtain

$$
||P_t(i, \cdot) - \pi||_f \le \pi (f^2)^{1/2} ||P_{t-s}^f(h_s(i, \cdot))||_{L^2(\nu)}
$$

$$
\le \pi (f^2)^{1/2} e^{-\sigma_{\max}(t-s)} ||h_s(i, \cdot)||_{L^2(\nu)}
$$

$$
= \pi (f^2)^{1/2} e^{-\sigma_{\max}t} \left[e^{\sigma_{\max}s} \left(\frac{P_{2s}(i, i)}{\pi_i} - 1 \right)^{1/2} \right].
$$

Let $s \to 0$ and denote $C(i, f)$ by

$$
C(i, f) := \pi \left(f^2\right)^{1/2} \left(\frac{1}{\pi_i} - 1\right)^{1/2},
$$

and then we get the exponential f -ergodicity

$$
||P_t(i, \cdot) - \pi||_f \leq C(i, f)e^{-\sigma_{\text{max}}t}, \qquad \forall i \in E, \ t \geq 0,
$$

with $\sigma_{\max} \leqslant \varepsilon_{\max}$. \Box

Depending on Theorem [3.3,](#page-4-2) the only thing left to consider is the relationship between gap(Q) and σ_{max} . The crucial method is Poincaré inequality.

Proof of Theorem [1.1.](#page-1-1) For any g satisfying $fg \in L^2(\pi)$, we have $g \in L^2(\nu)$, and then the function

$$
F(t) = \left\| \left(P_t^f - \pi^f \right) g \right\|_{L^2(\nu)}^2
$$

is well-define. Review the definition of the exponential convergence of P_t^f , we have $F(t) \leq F(0)e^{-2\sigma_{\text{max}}t}$. Dividing by t, we get

$$
\left. \frac{\mathrm{d}}{\mathrm{d}t} F(t) \right|_{t=0} \leqslant -2\sigma_{\max} F(0). \tag{9}
$$

By part (3) of Lemma [3.1,](#page-4-0) we have

$$
F(0) = ||g - \pi^{f}(g)||_{L^{2}(\nu)}^{2} = \pi (f^{2}g^{2}) - \pi^{2}(fg) = \text{Var}_{\pi}(fg),
$$

and

$$
\frac{\mathrm{d}}{\mathrm{d}t}F(t)\bigg|_{t=0} = \frac{\mathrm{d}}{\mathrm{d}t}\pi\left(P_t^2(fg)\right)\bigg|_{t=0} = 2(-Q(fg),fg)_\pi.
$$

Substituting these equations into [\(9\)](#page-9-1), then

$$
\sigma_{\max} \text{Var}_{\pi}(fg) \leqslant (-Q(fg), fg)_{\pi}, \qquad fg \in L^2(\pi),
$$

which is Poincaré inequality. Since the spectral gap can be redefined as the optimal constant of the Poincaré inequality (cf. [\[6,](#page-10-7) Chapter 9]), then we have $\sigma_{\text{max}} \leq \text{gap}(Q)$.

Conversely, assume $\text{gap}(L) > 0$. We use the same notations as aforesaid. Since $P_t(fg) \in L^2(\pi)$, by Poincaré inequality, we have

$$
gap(Q) \text{Var}_{\pi} (P_t(fg)) \leqslant (-Q(P_t(fg)), P_t(fg))_{\pi},
$$

and then $2\text{gap}(Q)F(t) \leq -F'(t)$ for every $t \geq 0$. Using Gronwall lemma, we have $F(t) \leqslant e^{-2\text{gap}(Q)t} F(0)$. Therefore, $\text{gap}(Q) \leqslant \sigma_{\text{max}}$. \Box

Proof of Proposition [1.2.](#page-2-0) Let P_t^* be the dual semigroup of P_t , and its generator is denoted by Q^* . Using the h-transform, we can consider the convergence of semigroup P_t^{*f} . Similar to the Definition [3.2,](#page-4-3) we denote the $L^2(\nu)$ -exponential convergence rate by σ_{\max}^* . In the same way of the proof of Theorem [1.1,](#page-1-1) we have $\sigma_{\max}^* = \text{gap}(Q^*) = \text{gap}(Q)$. The second equality is base on [\[6,](#page-10-7) Chapter 9].

It should be noted that Lemma [3.6](#page-6-2) is still effective in the irreversible case. Assume $0 < \text{gap}(Q) = \sigma_{\text{max}}^*$, then the semigroup P_t^{*f} converges exponentially in the $L^2(\nu)$ norm. By the method in part (iii) of the proof of Theorem [3.3,](#page-4-2) we obtain

$$
||P_t(i, \cdot) - \pi||_f \le \pi (f^2)^{1/2} ||P_{t-s}^{*f}(h_s(i, \cdot))||_{L^2(\nu)}
$$

$$
\le \pi (f^2)^{1/2} e^{-\sigma_{\max}^* t} \left[e^{\sigma_{\max}^* s} \left(\frac{P_{2s}(i, i)}{\pi_i} - 1 \right)^{1/2} \right]
$$

,

where $h_s(x, \cdot)$ is defined as [\(8\)](#page-8-0). Let $s \to 0$, and then we get the f-ergodicity immediately, which satisfies gap $(Q) \leq \varepsilon_{\text{max}}$. \Box
