#### Abstract

P. Hrubeš, S. Natarajan Ramamoorthy, A. Rao and A. Yehudayoff proved the following result:

Let $p$ be a prime and let $f \in \mathbb{F}_{p}\left[x_{1}, \ldots, x_{2 p}\right]$ be a polynomial. Suppose that $f\left(\mathbf{v}_{\mathbf{F}}\right)=0$ for each $F \subseteq[2 p]$, where $|F|=p$ and that $f(\mathbf{0}) \neq 0$. Then $\operatorname{deg}(f) \geq p$.

We prove here the following generalization of their result. Let $p$ be a prime and $q=p^{\alpha}>1, \alpha \geq 1$. Let $n>0$ be a positive integer and $q-1 \leq d \leq n-q+1$ be an integer. Let $\mathbb{F}$ be a field of characteristic $p$. Suppose that $f\left(\mathbf{v}_{\mathbf{F}}\right)=0$ for each $F \subseteq[n]$, where $|F|=d$ and $\operatorname{deg}(f) \leq q-1$. Then $f\left(\mathbf{v}_{\mathbf{F}}\right)=0$ for each $F \subseteq[n]$, where $|F| \equiv d(\bmod q)$.

Let $t=2 d$ be an even number and $L \subseteq[d-1]$ be a given subset. We say that $\mathcal{F} \subseteq 2^{[t]}$ is an $L$-balancing family if for each $F \subseteq[t]$, where $|F|=d$ there exists a $G \subseteq[n]$ such that $|F \cap G| \in L$.

We give a general upper bound for the size of an $L$-balancing family.

## 1 Introduction

First we introduce some notations.
Let $n$ be a positive integer and let $[n]$ stand for the set $\{1,2, \ldots, n\}$. The family of all subsets of $[n]$ is denoted by $2^{[n]}$. For an integer $0 \leq d \leq n$
we denote by $\binom{[n]}{d}$ the family of all $d$ element subsets of $[n]$, and $\binom{[n]}{\leq d}=$ $\binom{[n]}{0} \cup \ldots \cup\binom{[n]}{d}$ the subsets of size at most $d$.

Let $\mathbb{F}$ be a field. $\mathbb{F}\left[x_{1}, \ldots, x_{n}\right]$ denotes the ring of polynomials in variables $x_{1}, \ldots, x_{n}$ over $\mathbb{F}$. Let $S=\mathbb{F}\left[x_{1}, \ldots, x_{n}\right]$. In this paper $\mathbb{F}$ will be a finite prime field $\mathbb{F}_{p}$.

In the following $v_{F} \in\{0,1\}^{n}$ denotes the characteristic vector of a set $F \subseteq[n]$. For a family of subsets $\mathcal{F} \subseteq 2^{[n]}$, let

$$
V(\mathcal{F})=\left\{v_{F}: F \in \mathcal{F}\right\} \subseteq\{0,1\}^{n} \subseteq \mathbb{F}^{n}
$$

It is natural to consider the ideal $I(V(\mathcal{F}))$ :

$$
I(V(\mathcal{F})):=\{f \in S: f(v)=0 \text { whenever } v \in V(\mathcal{F})\} .
$$

Denote by $\mathbb{F}\left[x_{1}, \ldots, x_{n}\right]_{\leq s}$ the vector space of all polynomials over $\mathbb{F}$ with degree at most $s$.

Let $I$ be an ideal of the ring $S=\mathbb{F}\left[x_{1}, \ldots, x_{n}\right]$. Let $h_{S / I}(m)$ denote the dimension over $\mathbb{F}$ of the factor-space $\mathbb{F}\left[x_{1}, \ldots, x_{n}\right]_{\leq m} /\left(I \cap \mathbb{F}\left[x_{1}, \ldots, x_{n}\right]_{\leq m}\right)$ (see [8, Section 9.3]). The Hilbert function of the algebra $S / I$ is the sequence $h_{S / I}(0), h_{S / I}(1), \ldots$.

It is easy to verify that in the special case when $I=I(V(\mathcal{F}))$ for some set system $\mathcal{F} \subseteq 2^{[n]}$, the number $h_{\mathcal{F}}(m):=h_{S / I}(m)$ is the dimension of the space of functions from $V(\mathcal{F})$ to $\mathbb{F}$ which can be represented as polynomials of degree at most $m$.

Let $p$ be a prime and $n>1,0 \leq d \leq n$ be integers. Let $q=p^{\alpha}, \alpha \geq 1$. Define the family of sets

$$
\mathcal{F}(d, q)=\{K \subseteq[n]:|K| \equiv d(\bmod q)\} .
$$

I proved the following result in [11].
Lemma 1.1 Let $p$ be a prime and let $f \in \mathbb{F}_{p}\left[x_{1}, \ldots, x_{4 p}\right]$ be a polynomial. Suppose that $f \in I\left(V\binom{[4 p]}{2 p}\right)$ and that $f \notin I\left(V\binom{[4 p]}{3 p}\right)$. Then $\operatorname{deg}(f) \geq p$.

My proof used a combination of Gröbner basis methods and linear algebra. Srinivasan gave a simpler proof which combined Fermat's little Theorem with linear algebra (see [5]). Alon found a third proof based on the Combinatorial Nullstellensatz (see [3]).
P. Hrubeš, S. Natarajan Ramamoorthy, A. Rao and A. Yehudayoff proved a similar result to our Lemma 1.1.

Lemma 1.2 Let $p$ be a prime and let $f \in \mathbb{F}_{p}\left[x_{1}, \ldots, x_{2 p}\right]$ be a polynomial. Suppose that $f \in I\left(V\binom{[2 p]}{p}\right)$ and that $f(\mathbf{0}) \neq 0$. Then $\operatorname{deg}(f) \geq p$.

Let $m$ be a positive integer and and $n$ be an positive even integer. We say that a proper non-empty subsets $S_{1}, \ldots, S_{m}$ are a balancing set of family if for every $X \in\binom{[n]}{n / 2}$ there is an index $i \in[k]$ such that $\left|S_{i} \cap X\right|=\left|S_{i}\right| / 2$.

Let $n$ be an positive even integer. Let $B(n)$ denote the minimum $k$ for which a balancing set family of size $k$ exists. P. Hrubeš, S. Natarajan Ramamoorthy, A. Rao and A. Yehudayoff applied Lemma 1.2 to give a lower bound for $B(n)$ if $n$ is an even positive integer. They used their lower bounds to prove lower bounds on depth-2 majority and threshold circuits that compute the majority and the weighted threshold functions.

We give here a simple generalization of Lemma 1.1 and Lemma 1.2. Our proof method is based on the following technical result.

Theorem 1.3 Let $\mathbb{F}$ be an arbitrary field. Let $\mathcal{F} \subseteq \mathcal{G} \subseteq \mathbb{F}^{n}$ be affine subsets. Suppose that $m \geq 0$ is an integer such that $h_{S / I(\mathcal{F})}(m)=h_{S / I(\mathcal{G})}(m)$. Then $I(\mathcal{F})_{\leq m}=I(\mathcal{G})_{\leq m}$.

Remark. We can easily prove a weaker version of Combinatorial Nullstellensatz using Theorem [1.3, Namely let $T_{i} \subseteq \mathbb{F}$ be finite subsets and let $\mathcal{G}:=\prod_{i=1}^{n} T_{i} \subseteq \mathbb{F}^{n}$, where $t_{i}=\left|T_{i}\right| \geq 2$ are finite for each $i$. Let $\mathbf{w}=\left(w_{1}, \ldots, w_{n}\right) \in \mathcal{G}$ be a fixed element. Define $\mathcal{F}:=\mathcal{G} \backslash\{\mathbf{w}\}$. Let $f \in I(\mathcal{F})$ be a polynomial such that $\operatorname{deg}(f) \leq \sum_{i} t_{i}-n-1$. Let $m:=\sum_{i} t_{i}-n-1$. Then it is easy to check that $h_{S / I(\mathcal{F})}(m)=h_{S / I(\mathcal{G})}(m)=\left(\prod_{i} t_{i}\right)-1$. Hence $f \in I(\mathcal{G})$.

One of our main result is the following generalization of Lemma 1.1 and Lemma 1.2 .

Theorem 1.4 Let $p$ be a prime and $q=p^{\alpha}>1, \alpha \geq 1$. Let $n>0$ be a positive integer and $q-1 \leq d \leq n-q+1$ be an integer. Let $\mathbb{F}$ be a field of characteristic $p$. Suppose that $f \in I\left(V\binom{[n]}{d}\right)$ and $\operatorname{deg}(f) \leq q-1$. Then $f \in I(V(\mathcal{F}(d, q)))$.

We define now $L$-balancing families. Let $n=2 d$ be an even number and $L \subseteq[d-1]$ be a given subset. We say that $\mathcal{F} \subseteq 2^{[n]}$ is an $L$-balancing family if for each $F \in\binom{[n]}{d}$ there exists a $G \subseteq[n]$ such that $|F \cap G| \in L$.

We prove the following general upper bound for the size of an $L$-balancing family. Our proof is based completely on Lemma 1.2.

Theorem 1.5 Let $p$ be a prime. Let $n:=2 p$ and $L \subseteq[p-1]$ be a given subset. Define $s:=|L|$. Let $\mathcal{F} \subseteq 2^{[n]}$ be an L-balancing family. Then

$$
m:=|\mathcal{F}| \geq \frac{n}{2 s}
$$

We prove our results in Section 2.

## 2 Proofs

Proof of Theorem 1.3: It follows from the definition of the Hilbert function that

$$
h_{\mathcal{F}}(m)=\operatorname{dim}\left(S_{\leq m}\right)-\operatorname{dim}\left(I(\mathcal{F})_{\leq m}\right)
$$

and

$$
h_{\mathcal{G}}(m)=\operatorname{dim}\left(S_{\leq m}\right)-\operatorname{dim}\left(I(\mathcal{G})_{\leq m}\right)
$$

Since $h_{\mathcal{F}}(m)=h_{\mathcal{G}}(m)$, hence $\operatorname{dim}\left(I(\mathcal{F})_{\leq m}\right)=\operatorname{dim}\left(I(\mathcal{G})_{\leq m}\right)$.
But $\mathcal{F} \subseteq \mathcal{G}$ implies that $I(\mathcal{G})_{\leq m} \subseteq I(\mathcal{F})_{\leq m}$, consequently $I(\mathcal{F})_{\leq m}=$ $I(\mathcal{G})_{\leq m}$.

Proof of Theorem 1.4: We gave an alternative proof in [12] Corollary 3.1 using Gröbner basis theory for Wilson's theorem about the Hilbert function of complete uniform families.

Theorem 2.1 (Wilson, [16]) Let $0 \leq d \leq n, 0 \leq m \leq \min \{d, n-d\}$, and $\mathbb{F}$ be an arbitrary field. Then we have

$$
\begin{equation*}
h_{\binom{[n]}{d}}(m)=\binom{n}{m} . \tag{1}
\end{equation*}
$$

We determined the Hilbert function of the set system $\mathcal{F}(d, q)$ in 10 Corollary 4.5.

Theorem 2.2 et $p$ be a prime and $q=p^{\alpha}>1, \alpha \geq 1$. Let $\mathbb{F}$ be a field of characteristic $p$.Let $n>0,0 \leq d \leq n$ be integers and define $r=\min \{d, n-$ $d\}$. Let $h_{\mathcal{F}_{(d, q)}}(m)$ denote the Hilbert function of $\mathbb{F}[\mathbf{x}] / I(V(\mathcal{F}(d, q)))$. Then

$$
h_{\mathcal{F}_{(d, q)}}(m)=\sum_{i=0}^{\left\lfloor\frac{m}{q}\right\rfloor}\binom{n}{m-i q}
$$

if $0 \leq m \leq r$, and

$$
h_{\mathcal{F}_{(d, q)}}(m)=\sum_{i=-\left\lfloor\frac{r}{q}\right\rfloor}^{\left\lfloor\frac{n-r}{q}\right\rfloor}\binom{n}{r+i q}-\sum_{i=1}^{\left\lfloor\frac{n-m}{q}\right\rfloor}\binom{n}{m+i q}
$$

if $m>r$.
Let $q-1 \leq d \leq n-q+1$ be an integer. Suppose that $f \in I\left(V\binom{[n]}{d}\right)_{\leq q-1}$. It follows from Theorem [2.1] and Theorem 2.2] that $h_{\binom{[n]}{d}}(q-1)=h_{\mathcal{F}_{(d, q)}}(q-1)=$ $\binom{n}{q-1}$.

Hence Theorem 1.3 gives us that $f \in I(V(\mathcal{F}(d, q)))_{\leq q-1}$.
Proof of Theorem 1.5:
Let $\mathcal{F}=\left\{F_{1}, \ldots, F_{m}\right\}$ be an $L$-balancing family and let $\mathbf{v}_{i}:=\mathbf{v}_{F_{i}}$ denote the characteristic vector of $F_{i}$ for each $1 \leq i \leq m$.

Consider the polynomial

$$
P(\mathbf{x}):=\prod_{i=1}^{m} \prod_{\ell \in L}\left(\mathbf{x} \cdot \mathbf{v}_{i}-\ell\right) \in \mathbb{F}_{p}[\mathbf{x}] .
$$

Here • denotes the usual scalar product. Clearly $\operatorname{deg}(P) \leq m s$.
Then $P(\mathbf{0})=\left(\prod_{\ell \in L} \ell\right)^{m} \neq 0$. On the other hand, $P\left(\mathbf{v}_{G}\right)=0$ for each $G \in\binom{[n]}{p}$, because $\mathcal{F}$ is an $L$-balancing family.

Hence it follows from Lemma 1.2 that $\operatorname{deg}(P) \geq p$ and we get that $p \leq m s$.
