Abstract

Using the multiconfiguration Dirac-Hartree-Fock (MCDHF) and the relativistic configuration interaction (RCI) methods, a consistent set of transition energies and radiative transition data for the lowest 150 states of the $3s^23p^3$, $3s3p^4$, $3s^23p^23d$, $3s3p^33d$, $3p^5$, and $3s^23p3d^2$ configurations in P-like Ge XVIII is provided. To assess the accuracy of the MCDHF transition energies, we have also performed calculations using the many-body perturbation theory (MBPT). Comparisons are made between the present MCDHF and MBPT data sets, as well as with other available experimental and theoretical values. The resulting accurate and consistent MCDHF data set will be useful for line identification and modeling purposes. These data can be considered as a benchmark for other calculations.

Key words: atomic data; P-like Ge XVIII; multiconfiguration Dirac-Hartree-Fock method

1. Introduction

Because of its applications in fusion plasmas, the phosphorus isoelectronic sequence from Zn XVI to Kr XXII has received great attention [1–3]. The Zn XVI, Se XX, and Kr XXII spectra were measured in tokamak plasmas [4, 5]. Using the National Institute of Standards and Technology (NIST) electron beam ion trap (EBIT), the extreme-ultraviolet (EUV) spectra of Kr XXII were observed [6]. As regards P-like Ge XVIII, the electric-dipole (E1) transition array $(1s^22s^22p^6)3s^23p^3 - 3s^23p^23d$ was observed by Sugar et al. [7]. The magnetic dipole (M1) transitions within the $3s^23p^3$ configuration of Ge XVIII were measured by Denne et al. [8] in a tokamak discharge.

On the theoretical side, excitation energies and transition rates for the low-lying 41 states of the $3s^23p^3$, $3s3p^4$, and $3s^23p^23d$ configurations in Ge XVIII were provided by different calculations [9–14]. Atomic parameters for higher-lying levels of P-like ions, such as the $3s3p^33d$ levels, are also needed for applications in plasma physics [15–19].

The present study is a continuation of our recent work [18, 19] on P-like ions, in which a complete accurate data set of excitation energies and radiative rates involving high-lying levels in P-like Ge XVIII is provided. By using a state-of-the-art method, namely, the multi-configuration Dirac-Hartree-Fock (MCDHF) method combined with the relativistic configuration interaction (RCI) approach [20], excitation energies, wavelengths, lifetimes, and radiative transition data including line strengths, oscillator strengths, and transition rates, are provided for the lowest 150 levels of the $3s^23p^3$, $3s3p^4$, $3s^23p^23d$, $3s3p^33d$, $3p^5$, and $3s^23p3d^2$ configurations. To assess the accuracy of the MCDHF transition energies, we have also performed calculations and provided excitation energies for Ge XVIII using the many-body perturbation theory (MBPT) [21]. This work extends and complements our long-term theoretical efforts [18, 22–42] to provide atomic data for L- and M-shells systems with high accuracy.

The paper is organized as follows. The MCDHF and MBPT calculations are outlined in Sec. 2. In Sec. 3 we present our numerical results and compare them with measured values and previous calcu-

lations. Sec. 4 is a brief summary.

2. Calculations

2.1. MCDHF

The MCDHF method implemented in the GRASP2K code [43, 44] was reviewed by Froese Fischer et al. [20]. This method is also described in our recent papers [18, 19]. For this reason, only computational procedures are described below.

In our MCDHF calculations, the multireference (MR) sets for even and odd parities include

even configurations: $3p^43d$, $3s3p^23d^2$, $3s3p^34p$, $3s3p^4$, $3s^23d^3$, $3s^23p^23d$, $3s^23p^24d$, $3s^23p^24s$;

odd configurations: $3p^33d^2$, $3p^5$, $3s3p3d^3$, $3s3p^33d$, $3s3p^34s$, $3s^23p3d^2$, $3s^23p^24f$, $3s^23p^24p$, $3s^23p^3$.

By allowing single and double substitutions from the $n = 3, 4$ electrons of the MR sets to orbitals with $n \leq 8, l \leq 6$, and allowing single excitations of the $n = 2$ electrons to orbitals with $n \leq 6, l \leq 4$, configuration state function (CSF) expansions are generated. No substitutions are allowed from the $1s$ shell, which is defined as an inactive closed core. For both energy separations and transition probabilities, the neglected electron correlations from $n = 1, 2$ are comparatively unimportant [18, 19].

In the following RCI calculation, the transverse electron-photon interaction in the low-frequency limit and the leading quantum electrodynamic (QED) effects (vacuum polarization and self-energy) corrections are included. In the final CSF expansions for the different J symmetries, the number of CSFs is, respectively, about 5.9 millions for even parity and 8.1 millions for odd parity.

By using the jj - LSJ transformation approach [45, 46], the jj -coupled CSFs are transformed into LSJ -coupled CSFs, from which the LSJ labels used by experimentalists are obtained.

2.2. MBPT

The MBPT method [21] is implemented in the FAC code by Gu [47, 48]. This method was used in our recent papers [22–25, 29, 30] to provide high accuracy atomic data for L- and M- shell ions. In the

MBPT method, the Hilbert space of the full Hamiltonian is divided into two parts, i.e., a model space M and an orthogonal space N . We included all the CSFs of the MR set of the above MCDHF calculation in the M space. All the possible CSFs generated by permitting single and double substitutions from the electrons of the MR sets are included in the N space. With the maximum l value of 20, for single and double excitations the maximum n values are, respectively, 125 and 65. The configuration interaction effects in the model space M are considered in the self-consistent field calculations non-perturbatively. The effects involving both spaces M and N are considered by using the second-order perturbation method.

3. Results and Discussions

3.1. Excitation energies

In Table 1, excitation energies and lifetimes for the lowest 150 levels of the $3s^23p^3$, $3s3p^4$, $3s^23p^23d$, $3s3p^33d$, $3p^5$, and $3s^23p3d^2$ configurations in Ge XVIII from our MCDHF calculations are provided. Excitation energies from the present MBPT calculations, as well as the energy differences between the MBPT and MCDHF results, are also included in this table.

In Table 2, the present MCDHF and MBPT excitation energies are compared with experimental values compiled in the NIST Atomic Spectra Database (ASD) [49]. Calculated values obtained by Hu et al. [9] using the MCDHF method, and Vilkas and Ishikawa [10] using the multireference Møller-Plesset (MR-MP) perturbation theory are also included in the table. As shown in Table 2, the previous calculations [9, 10] were focused on the 41 low-lying states of the $3s^23p^3$, $3s3p^4$, and $3s^23p^23d$ configurations. The average difference with the standard deviation, derived based on formulas (3-4) in [29], between computed excitation energies and the NIST experimental values are 229 ± 446 cm $^{-1}$ for our MCDHF calculations, -610 ± 660 cm $^{-1}$ for our MBPT calculations, 106 ± 494 cm $^{-1}$ for Vilkas and Ishikawa [10], and 1359 ± 675 cm $^{-1}$ for Hu et al. [9], respectively. Comparing with the previous MCDHF calculated values reported by Hu et al. [9], there is

generally a better agreement between our MCDHF values and the NIST experimental values due to the larger extent of electron correlation effects included in the present MCDHF calculations. For all 41 states of the $3s^23p^3$, $3s3p^4$, and $3s^23p^23d$ configurations, the average difference from the present MCDHF excitation energies is -130 ± 412 cm $^{-1}$ for MR-MP, and -930 ± 285 cm $^{-1}$ for MBPT.

Looking at higher-lying levels (above the level with the key 41), good agreement between our two data sets (MCDHF and MBPT) is obtained. The energy difference in cm $^{-1}$ between our two calculations for each level is shown in Table 1. The average difference with standard deviation is found to be -1127 ± 446 cm $^{-1}$, corresponding to the average relative difference of $-0.09\% \pm 0.03\%$. The present MCDHF and MBPT results support each other, and certify the reliability of our calculations.

3.2. Wavelengths, transition rates, and lifetimes

Wavelengths λ and radiative transition data, including transition rates A , weighted oscillator strengths gf , line strength S , and branching fractions ($BF_{ji} = A_{ji} / \sum_{k=1}^{j-1} A_{jk}$) for E1, M1, electric quadrupole (E2), and magnetic quadrupole (M2) transitions among all the lowest 150 levels from the present MCDHF calculations are reported in Table 3. E1 and E2 radiative transition data are given in both length (l) and velocity (v) forms. Only transitions with $BF \geq 10^{-5}$ are presented in this table.

Using the uncertainty estimation approach [50, 51], for E1 and E2 transitions we provide the estimated uncertainties of line strengths S adopting the NIST ASD [49] terminology (AA $\leq 1\%$, A $^+$ $\leq 2\%$, A $\leq 3\%$, B $^+$ $\leq 7\%$, B $\leq 10\%$, C $^+$ $\leq 18\%$, C $\leq 25\%$, D $^+$ $\leq 40\%$, D $\leq 50\%$, and E $> 50\%$) in the last column of Table 3. The difference δS between line strengths S_l and S_v (in length and velocity forms respectively) is defined as $\delta S = |S_v - S_l|/\min(S_v, S_l)$. The averaged uncertainties δS_{av} for line strengths S for E1 transitions in various ranges of S are assessed to be 0.2 % for $S \geq 10^0$; 0.5 % for $10^0 > S \geq 10^{-1}$; 1.1 % for $10^{-1} > S \geq 10^{-2}$; 2.4 % for $10^{-2} > S \geq 10^{-3}$; 4.7 % for $10^{-3} > S \geq 10^{-4}$; 8 % for $10^{-4} > S \geq 10^{-5}$, and 35 % for $10^{-5} > S \geq 10^{-6}$. Then, the larger of δS_{av} and δS_{ji} is accepted as the

uncertainty of each particular line strength. In Table 3, about 8 % of E1 S values have uncertainties of ≤ 1 % (AA), 27 % have uncertainties of ≤ 2 % (A+), 25 % have uncertainties of ≤ 3 % (A), 24 % have uncertainties of ≤ 7 % (B+), 11 % have uncertainties of ≤ 10 % (B), 4 % have uncertainties of ≤ 18 % (C+), 0.6 % have uncertainties of ≤ 25 % (C), and 1 % have uncertainties of ≤ 40 % (D+), while only 0.2 % have uncertainties of > 40 % (D and E). In the spirit of the uncertainty estimation approach [50, 51], the estimated uncertainties of line strengths S for E2 transitions are also estimated and listed in Table 3.

Among different previous calculations [9–14], radiative rates for the M1 transitions within the lowest 5 levels of the $3s^23p^3$ configuration were provided by Huang [13] using the MCDHF method, and Froese Fischer and Godefroid [14] using the multi-configuration Hartree-Fock (MCHF) method. In Table 4, our MCDHF values are compared with previous results [13, 14]. Comparing with the previous MCHF radiative rates, the MCDHF results reported by Huang [13] show a better agreement with our MCDHF values. The difference from the present MCDHF values for those M1 transitions is a few percent for the previous MCDHF results obtained by Huang [13].

Our MCDHF radiative lifetimes τ_{MCDHF}^l (in s) in the length form and τ_{MCDHF}^v (in s) in the velocity form for the lowest 150 levels of the $3s^23p^3$, $3s3p^4$, $3s^23p^23d$, $3s3p^33d$, $3p^5$, and $3s^23p3d^2$ configurations in Ge XVIII, which are calculated by considering all possible E1, E2, M1, and M2 transitions, are provided in Table 1. Our MCDHF radiative lifetimes τ_{MCDHF}^l and τ_{MCDHF}^v show good agreement. The average deviation between τ_{MCDHF}^l and τ_{MCDHF}^v for all 150 levels is 1 %.

4. Conclusions

Using the MCDHF method combined with the RCI approach, including the transverse electron-photon interaction in the low-frequency limit and the leading QED corrections, calculations have been performed for the lowest 150 levels of the $3s^23p^3$, $3s3p^4$, $3s^23p^23d$, $3s3p^33d$, $3p^5$, and $3s^23p3d^2$ configurations in Ge XVIII. Excitation energies, radiative transition data, and lifetimes are reported.

The accuracy of energy levels from the MCDHF calculations is estimated by comparing the MCDHF results with available experimental data. The difference from the NIST experimental values is -229 ± 446 cm $^{-1}$ for the MCDHF excitation energies of the lowest 41 levels. To assess the accuracy of the MCDHF excitation energies involving higher-lying levels, we also perform calculations using the MBPT method, and provide excitation energies. The average absolute difference of the present MBPT and MCDHF energy values is -1127 ± 446 cm $^{-1}$ for high-lying levels (above the level with the key 41), corresponding to the average relative difference of $0.09 \% \pm 0.03$ %, where the standard deviations are indicated after the values. The uncertainty of the line strength is assessed for each transition, and is available in Table 3. The resulting accurate and consistent MCDHF data set will be useful for line identification and modeling purposes, which can also be considered as a benchmark for other calculations.

Table 2. Energy levels (in cm^{-1}) relative to the ground state for the lowest 41 states of the $3s^23p^3$, $3s3p^4$, and $3s^23p^23d$ configurations. NIST – experimental values from the NIST ASD [49]; MCDHF – present MCDF results; MBPT – present MBPT results; Vilkas – theoretical values from Vilkas and Ishikawa [10]. Hu – theoretical values from Hu et al. [9]; ΔE – differences (in cm^{-1}) between calculated energies from different calculations and the NIST values.

Table 3. Transition wavelengths λ (in Å), transition rates A (in s⁻¹), weighted oscillator strengths gf , and line strengths S (in a.u.) between the lowest 150 states listed in Table 1. E1 and E2 transition data in both the length (l) and velocity (v) forms are provided. Type is the type of the multipole, and BF is the branching fraction from the upper level. The last column (Acc.) represents the estimated accuracy of the S values using the terminology of the NIST ASD. Only transitions with $BF \geq 10^{-5}$ are presented.

Table 4. Comparison of radiative rates for the M1 transitions within the lowest 5 levels of the $3s^23p^3$ configuration. MCDHF – present MCDHF results; Huang – theoretical values from Huang [13]. Froese Fischer – theoretical values from Froese Fischer and Godefroid [14].

i	j	Lower level	Upper level	Type	A			Percentage difference for A	
					MCDHF	Huang	Froese Fischer	Huang & MCDHF	Froese Fischer & MCDHF
1	2	$3s^2 3p^3(^4S) 4S_{3/2}^o$	$3s^2 3p^3(^2D) 2D_{3/2}^o$	M1	1.340E+03	1.440E+03	1.50E+03	7	12
