

LOCAL ENERGY ESTIMATES FOR THE FRACTIONAL LAPLACIAN

JUAN PABLO BORTHAGARAY, DMITRIY LEYKEKHMAN,
AND RICARDO H. NOCHETTO

ABSTRACT. The integral fractional Laplacian of order $s \in (0, 1)$ is a nonlocal operator. It is known that solutions to the Dirichlet problem involving such an operator exhibit an algebraic boundary singularity regardless of the domain regularity. This, in turn, deteriorates the global regularity of solutions and as a result the global convergence rate of the numerical solutions. For finite element discretizations, we derive *local* error estimates in the H^s -seminorm and show optimal convergence rates in the interior of the domain by only assuming meshes to be shape-regular. These estimates quantify the fact that the reduced approximation error is concentrated near the boundary of the domain. We illustrate our theoretical results with several numerical examples.

1. INTRODUCTION

In this work we consider finite element discretizations of the problem

$$(1.1) \quad \begin{cases} (-\Delta)^s u = f & \text{in } \Omega, \\ u = 0 & \text{in } \Omega^c := \mathbb{R}^d \setminus \Omega, \end{cases}$$

where $\Omega \subset \mathbb{R}^d$ is a bounded domain and $(-\Delta)^s$ is the integral fractional Laplacian of order $s \in (0, 1)$,

$$(1.2) \quad (-\Delta)^s u(x) := C_{d,s} \text{ p.v.} \int_{\mathbb{R}^d} \frac{u(x) - u(y)}{|x - y|^{d+2s}} dy.$$

The normalization constant $C_{d,s} = \frac{2^{2s} s \Gamma(s + \frac{d}{2})}{\pi^{d/2} \Gamma(1-s)}$ makes the integral in (1.2), calculated in the principal value sense, coincide with the Fourier definition of $(-\Delta)^s u$. It is well understood that, even if the data is smooth (for example, if $\partial\Omega \in C^\infty$ and $f \in C^\infty(\bar{\Omega})$), then the unique solution to (1.1) develops an algebraic singularity near $\partial\Omega$, i.e. a singularity of the form $\text{dist}(x, \partial\Omega)^s$ (cf. Example 2.1). This is in stark contrast with the classical Laplacian equation.

Nevertheless, in such a case one expects the solution to be locally smooth in Ω , and thus the discretization error to be smaller in the interior of the domain. Our main result (Theorem 5.1) is a quantitative estimate of the fact that the finite element error is concentrated around $\partial\Omega$.

The fractional Laplacian (1.2) is a nonlocal operator: computing $(-\Delta)^s u(x)$ requires the values of u at points arbitrarily far away from x . Nonlocality is also reflected in the variational formulation of (1.1): the natural space in which the problem is set is the zero-extension fractional Sobolev space $\tilde{H}^s(\Omega)$, and the norm

therein is not subadditive with respect to domain partitions. Furthermore, it is not possible to localize the inner product in $\widetilde{H}^s(\Omega)$, because functions with supports arbitrarily far away from each other may have nonzero H^s -inner product. This is also in stark contrast with the local case (i.e., with the inner product in $H^1(\Omega)$), and makes the development of *local* estimates for such a *nonlocal* problem a more delicate matter, especially in the case of general shape-regular meshes. This is the main purpose of this paper.

In recent years, there has been significant progress in the numerical analysis and implementation of (1.1) and related fractional-order problems. Finite element discretizations provide naturally the best approximation in the energy norm. A priori convergence rates in the energy norm for approximations using piecewise linear basis functions on either quasi-uniform or graded meshes were derived in [2]; similar results, but regarding convergence in $H^1(\Omega)$ in case $s > \frac{1}{2}$, were obtained in [8]. The use of adaptive schemes and a posteriori error estimators has been studied in [3, 22, 25, 34, 38]. A non-conforming discretization, based on a Dunford-Taylor representation was proposed and analyzed in [7]. We refer to [6, 9] for further discussion on these methods. In contrast, the analysis of finite difference schemes typically leads to error estimates in the $L^\infty(\Omega)$ -norm under regularity assumptions that cannot be guaranteed in general [17, 18, 28].

We learned about [21] after our paper was submitted. Ref. [21] also performs a local error analysis for the problem (1.1). The local estimates in [21] differ from ours in several respects. The main differences lie in the form of the pollution term, which is expressed in the $H^{s-\frac{1}{2}}$ -norm instead of the L^2 -norm, and that the error estimates are measured in the H^1 -norm besides the H^s -energy norm. The analytical techniques differ as well. While the proof in [21] is based on the use of the Caffarelli-Silvestre extension, our approach is purely nonlocal and is based on Caccioppoli estimates that are valid for a more general class of kernels [14] and meshes.

The rest of the paper is organized as follows. In Section 2, we review the fractional-order spaces and the regularity of solutions to (1.1) in either standard or weighted Sobolev spaces. In Section 3, we describe our finite element discretization, review basic energy based error estimates, and combine such estimates with Aubin-Nitsche techniques to derive novel convergence rates in L^2 -norm. In Section 4, we provide a proof of Caccioppoli estimate for the continuous problem. In Section 5, which is the central part of the paper, we combine Caccioppoli estimates and superapproximation techniques, to obtain interior error estimates with respect to H^s -seminorms. At the end of this section we show some applications of our interior error estimates. In particular, we discuss the convergence rates of the finite element error in the interior of the domain with respect to smoothness of the domain and the right hand side in the case of quasi-uniform and graded meshes. The results are summarized in Tables 1 and 2. Finally, several numerical examples at the end of the paper illustrate the theoretical results from Section 5.

2. VARIATIONAL FORMULATION AND REGULARITY

In this section, we briefly discuss important features of fractional-order Sobolev spaces that are instrumental for our analysis. Furthermore, we consider regularity properties of the solution to (1.1) and review some negative results that lead to the use of certain weighted spaces, in which the weight compensates the singular

behavior of the gradient of the solution near the boundary of the domain. Having regularity estimates in such weighted spaces at hand, we shall be able to increase the convergence rates by constructing *a priori* graded meshes.

2.1. Sobolev spaces. Sobolev spaces of order $s \in (0, 1)$ provide the natural setting for the variational formulation of (1.1). More precisely, we consider $H^s(\mathbb{R}^d)$ to be the set of L^2 -functions $v : \mathbb{R}^d \rightarrow \mathbb{R}$ such that

$$(2.1) \quad |v|_{H^s(\mathbb{R}^d)} := \left(\frac{C_{d,s}}{2} \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} \frac{|v(x) - v(y)|^2}{|x - y|^{d+2s}} dy dx \right)^{1/2} < \infty,$$

where $C_{d,s}$ is taken as in (1.2). Clearly, these are Hilbert spaces; we shall denote by $(\cdot, \cdot)_s$ the bilinear form that gives rise to the fractional-order seminorms, namely,

$$(2.2) \quad (v, w)_s := \frac{C_{d,s}}{2} \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} \frac{(v(x) - v(y))(w(x) - w(y))}{|x - y|^{d+2s}} dy dx.$$

For the variational formulation of (1.1), we need the zero-extension spaces

$$\tilde{H}^s(\Omega) := \{v \in H^s(\mathbb{R}^d) : \text{supp}(v) \subset \bar{\Omega}\},$$

for which the form $(\cdot, \cdot)_s$ becomes an inner product. Moreover, if $v, w \in \tilde{H}^s(\Omega)$, then integration in (2.2) takes place in $(\mathbb{R}^d \times \mathbb{R}^d) \setminus (\Omega^c \times \Omega^c)$. We shall denote the $\tilde{H}^s(\Omega)$ -norm by $\|v\|_{\tilde{H}^s(\Omega)} := (v, v)_s^{1/2} = |v|_{H^s(\mathbb{R}^d)}$, and remark that the L^2 -norm of v is not needed because a Poincaré inequality holds in the zero-extension Sobolev spaces.

Fractional-order Sobolev spaces can be equivalently defined through interpolation of integer-order spaces; remarkably, if one suitably normalizes the standard K -functional, then the norm equivalence constants can be taken to be independent of s [31, Lemma 3.15 and Theorem B.9]. Although the constant $C_{d,s}$ in (2.1) is fundamental in terms of continuity of Sobolev seminorms as $s \rightarrow 0, 1$, we shall omit it whenever s is fixed. For simplicity of notation, throughout this paper we shall adopt the convention $H^0(\Omega) = L^2(\Omega)$.

Let $H^{-s}(\Omega)$ denote the dual space to $\tilde{H}^s(\Omega)$, and $\langle \cdot, \cdot \rangle$ be their duality pairing. Because of (2.2) it follows that if $v \in \tilde{H}^s(\Omega)$ then $(-\Delta)^s v \in H^{-s}(\Omega)$ and

$$(v, w)_s = \langle (-\Delta)^s v, w \rangle, \quad \forall w \in \tilde{H}^s(\Omega).$$

This integration by parts formula motivates the following weak formulation of (1.1): given $f \in H^{-s}(\Omega)$, find $u \in \tilde{H}^s(\Omega)$ such that

$$(2.3) \quad (u, v)_s = \langle f, v \rangle \quad \forall v \in \tilde{H}^s(\Omega).$$

Because this formulation can be cast in the setting of the Lax-Milgram Theorem, existence and uniqueness of weak solutions, and stability of the solution map $f \mapsto u$, are straightforward.

2.2. Sobolev regularity. Well-posedness of (2.3) in $\tilde{H}^s(\Omega)$ if $f \in H^{-s}(\Omega)$ is a consequence of the Lax-Milgram Theorem. A subsequent question is what additional regularity does u inherit for smoother f . For the sake of finite element analysis, here we shall focus on Sobolev regularity estimates.

By now it is well understood that for smooth domains Ω and data f , solutions to (1.1) develop an algebraic singular layer of the form (cf. for example [27, 35])

$$(2.4) \quad u(x) \text{dist}(x, \partial\Omega)^{-s} = v(x),$$

where v is Hölder continuous up to $\partial\Omega$; this limits the global smoothness of solutions. Indeed, if u is locally smooth in Ω but behaves as (2.4), then one cannot guarantee that u belongs to $H^{s+\frac{1}{2}}(\Omega)$; actually, in general $u \notin H^{s+\frac{1}{2}}(\Omega)$ (see Example 2.1).

We now quote a recent result [10], that characterizes regularity of solutions in terms of Besov norms. Its proof follows a technique introduced by Savaré [36], that consists in combining the classical Nirenberg difference quotient method with suitably localized translations and exploiting certain convexity properties. We refer to [36, Section 4] for a definition and basic properties of Besov spaces.

Theorem 2.1 (Besov regularity on Lipschitz domains). *Let Ω be a bounded Lipschitz domain, $s \in (0, 1)$ and $f \in L^2(\Omega)$. Then, there exist constants C, ζ depending on Ω, d such that the solution u to (1.1) belongs to the Besov space $B_{2,\infty}^{s+\theta}(\Omega)$, where $\theta = \frac{1}{2}$ for $\frac{1}{2} < s < 1$ and $\theta = s - \epsilon > 0$ for $0 < s \leq \frac{1}{2}$, and satisfies the estimates*

$$(2.5) \quad \|u\|_{B_{2,\infty}^{s+\theta}(\Omega)} \leq \begin{cases} C \left(\frac{1}{2s-1}\right)^\zeta \|f\|_{L^2(\Omega)} & \frac{1}{2} < s < 1, \\ C \left(\frac{s}{\epsilon}\right)^\zeta \|f\|_{L^2(\Omega)} & 0 < s \leq \frac{1}{2}. \end{cases}$$

Combining (2.5) with the Sobolev embedding $\|u\|_{H^{s+\theta-\epsilon}(\Omega)} \leq \frac{C}{\sqrt{\epsilon}} \|u\|_{B_{2,\infty}^{s+\theta}(\Omega)}$ yields

$$(2.6) \quad \|u\|_{H^{s+\theta-\epsilon}(\Omega)} \leq \frac{C}{\epsilon^\xi} \|f\|_{L^2(\Omega)} \quad \forall 0 < \epsilon < s,$$

where $\xi = 1/2$ for $\frac{1}{2} < s < 1$ and $\xi = 1/2 + \zeta$ for $0 < s \leq \frac{1}{2}$ and $C = C(\Omega, d, s)$.

There are two conclusions to be drawn from the previous result. In first place, assuming the domain to be Lipschitz is optimal, in the sense that if Ω was a C^∞ domain then no further regularity could be inferred. Thus, reentrant corners play no role on the global regularity of solutions: the boundary behavior (2.4) dominates any point singularities that could originate from them; we refer to [24] for further discussion on this point. In second place, in general the smoothness of the right hand side cannot make solutions any smoother than $\cap_{\epsilon>0} \tilde{H}^{s+\frac{1}{2}-\epsilon}(\Omega)$. The expression (2.4) holds in spite of the smoothness of f near $\partial\Omega$. We illustrate these two points with a well-known example [23].

Example 2.1 (limited regularity). *Let $\Omega = B(0, 1) \subset \mathbb{R}^d$ and $f \equiv 1$. Then, the solution to (1.1) is*

$$(2.7) \quad u(x) = \frac{\Gamma(\frac{d}{2})}{2^{2s}\Gamma(\frac{d+2s}{2})\Gamma(1+s)} (1 - |x|^2)_+^s,$$

where $t_+ = \max\{t, 0\}$. Therefore, $u \in \cap_{\epsilon>0} \tilde{H}^{s+\frac{1}{2}-\epsilon}(\Omega)$.

We also point out a limitation in the technique of proof in Theorem 2.1 from [10] that is related to the example above. Namely, in case $s < \frac{1}{2}$ and $f \in H^r(\Omega)$ for some $r > 0$, solutions are expected to be smoother than just $H^{2s}(\Omega)$; however, one cannot derive such higher regularity estimates from Theorem 2.1. For smooth domains (i.e., $\partial\Omega \in C^\infty$), the following estimate holds [37]:

$$(2.8) \quad f \in H^r(\Omega), \quad -s \leq r < \frac{1}{2} - s \quad \Rightarrow \quad u \in \tilde{H}^{2s+r}(\Omega).$$

2.3. Regularity in weighted Sobolev spaces. By developing a fractional analog of the Krylov boundary Harnack method, Ros-Oton and Serra [35] obtained a fine characterization of boundary behavior of solutions to (1.1) and derived Hölder regularity estimates. In order to exploit these estimates and apply them in a finite element analysis, reference [2] introduced certain weighted Sobolev spaces, where the weight is a power of the distance to $\partial\Omega$. Let

$$\delta(x) := \text{dist}(x, \partial\Omega), \quad \delta(x, y) := \min\{\delta(x), \delta(y)\}.$$

Then, for $k \in \mathbb{N} \cup \{0\}$ and $\gamma \geq 0$, we consider the norm

$$(2.9) \quad \|v\|_{H_\gamma^k(\Omega)}^2 = \int_{\Omega} \left(|v(x)|^2 + \sum_{|\beta| \leq k} |\partial^\beta v(x)|^2 \right) \delta(x)^{2\gamma} dx$$

and define $H_\gamma^k(\Omega)$ and $\tilde{H}_\gamma^k(\Omega)$ as the closures of $C^\infty(\Omega)$ and $C_0^\infty(\Omega)$, respectively, with respect to the norm (2.9).

Next, for $t = k + s$, with $k \in \mathbb{N} \cup \{0\}$ and $s \in (0, 1)$, and $\gamma \geq 0$, we consider

$$\begin{aligned} \|v\|_{\tilde{H}_\gamma^t(\Omega)}^2 &:= \|v\|_{H_\gamma^k(\Omega)}^2 + |v|_{H_\gamma^s(\Omega)}^2, \\ |v|_{H_\gamma^s(\Omega)}^2 &:= \int_{\Omega} \int_{\Omega} \frac{|\nabla^k v(x) - \nabla^k v(y)|^2}{|x - y|^{d+2s}} \delta(x, y)^{2\gamma} dy dx \end{aligned}$$

and the associated space $H_\gamma^t(\Omega) := \left\{ v \in H_\gamma^k(\Omega) : \|v\|_{H_\gamma^t(\Omega)} < \infty \right\}$.

In analogy with the notation for their unweighted counterparts, we define zero-extension weighted Sobolev spaces by

$$(2.10) \quad \tilde{H}_\gamma^t(\Omega) := \{v \in H_\gamma^t(\mathbb{R}^d) : v = 0 \text{ a.e. in } \Omega^c\}$$

with $\|v\|_{\tilde{H}_\gamma^t(\Omega)}^2 := \|v\|_{\tilde{H}_\gamma^k(\Omega)}^2 + |v|_{H_\gamma^s(\mathbb{R}^d)}^2$. The convenience of using the same weight in both the function and its fractional-order derivatives is discussed in [11, Section 3].

We have the following regularity estimate in the scale (2.10) [2, Proposition 3.12], [6, Formula (3.6)].

Theorem 2.2 (weighted Sobolev estimate). *Let Ω be a bounded, Lipschitz domain satisfying the exterior ball condition, (i.e., there exists $r > 0$ such that for all $x \in \partial\Omega$, there exists $B(y, r) \subset \Omega^c$ satisfying $\overline{B}(y, r) \cap \overline{\Omega} = \{x\}$), $s \in (0, 1)$, $f \in C^\beta(\overline{\Omega})$ for some $\beta \in (0, 2 - 2s)$, $\gamma \geq 0$, $t < \min\{\beta + 2s, \gamma + s + \frac{1}{2}\}$ and u be the solution of (2.3). Then, it holds that $u \in \tilde{H}_\gamma^t(\Omega)$ and*

$$\|u\|_{\tilde{H}_\gamma^t(\Omega)} \leq \frac{C(\Omega, d, s)}{\sqrt{(\beta + 2s - t)(1 + 2(\gamma + s - t))}} \|f\|_{C^\beta(\overline{\Omega})}.$$

Remark 1 (optimal parameters). In finite element applications of Theorem 2.2, discussed in Section 3, we will design graded meshes with a grading dictated by γ . The optimal choice of parameters t and γ depends on both the smoothness of the right hand side $f \in C^\beta(\overline{\Omega})$ and the dimension d of the space. We illustrate this now: let $d \geq 2$, $s < \frac{d}{2(d-1)}$, $\beta = \frac{d}{2(d-1)} - s$, and $\varepsilon > 0$ be sufficiently small, and choose $t = s + \frac{d}{2(d-1)} - \varepsilon d$ and $\gamma = \frac{1}{2(d-1)} - \varepsilon$, to obtain the optimal regularity estimate

$$\|u\|_{\tilde{H}_\gamma^t(\Omega)} \leq \frac{C(\Omega, d, s)}{\varepsilon} \|f\|_{C^\beta(\overline{\Omega})}.$$

In contrast, if $s \geq \frac{d}{2(d-1)}$, we set β to be any positive number and take t, γ as above to arrive at

$$\|u\|_{\tilde{H}_\gamma^t(\Omega)} \leq \frac{C(\Omega, d, s, \beta)}{\sqrt{\varepsilon}} \|f\|_{C^\beta(\bar{\Omega})}.$$

Remark 2 (exterior ball condition). Taking into account the results from [24], the exterior ball condition could be relaxed. Indeed, such a reference proves that the asymptotic expansion (2.4) is valid also for corner singularities, which implies that graded meshes also give rise to optimal convergence rates in that situation. Nevertheless, because the analysis of effects of reentrant corners is beyond the scope of this paper, we leave the exterior ball assumption on Ω .

3. FINITE ELEMENT DISCRETIZATION

We next consider finite element discretizations of (2.3) by using piecewise linear continuous functions. Let $h_0 > 0$; for $h \in (0, h_0]$, we let \mathcal{T}_h denote a triangulation of Ω , i.e., $\mathcal{T}_h = \{T\}$ is a partition of Ω into simplices T of diameter h_T . We assume the family $\{\mathcal{T}_h\}_{h>0}$ to be shape-regular, namely,

$$\sigma := \sup_{h>0} \max_{T \in \mathcal{T}_h} \frac{h_T}{\rho_T} < \infty,$$

where $h_T = \text{diam}(T)$ and ρ_T is the diameter of the largest ball contained in T . As usual, the subindex h denotes the element size, $h = \max_{T \in \mathcal{T}_h} h_T$; moreover, we take elements to be closed sets.

We shall also need a smooth mesh function $h(x)$, which is locally comparable with the element size. Note that shape-regularity yields $|\nabla h| \leq C(\sigma)$ (cf. [33, Lemma 5.1]), and thus

$$(3.1) \quad |h(x) - h(y)| \leq C(\sigma)|x - y|, \quad \forall x, y \in \Omega.$$

Let \mathcal{N}_h be the set of interior vertices of \mathcal{T}_h , N be its cardinality, and $\{\varphi_i\}_{i=1}^N$ the standard piecewise linear Lagrangian basis, with φ_i associated to the node $\mathbf{x}_i \in \mathcal{N}_h$. With this notation, the set of discrete functions is

$$\mathbb{V}_h := \left\{ v \in C_0(\Omega) : v = \sum_{i=1}^N v_i \varphi_i \right\}.$$

It is clear that $\mathbb{V}_h \subset \tilde{H}^s(\Omega)$ for all $s \in (0, 1)$ and therefore we have a conforming discretization.

3.1. Interpolation and inverse estimates. Fractional-order seminorms are not subadditive with respect to domain decompositions; therefore, some caution must be exercised when localizing them. With the goal of deriving interpolation estimates, we define the star (or patch) of a set $A \in \Omega$ by

$$S_A := \bigcup \{T \in \mathcal{T}_h : T \cap A \neq \emptyset\}.$$

Given $T \in \mathcal{T}_h$, the star S_T of T is the first ring of T and the star S_{S_T} of S_T is the second ring of T . The star of the node $\mathbf{x}_i \in \mathcal{N}_h$ is $S_i := \text{supp}(\varphi_i)$.

We have the following localization estimate for all $v \in H^s(\Omega)$ [19, 20]

$$(3.2) \quad |v|_{H^s(\Omega)}^2 \leq \sum_{T \in \mathcal{T}_h} \left[\int_T \int_{S_T} \frac{|v(x) - v(y)|^2}{|x - y|^{d+2s}} dy dx + \frac{C(d, \sigma)}{sh_T^{2s}} \|v\|_{L^2(T)}^2 \right].$$

This inequality shows that to estimate fractional seminorms over Ω , it suffices to compute integrals over the set of patches $\{T \times S_T\}_{T \in \mathcal{T}_h}$ plus local zero-order contributions. In addition, if these L^2 contributions have vanishing means over elements –as is often the case whenever v is an interpolation error– a Poincaré inequality allows one to estimate them in terms of local H^s -seminorms. Thus, one can prove the following local quasi-interpolation estimates (see, for example, [2, 11, 13]).

Proposition 3.1 (local interpolation estimates). *Let $T \in \mathcal{T}_h$, $s \in (0, 1)$, $t \in (s, 2]$, and Π_h be a suitable quasi-interpolation operator. If $v \in H^t(S_{S_T})$, then*

$$(3.3) \quad \int_T \int_{S_T} \frac{|(v - \Pi_h v)(x) - (v - \Pi_h v)(y)|^2}{|x - y|^{d+2s}} dy dx \leq C h_T^{2(t-s)} |v|_{H^t(S_{S_T})}^2,$$

where $C = C(\Omega, d, s, \sigma, t)$. Moreover, considering the weighted Sobolev scale (2.10), it holds that for all $v \in H_\gamma^t(S_{S_T})$,

$$(3.4) \quad \int_T \int_{S_T} \frac{|(v - \Pi_h v)(x) - (v - \Pi_h v)(y)|^2}{|x - y|^{d+2s}} dy dx \leq C h_T^{2(t-s-\gamma)} |v|_{H_\gamma^t(S_{S_T})}^2.$$

For the purpose of this paper, we shall make use of a variant of (3.2). Even though the fractional-order norms can be localized, it is clear that the H^s -inner product of two arbitrary functions cannot: it suffices to consider two positive functions with supports sufficiently far from each other. The following observation is due to Faermann [20, Lemma 3.1]. Since we use it extensively, we reproduce it here for completeness.

Lemma 3.1 (symmetry). *For any $v, w \in L^1(\Omega)$ and $\rho : \mathbb{R}^+ \rightarrow \mathbb{R}^+$ bounded, there holds*

$$\sum_{T \in \mathcal{T}_h} \int_T \int_{S_T^c} v(y) w(x) \rho(|x - y|) dy dx = \sum_{T \in \mathcal{T}_h} \int_T \int_{S_T^c} v(x) w(y) \rho(|x - y|) dy dx.$$

Proof. We note that, for any two elements $T, T' \in \mathcal{T}_h$, it holds $T' \in S_T^c$ if and only if $T \in S_{T'}^c$. Thus, we can write

$$\begin{aligned} \sum_{T \in \mathcal{T}_h} \int_T \int_{S_T^c} v(y) w(x) \rho(|x - y|) dy dx &= \sum_{T \in \mathcal{T}_h} \sum_{T' \in S_T^c} \int_T \int_{T'} v(y) w(x) \rho(|x - y|) dy dx \\ &= \sum_{T' \in \mathcal{T}_h} \sum_{T \in S_{T'}^c} \int_T \int_{T'} v(y) w(x) \rho(|x - y|) dy dx. \end{aligned}$$

The proof follows by applying Fubini's Theorem and interchanging the roles of x and y . \square

Proposition 3.2 (equivalent fractional inner product). *Let $v, w \in H^s(\Omega)$. Then, it holds that*

$$\begin{aligned} (v, w)_{H^s(\Omega)} &= \sum_{T \in \mathcal{T}_h} \left[\int_T \int_{S_T} \frac{(v(x) - v(y))(w(x) - w(y))}{|x - y|^{d+2s}} dy dx \right. \\ &\quad \left. + 2 \int_T \int_{S_T^c} \frac{v(x)(w(x) - w(y))}{|x - y|^{d+2s}} dy dx \right]. \end{aligned}$$

Proof. It suffices to write

$$(v, w)_{H^s(\Omega)} = \sum_{T \in \mathcal{T}_h} \left[\int_T \int_{S_T} \frac{(v(x) - v(y))(w(x) - w(y))}{|x - y|^{d+2s}} dy dx + \int_T \int_{S_T^c} \frac{(v(x) - v(y))(w(x) - w(y))}{|x - y|^{d+2s}} dy dx \right].$$

and notice that

$$\sum_{T \in \mathcal{T}_h} \int_T \int_{S_T^c} \frac{v(x)w(x)}{|x - y|^{d+2s}} dy dx = \sum_{T \in \mathcal{T}_h} \int_T \int_{S_T^c} \frac{v(y)w(y)}{|x - y|^{d+2s}} dy dx,$$

and

$$\sum_{T \in \mathcal{T}_h} \int_T \int_{S_T^c} \frac{v(x)w(y)}{|x - y|^{d+2s}} dy dx = \sum_{T \in \mathcal{T}_h} \int_T \int_{S_T^c} \frac{v(y)w(x)}{|x - y|^{d+2s}} dy dx$$

in view of Lemma 3.1 (symmetry) with $\rho(t) = t^{-d-2s} \chi_{[\rho_{min}, \infty)}(t)$, where $\rho_{min} = \min_{T \in \mathcal{T}_h} \rho_T$ and we recall that ρ_T is the diameter of the largest ball contained in T . This completes the proof. \square

Remark 3 (fractional inner product on subdomains). Proposition 3.2 is also valid for any subdomain $D \subset \Omega$, i.e.

$$(v, w)_{H^s(D)} = \sum_{T \in \mathcal{T}_h} \left[\int_{T \cap D} \int_{S_T \cap D} \frac{(v(x) - v(y))(w(x) - w(y))}{|x - y|^{d+2s}} dy dx + 2 \int_{T \cap D} \int_{S_T^c \cap D} \frac{v(x)(w(x) - w(y))}{|x - y|^{d+2s}} dy dx \right].$$

Next, we write some inverse estimates that we shall use in what follows. By using standard scaling arguments, one can immediately derive the estimate

$$(3.5) \quad \|v_h\|_{H^t(T)} \leq C_{inv} h_T^{s-t} \|v_h\|_{H^s(T)}, \quad \forall v_h \in \mathbb{V}_h, \quad 0 \leq s \leq t \leq 1.$$

Let $\eta : \Omega \rightarrow \mathbb{R}$ be a fixed smooth function. We shall also need the following variant of (3.5) with $t = 1$, whose proof follows immediately because the space $\eta \mathbb{V}_h$ is finite dimensional:

$$(3.6) \quad |\eta v_h|_{H^1(S_T)} \leq C h_T^{s-1} |\eta v_h|_{H^s(S_T)} \quad \forall v_h \in \mathbb{V}_h, \quad T \in \mathcal{T}_h, \quad 0 \leq s \leq 1.$$

3.2. Energy-norm error estimates. The discrete counterpart of (2.3) reads: find $u_h \in \mathbb{V}_h$ such that

$$(3.7) \quad (u_h, v_h)_s = \langle f, v_h \rangle \quad \forall v_h \in \mathbb{V}_h.$$

Subtracting (3.7) from (2.3) we get Galerkin orthogonality

$$(3.8) \quad (u - u_h, v_h)_s = 0 \quad \forall v_h \in \mathbb{V}_h.$$

The best approximation property

$$(3.9) \quad \|u - u_h\|_{\tilde{H}^s(\Omega)} = \min_{v_h \in \mathbb{V}_h} \|u - v_h\|_{\tilde{H}^s(\Omega)}$$

follows immediately from (3.8). Consequently, in view of the regularity estimates of u discussed in Section 2, the only ingredient missing to derive convergence rates in the energy norm is some *global* interpolation estimate. Even though the bilinear

form $(\cdot, \cdot)_s$ involves integration over $\Omega \times \mathbb{R}^d$, it is possible to prove that the corresponding energy norm $\|\cdot\|_{\tilde{H}^s(\Omega)}$ is bounded in terms of fractional-order norms $\|\cdot\|_{H^s(\Omega)}$ on Ω by resorting to fractional Hardy inequalities (see [2]).

Therefore, for *quasi-uniform* meshes, if $s \neq \frac{1}{2}$ one can simply combine (3.2) and (3.3) with a fractional Hardy inequality [26, Theorem 1.4.4.4] to replace $\|\cdot\|_{\tilde{H}^s(\Omega)}$ by $\|\cdot\|_{H^s(\Omega)}$ [2, 11] and obtain for $t \in (s, 1)$

$$(3.10) \quad \|v - \Pi_h v\|_{\tilde{H}^s(\Omega)} \leq C(\Omega, d, s, \sigma, t) h^{t-s} |v|_{H^t(\Omega)} \quad \forall v \in H^t(\Omega).$$

In case $s = \frac{1}{2}$, one cannot apply a fractional Hardy inequality. Instead, one may exploit the precise blow-up of the Hardy constant of $H^{\frac{1}{2}+\epsilon}(\Omega)$ as $\epsilon \downarrow 0$ to deduce [2, §3.4], [11, Theorem 4.1] for $t \in (\frac{1}{2}, 1)$ and $\epsilon \in (0, t - \frac{1}{2})$

$$(3.11) \quad \|v - \Pi_h v\|_{\tilde{H}^{\frac{1}{2}}(\Omega)} \leq \frac{C(\Omega, d, \sigma, t)}{\epsilon} h^{t-\frac{1}{2}-\epsilon} |v|_{H^t(\Omega)} \quad \forall v \in H^t(\Omega).$$

Alternatively, one could derive either (3.10) or (3.11) by simply interpolating standard global L^2 and H^1 estimates. However, if we aim to exploit Theorem 2.2 (weighted Sobolev estimate), then we require a suitable mesh refinement near the boundary of Ω . For that purpose, following [26, Section 8.4] we now let the parameter h represent the local mesh size in the interior of Ω , and assume that, besides being shape-regular, the family $\{\mathcal{T}_h\}$ is such that there is a number $\mu \geq 1$ such that for every $T \in \mathcal{T}_h$

$$(3.12) \quad h_T \leq C(\sigma) \begin{cases} h^\mu, & \text{if } T \cap \partial\Omega \neq \emptyset, \\ h \text{dist}(T, \partial\Omega)^{(\mu-1)/\mu}, & \text{if } T \cap \partial\Omega = \emptyset. \end{cases}$$

This construction yields a total number of degrees of freedom (see [4, 11])

$$(3.13) \quad N = \dim \mathbb{V}_h \approx \begin{cases} h^{-d}, & \text{if } \mu < \frac{d}{d-1}, \\ h^{-d} |\log h|, & \text{if } \mu = \frac{d}{d-1}, \\ h^{(1-d)\mu}, & \text{if } \mu > \frac{d}{d-1}. \end{cases}$$

Thus, if $\mu \leq \frac{d}{d-1}$ the interior mesh size h and the dimension N of \mathbb{V}_h satisfy the optimal relation $h \simeq N^{-1/d}$ (up to logarithmic factors if $\mu = \frac{d}{d-1}$). As anticipated in Remark 1 (optimal parameters), the weight γ in Theorem 2.2 (weighted Sobolev estimate) needs to be related to the parameter μ , which satisfies (3.12). To do so, we combine (3.2) with either (3.4) or (3.3), depending on whether S_{S_T} intersects $\partial\Omega$ or not, to find the relation $\gamma = (t-s) \left(\frac{\mu-1}{\mu}\right)$ for $t \in (s, 2]$. If $s \neq \frac{1}{2}$, it suffices to use a fractional Hardy inequality to replace $\|\cdot\|_{\tilde{H}^s(\Omega)}$ by $\|\cdot\|_{H^s(\Omega)}$ [2, 11] and obtain

$$(3.14) \quad \|v - \Pi_h v\|_{\tilde{H}^s(\Omega)} \leq \begin{cases} Ch^{t-s} |v|_{H_\gamma^t(\Omega)} & \text{if } s \neq \frac{1}{2}, \\ \frac{C}{\epsilon} h^{t-s-\epsilon} |v|_{H_\gamma^t(\Omega)} & \text{if } s = \frac{1}{2}, \end{cases}$$

for all $v \in H_\gamma^t(\Omega)$ with a constant that depends on Ω, d, s, σ, t and γ . On the other hand, if $s = \frac{1}{2}$, we choose $\gamma = (t-s) \left(\frac{\mu-1}{\mu}\right) - \epsilon$, where $\epsilon > 0$ is sufficiently small, and exploit the explicit blow-up of the Hardy constant of $H^{\frac{1}{2}+\epsilon}(\Omega)$ as $\epsilon \downarrow 0$, as we did earlier with (3.11), to derive the second estimate in (3.14). We point out that (3.14) does not follow by interpolation of global estimates.

We gather the energy error estimates for quasi-uniform and graded meshes in a single theorem.

Theorem 3.1 (global energy-norm convergence rates). *Let $\Omega \subset \mathbb{R}^d$ be a bounded Lipschitz domain, and u denote the solution to (2.3) and denote by $u_h \in \mathbb{V}_h$ the solution of the discrete problem (3.7), computed over a mesh \mathcal{T}_h consisting of elements with maximum diameter h . If $f \in L^2(\Omega)$, then we have*

$$(3.15) \quad \|u - u_h\|_{\tilde{H}^s(\Omega)} \leq C(\Omega, d, s, \sigma) h^\alpha |\log h|^\kappa \|f\|_{L^2(\Omega)},$$

where $\alpha = \min\{s, \frac{1}{2}\}$ and $\kappa = \xi$ if $s \neq \frac{1}{2}$, $\kappa = 1 + \xi$ if $s = \frac{1}{2}$, and $\xi \geq 1/2$ is the constant in Theorem 2.1. Additionally, if Ω satisfies an exterior ball condition, let $\beta > 0$ be such that

$$(3.16) \quad \beta \geq \begin{cases} 2 - 2s & \text{if } d = 1, \\ \frac{d}{2(d-1)} - s & \text{if } d \geq 2, \end{cases} \quad \text{and} \quad \mu = \begin{cases} 2 - s & \text{if } d = 1, \\ \frac{d}{d-1} & \text{if } d \geq 2. \end{cases}$$

Then, if $f \in C^\beta(\bar{\Omega})$, and the family $\{\mathcal{T}_h\}$ satisfies (3.12) with μ as above, we have

$$(3.17) \quad \|u - u_h\|_{\tilde{H}^s(\Omega)} \leq C(\Omega, s, \sigma) \begin{cases} h^{2-s} |\log h|^{\kappa-1} \|f\|_{C^\beta(\bar{\Omega})} & \text{if } d = 1, \\ h^{\frac{d}{2(d-1)}} |\log h|^\kappa \|f\|_{C^\beta(\bar{\Omega})} & \text{if } d \geq 2, \end{cases}$$

where $\kappa = 1$ if $s \neq \frac{1}{2}$ and $\kappa = 2$ if $s = \frac{1}{2}$. In terms of the number of degrees of freedom N , the estimate (3.17) reads

$$(3.18) \quad \|u - u_h\|_{\tilde{H}^s(\Omega)} \leq C(\Omega, s, \sigma) \begin{cases} N^{-(2-s)} (\log N)^{\kappa-1} \|f\|_{C^\beta(\bar{\Omega})} & \text{if } d = 1, \\ N^{-\frac{1}{2(d-1)}} (\log N)^{\frac{1}{2(d-1)} + \kappa} \|f\|_{C^\beta(\bar{\Omega})} & \text{if } d \geq 2. \end{cases}$$

Proof. If $s \neq \frac{1}{2}$, we combine (3.9) and (3.10) with (2.6) to obtain

$$(3.19) \quad \|u - u_h\|_{\tilde{H}^s(\Omega)} \leq Ch^{\theta-\varepsilon} |u|_{H^{s+\theta-\varepsilon}(\Omega)} \leq C \frac{h^{\theta-\varepsilon}}{\varepsilon^\xi} \|f\|_{L^2(\Omega)},$$

where $\theta = \min\{s - \varepsilon, 1/2\}$, namely $\theta = \alpha$ if $s > 1/2$ and $\theta = \alpha - \varepsilon$ if $s \leq 1/2$. In case $s = \frac{1}{2}$, instead of (3.10) we use (3.11) with the same ε as in (2.6) to get

$$(3.20) \quad \|u - u_h\|_{\tilde{H}^s(\Omega)} \leq \frac{C}{\varepsilon} h^{\theta-2\varepsilon} |u|_{H^{s+\theta-\varepsilon}(\Omega)} \leq C \frac{h^{\theta-2\varepsilon}}{\varepsilon_{1+\xi}} \|f\|_{L^2(\Omega)}.$$

Moreover, coupling (3.9), the first estimate in (3.14) and Theorem 2.2 (weighted Sobolev estimate) with $t = 2 - \varepsilon$ and $\gamma = 2 - s$ if $d = 1$ and $t = s + \frac{d}{2(d-1)} - \varepsilon d$ and $\gamma = \frac{1}{2(d-1)} - \varepsilon$ if $d \geq 2$ yields for $s \neq \frac{1}{2}$

$$(3.21) \quad \|u - u_h\|_{\tilde{H}^s(\Omega)} \leq Ch^{t-s} |u|_{H_t^s(\Omega)} \leq \begin{cases} Ch^{2-s-\varepsilon} \|f\|_{C^\beta(\bar{\Omega})} & \text{if } d = 1, \\ \frac{C}{\varepsilon} h^{\frac{d}{2(d-1)} - \varepsilon d} \|f\|_{C^\beta(\bar{\Omega})} & \text{if } d \geq 2; \end{cases}$$

analogous estimates hold if $s = \frac{1}{2}$ but with an additional factor $\varepsilon^{-1} h^{-\varepsilon}$ according to the second estimate in (3.14). Upon taking $\varepsilon = |\log h|^{-1}$, we end up with (3.15) and (3.17), as asserted. Inequality (3.18) follows by the choice of μ and (3.13). \square

Remark 4 (exponents of logarithms). In case $s \geq \frac{d}{2(d-1)}$, which can only happen if $d \geq 3$, the exponents of logarithms in Theorem 3.1 can actually be reduced by a factor of $\frac{1}{2}$ (see discussion in Remark 1).

Remark 5 (optimality). The convergence rates derived in Theorem 3.1 are theoretically optimal for shape-regular elements. Nevertheless, because we deal with continuous piecewise linear basis functions, one would expect convergence rate $\frac{-(2-s)}{d}$ with respect to N . It is remarkable that such a rate can only be achieved if $d = 1$

upon grading meshes according to (3.12). For dimensions $d \geq 2$, anisotropic meshes are required in order to obtain optimal convergence rates. This limitation stems from the algebraic singular layer (2.4) and becomes more apparent as d increases, but comparison of (3.15) and (3.17) shows that in all cases graded meshes improve the convergence rates with respect to N .

We also point out that setting the grading parameter to be $\mu > \frac{d}{d-1}$ would lead to a higher rate in (3.17) in terms of the interior mesh size h . However, the resulting rate in (3.18) would be the same as for $\mu = \frac{d}{d-1}$ (up to logarithmic factors) but the finite element matrix would turn out to be worse conditioned.

3.3. L^2 -norm error estimates. Upon invoking the new regularity estimates of Theorem 2.1 for data $f \in L^2(\Omega)$, we now perform a standard Aubin-Nitsche duality argument to derive novel convergence rates in $L^2(\Omega)$. We distinguish between quasi-uniform and graded meshes.

Proposition 3.3 (convergence rates in $L^2(\Omega)$ for quasi-uniform meshes). *Let Ω be a bounded Lipschitz domain. If $f \in L^2(\Omega)$, then for all $0 < s < 1$ we have*

$$(3.22) \quad \|u - u_h\|_{L^2(\Omega)} \leq Ch^{2\alpha} |\log h|^{2\kappa} \|f\|_{L^2(\Omega)},$$

where $\alpha = \min\{s, \frac{1}{2}\}$, $\kappa = \xi$ if $s \neq \frac{1}{2}$, $\kappa = 1 + \xi$ if $s = \frac{1}{2}$, and $\xi \geq 1/2$ is the constant in (2.6).

Proof. Let $e = u - u_h$ be the error, and let ϕ be the solution to (2.3) with e instead of the right hand side f . Then, the Galerkin orthogonality (3.8) and the Cauchy-Schwarz inequality yield

$$\|e\|_{L^2(\Omega)}^2 = (\phi, e)_s = (\phi - \Pi_h \phi, e)_s \leq \|\phi - \Pi_h \phi\|_{\tilde{H}^s(\Omega)} \|e\|_{\tilde{H}^s(\Omega)},$$

where Π_h is a quasi-interpolation operator satisfying (3.10) if $s \neq \frac{1}{2}$ or (3.11) if $s = \frac{1}{2}$. Combining these estimates with (2.6), we deduce for $\varepsilon > 0$ sufficiently small

$$(3.23) \quad \|\phi - \Pi_h \phi\|_{\tilde{H}^s(\Omega)} \lesssim \begin{cases} \frac{h^{\theta-\varepsilon}}{\varepsilon^\xi} \|e\|_{L^2(\Omega)} & s \neq \frac{1}{2} \\ \frac{h^{\theta-2\varepsilon}}{\varepsilon^{1+\xi}} \|e\|_{L^2(\Omega)} & s = \frac{1}{2}, \end{cases}$$

where $\theta = \min\{s - \varepsilon, 1/2\}$, precisely as with (3.19) and (3.20). The latter, together with (3.23), imply

$$\|e\|_{L^2(\Omega)} \lesssim \begin{cases} \frac{h^{2(\theta-\varepsilon)}}{\varepsilon^{2\xi}} \|f\|_{L^2(\Omega)} & s \neq \frac{1}{2} \\ \frac{h^{2(\theta-2\varepsilon)}}{\varepsilon^{2(1+\xi)}} \|f\|_{L^2(\Omega)} & s = \frac{1}{2}. \end{cases}$$

Finally, taking $\varepsilon = |\log h|^{-1}$ gives rise to (3.22). \square

In Proposition 3.3, the assumption $f \in L^2(\Omega)$ is made in order to apply Theorem 2.1 (Besov regularity on Lipschitz domains). Stronger estimates are valid provided Ω is smooth.

Lemma 3.2 (further regularity). *Let $\partial\Omega \in C^\infty$ and $f \in H^r(\Omega)$ for some $r \geq -s$. If $\gamma = \min\{s + r, \frac{1}{2}\}$, $\alpha = \min\{s, \frac{1}{2}\}$ and $\kappa = 1$ if $s \neq \frac{1}{2}$, $\kappa = 2$ if $s = \frac{1}{2}$, then there holds*

$$(3.24) \quad \begin{aligned} \|u - u_h\|_{\tilde{H}^s(\Omega)} &\leq Ch^\gamma |\log h|^\kappa \|f\|_{H^r(\Omega)}, \\ \|u - u_h\|_{L^2(\Omega)} &\leq Ch^{\alpha+\gamma} |\log h|^{2\kappa} \|f\|_{H^r(\Omega)}. \end{aligned}$$

Proof. Use the regularity result from [27, Theorem 7.1] (which coincides with (2.8) if $s < \frac{1}{2}$) in the proofs of Theorem 3.1 and Proposition 3.3. \square

As discussed in Sections 2.2 and 3.2, we obtain a finer characterization of the boundary behavior of solutions by using weighted spaces, and we can take advantage of this by constructing suitably graded meshes. In such a case, the same standard argument as above, but using (3.21) instead of (3.19), leads to the following estimate.

Proposition 3.4 (convergence rates in $L^2(\Omega)$ for graded meshes). *Let $\Omega \subset \mathbb{R}^d$ be a bounded Lipschitz domain satisfying an exterior ball condition, $f \in C^\beta(\bar{\Omega})$ and the family $\{\mathcal{T}_h\}$ satisfy (3.12), where β and μ are taken according to (3.16). Then, there exists a constant $C = C(\Omega, s, \sigma)$ such that*

$$(3.25) \quad \|u - u_h\|_{L^2(\Omega)} \leq C \begin{cases} h^{2-s+\alpha} |\log h|^{\kappa-1} \|f\|_{C^\beta(\bar{\Omega})} & \text{if } d = 1, \\ h^{\frac{d}{2(d-1)}+\alpha} |\log h|^\kappa \|f\|_{C^\beta(\bar{\Omega})} & \text{if } d \geq 2, \end{cases}$$

where $\alpha = \min\{s, \frac{1}{2}\}$, $\kappa = \xi + 1$ if $s \neq \frac{1}{2}$, $\kappa = \xi + 2$ if $s = \frac{1}{2}$, and ξ is the constant in (2.6). In terms of the number of degrees of freedom N , the estimate (3.25) reads

$$\|u - u_h\|_{L^2(\Omega)} \leq C \begin{cases} N^{-(2-s+\alpha)} (\log N)^{\kappa-1} \|f\|_{C^\beta(\bar{\Omega})} & \text{if } d = 1, \\ N^{-\frac{\alpha}{d} - \frac{1}{2(d-1)}} (\log N)^{\frac{\alpha}{d} + \frac{1}{2(d-1)} + \kappa} \|f\|_{C^\beta(\bar{\Omega})} & \text{if } d \geq 2. \end{cases}$$

Remark 6 (sharpness of the L^2 -estimates). Combining Galerkin orthogonality (3.8) with (2.3), and applying the Cauchy-Schwarz inequality, we immediately obtain

$$\|u - u_h\|_{\tilde{H}^s(\Omega)}^2 = (u - u_h, u)_s = (u - u_h, f)_0 \leq \|u - u_h\|_{L^2(\Omega)} \|f\|_{L^2(\Omega)},$$

from which we deduce that

$$(3.26) \quad \|u - u_h\|_{L^2(\Omega)} \geq \frac{\|u - u_h\|_{\tilde{H}^s(\Omega)}^2}{\|f\|_{L^2(\Omega)}}.$$

If we knew that the error bound (3.15) were sharp in the sense that $\|u - u_h\|_{\tilde{H}^s(\Omega)} \simeq h^\alpha |\log h|^\kappa \|f\|_{L^2(\Omega)}$, a reasonable assumption in practice unless $u \in \mathbb{V}_h$ [30], then we would obtain from (3.22) and (3.26)

$$(3.27) \quad \|u - u_h\|_{L^2(\Omega)} \simeq h^{2\alpha} |\log h|^{2\kappa} \|f\|_{L^2(\Omega)}.$$

We point out that a similar consideration cannot be made if we inspect weighted estimates. Indeed, let us assume $d \geq 2$ and meshes are graded with parameter $\mu = \frac{d}{d-1}$; similar considerations are valid if the meshes are graded differently. If (3.17) were sharp, then we could only deduce (up to logarithmic factors)

$$h^{\frac{d}{d-1}} \frac{\|f\|_{C^\beta(\bar{\Omega})}^2}{\|f\|_{L^2(\Omega)}} \lesssim \|u - u_h\|_{L^2(\Omega)} \lesssim h^{\frac{d}{2(d-1)}+\alpha} \|f\|_{C^\beta(\bar{\Omega})},$$

and $\alpha = \min\{s, \frac{1}{2}\} < \frac{d}{2(d-1)}$. The issue here is that Theorem 2.2 (weighted Sobolev estimate) does not yield a regularity estimate in terms of L^2 -norms of the data. Therefore, we still need to use (3.23) which, in turn, is based on the unweighted estimate (2.6), a consequence of Theorem 2.1 (Besov regularity on Lipschitz domains).

4. CACCIOPOLI ESTIMATE

The following result is well-known for usual harmonic functions. For the fractional Laplacian (1.2) it can be found, for example, in [14] (see also [12, 16, 29]). We present a proof below, because for our purposes it is crucial to trace the dependence of the constants on the radius R and the exact form of the global term. Moreover, it turns out that the technique of proof will be instrumental in Section 5.

Lemma 4.1 (Caccioppoli estimate). *Let B_R denote a ball of radius R centered at $x_0 \in \Omega$. If $u \in H^s(\mathbb{R}^d)$ is a function satisfying $\int_{B_R^c} \frac{|u(x)|}{|x-x_0|^{d+2s}} dx < \infty$ and $(u, v)_s = 0$ for all $v \in H^s(\mathbb{R}^d)$ supported in B_R , then there exists a constant C independent of R such that*

$$(4.1) \quad |u|_{H^s(B_{R/2})}^2 \leq \frac{C}{R^{2s}} \|u\|_{L^2(B_R)}^2 + CR^{d+2s} \left(\int_{B_R^c} \frac{|u(x)|}{|x-x_0|^{d+2s}} dx \right)^2.$$

Proof. Let $\eta : \mathbb{R}^d \rightarrow [0, 1]$ be a smooth cut-off function with the following properties:

$$(4.2a) \quad \eta \equiv 1 \quad \text{in } B_{R/2}$$

$$(4.2b) \quad \eta \equiv 0 \quad \text{in } B_{3R/4}^c$$

$$(4.2c) \quad |\nabla \eta| \leq CR^{-1}.$$

Thus,

$$0 = (u, \eta^2 u)_s = \int_{\mathbb{R}^d} \int_{\mathbb{R}^d} \frac{(u(x) - u(y))(\eta^2(x)u(x) - \eta^2(y)u(y))}{|x-y|^{d+2s}} dy dx = I_1 + I_2,$$

where

$$I_1 := \int_{B_R} \int_{B_R} \frac{(u(x) - u(y))(\eta^2(x)u(x) - \eta^2(y)u(y))}{|x-y|^{d+2s}} dy dx,$$

$$I_2 := 2 \int_{B_R} \int_{B_R^c} \frac{(u(x) - u(y))(\eta^2(x)u(x) - \eta^2(y)u(y))}{|x-y|^{d+2s}} dy dx.$$

Using the identity

$$(u(x) - u(y))(\eta(x)^2 u(x) - \eta(y)^2 u(y)) = [\eta(x)u(x) - \eta(y)u(y)]^2 - u(x)u(y)[\eta(x) - \eta(y)]^2,$$

we obtain $I_1 = |\eta u|_{H^s(B_R)}^2 - I_{11}$, where

$$I_{11} = \int_{B_R} \int_{B_R} \frac{u(x)u(y)[\eta(x) - \eta(y)]^2}{|x-y|^{d+2s}} dy dx.$$

In view of (4.2c), we have $|\eta(x) - \eta(y)| \leq CR^{-1}|x-y|$ and, applying the Cauchy-Schwarz inequality, we deduce

$$I_{11} \leq \frac{C}{R^2} \int_{B_R} \int_{B_R} \frac{|u(x)||u(y)|}{|x-y|^{d-2+2s}} dy dx$$

$$\leq \frac{C}{R^2} \int_{B_R} \int_{B_R} \frac{|u(x)|^2}{|x-y|^{d-2+2s}} dy dx \leq \frac{C}{R^{2s}} \|u\|_{L^2(B_R)}^2,$$

because the kernel $|x - y|^{-d+2-2s}$ is integrable on $\{x = y\}$ and using polar coordinates $\rho = |x - y|$ yields

$$\int_{B_R} \frac{dy}{|x - y|^{d-2+2s}} \leq c \int_0^R \rho^{1-2s} d\rho = cR^{2-2s}.$$

Next, since η is supported in $B_{3R/4}$, according to (4.2b), and bounded by 1, we have

$$\begin{aligned} |I_2| &\leq 2 \int_{B_R} \int_{B_R^c} \frac{|u(x) - u(y)|\eta^2(x)|u(x)|}{|x - y|^{d+2s}} dy dx \\ &\leq 2 \int_{B_{3R/4}} |u(x)| \int_{B_R^c} \frac{|u(x) - u(y)|}{|x - y|^{d+2s}} dy dx \leq I_{21} + I_{22}, \end{aligned}$$

with

$$\begin{aligned} I_{21} &:= 2 \int_{B_{3R/4}} \left(|u(x)|^2 \int_{B_R^c} \frac{dy}{|x - y|^{d+2s}} \right) dx \\ I_{22} &:= 2 \int_{B_{3R/4}} \left(|u(x)| \int_{B_R^c} \frac{|u(y)|}{|x - y|^{d+2s}} dy \right) dx. \end{aligned}$$

Using that $\text{dist}(B_{3R/4}, B_R^c) = R/4$, and integrating in polar coordinates, we deduce

$$\int_{B_R^c} \frac{dy}{|x - y|^{d+2s}} \leq C \int_{R/4}^\infty \rho^{-1-2s} d\rho = CR^{-2s} \quad \forall x \in B_{3R/4},$$

and as a consequence

$$I_{21} \leq \frac{C}{R^{2s}} \|u\|_{L^2(B_R)}^2.$$

To estimate I_{22} , we first observe that for all $x \in B_{3R/4}$ and $y \in B_R^c$, we have

$$R < |y - x_0| \leq |x - x_0| + |y - x| \leq \frac{3R}{4} + |y - x| \leq \frac{3}{4}|y - x_0| + |y - x| \Rightarrow \frac{1}{4}|y - x_0| \leq |y - x|.$$

Utilizing now the Hölder's inequality, in conjunction with the Young's inequality, yields

$$\begin{aligned} I_{22} &\leq 2 \|u\|_{L^1(B_R)} \sup_{x \in B_{3R/4}} \int_{B_R^c} \frac{|u(y)|}{|x - y|^{d+2s}} dy \leq CR^{d/2} \|u\|_{L^2(B_R)} \int_{B_R^c} \frac{|u(y)|}{|y - x_0|^{d+2s}} dy \\ &\leq \frac{C}{R^{2s}} \|u\|_{L^2(B_R)}^2 + CR^{d+2s} \left(\int_{B_R^c} \frac{|u(y)|}{|y - x_0|^{d+2s}} dy \right)^2. \end{aligned}$$

Writing $|\eta u|_{H^s(B_R)}^2 = I_{11} - I_2$, and combining the estimates above, we obtain

$$|\eta u|_{H^s(B_R)}^2 \leq \frac{C}{R^{2s}} \|u\|_{L^2(B_R)}^2 + CR^{d+2s} \left(\int_{B_R^c} \frac{|u(y)|}{|y - x_0|^{d+2s}} dy \right)^2.$$

The estimate (4.1) follows because

$$|u|_{H^s(B_{R/2})}^2 \leq |\eta u|_{H^s(B_R)}^2,$$

due to (4.2a). This concludes the proof. \square

5. LOCAL ENERGY ESTIMATES

In this section we derive error estimates in local H^s -seminorms. For that purpose, we first develop a local superapproximation theory in fractional norms and afterwards combine it with the techniques used in the derivation of the Caccioppoli estimate (4.1).

Here we consider the usual nodal interpolation operator $I_h : C_0(\overline{\Omega}) \rightarrow \mathbb{V}_h$, which satisfies for $1 \leq p \leq \infty$, $j \leq k \leq 2$, $k > \frac{d}{p}$

$$(5.1) \quad |v - I_h v|_{W^{j,p}(T)} \leq Ch^{k-j} |v|_{W^{k,p}(T)} \quad \forall v \in W^{k,p}(T).$$

5.1. Superapproximation. Superapproximation is an essential tool in *local* energy finite element error estimates [32]. Below we adapt the ideas from [15], which lead to improved superapproximation estimates applicable to a general class of meshes. Similarly to [15], we require only shape-regularity.

For an arbitrary $\eta \in C^2(\overline{\Omega})$ and $v_h \in \mathbb{V}_h$, it turns out that the function

$$(5.2) \quad \psi := \eta^2 v_h - I_h(\eta^2 v_h)$$

is smaller than expected in various norms, a property called superapproximation [32]. To see this, we let $T \in \mathcal{T}_h$ be arbitrary and combine (5.1) with the fact that v_h is linear on T , to obtain the following L^p -type superapproximation estimate for ψ in (5.2) and any $1 \leq p \leq \infty$:

$$(5.3) \quad \begin{aligned} \|\psi\|_{L^p(T)} + h_T |\psi|_{W^{1,p}(T)} &\leq Ch_T^2 |\eta^2 v_h|_{W^{2,p}(T)} \\ &\leq Ch_T^2 \left(\|\nabla \eta\|_{L^\infty(T)} \|\nabla(\eta v_h)\|_{L^p(T)} \right. \\ &\quad \left. + (\|\eta\|_{L^\infty(T)} \|\nabla^2 \eta\|_{L^\infty(T)} + \|\nabla \eta\|_{L^\infty(T)}^2) \|v_h\|_{L^p(T)} \right), \end{aligned}$$

where we used that

$$\begin{aligned} \partial^2(\eta^2 v_h) &= \partial^2 \eta (\eta v_h) + 2 \partial \eta \partial(\eta v_h) + \eta \partial^2(\eta v_h) \\ &= \partial^2 \eta (\eta v_h) + 2 \partial \eta \partial(\eta v_h) + \eta (\partial^2 \eta v_h + 2 \partial \eta \partial v_h) \\ &= 2 \partial^2 \eta (\eta v_h) + 4 \partial \eta \partial(\eta v_h) - 2 (\partial \eta)^2 v_h, \end{aligned}$$

with ∂ denoting any partial derivative. These estimates suffice for second order elliptic problems. However, for fractional problems we need to account for the fact that the H^s -norm is nonlocal. We embark on this endeavor now upon first examining stars S_T and next interior balls

$$B_R := B(x_0, R) \subset \Omega, \quad h_R := \max_{T \in \Lambda_R} h_T, \quad \Lambda_R := \{T \in \mathcal{T}_h : T \cap B_R \neq \emptyset\}.$$

In this setting, η is a suitable localization function, namely $\eta \in C^\infty(\Omega)$ is the cut-off function of (4.2):

$$(5.4) \quad 0 \leq \eta \leq 1, \quad \eta \equiv 1 \quad \text{in } B_{R/2}, \quad \eta \equiv 0 \quad \text{in } B_{3R/4}^c, \quad |\nabla^k \eta| \leq CR^{-k} \quad (k \geq 1).$$

Lemma 5.1 (superapproximation in $H^s(S_T)$). *Let $T \in \mathcal{T}_h$, $0 \leq s \leq 1$, and η satisfy (5.4). For any $v_h \in \mathbb{V}_h$ and ψ given by (5.2), there is a constant C depending on shape-regularity of \mathcal{T}_h such that*

$$(5.5) \quad |\psi|_{H^s(S_T)} \leq C \frac{h_T}{R} |\eta v_h|_{H^s(S_T)} + C \frac{h_T^{2-s}}{R^2} \|v_h\|_{L^2(S_T)}.$$

Proof. Since the norms involved in (5.3) are local, and the size of S_T is proportional to h_T because \mathcal{T}_h is shape-regular, we realize that (5.3) is also valid in S_T . This leads to the desired estimate for $s = 0, 1$. For $s \in (0, 1)$, we apply space interpolation theory to (5.3) over S_T to infer that

$$(5.6) \quad |\psi|_{H^s(S_T)} \leq C \frac{h_T^{2-s}}{R} \|\nabla(\eta v_h)\|_{L^2(S_T)} + C \frac{h_T^{2-s}}{R^2} \|v_h\|_{L^2(S_T)}.$$

We finally resort to (3.6), namely $\|\nabla(\eta v_h)\|_{L^2(S_T)} \lesssim h_T^{s-1} |\eta v_h|_{H^s(S_T)}$, to finish the proof. \square

Lemma 5.2 (superapproximation in $H^s(B_R)$). *Let h_R satisfy $16h_R \leq R$ and let $0 \leq s \leq 1$. For any $v_h \in \mathbb{V}_h$ and ψ given in (5.2), there exists a constant C depending on shape-regularity of \mathcal{T}_h such that*

$$(5.7) \quad |\psi|_{H^s(B_R)} \leq CR^{-s} \|v_h\|_{L^2(B_R)}.$$

Proof. If $s = 0, 1$, then the estimate follows immediately from (5.3), the additivity of squares of integer-order L^2 -norms with respect to domain partitions, the inverse inequality (3.6) and the fact that $h_R \leq R/16$.

For $s \in (0, 1)$, we make use of (3.2) to obtain

$$|\psi|_{H^s(B_R)}^2 \leq \sum_{T \in \Lambda_R} \left(\int_T \int_{S_T} \frac{|\psi(x) - \psi(y)|^2}{|x - y|^{d+2s}} dy dx + \frac{C}{h_T^{2s}} \|\psi\|_{L^2(T)}^2 \right).$$

Let $T \in \Lambda_R$ and $x \in T$ be a generic point. We first point out that if $x \in B_{7R/8}^c$ then the vertices y of T satisfy $|x_0 - y| \geq \frac{7}{8}R - \frac{1}{16}R > \frac{3}{4}R$ and $\psi(x) = 0$ according to the definition (5.2). We now let $y \in S_T$ and examine two mutually exclusive cases.

If $x \in B_{7R/8}$, then y belongs to a triangle in Λ_R because the vertices of T are at distance $\frac{7}{8}R + \frac{1}{16}R < R$ from x_0 , whence $|x - y| \leq 2h_R \leq \frac{1}{8}R$. Therefore

$$|x - x_0| \leq \frac{7}{8}R \quad \Rightarrow \quad |y - x_0| \leq |x - x_0| + |y - x| \leq R \quad \Rightarrow \quad S_T \subset B_R.$$

On the other hand, if $x \in B_{7R/8}^c$ and $y \in T' \in \Lambda_R$, then $|x - y| \leq 2h_R \leq \frac{1}{8}R$ and

$$|x - x_0| \geq \frac{7}{8}R \quad \Rightarrow \quad |y - x_0| \geq |x - x_0| - |y - x| \geq \frac{3}{4}R.$$

Since y is allowed to be any element vertex on S_T , the latter implies that

$$(5.8) \quad \psi|_{S_T} \equiv 0 \quad \forall T \in \Lambda_R \setminus \Lambda_{7R/8}.$$

We thus realize that the only T 's that matter in the sum above are those $T \in \Lambda_{7R/8}$

$$|\psi|_{H^s(B_R)}^2 \leq \sum_{T \in \Lambda_{7R/8}} \left(|\psi|_{H^s(S_T)}^2 + \frac{C}{h_T^{2s}} \|\psi\|_{L^2(T)}^2 \right).$$

To estimate each term on the right-hand side we exploit the property that $S_T \subset B_R$ for all $T \in \Lambda_{7R/8}$. For the first term, we also employ (5.6), together with (3.6) with $s = 0$ and (5.4). For the second term we resort to (5.3) for $p = 2$ together with (3.6) for $s = 0$. In both cases, we get

$$\begin{aligned} \sum_{T \in \Lambda_{7R/8}} \left(|\psi|_{H^s(S_T)}^2 + \frac{C}{h_T^{2s}} \|\psi\|_{L^2(T)}^2 \right) &\leq C \sum_{T \in \Lambda_{7R/8}} \left(\frac{h_T^{2-2s}}{R^2} + \frac{h_T^{4-2s}}{R^4} \right) \|v_h\|_{L^2(S_T)}^2 \\ &\leq \frac{C}{R^{2s}} \|v_h\|_{L^2(B_R)}^2, \end{aligned}$$

because $h_T \leq \frac{1}{16}R$. The desired estimate follows immediately. \square

The proof of Lemma 5.2 (superapproximation in $H^s(B_R)$) reveals that

$$(5.9) \quad \psi|_{B_{7R/8}^c} = 0.$$

5.2. Local Energy Estimates. Recall that the finite element solution to (2.3) satisfies (3.7), which gives the Galerkin orthogonality relation (3.8). In order to localize such relation, given a subdomain $D \subset \Omega$, we define $\mathbb{V}_h(D) = \mathbb{V}_h \cap H_0^1(D)$ as the space of continuous piecewise linear functions restricted to D that vanish on ∂D . We will derive error estimates for a function $\tilde{u}_h \in \mathbb{V}_h$ that satisfies the *local Galerkin orthogonality* relation

$$(5.10) \quad (u - \tilde{u}_h, v_h)_s = 0, \quad \forall v_h \in \mathbb{V}_h(B_R).$$

Theorem 5.1 (local energy error estimate). *Let $u \in \tilde{H}^s(\Omega)$ and $\tilde{u}_h \in \mathbb{V}_h$ satisfy (5.10). If $16h_R \leq R$, then there exists a constant C depending on shape regularity such that for any $v_h \in \mathbb{V}_h$,*

$$\begin{aligned} |u - \tilde{u}_h|_{H^s(B_{R/2})}^2 &\leq C|u - v_h|_{H^s(B_R)}^2 + \frac{C}{R^{2s}}\|u - v_h\|_{L^2(B_R)}^2 \\ &\quad + CR^{d+2s} \left(\int_{B_R^c} \frac{|u(x) - v_h(x)|}{|x - x_0|^{d+2s}} dx \right)^2 \\ &\quad + \frac{C}{R^{2s}}\|u - \tilde{u}_h\|_{L^2(B_R)}^2 + CR^{d+2s} \left(\int_{B_R^c} \frac{|u(x) - \tilde{u}_h(x)|}{|x - x_0|^{d+2s}} dx \right)^2. \end{aligned}$$

Proof. To simplify the notation, we assume that $B_R = B(0, R)$ is centered at the origin, i.e. we take $x_0 = 0$. We point out that it is sufficient to establish

$$(5.11) \quad \begin{aligned} |\tilde{u}_h|_{H^s(B_{R/2})}^2 &\leq C|u|_{H^s(B_R)}^2 + \frac{C}{R^{2s}}\|u\|_{L^2(B_R)}^2 + CR^{d+2s} \left(\int_{B_R^c} \frac{|u(x)|}{|x|^{d+2s}} dx \right)^2 \\ &\quad + \frac{C}{R^{2s}}\|\tilde{u}_h\|_{L^2(B_R)}^2 + CR^{d+2s} \left(\int_{B_R^c} \frac{|\tilde{u}_h(x)|}{|x|^{d+2s}} dx \right)^2. \end{aligned}$$

In fact, the assertion would then follow upon writing $u - \tilde{u}_h = (u - v_h) + (v_h - \tilde{u}_h)$ and using the fact that the local Galerkin orthogonality (5.10) holds with $u \mapsto u - v_h$ and $\tilde{u}_h \mapsto \tilde{u}_h - v_h$ and the triangle inequality. We argue along the lines of Lemma 4.1 (Caccioppoli estimate). We divide the proof into several steps.

Step 1: Decomposing the H^s -seminorm. Let $\eta \in C^\infty(\Omega)$ be as in (5.4). Recalling the definition (5.2) of $\psi = \eta^2 \tilde{u}_h - I_h(\eta^2 \tilde{u}_h)$, whence $I_h(\eta^2 \tilde{u}_h) = 0$ in $B_{7R/8}^c$ according to the proof of Lemma 5.2, and using the local Galerkin orthogonality (5.10), we have

$$(5.12) \quad \begin{aligned} (\tilde{u}_h, \eta^2 \tilde{u}_h)_s &= (\tilde{u}_h, I_h(\eta^2 \tilde{u}_h))_s + (\tilde{u}_h, \psi)_s \\ &= (u, I_h(\eta^2 \tilde{u}_h))_s + (\tilde{u}_h, \psi)_s \\ &= (u, \eta^2 \tilde{u}_h)_s - (u, \psi)_s + (\tilde{u}_h, \psi)_s. \end{aligned}$$

In the same fashion as in the proof of Lemma 4.1, we have

$$\begin{aligned} (\tilde{u}_h, \eta^2 \tilde{u}_h)_s &= |\eta \tilde{u}_h|_{H^s(B_R)}^2 - \int_{B_R} \int_{B_R} \frac{\tilde{u}_h(x) \tilde{u}_h(y) [\eta(x) - \eta(y)]^2}{|x - y|^{d+2s}} dy dx \\ &\quad + 2 \int_{B_R} \int_{B_R^c} \frac{(\tilde{u}_h(x) - \tilde{u}_h(y)) \eta^2(x) \tilde{u}_h(x)}{|x - y|^{d+2s}} dy dx. \end{aligned}$$

Invoking (5.12) we thus obtain the decomposition $|\eta \tilde{u}_h|_{H^s(B_R)}^2 = \sum_{k=1}^5 I_k$, where

$$\begin{aligned} (5.13) \quad I_1 &:= \int_{B_R} \int_{B_R} \frac{\tilde{u}_h(x) \tilde{u}_h(y) [\eta(x) - \eta(y)]^2}{|x - y|^{d+2s}} dy dx, \\ I_2 &:= -2 \int_{B_R} \int_{B_R^c} \frac{(\tilde{u}_h(x) - \tilde{u}_h(y)) \eta^2(x) \tilde{u}_h(x)}{|x - y|^{d+2s}} dy dx, \\ I_3 &:= (u, \eta^2 \tilde{u}_h)_s, \quad I_4 := -(u, \psi)_s, \quad I_5 := (\tilde{u}_h, \psi)_s. \end{aligned}$$

Step 2: Bounding $I_1 + I_2$. Proceeding exactly as in the proof of Lemma 4.1, we obtain

$$I_1 + I_2 \leq \frac{C}{R^{2s}} \|\tilde{u}_h\|_{L^2(B_R)}^2 + CR^{d+2s} \left(\int_{B_R^c} \frac{|\tilde{u}_h(x)|}{|x|^{d+2s}} dx \right)^2.$$

Step 3: Bounding I_3 . Using the definition of H^s -inner product, we write $I_3 = I_{31} + I_{32}$ with

$$\begin{aligned} I_{31} &:= \int_{B_R} \int_{B_R} \frac{[u(x) - u(y)] [\eta^2(x) \tilde{u}_h(x) - \eta^2(y) \tilde{u}_h(y)]}{|x - y|^{d+2s}} dy dx, \\ I_{32} &:= 2 \int_{B_R} \int_{B_R^c} \frac{[u(x) - u(y)] [\eta^2(x) \tilde{u}_h(x) - \eta^2(y) \tilde{u}_h(y)]}{|x - y|^{d+2s}} dy dx. \end{aligned}$$

In light of the identity

$$\eta^2(x) \tilde{u}_h(x) - \eta^2(y) \tilde{u}_h(y) = \eta(x) [\eta(x) \tilde{u}_h(x) - \eta(y) \tilde{u}_h(y)] + \eta(y) [\eta(x) - \eta(y)] \tilde{u}_h(y),$$

we arrive at

$$\begin{aligned} I_{31} &= \int_{B_R} \int_{B_R} \frac{[u(x) - u(y)] \eta(x) [\eta(x) \tilde{u}_h(x) - \eta(y) \tilde{u}_h(y)]}{|x - y|^{d+2s}} dy dx \\ &\quad + \int_{B_R} \int_{B_R} \frac{[u(x) - u(y)] \eta(y) [\eta(x) - \eta(y)] \tilde{u}_h(y)}{|x - y|^{d+2s}} dy dx \\ &\leq |u|_{H^s(B_R)} |\eta \tilde{u}_h|_{H^s(B_R)} + \frac{C}{R} \int_{B_R} \int_{B_R} \frac{|u(x) - u(y)| |\tilde{u}_h(y)|}{|x - y|^{d-1+2s}} dy dx, \end{aligned}$$

where in the last step we used that $|\eta| \leq 1$ and $|\eta(x) - \eta(y)| \leq CR^{-1}|x - y|$ according to (5.4). Employing the Cauchy-Schwarz inequality, we estimate

$$\begin{aligned} &\int_{B_R} \int_{B_R} \frac{|u(x) - u(y)| |\tilde{u}_h(y)|}{|x - y|^{d-1+2s}} dy dx \\ &\leq \left(\int_{B_R} \int_{B_R} \frac{|u(x) - u(y)|^2}{|x - y|^{d+2s}} dy dx \right)^{\frac{1}{2}} \left(\int_{B_R} \int_{B_R} \frac{|\tilde{u}_h(y)|^2}{|x - y|^{d-2+2s}} dy dx \right)^{\frac{1}{2}} \\ &\leq CR^{1-s} |u|_{H^s(B_R)} \|\tilde{u}_h\|_{L^2(B_R)}. \end{aligned}$$

In the last step above we used that the kernel $|x-y|^{d-2+2s}$ is integrable at $\{x=y\}$, and combined Fubini's theorem with integration in polar coordinates, to deduce

$$\int_{B_R} \frac{dx}{|x-y|^{d-2+2s}} \leq C \int_0^{2R} \rho^{d-1-d+2-2s} d\rho = CR^{2-2s} \quad \forall y \in B_R.$$

As a result, the Young's inequality yields

$$I_{31} \leq C_\varepsilon |u|_{H^s(B_R)}^2 + \varepsilon |\eta \tilde{u}_h|_{H^s(B_R)}^2 + \frac{C}{R^{2s}} \|\tilde{u}_h\|_{L^2(B_R)}^2,$$

where $\varepsilon > 0$ is a number to be chosen.

To deal with I_{32} we proceed similarly to the estimate of I_2 in the proof of Lemma 4.1. Since $|\eta| \leq 1$ and $\eta = 0$ on $B_{3R/4}^c$, in view of (5.4), we thus get

$$I_{32} \leq 2 \int_{B_{3R/4}} |\tilde{u}_h(x)| \int_{B_R^c} \frac{|u(x) - u(y)|}{|x-y|^{d+2s}} dy dx \leq I_{321} + I_{322}$$

with

$$I_{321} := 2 \int_{B_{3R/4}} \left(|u(x)| \cdot |\tilde{u}_h(x)| \int_{B_R^c} \frac{dy}{|x-y|^{d+2s}} \right) dx,$$

$$I_{322} := 2 \int_{B_{3R/4}} \left(|\tilde{u}_h(x)| \int_{B_R^c} \frac{|u(y)|}{|x-y|^{d+2s}} dy \right) dx.$$

Consequently, integrating in polar coordinates

$$\int_{B_R^c} \frac{dy}{|x-y|^{d+2s}} \leq C \int_{R/4}^\infty \rho^{-1-2s} d\rho = \frac{C}{R^{2s}} \quad \forall x \in B_{3R/4},$$

and using the Cauchy-Schwarz inequality, leads to

$$I_{321} \leq CR^{-2s} \|\tilde{u}_h\|_{L^2(B_R)} \|u\|_{L^2(B_R)} \leq CR^{-2s} \|\tilde{u}_h\|_{L^2(B_R)}^2 + CR^{-2s} \|u\|_{L^2(B_R)}^2.$$

By the Hölder's inequality and the fact that $\frac{1}{4}|y| \leq |x-y|$ for all $x \in B_{3R/4}$ and $y \in B_R^c$, we have

$$I_{322} \leq \|\tilde{u}_h\|_{L^1(B_R)} \sup_{x \in B_{3R/4}} \int_{B_R^c} \frac{|u(y)|}{|x-y|^{d+2s}} dy \leq CR^{d/2} \|\tilde{u}_h\|_{L^2(B_R)} \int_{B_R^c} \frac{|u(y)|}{|y|^{d+2s}} dy$$

$$\leq \frac{C}{R^{2s}} \|\tilde{u}_h\|_{L^2(B_R)}^2 + CR^{d+2s} \left(\int_{B_R^c} \frac{|u(y)|}{|y|^{d+2s}} dy \right)^2.$$

Collecting the estimates above, we deduce

$$I_3 \leq \varepsilon |\eta \tilde{u}_h|_{H^s(B_R)}^2 + C_\varepsilon |u|_{H^s(B_R)}^2 + \frac{C}{R^{2s}} \|u\|_{L^2(B_R)}^2$$

$$+ \frac{C}{R^{2s}} \|\tilde{u}_h\|_{L^2(B_R)}^2 + CR^{d+2s} \left(\int_{B_R^c} \frac{|u(y)|}{|y|^{d+2s}} dy \right)^2.$$

Step 4: Bounding I_4 . Using that $\psi = 0$ on B_R^c yields the splitting $I_4 = I_{41} + I_{42}$ with

$$\begin{aligned} I_{41} &:= - \int_{B_R} \int_{B_R} \frac{[u(x) - u(y)][\psi(x) - \psi(y)]}{|x - y|^{d+2s}} dy dx, \\ I_{42} &:= -2 \int_{B_R} \int_{B_R^c} \frac{[u(x) - u(y)]\psi(x)}{|x - y|^{d+2s}} dy dx. \end{aligned}$$

Employing (5.7) and the Young's inequality, we obtain

$$I_{41} \leq |u|_{H^s(B_R)} |\psi|_{H^s(B_R)} \leq C |u|_{H^s(B_R)}^2 + \frac{C}{R^{2s}} \|\tilde{u}_h\|_{L^2(B_R)}^2.$$

We handle I_{42} similarly to I_{32} , namely use (5.9) to write $I_{42} \leq I_{421} + I_{422}$ with

$$I_{421} := 2 \int_{B_{7R/8}} \left(|u(x)| |\psi(x)| \int_{B_R^c} \frac{dy}{|x - y|^{d+2s}} \right) dx \leq \frac{C}{R^{2s}} \|u\|_{L^2(B_R)}^2 + \frac{C}{R^{2s}} \|\tilde{u}_h\|_{L^2(B_R)}^2,$$

and

$$\begin{aligned} I_{422} &:= 2 \int_{B_{7R/8}} \left(|\psi(x)| \int_{B_R^c} \frac{|u(y)|}{|x - y|^{d+2s}} dy \right) dx \leq C \|\psi\|_{L^1(B_R)} \int_{B_R^c} \frac{|u(y)|}{|y|^{d+2s}} dy \\ &\leq \frac{C}{R^{2s}} \|\tilde{u}_h\|_{L^2(B_R)}^2 + CR^{d+2s} \left(\int_{B_R^c} \frac{|u(y)|}{|y|^{d+2s}} dy \right)^2, \end{aligned}$$

in view of (5.7) with $s = 0$, and the fact that $\frac{1}{8}|y| \leq |x - y|$ for all $x \in B_{7R/8}$ and $y \in B_R^c$ and argue as in Step 3. Combining the estimates above, we obtain

$$I_4 \leq C |u|_{H^s(B_R)}^2 + \frac{C}{R^{2s}} \|u\|_{L^2(B_R)}^2 + \frac{C}{R^{2s}} \|\tilde{u}_h\|_{L^2(B_R)}^2 + CR^{d+2s} \left(\int_{B_R^c} \frac{|u(y)|}{|y|^{d+2s}} dy \right)^2.$$

Step 5: Bounding I_5 . We will treat I_5 differently from I_4 , because it contains \tilde{u}_h in place of u , which causes serious challenges on shape-regular meshes. Using that $\psi = 0$ on B_R^c , we split $I_5 = I_{51} + I_{52}$ with

$$\begin{aligned} I_{51} &:= \int_{B_R} \int_{B_R} \frac{[\tilde{u}_h(x) - \tilde{u}_h(y)][\psi(x) - \psi(y)]}{|x - y|^{d+2s}} dy dx, \\ I_{52} &:= 2 \int_{B_R} \int_{B_R^c} \frac{[\tilde{u}_h(x) - \tilde{u}_h(y)]\psi(x)}{|x - y|^{d+2s}} dy dx. \end{aligned}$$

Recalling Remark 3 (fractional inner product on subdomains), we decompose the integral over $B_R \times B_R$ into sums over $(T \cap B_R) \times (S_T \cap B_R)$ and $(T \cap B_R) \times (S_T^c \cap B_R)$ for $T \in \Lambda_R$, and use the fact that $\int_{S_T^c} |x - y|^{-d-2s} dy \leq Ch_T^{-2s}$ for every $x \in T$, to end up with $I_{51} \leq I_{511} + I_{512} + I_{513}$ where

$$\begin{aligned} I_{511} &:= \sum_{T \in \Lambda_{7R/8}} |\tilde{u}_h|_{H^s(S_T)} |\psi|_{H^s(S_T)}, \\ I_{512} &:= \sum_{T \in \Lambda_{7R/8}} \frac{C}{h_T^{2s}} \int_T |\tilde{u}_h(x)| |\psi(x)| dx, \\ I_{513} &:= 2 \sum_{T \in \Lambda_R} \int_{T \cap B_R} \int_{S_T^c \cap B_R} \frac{|\tilde{u}_h(x)| |\psi(y)|}{|x - y|^{d+2s}} dy dx. \end{aligned}$$

Note that we have used (5.8) in the definition of I_{511} and exploited (5.9) in the definition of I_{512} to replace Λ_R by $\Lambda_{7R/8}$. We next apply the local inverse inequality (3.5) in conjunction with the superapproximation estimate (5.5) to deduce

$$\begin{aligned} I_{511} &:= \sum_{T \in \Lambda_{7R/8}} |\tilde{u}_h|_{H^s(S_T)} |\psi|_{H^s(S_T)} \\ &\leq C \sum_{T \in \Lambda_{7R/8}} \|\tilde{u}_h\|_{L^2(S_T)} \left(\frac{h_T^{1-s}}{R} |\eta \tilde{u}_h|_{H^s(S_T)} + \frac{h_T^{2-2s}}{R^2} \|\tilde{u}_h\|_{L^2(S_T)} \right) \\ &\leq \varepsilon |\eta \tilde{u}_h|_{H^s(B_R)}^2 + \frac{C_\varepsilon}{R^{2s}} \|\tilde{u}_h\|_{L^2(B_R)}^2, \end{aligned}$$

because $16h_T \leq R$ and $\sum_{T \in \Lambda_{7R/8}} |v|_{H^s(S_T)}^2 \leq C(\sigma) |v|_{H^s(B_R)}^2$ for all $v \in H^s(B_R)$, the latter due to the uniformly bounded overlap of stars S_T in the shape-regular mesh \mathcal{T}_h . The upper bound for I_{512} employs instead the superapproximation estimate (5.3) with $p = 2$, the inverse inequality (3.6) and Young's inequality

$$\begin{aligned} I_{512} &\leq C \sum_{T \in \Lambda_{7R/8}} \frac{1}{h_T^{2s}} \|\tilde{u}_h\|_{L^2(T)} \|\psi\|_{L^2(T)} \\ &\leq C \sum_{T \in \Lambda_{7R/8}} \|\tilde{u}_h\|_{L^2(S_T)} \left(\frac{h_T^{1-s}}{R} |\eta \tilde{u}_h|_{H^s(S_T)} + \frac{h_T^{2-2s}}{R^2} \|\tilde{u}_h\|_{L^2(S_T)} \right) \\ &\leq \varepsilon |\eta \tilde{u}_h|_{H^s(B_R)}^2 + \frac{C_\varepsilon}{R^{2s}} \|\tilde{u}_h\|_{L^2(B_R)}^2. \end{aligned}$$

The remaining term I_{513} is rather tricky and reveals the nonlocal nature of our problem. Manipulating I_{513} is the most delicate and innovative part of the proof relative to the second order case [15, 32]. To keep notation short, we set

$$T_R := T \cap B_R, \quad S_{T,R}^c := S_T^c \cap B_{7R/8}, \quad \Lambda_{T,R}^c := \{T' \in \mathcal{T}_h : T' \cap S_{T,R}^c \neq \emptyset\}.$$

We exploit (5.9) to rewrite I_{513} as

$$\begin{aligned} I_{513} &= 2 \sum_{T \in \Lambda_R} \sum_{T' \in \Lambda_{T,R}^c} \int_{T_R} |\tilde{u}_h(x)| \int_{T'_R} \frac{|\psi(y)|}{|x-y|^{d+2s}} dy dx \\ &\leq C \sum_{T \in \Lambda_R} \sum_{T' \in \Lambda_{T,R}^c} \|\tilde{u}_h\|_{L^1(T_R)} \|\psi\|_{L^1(T'_R)} d(T, T')^{-d-2s}, \end{aligned}$$

where $d(T, T')$ denotes the distance between elements T and T' . We make use of the superapproximation estimate (5.3) with $p = 1$ to infer that $I_{513} \leq I_{513}^1 + I_{513}^2$, where

$$\begin{aligned} I_{513}^1 &:= C \sum_{T \in \Lambda_R} \sum_{T' \in \Lambda_{T,R}^c} \|\tilde{u}_h\|_{L^1(T_R)} \|\tilde{u}_h\|_{L^1(T'_R)} d(T, T')^{-d-2s} \frac{h_{T'}^2}{R^2}, \\ I_{513}^2 &:= C \sum_{T \in \Lambda_R} \sum_{T' \in \Lambda_{T,R}^c} \|\tilde{u}_h\|_{L^1(T_R)} \|\nabla(\eta \tilde{u}_h)\|_{L^1(T'_R)} d(T, T')^{-d-2s} \frac{h_{T'}^2}{R}. \end{aligned}$$

The first term I_{513}^1 is problematic. We rewrite it again in integral form upon invoking the meshsize function $h(y)$, which is locally equivalent to the element

meshsize, namely $h(y) \approx h_{T'}$ for all $y \in T'$:

$$I_{513}^1 \leq CR^{-2} \sum_{T \in \Lambda_R} \int_{T_R} \int_{S_{T,R}^c} |\tilde{u}_h(x)| \frac{h(y)^2 |\tilde{u}_h(y)|}{|x-y|^{d+2s}} dy dx \leq I_{513}^{11} + I_{513}^{12},$$

with

$$I_{513}^{11} = CR^{-2} \sum_{T \in \Lambda_R} \int_{T_R} |\tilde{u}_h(x)|^2 \int_{S_{T,R}^c} \frac{h(y)^2}{|x-y|^{d+2s}} dy dx,$$

$$I_{513}^{12} = CR^{-2} \sum_{T \in \Lambda_R} \int_{T_R} \int_{S_{T,R}^c} \frac{h(y)^2 |\tilde{u}_h(y)|^2}{|x-y|^{d+2s}} dy dx.$$

The first term does not scale correctly unless the meshsize is quasi-uniform, a restriction on \mathcal{T}_h that is too severe for us to assume. It is here that we resort to the Lipschitz property (3.1) of $h(y)$, valid for shape-regular \mathcal{T}_h , and integrate in polar coordinates $|x-y| = \rho$, to compute for $x \in T \in \Lambda_R$

$$\begin{aligned} \int_{S_{T,R}^c} \frac{h(y)^2}{|x-y|^{d+2s}} dy &\leq C \int_{S_T^c \cap B_R} \frac{h(x)^2 + C|x-y|^2}{|x-y|^{d+2s}} dy \\ &\leq C \int_{Ch_T}^R \frac{h(x)^2 + \rho^2}{\rho^{d+2s}} \rho^{d-1} d\rho \leq CR^{2-2s}, \end{aligned}$$

whence

$$I_{513}^{11} \leq \frac{C}{R^{2s}} \sum_{T \in \Lambda_R} \int_{T_R} |\tilde{u}_h(x)|^2 dx \leq \frac{C}{R^{2s}} \|\tilde{u}_h\|_{L^2(B_R)}^2.$$

On the other hand, resorting to Lemma 3.1 (symmetry), we have

$$\begin{aligned} I_{513}^{12} &\leq CR^{-2} \sum_{T \in \mathcal{T}_h} \int_T \int_{S_T^c} \frac{h(y)^2 |\tilde{u}_h(y)|^2 \chi_{B_R}(y) \chi_{B_R}(x)}{|x-y|^{d+2s}} dy dx \\ &= CR^{-2} \sum_{T \in \mathcal{T}_h} \int_T \int_{S_T^c} \frac{h(x)^2 |\tilde{u}_h(x)|^2 \chi_{B_R}(x) \chi_{B_R}(y)}{|x-y|^{d+2s}} dy dx \\ &= CR^{-2} \sum_{T \in \mathcal{T}_h} \int_T h(x)^2 |\tilde{u}_h(x)|^2 \chi_{B_R}(x) \int_{S_T^c} \frac{\chi_{B_R}(y)}{|x-y|^{d+2s}} dy dx, \end{aligned}$$

where χ_{B_R} denotes the characteristic function of B_R . Since

$$\int_{S_T^c} \frac{\chi_{B_R}(y)}{|x-y|^{d+2s}} dy \leq C \int_{Ch_T}^R \rho^{-1-2s} d\rho \leq Ch_T^{-2s} \quad \forall x \in T,$$

$h(x) \approx h_T$ for all $x \in T$ and $16h_T \leq R$, we see that

$$I_{513}^{12} \leq CR^{-2} \sum_{T \in \mathcal{T}_h} h_T^{2-2s} \int_T \chi_{B_R}(x) |\tilde{u}_h(x)|^2 dx \leq CR^{-2s} \|\tilde{u}_h\|_{L^2(B_R)}^2.$$

Collecting the preceding estimates for I_{513}^1 , we realize that

$$I_{513}^1 \leq CR^{-2s} \|\tilde{u}_h\|_{L^2(B_R)}^2.$$

We handle I_{513}^2 similarly to I_{513}^1 , namely

$$\begin{aligned}
I_{513}^2 &\leq CR^{-1} \sum_{T \in \Lambda_R} \int_{T_R} \int_{S_{T,R}^c} |\tilde{u}_h(x)| \frac{h(y)^2 |\nabla(\eta \tilde{u}_h)(y)|}{|x-y|^{d+2s}} dy dx \\
&\leq C_\varepsilon R^{-2} \sum_{T \in \Lambda_R} \int_{T_R} \int_{S_{T,R}^c} \frac{|\tilde{u}_h(x)|^2 h(y)^2}{|x-y|^{d+2s}} dy dx \\
&\quad + C_\varepsilon \sum_{T \in \Lambda_R} \int_{T_R} \int_{S_{T,R}^c} \frac{h(y)^2 |\nabla(\eta \tilde{u}_h)(y)|^2}{|x-y|^{d+2s}} dy dx \\
&\leq C_\varepsilon R^{-2s} \|\tilde{u}_h\|_{L^2(B_R)}^2 + C_\varepsilon \sum_{T \in \Lambda_R} \int_{T_R} \int_{S_{T,R}^c} \frac{h(y)^2 |\nabla(\eta \tilde{u}_h)(y)|^2}{|x-y|^{d+2s}} dy dx,
\end{aligned}$$

since the first term is identical to I_{513}^{11} . For the other term in the right hand side, we proceed exactly as with I_{513}^{12} , thereby exploiting again Lemma 3.1 (symmetry) and combining it with the inverse-type estimate (3.6), to obtain

$$\sum_{T \in \Lambda_R} \int_{T_R} \int_{S_{T,R}^c} \frac{h(y)^2 |\nabla(\eta \tilde{u}_h)(y)|^2}{|x-y|^{d+2s}} dy dx \leq C \sum_{T \in \mathcal{T}_h} h_T^{2-2s} |\eta \tilde{u}_h|_{H^1(T)}^2 \leq C |\eta \tilde{u}_h|_{H^s(B_R)}^2.$$

Combining the estimates for I_{511} , I_{512} , I_{513} we deduce that

$$I_{51} \leq C_\varepsilon R^{-2s} \|\tilde{u}_h\|_{L^2(B_R)}^2 + C_\varepsilon |\eta \tilde{u}_h|_{H^s(B_R)}^2.$$

It only remains to bound I_{52} , which is exactly the same as I_{42} but with u replaced by \tilde{u}_h . Hence, proceeding similarly to the estimate for I_{42} , we readily arrive at

$$I_{52} \leq \frac{C}{R^{2s}} \|\tilde{u}_h\|_{L^2(B_R)}^2 + CR^{d+2s} \left(\int_{B_R^c} \frac{|\tilde{u}_h(y)|}{|y|^{d+2s}} dy \right)^2.$$

This together with the previous estimate yields

$$I_5 \leq C_\varepsilon |\eta \tilde{u}_h|_{H^s(B_R)}^2 + \frac{C_\varepsilon}{R^{2s}} \|\tilde{u}_h\|_{L^2(B_R)}^2 + CR^{d+2s} \left(\int_{B_R^c} \frac{|\tilde{u}_h(y)|}{|y|^{d+2s}} dy \right)^2.$$

Step 6: Conclusion. Inserting the bounds proved in Steps 2 through 5 for I_i , $1 \leq i \leq 5$ into (5.13), we deduce that

$$\begin{aligned}
|\eta \tilde{u}_h|_{H^s(B_R)}^2 &\leq C_\varepsilon |u|_{H^s(B_R)}^2 + \frac{C}{R^{2s}} \|u\|_{L^2(B_R)}^2 + CR^{d+2s} \left(\int_{B_R^c} \frac{|u(x)|}{|x|^{d+2s}} dx \right)^2 \\
&\quad + C_\varepsilon |\eta \tilde{u}_h|_{H^s(B_R)}^2 + \frac{C_\varepsilon}{R^{2s}} \|\tilde{u}_h\|_{L^2(B_R)}^2 + CR^{d+2s} \left(\int_{B_R^c} \frac{|\tilde{u}_h(x)|}{|x|^{d+2s}} dx \right)^2,
\end{aligned}$$

for all $\varepsilon > 0$. We now set ε to be such that the factor multiplying $|\eta \tilde{u}_h|_{H^s(B_R)}^2$ in the right hand side equals $\frac{1}{2}$ and kick that term back to the left hand side. This finally implies the estimate (5.11) because $|\tilde{u}_h|_{H^s(B_{R/2})}^2 \leq |\eta \tilde{u}_h|_{H^s(B_R)}^2$. \square

We can derive explicit local H^s -convergence rates by combining Theorem 5.1 with the convergence estimates from Section 3. We explore this next.

5.3. Applications to interior error estimates. Theorem 5.1 (local energy error estimate) gives us new ways to examine the behavior of the numerical error and, more importantly, check the sharpness of known estimates. Bounding the low order terms in Theorem 5.1 by global L^2 -terms, we get the following immediate consequence of Theorem 5.1.

Corollary 5.1 (local error estimate). *Let $u \in H^s(\Omega)$ be the solution of (2.3) and u_h be the finite element solution of (3.7). Then there is a constant C depending on shape regularity such that*

$$|u - u_h|_{H^s(B_{R/2})} \leq C \inf_{v_h \in \mathbb{V}_h} \left(|u - v_h|_{H^s(B_R)} + \frac{1}{R^s} \|u - v_h\|_{L^2(\Omega)} \right) + \frac{C}{R^s} \|u - u_h\|_{L^2(\Omega)}.$$

Proof. We apply Theorem 5.1 to u and u_h , which clearly satisfies the local Galerkin orthogonality condition (5.10). The proof then follows from the Cauchy-Schwarz inequality and integration in polar coordinates

$$\begin{aligned} R^{d+2s} \left(\int_{B_R^c} \frac{w(x)}{|x - x_0|^{d+2s}} dx \right)^2 &\leq R^{d+2s} \|w\|_{L^2(\Omega)}^2 \int_{B_R^c} \frac{1}{|x - x_0|^{2d+4s}} dx \\ &\leq CR^{d+2s} \|w\|_{L^2(\Omega)}^2 \int_R^\infty \frac{\rho^{d-1}}{\rho^{2d+4s}} d\rho = \frac{C}{R^{2s}} \|w\|_{L^2(\Omega)}^2, \end{aligned}$$

for $w = |u - v_h|$ and $w = |u - u_h|$. This concludes the proof. \square

Since $\|u - \Pi_h u\|_{L^2(\Omega)} \leq C \|u - u_h\|_{L^2(\Omega)}$ generically, Corollary 5.1 shows that the interior H^s -error consists of a local approximation error in the H^s -norm and a global L^2 -Galerkin error that accounts for *pollution* from the rest of the domain. We observe that this estimate is similar to local estimates for second order elliptic problems [15, 32], except that the L^2 -terms are now global. This is a mild manifestation of the nonlocal nature of (1.1). We examine below the extreme cases of quasi-uniform and graded meshes.

Since the polynomial degree of \mathbb{V}_h is 1, no error estimate can be of order larger than 2 and exploit regularity of u beyond H^2 regardless of mesh structure. With this in mind, we let $f \in H^r(\Omega)$ for $0 \leq r \leq 2 - 2s$, and assume it leads to the *local* H_{loc}^{2s+r} -regularity of u and the local approximation error

$$(5.14) \quad \inf_{v_h \in \mathbb{V}_h} |u - v_h|_{H^s(B_R)} \leq Ch^{s+r} \|f\|_{H^r(\Omega)}.$$

We remark that this regularity assumption is plausible and known to be true for $r \leq 1 - s$ (see for example [21], and [5] for a proof in the case $r = 0$) and that if Ω is smooth and $f \in W^{r,p}(\Omega)$ for some $p > d/s$ then $u \in W_{loc}^{r+2s,p}(\Omega)$ [27]. In order to compare with the global H^s -estimate of Theorem 3.1 (global energy-norm convergence rates), we consider below the best scenario of maximal interior regularity, namely the case where the rate $s+r$ in (5.14) is sufficiently large $s+r \geq 1$, so that the local H^s -rate is dictated by the global L^2 -error.

Quasi-uniform meshes. Combining (5.14) with the estimates of Proposition 3.3 (convergence rates in $L^2(\Omega)$ for quasi-uniform meshes) and Lemma 3.2 (further regularity) of Section 3.3, we obtain

$$|u - u_h|_{H^s(B_{R/2})} \leq Ch^{s+r} \|f\|_{H^r(\Omega)} + \begin{cases} Ch^{2\alpha} |\log h|^{2\kappa} \|f\|_{L^2(\Omega)} & \text{for } \Omega \text{ Lipschitz} \\ Ch^{\alpha+\gamma} |\log h|^{2\kappa} \|f\|_{H^r(\Omega)} & \text{for } \Omega \text{ smooth,} \end{cases}$$

where $\alpha = \min\{s, \frac{1}{2}\}$, $\gamma = \min\{s+r, \frac{1}{2}\}$ and if Ω is Lipschitz then $\kappa = \xi$ for $s \neq \frac{1}{2}$ and $\kappa = \xi + 1$ for $s = \frac{1}{2}$ (ξ is the constant in (2.6)), whereas if Ω is smooth then $\kappa = 1$ for $s \neq \frac{1}{2}$ and $\kappa = 2$ for $s = \frac{1}{2}$. We summarize these estimates in Table 1 (up to logarithmic factors); we remark that the rates therein for Lipschitz domains do not require the exterior ball condition. Compared with Theorem 3.1 (global energy-norm convergence rates)

$$(5.15) \quad \|u - u_h\|_{\tilde{H}^s(\Omega)} \leq Ch^{\min\{s, \frac{1}{2}\}} |\log h|^\kappa \|f\|_{L^2(\Omega)},$$

we see that all interior H^s -rates of Table 1 are improvements over the global rate of (5.15). For a more regular right hand side $f \in H^r(\Omega)$ with $s+r \geq \frac{1}{2}$ and in smooth domains, we observe an improvement over the global rate dictated by Lemma 3.2,

$$\|u - u_h\|_{\tilde{H}^s(\Omega)} \leq Ch^{\frac{1}{2}} |\log h|^\kappa \|f\|_{H^r(\Omega)}.$$

| | Local rates | | Global rates | |
|----------------------|---------------------|---------------------|-------------------|---------------------|
| | Ω -smooth | Ω -Lipschitz | Ω -smooth | Ω -Lipschitz |
| $s \leq \frac{1}{2}$ | $h^{s+\frac{1}{2}}$ | h^{2s} | $h^{\frac{1}{2}}$ | h^s |
| $s > \frac{1}{2}$ | h | h | $h^{\frac{1}{2}}$ | $h^{\frac{1}{2}}$ |

TABLE 1. Comparison of convergence rates (up to logarithmic factors) between interior $|u - u_h|_{H^s(B_{R/2})}$ and global $|u - u_h|_{H^s(\Omega)}$ error estimates on quasi-uniform meshes for $f \in H^r(\Omega)$ with $s+r \geq 1$. The interior estimates exhibit an improvement $h^{\min\{s, 1/2\}}$ regardless of the regularity of Ω .

Graded meshes. Section 3 shows that graded meshes satisfying (3.12) are able to compensate for the singular boundary layer for Lipschitz domains satisfying the exterior ball condition and smooth right-hand sides. Even though the next discussion is valid for any dimension d , for the sake of clarity and because our numerical experiments in Section 6 are carried out for $d = 2$, we shall focus on this case. Moreover, we assume $s \neq \frac{1}{2}$, for otherwise additional logarithmic factors arise in our estimates below. We set $\mu = 2$ and $\beta = 1 - s$ in Theorem 3.1 (global energy-norm convergence rates) and Proposition 3.4 (convergence rates in $L^2(\Omega)$ for graded meshes) to establish the global rates of convergence in $\tilde{H}^s(\Omega)$ and $L^2(\Omega)$

$$(5.16) \quad \|u - u_h\|_{\tilde{H}^s(\Omega)} \leq Ch |\log h| \|f\|_{C^{1-s}(\bar{\Omega})},$$

$$(5.17) \quad \|u - u_h\|_{L^2(\Omega)} \leq Ch^{\min\{1+s, 3/2\}} |\log h|^{\xi+1} \|f\|_{C^{1-s}(\bar{\Omega})};$$

ξ is the constant in (2.6). In contrast, Theorem 5.1 (local energy error estimate) in conjunction with (5.17) for $f \in C^{1-s}(\bar{\Omega}) \cap H^r(\Omega)$, $0 \leq r \leq 2 - 2s$, gives the local H^s -estimate

$$\|u - u_h\|_{H^s(B_{R/2})} \leq Ch^{s+r} \|f\|_{H^r(\Omega)} + Ch^{\min\{1+s, 3/2\}} |\log h|^{\xi+1} \|f\|_{C^{1-s}(\bar{\Omega})}.$$

The condition $r \leq 2 - 2s$ above is related to the use of piecewise linear finite elements. We now assume that $s+r = 2 - s$ to write

$$\|u - u_h\|_{H^s(B_{R/2})} \leq Ch^{\min\{1+s, 2-s\}} |\log h|^{\xi+1} \left(\|f\|_{C^{1-s}(\bar{\Omega})} + \|f\|_{H^{2-2s}(\Omega)} \right).$$

| | Ω -smooth or Lipschitz e.b.c. | |
|----------------------|--------------------------------------|--------------|
| | Local rates | Global rates |
| $s \leq \frac{1}{2}$ | h^{s+1} | h |
| $s > \frac{1}{2}$ | h^{2-s} | h |

TABLE 2. Comparison of order of convergence (up to logarithmic factors) between interior $|u - u_h|_{H^s(B_{R/2})}$ and global $|u - u_h|_{H^s(\Omega)}$ error estimates on graded meshes with parameter $\mu = 2$ for $f \in H^{2-2s}(\Omega) \cap C^{1-s}(\bar{\Omega})$. The interior estimates exhibit an improvement rate $h^{\min\{s, 1-s\}}$ for Ω either smooth or Lipschitz with an exterior ball condition (e.b.c.).

Comparing with the global H^s -error estimate in (5.16), we thus see an overall improvement rate $h^{\min\{s, 1-s\}}$. We summarize these results in Table 2.

We conclude with a comparison between local error rates on quasi-uniform and graded meshes for smooth data (domain and right-hand side). Tables 1 and 2 show that graded meshes yield an improvement of order $h^{\frac{1}{2}}$ for all $s \leq \frac{1}{2}$, whereas the improvement is of order h^{1-s} for $s > \frac{1}{2}$. Therefore, such an improvement is valid for all $0 < s < 1$ but becomes less significant in the limit $s \rightarrow 1$ of classical diffusion.

6. NUMERICAL EXPERIMENTS

In this section we present some numerical experiments in a two-dimensional domain that illustrate the sharpness of our theoretical estimates. These experiments were performed with the aid of the code documented in [1]; we also refer to [1] for details on the implementation. Some discussion about the construction of graded meshes satisfying (3.12) can be found in [2].

In all of the experiments below we set $\Omega = B(0, 1) \subset \mathbb{R}^2$ and $f \equiv 1$, so that we have an explicit solution at hand (cf. Example 2.1). This corresponds to smooth data (both domain and right-hand side) and the discussion of Section 5.3 applies. We computed errors with respect to the dimension N of the finite element spaces \mathbb{V}_h because $N = \#\text{Dofs}$ is a measure of complexity. In view of (3.13) with $\mu = 2$, we always have the relation $N \approx h^{-2}$ for both quasi-uniform and graded meshes, the latter up to logarithmic terms. Therefore, the rates of convergence of Section 5.3 can be expressed in terms of N as follows

$$(6.1) \quad h^\beta \approx N^{-\beta/2},$$

for appropriate exponents $\beta > 0$. We next explore computationally our error estimates in Section 3.3 for both the global L^2 -norm and local H^s -seminorm.

6.1. Global L^2 -norm error estimates. We start with quasi-uniform meshes and $s = 0.5, 0.6, 0.7, 0.8, 0.9$. Our findings are summarized in Figure 6.1: in all cases, we see good agreement with the linear convergence rate $\beta = 1$ predicted by Proposition 3.3 for $s \geq 1/2$, or equivalently $N^{-1/2}$ according to (6.1). Since the exact solution satisfies $u \in \cap_{\varepsilon>0} \tilde{H}^{s+1/2-\varepsilon}(\Omega)$, we infer that the L^2 -interpolation error obeys the inequality $\|u - I_h u\|_{L^2(\Omega)} \leq Ch^{s+1/2} |\log h|$. Interestingly, the finite element error $\|u - u_h\|_{L^2(\Omega)} \leq Ch |\log h|^2$ is of lower order for $s > 1/2$, which turns out to be consistent with (3.27).

FIGURE 6.1. Global L^2 -errors for the finite element solution to Example 2.1 over quasi-uniform meshes with $s = 0.5, 0.6, 0.7, 0.8, 0.9$. The decay rate $N^{-1/2}$, which is of lower order than the interpolation error, is consistent with (3.22) for $s \geq 1/2$.

We next consider approximations using graded meshes that satisfy (3.12) with $\mu = 2$. By Proposition 3.4, we expect a convergence rate of order $N^{-\min\{1/2+s/2, 3/4\}}$, according to (6.1). In Figure 6.2 we display the computational rates of convergence for $s = 0.2, 0.4, 0.6, 0.8$, which are in good agreement with theory.

FIGURE 6.2. Global L^2 -errors for the finite element solution to Example 2.1 over graded meshes with $\mu = 2$ and $s = 0.2, 0.4, 0.6, 0.8$. The computational decay rates are consistent with the theoretical prediction $N^{-\min\{1/2+s/2, 3/4\}}$ of (3.25).

6.2. Local H^s -norm error estimates. We next explore the sharpness of our local error estimates derived in Section 5 and summarized in Tables 1 and 2. More precisely, we find computational rates of convergence in $H^s(B(0, 0.3))$, namely the ball of radius 0.3 centered at the origin, upon evaluating $|I_h u - u_h|_{H^s(B(0, 0.3))}$ via the same techniques used when building the stiffness matrix. This is because

$$|u - u_h|_{H^s(B(0, 0.3))} \leq |u - I_h u|_{H^s(B(0, 0.3))} + |I_h u - u_h|_{H^s(B(0, 0.3))}$$

and the first term in the right hand side above is of higher order than the second for the locally smooth function u of (2.7). We display the errors in $H^s(B(0,0.3))$ for $s = 0.2, 0.4, 0.6, 0.8$ in Figures 6.3 and 6.4 for quasi-uniform and graded meshes, respectively. We observe good agreement with the theoretical rates $N^{-\min\{\frac{1}{4}+\frac{s}{2}, \frac{1}{2}\}}$ of Table 1 and $N^{-\min\{\frac{1}{2}+\frac{s}{2}, 1-\frac{s}{2}\}}$ of Table 2 in each case.

FIGURE 6.3. Errors in $H^s(B(0,0.3))$ for the finite element solution to Example 2.1 over quasi-uniform meshes with $s = 0.2, 0.4, 0.6, 0.8$. Computational rates are consistent with the theoretical rates $N^{-\min\{\frac{1}{4}+\frac{s}{2}, \frac{1}{2}\}}$ of Table 1.

FIGURE 6.4. Errors in $H^s(B(0,0.3))$ for the finite element solution to Example 2.1 over graded uniform meshes with $\mu = 2$ and $s = 0.2, 0.4, 0.6, 0.8$. Computational rates are consistent with the theoretical rates $N^{-\min\{\frac{1}{2}+\frac{s}{2}, 1-\frac{s}{2}\}}$ of Table 2.

Finally we emphasize that, according to our discussion in Section 3.2, the *global* H^s -errors decay with rate $N^{-1/4}$ (for uniform meshes) and $N^{-\frac{1}{2}}$ (for graded meshes); see (3.24) and (3.17). It can be seen from our numerical experiments that in all cases the finite element solutions converge with higher order in $H^s(B(0,0.3))$. Therefore, these experiments illustrate that the finite element error is effectively concentrated around $\partial\Omega$.
