# GEOMETRIC DEDUCTION OF THE SOLUTIONS TO MODULAR EQUATIONS 

MD. SHAFIUL ALAM AND TOSHIYUKI SUGAWA

#### Abstract

In his notebooks, Ramanujan presented without proof many remarkable formulae for the solutions to generalized modular equations. Much later, proofs of the formulae were provided by making use of highly nontrivial identities for theta series and hypergeometric functions. We offer a geometric approach to the proof of those formulae. We emphasize that our proofs are geometric and independent of such identities.

## 1. Introduction

For given integers $p \geq 2$, Ramanujan, an Indian mathematical genius, considered the equation

$$
\begin{equation*}
\frac{{ }_{2} F_{1}(a, 1-a ; 1 ; 1-\beta)}{{ }_{2} F_{1}(a, 1-a ; 1 ; \beta)}=p \frac{{ }_{2} F_{1}(a, 1-a ; 1 ; 1-\alpha)}{{ }_{2} F_{1}(a, 1-a ; 1 ; \alpha)}, \tag{1.1}
\end{equation*}
$$

known as the generalized modular equation of degree $p$ and signature $1 / a$. He left many formulae describing relations between $\alpha$ and $\beta$ in his unpublished notebooks but he did not record any proof of those formulae (see [9] and [23]). Here, ${ }_{2} F_{1}(a, b ; c ; z)$ denotes the hypergeometric function whose definition will be given in Section 2. The case when $1 / a=2$ corresponds to the classical modular equation. Indeed, the complete elliptic integral of the first kind is described by

$$
\mathbf{K}(r)=\int_{0}^{1} \frac{d x}{\sqrt{\left(1-x^{2}\right)\left(1-r^{2} x^{2}\right)}}=\frac{\pi}{2}{ }_{2} F_{1}\left(\frac{1}{2}, \frac{1}{2} ; 1 ; r^{2}\right)
$$

and the function

$$
\mu(r)=\frac{\pi}{2} \cdot \frac{\mathbf{K}\left(\sqrt{1-r^{2}}\right)}{\mathbf{K}(r)}=\frac{\pi}{2} \cdot \frac{{ }_{2} F_{1}\left(\frac{1}{2}, \frac{1}{2} ; 1 ; 1-r^{2}\right)}{{ }_{2} F_{1}\left(\frac{1}{2}, \frac{1}{2} ; 1 ; r^{2}\right)}
$$

is known to be the modulus of the Grötzsch ring $\{z \in \mathbb{C}:|z|<1\} \backslash[0, r]$ for $0<r<1$ and plays an important role in the theory of plane quasiconformal mappings (see, for instance,

[^0][21] or [5]). The modular equation (1.1) for $1 / a=2$ now takes the form $\mu(s)=p \mu(r)$ with $\alpha=r^{2}$ and $\beta=s^{2}$. When $p=2$, the solution to this modular equation is given by
\[

$$
\begin{equation*}
s=\frac{1-\sqrt{1-r^{2}}}{1+\sqrt{1-r^{2}}}=\left(\frac{1-\sqrt{1-r^{2}}}{r}\right)^{2} \tag{1.2}
\end{equation*}
$$

\]

(see [21, (2.4) in p. 60] or [5, (5.4)]).
Ramanujan mainly considered the case when the signature $1 / a$ is 3,4 or 6 . See [7], [8], 9], [10, [12] and [22] for his work in relation with the modular equations. Berndt, Bhargava and Garvan [11] gave proofs for those formulae of Ramanujan (see also [3]). Their proofs make use of highly nontrivial identities for Jacobi's theta functions and hypergeometric functions in addition to a number of ingeneous ideas. For example, they gave rigorous proofs for the following results.
Theorem 1.3 ([11, Theorem 7.1]). When $p=2$ and $q=3$, the solutions $\alpha$ and $\beta$ to the equation (1.1) are related by

$$
\begin{equation*}
(\alpha \beta)^{1 / 3}+\{(1-\alpha)(1-\beta)\}^{1 / 3}=1 \tag{1.4}
\end{equation*}
$$

Theorem 1.5 ([11, Lemma 7.4]). When $p=3$ and $q=3$, the solutions $\alpha$ and $\beta$ to the equation (1.1) are related by

$$
\begin{equation*}
(1-\alpha)^{1 / 3}=\frac{1-\beta^{1 / 3}}{1+2 \beta^{1 / 3}} \tag{1.6}
\end{equation*}
$$

We note that the above relations can be transformed to polynomial equations. For instance, (1.4) may be transformed to

$$
\begin{equation*}
(2 \alpha-1)^{3} \beta^{3}-3 \alpha\left(4 \alpha^{2}-13 \alpha+10\right) \beta^{2}+3 \alpha\left(2 \alpha^{2}-10 \alpha+9\right) \beta-\alpha^{3}=0 \tag{1.7}
\end{equation*}
$$

In particular, we observe that there are at most three values of $\beta$ satisfying the modular equation (1.4) for each $\alpha$. We can say that $\alpha$ and $\beta$ satisfy a polynomial equation of degree 3 in this case. It is rather surprising that $\alpha$ and $\beta$ are related algebraically, because the hypergeometric function is transcendental for the corresponding parameters. For instance, we do not have a complete answer to the question for which $p$ and $a$ the solutions to the modular equation (1.1) is algebraic. In this note, we propose a geometric approach to this problem. In particular, the geometric observation suggests that it is more natural to look at $q=1 /(1-2 a)$ rather than the signature $1 / a$. We will call $q$ the order of the modular equation (1.1). For instance, the signatures $1 / a=2,3,4,6$ correspond to $q=\infty, 3,2,3 / 2$, respectively. Though our approach does not cover the case $1 / a=6$, it may allow us to approach other cases when $q$ are integers $>3$. Let $G_{q}=\langle T, W\rangle$ be the Fuchsian group generated by $T \tau=\tau+\lambda$ and $W \tau=\tau /(1+\lambda \tau)$, where $\lambda=2 \cos \frac{\pi}{2 q}$ and let $M_{p}$ be the Möbius transformation defined by $M_{p} \tau=p \tau$. To speak about the solutions to (1.1), we have to clarify the range of the solutions. Originally, the range of $\alpha$ and $\beta$ was the interval $[0,1]$. However, in our setting, it is natural to choose the quotient Riemann surface $X=G_{q} \backslash \mathbb{H}$ as the range of the solutions. Here, we take $X=\widehat{\mathbb{C}} \backslash\{0,1\}$ for finite $q$ and $X=\mathbb{C} \backslash\{0,1\}$ for $q=\infty$. Then we have the following result.

Theorem 1.8. Let $n, p$ and $q$ be integers with $n, p, q \geq 2$ (possibly $q=\infty)$ and set $a=(q-1) /(2 q)$. Then, the solutions $(\alpha, \beta)$ to the equation (1.1) in $X=G_{q} \backslash \mathbb{H}$ satisfy the equation $P(\alpha, \beta)=0$ for an irreducible polynomial $P(x, y)$ of degree $n$ if and only if $G_{q} \cap G_{q}^{M_{p}}$ is a subgroup of $G_{q}$ of index $n$, where $G_{q}^{M_{p}}=M_{p}^{-1} G_{q} M_{p}$.

As we will see in the proof, the solutions $\alpha$ and $\beta$ are parametrized as $\alpha=\varphi(z)$ and $\beta=\psi(z)$ on the Riemann surface $Z=\left(G_{q} \cap G_{q}^{M_{p}}\right) \backslash \mathbb{H}$ and they satisfy the polynomial equation $P(\alpha, \beta)=0$ of order $n$. More precisely, $P(x, y)$ has the forms

$$
\begin{aligned}
P(x, y) & =a_{0}(x) y^{n}+a_{1}(x) y^{n-1}+\cdots+a_{n-1}(x) y+a_{n}(x) \\
& =b_{0}(y) x^{n}+b_{1}(y) x^{n-1}+\cdots+b_{n-1}(y) x+b_{n}(y),
\end{aligned}
$$

where $a_{j}(x) \in \mathbb{C}[x], b_{j}(y) \in \mathbb{C}[y](j=0,1, \ldots, n)$, such that $P(x, y)$ is irreducible as an element of $\mathbb{C}(x)[y]$ and $\mathbb{C}(y)[x]$, respectively. (Recall that $\mathbb{C}[x]$ and $\mathbb{C}(x)$ stand for the $\mathbb{C}$-algebra of polynomials in $x$ and the field of rational functions of $x$ with coefficients in $\mathbb{C}$, respectively.)

As applications of it, we will show (1.2) and Theorems 1.3 and 1.5 in Sections 4 and 5. In Section 2, we recall basic facts about hypergeometric functions and Hecke groups and its subgroup of index 2 . Section 3 is devoted to the statement of our main lemma and its proof. Theorem 1.8 is also proved in Section 3 with the help of the main lemma. We emphasize that our approach does not need ingenious ideas as in [11. Without knowledge about Ramanujan's formulae, we can deduce those formulae possibly with laborious computations only. In this paper, we treat only the case when the Riemann surface $Z$ is planar. When $Z$ is non-planar, it is technically difficult to find an explicit form of the polynomial $P(x, y)$. Let $\hat{Z}$ be the compactification of $Z$. Since the parametrizations $\varphi, \psi: \hat{Z} \rightarrow \widehat{\mathbb{C}}$ are $n$-sheeted covering maps with critical values contained in $\{0,1, \infty\}$ if $\left|G_{q}: G_{q} \cap G_{q}^{M_{p}}\right|=n$, Belyi's theorem implies that the compact Riemann surface $\hat{Z}$ is an algebraic curve defined over $\overline{\mathbb{Q}}$ (see [19]). Therefore, in principle, we could determine the surface $Z$ and maps $\varphi, \psi$ by the combinatorial information about the coverings. We hope to give further examples when $Z$ is non-planar in the future work.

Acknowledgement. The authors would like to thank Professor Hiroshige Shiga for suggestions which simplified the proof of Lemma 3.2 in the early version of the manuscript. They also thank Professor Matti Vuorinen for many suggestions.

## 2. Hypergeometric functions and Hecke groups

The hypergeometric function ${ }_{2} F_{1}(a, b ; c ; z)$ is defined by

$$
{ }_{2} F_{1}(a, b ; c ; z)=\sum_{n=0}^{\infty} \frac{(a)_{n}(b)_{n}}{(c)_{n} n!} z^{n}, \quad|z|<1,
$$

for parameters $a, b, c \in \mathbb{C}$ with $c \neq 0,-1,-2, \ldots$ By Euler's integral representation formula, we know that ${ }_{2} F_{1}(a, b ; c ; z)$ analytically extends to the slit domain $\mathbb{C} \backslash[1,+\infty)$.

Let $0<a \leq 1 / 2$. Then it is classically known [13] that the function

$$
\tau=f_{a}(z)=i \cdot \frac{{ }_{2} F_{1}(a, 1-a ; 1 ; 1-z)}{{ }_{2} F_{1}(a, 1-a ; 1 ; z)}
$$

maps the upper half-plane $\mathbb{H}=\{z \in \mathbb{C}: \operatorname{Im} z>0\}$ onto the domain $\Delta_{a}=\{\tau \in \mathbb{H}: 0<$ $\operatorname{Re} \tau<\sin \pi a,|2 \tau \sin \pi a-1|>1\}$ and that $\Delta_{a}$ is the hyperbolic triangle with vertices at $0, \infty$ and $i e^{-\pi a i}$ of interior angles 0,0 and $(1-2 a) \pi$, respectively (see also [4, Lemma 4.1]). Note also that $f_{a}$ extends homeomorphically to the boundary and

$$
\begin{equation*}
f_{a}(0)=\infty, \quad f_{a}(1)=0, \quad f_{a}(\infty)=i e^{-\pi a i}=e^{\pi i(1-2 a) / 2} \tag{2.1}
\end{equation*}
$$

Suppose now that $q=1 /(1-2 a)$ is an integer or $\infty$. Let $\pi_{q}: \Delta_{a} \rightarrow \mathbb{H}$ be the inverse map $z=f_{a}^{-1}(\tau)$ of $\tau=f_{a}(z)$. Then, by repeated applications of the Schwarz reflection principle, $\pi_{q}$ extends to a holomorphic map from $\mathbb{H}$ into $\widehat{\mathbb{C}} \backslash\{0,1\}$. Here, we note that $\pi_{q}$ is locally $q$ to 1 at the point $i e^{-\pi a i}$. By construction, the covering group $G_{q}=\{\gamma \in \operatorname{Aut}(\mathbb{H})$ : $\left.\pi_{q} \circ \gamma=\pi_{q}\right\}$ is the triangle group of signature $(q, \infty, \infty)$ arising from the hyperbolic triangle $\Delta_{a}, q=1 /(1-2 a)$. Here, the group $\operatorname{Aut}(\mathbb{H})$ of analytic automorphism of $\mathbb{H}$ is identified with $\operatorname{PSL}(2, \mathbb{R})=\operatorname{SL}(2, \mathbb{R}) /\{ \pm I\}$. Since $G_{q}$ is a subgroup of the Hecke group $H_{2 q}$ of index 2, we recall basics of Hecke groups. See [14] for details about the Hecke groups. Moreover, we refer to [6] and [20] as general references for Fuchsian groups.

By its form, the function $f_{a}$ satisfies the relation $f_{a}(1-z)=-1 / f_{a}(z)$. Since $\pi_{q}=f_{a}^{-1}$ on $\Delta_{a}$, the following result follows.

Lemma 2.2. The covering map $\pi_{q}$ satisfies the functional equation

$$
\pi_{q}(\tau)+\pi_{q}(-1 / \tau)=1, \quad \tau \in \mathbb{H}
$$

For an integer $k \geq 3$, the Hecke group $H_{k}$ is defined as the discrete subgroup of $\operatorname{PSL}(2, \mathbb{R})$ generated by the two elements $\pm S$ and $\pm T_{k}$, where

$$
S=\left(\begin{array}{cc}
0 & -1 \\
1 & 0
\end{array}\right), \quad T_{k}=\left(\begin{array}{cc}
1 & \lambda_{k} \\
0 & 1
\end{array}\right) \quad \text { and } \quad \lambda_{k}=2 \cos \frac{\pi}{k} .
$$

See [6] or [14]. Here and in what follows, we often identify a matrix $A=\left(\begin{array}{ll}a & b \\ c & d\end{array}\right)$ with the Möbius transformation $\tau \mapsto A \tau=(a \tau+b) /(c \tau+d)$ so that $S, T_{k}$ are regarded as elements of $\operatorname{Aut}(\mathbb{H})=\operatorname{PSL}(2, \mathbb{R})$. Note that $H_{3}$ is the classical modular group $\operatorname{PSL}(2, \mathbb{Z})$. We put

$$
U_{k}=T_{k} S=\left(\begin{array}{cc}
\lambda_{k} & -1 \\
1 & 0
\end{array}\right)
$$

Then $U_{k}$ is an elliptic element of order $k$ with fixed point at $e^{\pi i / k}$. Let $F_{k}$ be the set of points $\tau \in \mathbb{H}$ with $|\operatorname{Re} \tau| \leq \cos \frac{\pi}{k},|\tau| \geq 1$. Then $F_{k}$ is a fundamental domain for $H_{k}$ with side pairing transformations $S, T_{k}$. (Note that $S$ has a fixed point at $\tau=i$.) In particular, we see that $H_{k}$ is a triangle group of signature $(2, k, \infty)$.

From now on, we restrict ourselves on the case when $k=2 q$ is an even number with $q \geq 2$. Then $\hat{F}_{q}=F_{2 q} \cup S\left(F_{2 q}\right)$ is a fundamental domain for the (normal) subgroup $G$ of $H_{2 q}$ of index 2 generated by

$$
T_{2 q}=\left(\begin{array}{cc}
1 & \lambda_{2 q} \\
0 & 1
\end{array}\right) \quad \text { and } \quad W_{2 q}=S^{-1} T_{2 q}^{-1} S=\left(\begin{array}{cc}
1 & 0 \\
\lambda_{2 q} & 1
\end{array}\right)
$$

To adapt with our aim, we modify the fundamental domain as follows. For $a=(q-$ $1) /(2 q)$, let $\tilde{F}_{q}=\Delta_{a} \cup \Delta_{a}^{\prime}$, where $\Delta_{a}^{\prime}$ is the reflection of $\Delta_{a}$ across the line $\operatorname{Re} \tau=\sin \pi a$. Then, $\tilde{F}_{q}$ serves as a fundamental domain of $G$, which is the same as $G_{q}$ introduced in Introduction and the above-defined covering group of $\pi_{q}$. (This appears in Example 1.3 of [14].) Note that the element

$$
V_{q}:=T_{2 q} W_{2 q}^{-1}=U_{2 q}^{2}=\left(\begin{array}{cc}
\lambda_{2 q}^{2}-1 & -\lambda_{2 q} \\
\lambda_{2 q} & -1
\end{array}\right)=\left(\begin{array}{cc}
\lambda_{q}+1 & -\lambda_{2 q} \\
\lambda_{2 q} & -1
\end{array}\right)
$$

is elliptic of order $q$ and that $G_{q}$ is generated by $T_{2 q}$ and $V_{q}$ (see Figure 1 and Figure 2). Here, we note the following property.

Figure 1. Fundamental domains of $H_{2 q}=\left\langle T_{2 q}, S\right\rangle$ and $G=\left\langle T_{2 q}, W_{2 q}\right\rangle$.

Lemma 2.3. Let $p, q$ be integers with $p, q \geq 2$ (where $q$ may be $\infty$ ) and let $K=G_{q} \cap G_{q}^{M_{p}}$, where $M_{p} \tau=p \tau$. Then $\left|G_{q}: K\right|=\left|G_{q}^{M_{p}}: K\right|$.

Proof. If both of the indices are infinite, there is nothing to show. Assume $n=\left|G_{q}: K\right|<$ $\infty$. Then the hyperbolic area $\operatorname{Area}(Z)$ of the Riemann orbifold $Z=K \backslash \mathbb{H}$ is computed as (see [6, p. 150] or [20, p. 13])

$$
\operatorname{Area}(Z)=n \operatorname{Area}\left(G_{q} \backslash \mathbb{H}\right)=n \operatorname{Area}\left(\tilde{F}_{q}\right)=2 n(\pi-\pi / q)
$$

Figure 2. Fundamental domain $\tilde{F}_{q}$ of $G_{q}=\left\langle T_{2 q}, V_{q}\right\rangle$.
Since $G_{q}^{M_{p}} \backslash \mathbb{H}$ has the same hyperbolic area as $G_{q} \backslash \mathbb{H}$, we have

$$
\left|G_{q}^{M_{p}}: K\right|=\frac{\operatorname{Area}(K \backslash \mathbb{H})}{\operatorname{Area}\left(G_{q}^{M_{p}} \backslash \mathbb{H}\right)}=\frac{\operatorname{Area}(Z)}{\operatorname{Area}\left(G_{q} \backslash \mathbb{H}\right)}=n
$$

as required. When $\left|G_{q}^{M_{p}}: K\right|<\infty$, the same argument works for the proof.

Remark 2.4. In view of the proof, one can also show that the formula $\left|G: G \cap G^{M}\right|=$ $\left|G^{M}: G \cap G^{M}\right|$ holds for a cofinite Fuchsian group $G$; namely, if the surface $G \backslash \mathbb{H}$ has finite hyperbolic area. However, this formula is not true in general. For instance, Jørgensen, Marden and Pommerenke [18] constructed a Fuchsian group $\Gamma$ and its subgroup $G$ of index 2 such that $G^{M}=M^{-1} G M$ is a proper subgroup of $G$ for some $M \in \Gamma$ so that $G \cap G^{M}=G^{M}$. In particular, $\left|G: G \cap G^{M}\right|>\left|G^{M}: G \cap G^{M}\right|=1$.

The index $\left|G_{q}: K\right|$ can be computed explicitly when $q=3,4, \infty$ (see [2]). In the present paper, our main concerns are about the limiting case as $q \rightarrow \infty$ and the case of $q=3$. Those cases will be discussed in Sections 4 and 5, respectively.

## 3. A result on Fuchsian groups

Let $\Gamma$ be a Fuchsian group acting on the upper half-plane $\mathbb{H}$ and $X$ be the quotient Riemann surface $\Gamma \backslash \mathbb{H}$. We denote by $\pi$ the canonical projection $\pi: \mathbb{H} \rightarrow X$. When $\gamma \in \Gamma$ is a parabolic element with fixed point at $\tau_{0} \in \partial \mathbb{H}$, it is known that $\pi(\tau)$ tends to a puncture, say $P$, of $X$ as $\tau \rightarrow \tau_{0}$ nontangentially. As a convention, we will write $\pi\left(\tau_{0}\right)=P$ in the sequel. A point $\tau_{0} \in \mathbb{H}$ is called a fixed point of an element $\gamma$ of $\operatorname{PSL}(2, \mathbb{R})$ if $\gamma \tau_{0}=\tau_{0}$ and the set of fixed points of $\gamma$ in $\mathbb{H}$ is denoted by $\operatorname{Fix}(\gamma)$. A non-identity element $\gamma$ is called elliptic if $\operatorname{Fix}(\gamma) \neq \emptyset$. Let $M \in \operatorname{PSL}(2, \mathbb{R})=\operatorname{Aut}(\mathbb{H})$ such that $M \notin \Gamma$. Then we consider
the number (possibly $\infty$ ) defined by

$$
\begin{equation*}
N_{X_{0}}(M, \Gamma)=\sup _{x \in X_{0}} \#\left\{\pi(M \tau): \tau \in \pi^{-1}(x)\right\} \tag{3.1}
\end{equation*}
$$

for $X_{0} \subset X$. The next result is our main lemma and it gives a criterion for finiteness of $N_{X_{0}}(M, \Gamma)$.

Lemma 3.2. Let $\Gamma$ be a Fuchsian group and $M \in \operatorname{PSL}(2, \mathbb{R}) \backslash \Gamma$. Suppose that $X_{0}$ is an uncountable subset of the quotient Riemann surface $X=\Gamma \backslash \mathbb{H}$. Then $N_{X_{0}}(M, \Gamma)<\infty$ if and only if $\Gamma^{M}:=M^{-1} \Gamma M$ is commensurable with $\Gamma$ in the sense that $|\Gamma: G|<\infty$ for $G=\Gamma \cap \Gamma^{M}$. Moreover, in this case, $N_{X_{0}}(M, \Gamma)=|\Gamma: G|$.

Proof. The "if" part is almost trivial. Let $N:=|\Gamma: G|<\infty$. Then we take $\gamma_{1}, \ldots, \gamma_{N} \in \Gamma$ so that $\Gamma=G \gamma_{1} \cup \cdots \cup G \gamma_{N}$. For $x \in X$ and $\tau_{0} \in \pi^{-1}(x)$, we observe

$$
M\left(\pi^{-1}(x)\right)=M \Gamma \tau_{0}=\bigcup_{j=1}^{N} M G \gamma_{j} \tau_{0}=\bigcup_{j=1}^{N} M G M^{-1} \cdot M \gamma_{j} \tau_{0}
$$

Since $M G M^{-1} \subset \Gamma$, the set $M G M^{-1} \cdot M \gamma_{j} \tau_{0}$ is projected to the point $\pi\left(M \gamma_{j} \tau_{0}\right)$ by $\pi$. Therefore, $\#\left(\pi\left(M\left(\pi^{-1}(x)\right)\right)\right) \leq N$. Hence, we conclude that

$$
\begin{equation*}
N_{X_{0}}(M, \Gamma) \leq|\Gamma: G| \tag{3.3}
\end{equation*}
$$

To show the "only if" part, we assume that $N:=N_{X_{0}}(M, \Gamma)$ is finite. Let

$$
E_{1}=\bigcup_{\gamma, \delta} \operatorname{Fix}\left(\gamma^{-1} \delta\right)
$$

where $\gamma$ and $\delta$ range over $\gamma \in \Gamma$ and $\delta \in \Gamma^{M}$ with $\gamma \neq \delta$. Since each $\operatorname{Fix}\left(\gamma^{-1} \delta\right)$ contains at most one point, the set $E_{1}$ is at most countable. Moreover, the set $E=\Gamma \cdot E_{1}=\{\gamma \tau$ : $\left.\gamma \in \Gamma, \tau \in E_{1}\right\}$ is also at most countable. Take a point $\tau_{0}$ from the uncountable subset $\pi^{-1}\left(X_{0}\right) \backslash E$ of $\mathbb{H}$ and fix it. We regard $G \backslash \Gamma$ as the set of right cosets $\{G \gamma: \gamma \in \Gamma\}$. As we saw above, each set $G \gamma \cdot \tau_{0}$ projects to one point $\pi\left(M \gamma \tau_{0}\right)$ under the mapping $\pi \circ M$ : $\mathbb{H} \rightarrow X$. We now show that the mapping $\phi: G \backslash \Gamma \rightarrow X$ defined by $\phi(G \gamma)=\pi\left(M \gamma \tau_{0}\right)$ is injective. To this end, we suppose that $\phi\left(G \gamma_{1}\right)=\phi\left(G \gamma_{2}\right)$ for some $\gamma_{1}, \gamma_{2} \in \Gamma$. Then $M \gamma_{2} \tau_{0}=\gamma M \gamma_{1} \tau_{0}$ for some $\gamma \in \Gamma$. It says that $\gamma_{1} \tau_{0}$ is a fixed point of $\left(\gamma_{2} \gamma_{1}^{-1}\right)^{-1} \delta$, where $\delta=M^{-1} \gamma M \in \Gamma^{M}$. Since $\gamma_{1} \tau_{0} \notin E$, the element $\left(\gamma_{2} \gamma_{1}^{-1}\right)^{-1} \delta$ must be the identity, which implies $\gamma_{2} \gamma_{1}^{-1}=\delta \in \Gamma \cap \Gamma^{M}=G$. Hence $G \gamma_{1}=G \gamma_{2}$.

We have seen that $\phi: G \backslash \Gamma \rightarrow X$ is injective. On the other hand, the image $\phi(G \backslash \Gamma)=$ $\pi\left(M \Gamma \tau_{0}\right)$ consists of at most $N$ points. Therefore, we obtain

$$
|\Gamma: G|=\#(G \backslash \Gamma) \leq N
$$

Combining with (3.3), we obtain $|\Gamma: G|=N_{X_{0}}(M, \Gamma)$ as required.
In particular, we see that $N_{X_{0}}(M, \Gamma)$ does not depend on the uncountable set $X_{0} \subset X$. Thus we denote by $N(M, \Gamma)$ the common number $N_{X_{0}}(M, \Gamma)$.

We are now ready to prove Theorem 1.8 .
Proof of Theorem 1.8. Recall that $a=(q-1) /(2 q)$ and $M_{p} \tau=p \tau$. In this proof, we will use the notation introduced in Section 2. By definition, the generalized modular equation (1.1) may be expressed by $f_{a}(\beta)=p f_{a}(\alpha)$. Therefore, $\alpha$ and $\beta$ in $\widehat{\mathbb{C}} \backslash\{0,1\}$ satisfy (1.1) if and only if $\alpha=\pi_{q}(\tau), \beta=\pi_{q}(p \tau)$ for some $\tau \in \mathbb{H}$.

First we assume that $\alpha$ and $\beta$ in (1.1) satisfy the algebraic equation $P(\alpha, \beta)=0$, where

$$
P(x, y)=\sum_{j=0}^{n} a_{j}(x) y^{j}, \quad a_{j}(x) \in \mathbb{C}[x](j=0,1, \ldots, n),
$$

is an irreducible polynomial of degree $n$ in $\mathbb{C}(x)[y]$. Let $X_{0}$ be the set of those points $x \in X$ for which $a_{k}(x) \neq 0$ for some $k$. Then for a fixed $x_{0} \in X_{0}$, the algebraic equation $P\left(x_{0}, y\right)=0$ in $y$ has at most $n$ solutions. Thus we conclude that $N_{X_{0}}\left(M_{p}, G_{q}\right) \leq n$. The previous lemma now implies that $\left|G_{q}: G_{q} \cap G_{q}^{M_{p}}\right| \leq n$. By the irreducibility of $P(x, y)$, we see that equality holds.

Conversely, we assume that the equality $\left|G_{q}: K\right|=n$ holds, where $K=G_{q} \cap G_{q}^{M_{p}}$. Note that $\left|G_{q}^{M_{p}}: K\right|=n$ by Lemma 2.3. We denote by $Z$ the quotient Riemann surface $K \backslash \mathbb{H}$. Let $\rho: \mathbb{H} \rightarrow Z$ be the canonical projection and let $\varphi: Z \rightarrow X$ and $\psi: Z \rightarrow X$ be the induced mappings satisfying the relations $\pi_{q}=\varphi \circ \rho$ and $\pi_{q} \circ M_{p}=\psi \circ \rho$, respectively. Thus we have the following commutative diagram:

Note that the solution $(\alpha, \beta)$ to the modular equation (1.1) is now parametrized by $\alpha=\varphi(z)$ and $\beta=\psi(z)$ for $z \in Z$. We denote by $\hat{X}$ and $\hat{Z}$ the compact Riemann surfaces obtained by filling in the punctures of $X$ and $Z$, respectively. Note that $\widehat{\mathbb{C}}$ can be taken as $\hat{X}$. Then $\varphi$ and $\psi$ extend to $n$-sheeted branched covering maps of $\hat{Z}$ onto $\hat{X}=\widehat{\mathbb{C}}$. In particular, $\psi$ may be regarded as a meromorphic function on $\hat{Z}$. Let $X_{0}$ denote $X$ minus the set of critical values of $\varphi: Z \rightarrow X$; indeed $X_{0}=\widehat{\mathbb{C}} \backslash\{0,1, \infty\}$ in this case. Similarly, $X_{1}$ is defined for $\psi: Z \rightarrow X$. For a point $x_{0} \in X_{0}$ we choose a small disk $U=U\left(x_{0}\right)$ with $x_{0} \in U \subset X_{0}$. Let $s_{j}$ be the elementary symmetric functions of $\psi \circ \eta_{1}, \ldots, \psi \circ \eta_{n}$ of degree $j$, where $\eta_{1}, \ldots, \eta_{n}$ are local inverses of $\varphi$ of $U$. Then for each $j=1,2, \ldots, n$, all $s_{j}: U\left(x_{0}\right) \rightarrow X$ piece together to one function and it extends meromorphically to $\hat{X}=\widehat{\mathbb{C}}$ and $\psi$ satisfies the equation

$$
\psi^{n}-s_{1} \circ \varphi \cdot \psi^{n-1}+\cdots+(-1)^{n-1} s_{n-1} \circ \varphi \cdot \psi+(-1)^{n} s_{n} \circ \varphi=0
$$

(see [16, Theorem 8.3] for details). Note that each $s_{j}: \widehat{\mathbb{C}} \rightarrow \widehat{\mathbb{C}}$ is a rational function. By writing $(-1)^{j} s_{j}(x)=a_{j}(x) / a_{0}(x)$ for polynomials $a_{0}(x), \ldots, a_{n}(x) \in \mathbb{C}[x]$ without
non-trivial common factor, we define

$$
P(x, y)=a_{0}(x) y^{n}+a_{1}(x) y^{n-1}+\cdots+a_{n-1}(x) y+a_{n}(x) .
$$

Then $P(\alpha, \beta)=P(\varphi(z), \psi(z))=0$ for $z \in Z$. Conversely, suppose that $x_{0} \in X_{0}$ with $a_{0}\left(x_{0}\right) \neq 0$ and $y_{0} \in X_{1}$ satisfy $P\left(x_{0}, y_{0}\right)=0$. Let $\varphi^{-1}\left(x_{0}\right)=\left\{z_{1}, \ldots, z_{n}\right\}$ and let $\sigma_{1}, \ldots, \sigma_{n}$ be the elementary symmetric functions of $\psi\left(z_{1}\right), \ldots, \psi\left(z_{n}\right)$. Note that $\sigma_{j}=s_{j}\left(x_{0}\right)$ for $j=1, \ldots, n$. Then,

$$
\begin{aligned}
a_{0}\left(x_{0}\right)\left(y_{0}-\psi\left(z_{1}\right)\right) \cdots\left(y_{0}-\psi\left(z_{n}\right)\right) & =a_{0}\left(x_{0}\right)\left(y_{0}^{n}-\sigma_{1} y_{0}^{n-1}+\cdots+(-1)^{n} \sigma_{n}\right) \\
& =\sum_{j=0}^{n} a_{j}\left(x_{0}\right) y_{0}^{n-j}=P\left(x_{0}, y_{0}\right)=0
\end{aligned}
$$

Hence, $y_{0}=\psi\left(z_{k}\right)$ for some $k$. Since $x_{0}=\varphi\left(z_{k}\right), y_{0}=\psi\left(z_{k}\right)$, we have shown that the converse is true. We next show that the polynomial $P(x, y)$ is irreducible in $y$ with coefficients in $\mathbb{C}[x]$. Suppose, on the contrary, that $P(x, y)$ reduces to the product $P_{1}(x, y) P_{2}(x, y)$ of nonconstant polynomials $P_{1}, P_{2}$. Let $Y_{l}=\left\{(x, y) \in X_{0} \times X_{1}: P_{l}(x, y)=0\right\}$ for $l=1,2$. We claim that $Y_{1} \cap Y_{2}=\emptyset$. Indeed, if $\left(x_{0}, y_{0}\right) \in Y_{1} \cap Y_{2}$, then the polynomial $P\left(x_{0}, y\right)=P_{1}\left(x_{0}, y\right) P_{2}\left(x_{0}, y\right)$ has a multiple zero at $y=y_{0}$, which is impossible because the set $\psi^{-1}\left(y_{0}\right)$ consists of $n$ points for $y_{0} \in X_{1}$. Since $\varphi \times \psi: Z_{0} \rightarrow X_{0} \times X_{1}$ is continuous, where $Z_{0}=\varphi^{-1}\left(X_{0}\right) \cap \psi^{-1}\left(X_{1}\right)$, and $Z_{0}$ is connected, the image $(\varphi \times \psi)\left(Z_{0}\right)$ is contained in either $Y_{1}$ or $Y_{2}$. However, this is impossible. The claim has been shown.

Finally, consider the polynomial $P(x, y)$ in $\mathbb{C}(y)[x]$. Then, $P(x, y)$ is a polynomial in $x$ with coefficients in $\mathbb{C}[y]$, and we may write

$$
P(x, y)=b_{0}(y) x^{m}+b_{1}(y) x^{m-1}+\cdots+b_{m-1}(y) x+b_{m}(y), \quad b_{j}[y] \in \mathbb{C}[y],
$$

where $m=\max _{0 \leq j \leq n} \operatorname{deg} a_{j}(x)$. Note that $b_{0} \neq 0$. Since $\psi: Z \rightarrow X$ is $n$-sheeted, as in the case of $\varphi: Z \rightarrow X$, we can see that $m=n$ and $P(x, y)$ is irreducible in $\mathbb{C}(y)[x]$.

Let us summarize the above observations for later use. Suppose that $K=G_{q} \cap G_{q}^{M_{p}}$ is a subgroup of $G_{q}$ of finite index $n$. The intermediate Riemann surface $Z=K \backslash \mathbb{H}$ may be used as a parameter space of the solutions $(\alpha, \beta)$ to 1.1). Indeed, the solutions are given by $\alpha=\varphi(z), \beta=\psi(z)$ for $z \in Z$, where $\varphi, \psi: Z \rightarrow X=G_{q} \backslash \mathbb{H}$ are (possibly branched) covering maps satisfying the relations $\varphi(\rho(\tau))=\pi_{q}(\tau)$ and $\psi(\rho(\tau))=\pi_{q}(p \tau)$ for $\tau \in \mathbb{H}$. Note that $\varphi$ and $\psi$ extend to the compactifications $\hat{Z}$ to $\hat{X}=\widehat{\mathbb{C}}$ as $n$-sheeted branched (analytic) covering maps. The polynomial $P(x, y)$ whose zero set describes the solutions $(\alpha, \beta)$ can be computed as in the above proof. The following lemma helps us to compute $\psi$ when we know about $\varphi$.

Lemma 3.4. Under the assumption of Theorem 1.8, the Möbius transformation $S M_{p} \tau=$ $-1 /(p \tau)$ induces an analytic involution $\omega: Z \rightarrow Z$ which satisfies the relation $\rho \circ S M_{p}=$ $\omega \circ \rho$ and the functional equation

$$
\psi=1-\varphi \circ \omega
$$

Proof. Let $K=G_{q} \cap G_{q}^{M_{p}}$. We first note that the Möbius transformations $S$ and $M_{p}$ satisfy the relation $S M_{p}=M_{p}^{-1} S$ and thus $M_{p} S M_{p}=S$. Recall that $S$ normalizes $G_{q}$; namely, $G_{q}^{S}:=S^{-1} G_{q} S=G_{q}$. Therefore,

$$
K^{S M_{p}}=G_{q}^{S M_{p}} \cap\left(G_{q}^{M_{p}}\right)^{S M_{p}}=G_{q}^{M_{p}} \cap G_{q}^{M_{p} S M_{p}}=G_{q}^{M_{p}} \cap G_{q}^{S}=K,
$$

which means that $S M_{p}: \mathbb{H} \rightarrow \mathbb{H}$ descends to an automorphism $\omega: Z \rightarrow Z$ such that $\rho \circ S M_{p}=\omega \circ \rho$. Since $\left(S M_{p}\right)^{2}=I$, we see that $\omega \circ \omega=$ id. We recall Lemma 2.2 which says that $\pi_{q} \circ S=1-\pi_{q}$. Then we compute

$$
\psi \circ \omega \circ \rho=\psi \circ \rho \circ S M_{p}=\left(\pi_{q} \circ M_{p}\right) \circ S M_{p}=\pi_{q} \circ S=1-\pi_{q}=1-\varphi \circ \rho
$$

and therefore we have $\psi \circ \omega=1-\varphi$. Since $\omega$ is an involution, we obtain the required relation.

Remark 3.5. Since $\omega$ comes from the normalizer of $K, \omega$ is indeed an automorphism of the Riemann orbifold $K \backslash \mathbb{H}$. In particular, $\omega$ maps a cone point of angle $2 \pi / \mathrm{m}$ to another (possibly the same) cone point of the same angle for an integer $m \geq 2$.

## 4. Applications to the classical case $q=\infty$

As $q \rightarrow \infty$, the Hecke group $H_{2 q}$ converges to the group $H_{\infty}=\left\langle S, T_{\infty}\right\rangle$, which is a subgroup of the modular group $\operatorname{PSL}(2, \mathbb{Z})$ of index 3 , where $T_{\infty} z=z+2$. At the same time, the subgroup $G_{q}$ converges to the principal congruence subgroup $\Gamma(2)$ of level 2 , which will be denoted by $G_{\infty}$ in this section. That is to say,

$$
G_{\infty}=\{A \in \operatorname{SL}(2, \mathbb{Z}): A \equiv I \bmod 2\} /\{ \pm I\}
$$

This corresponds to the case when $a=1 / 2$ in the modular equation (1.1). The fundamental domain $\tilde{F}_{\infty}$ is described by $0 \leq \operatorname{Re} \tau \leq 2,|\tau-1 / 2| \geq 1 / 2,|\tau-3 / 2| \geq 1 / 2$ for $\tau \in \mathbb{H}$. A pair of generators of $G_{\infty}$ are given by

$$
T=T_{\infty}=\left(\begin{array}{ll}
1 & 2 \\
0 & 1
\end{array}\right) \quad \text { and } \quad V=\left(\begin{array}{ll}
3 & -2 \\
2 & -1
\end{array}\right) .
$$

Note that $V$ is a parabolic element with fixed point at $\tau=1$ and that $V(0)=2$. Also, let

$$
W=-V^{-1} T=\left(\begin{array}{ll}
1 & 0 \\
2 & 1
\end{array}\right)
$$

It is well known that $\Gamma(2)=G_{\infty}$ is a Fuchsian group uniformizing the thrice punctured sphere $\widehat{\mathbb{C}} \backslash\{0,1, \infty\}$ (see $\S \S 3.4-5$ in Chapter 7 of [1] and $\S \S 4.3$ in Chapter 1 of [15], where the symbol $\lambda$ is used for $\pi_{\infty}$ ). The canonical projection $\pi_{\infty}: \mathbb{H} \rightarrow X$ may be considered to be $\pi_{\infty}: \mathbb{H} \rightarrow \widehat{\mathbb{C}} \backslash\{0,1, \infty\}=\mathbb{C} \backslash\{0,1\}$ with

$$
\begin{equation*}
\pi_{\infty}(0)=1, \quad \pi_{\infty}(\infty)=0 \quad \text { and } \quad \pi_{\infty}(1)=\infty \tag{4.1}
\end{equation*}
$$

by (2.1). Let $\rho: \mathbb{H} \rightarrow Z, \varphi, \psi: Z \rightarrow X$ be as in the proof of Theorem 1.8. Here is a simple but useful observation. The conjugation of a matrix by the Möbius transformation $M_{p}$ is computed by

$$
M_{p}^{-1}\left(\begin{array}{ll}
a & b \\
c & d
\end{array}\right) M_{p}=\left(\begin{array}{cc}
a & b / p \\
p c & d
\end{array}\right) .
$$

Hence, an element $A=\left(\begin{array}{ll}a & b \\ c & d\end{array}\right)$ of $G_{\infty}$ is a member of $G_{\infty}^{M_{p}}$ precisely if $c \equiv 0(\bmod 2 p)$.
4.1. Case $p=2$. We first look at the most classical case when $p=2$. Let $K=G_{\infty} \cap G_{\infty}^{M_{2}}$. Then

$$
A_{1}:=T=\left(\begin{array}{ll}
1 & 2 \\
0 & 1
\end{array}\right), \quad A_{2}:=V^{2}=\left(\begin{array}{ll}
5 & -4 \\
4 & -3
\end{array}\right), \quad A_{3}:=V^{-1} T V=\left(\begin{array}{ll}
-3 & 2 \\
-8 & 5
\end{array}\right)
$$

are side-paring transformations of the hyperbolic polygon $F=\tilde{F}_{\infty} \cup V^{-1}\left(\tilde{F}_{\infty}\right)$ (see Figure (3).

Figure 3. Fundamental domain $F$ of $K=G_{\infty} \cap G_{\infty}^{M_{2}}$.
Therefore, the elements $A_{1}, A_{2}, A_{3}$ generate a subgroup of $G_{\infty}$ of index 2. In view of the forms of $A_{j}$, we see that $A_{j} \in K$ for $j=1,2,3$ and thus we have $K=\left\langle A_{1}, A_{2}, A_{3}\right\rangle$ and $\left|G_{\infty}: K\right|=2$. It is easy to observe that the quotient surface $Z=K \backslash \mathbb{H}$ is conformally equivalent to a four-times punctured sphere. Thus we can assume that $Z=\widehat{\mathbb{C}} \backslash\{0, \infty, 1, b\}$, where $\rho(0)=0, \rho(1)=\infty, \rho(\infty)=1, \rho(1 / 2)=b$. In view of (4.1), we have the conditions $\varphi(0)=1, \varphi(\infty)=\infty, \varphi(1)=\varphi(b)=0$. Here we used the fact that $1 / 2$ is conjugate to $\infty$ under the action of $G_{\infty}$. We note that the extension $\varphi: \hat{Z}=\widehat{\mathbb{C}} \rightarrow \hat{X}=\widehat{\mathbb{C}}$ is a rational map of degree 2. Since $\varphi^{-1}(1)=\{0\}, \varphi^{-1}(\infty)=\{\infty\}$, we see that $\varphi$ takes the values 0 and
$\infty$ with multiplicity 2 . Therefore, $\varphi$ should have the form $\varphi(z)=c z^{2}+1$ for a constant $c \neq 0$. Since $\varphi(1)=0$, we conclude that $c=-1$ and $b=-1$. Hence, $\varphi(z)=1-z^{2}$ under the above normalization.

Next we determine the form of $\psi: Z \rightarrow X$. By the relation $\pi_{\infty}(2 \tau)=\psi(\rho(\tau))$, we have the necessary conditions $\psi(0)=\pi_{\infty}(0)=1, \psi(\infty)=\pi_{\infty}(2)=\pi_{\infty}(0)=1, \psi(1)=$ $\pi_{\infty}(\infty)=0$ and $\psi(-1)=\pi_{\infty}(1)=\infty$. In particular, $\psi^{-1}(0)=\{1\}, \psi^{-1}(\infty)=\{-1\}$. Since $\psi: \hat{Z}=\widehat{\mathbb{C}} \rightarrow \hat{X}=\widehat{\mathbb{C}}$ is a rational map of degree $2, \psi$ has the form

$$
\psi(z)=\frac{c(z-1)^{2}}{(z+1)^{2}}
$$

for a constant $c \neq 0$. Since $\psi(0)=1$, we have $c=1$. We note that $\psi(\infty)=1$ is also satisfied. In this way, the solution $(\alpha, \beta)$ of the modular equation (1.1) with $a=1 / 2, p=2$ is parametrized by

$$
\alpha=\varphi(z)=1-z^{2} \quad \text { and } \quad \beta=\psi(z)=\frac{(z-1)^{2}}{(z+1)^{2}}
$$

Eliminating the variable $z$, we see that

$$
\beta=\left(\frac{1-\sqrt{1-\alpha}}{1+\sqrt{1-\alpha}}\right)^{2}
$$

which is equivalent to 1.2 with $\alpha=r^{2}$ and $\beta=s^{2}$. The polynomial in Theorem 1.8 is given by

$$
P(x, y)=x^{2} y^{2}-2\left(x^{2}-8 x+8\right) y+x^{2}
$$

In this case, the polynomial is not symmetric in $x$ and $y$.
4.2. Case $p=3$. Next we consider the case when $p=3$. We now consider the hyperbolic 10-gon $F=\tilde{F}_{\infty} \cup V\left(\tilde{F}_{\infty}\right) \cup V^{-1}\left(\tilde{F}_{\infty}\right) \cup W\left(\tilde{F}_{\infty}\right)$ with vertices at $0,1 / 3,2 / 5,1 / 2,2 / 3,1,4 / 3$, $3 / 2,2, \infty$ in the counterclockwise order. Then the elements

$$
\begin{aligned}
& A_{1}:=T, \quad A_{2}:=V^{-1} T^{2} V^{-1}=\left(\begin{array}{cc}
5 & -8 \\
12 & -19
\end{array}\right), \quad A_{3}:=V^{-1} T^{-1} V^{-1}=\left(\begin{array}{cc}
-7 & 10 \\
-12 & 17
\end{array}\right), \\
& A_{4}:=V^{-3}=\left(\begin{array}{ll}
-5 & 6 \\
-6 & 7
\end{array}\right), \quad A_{5}:=V^{-1} T V^{-1} T^{-1} V=\left(\begin{array}{cc}
-5 & 2 \\
-18 & 7
\end{array}\right)
\end{aligned}
$$

form side-pairing transformations of $F$ (see Figure 44).
Therefore, $K=\left\langle A_{1}, A_{2}, A_{3}, A_{4}, A_{5}\right\rangle$ is a subgroup of $G_{\infty}$ for which $F$ is a fundamental domain. In view of the forms of $A_{j}$, we observe that $K \subset G_{\infty} \cap G_{\infty}^{M_{3}}$. On the other hand, the elements $V, V^{-1}, W$ are not contained in $G_{\infty}^{M_{3}}$, therefore $K=G_{\infty} \cap G_{\infty}^{M_{3}}$ and $\left|G_{\infty}: K\right|=4$. It is a simple task to see that the quotient surface $Z=K \backslash \mathbb{H}$ is a six-times punctured sphere. Recall that $\varphi, \psi: Z \rightarrow X$ extend to rational functions of degree 4. We may normalize the punctures so that $\rho(\infty)=0, \rho(0)=\rho(2 / 5)=\rho(2)=1, \rho(1 / 3)=$ $\infty, \rho(1 / 2)=\rho(3 / 2)=b, \rho(1)=c, \rho(2 / 3)=\rho(4 / 3)=d$. Thus $\varphi(0)=\pi_{\infty}(\infty)=0$. Similarly, we obtain $\varphi(1)=1, \varphi(\infty)=\infty, \varphi(b)=0, \varphi(c)=\infty, \varphi(d)=1$. We have to

Figure 4. Fundamental domain $F$ of $K=G_{\infty} \cap G_{\infty}^{M_{3}}$.
compute multiplicities of these values. For instance, we have $\varphi^{-1}(\infty)=\{\infty, c\}$. The part of the basic fundamental domain $\tilde{F}_{\infty}$ corresponding to $\infty$ under $\pi_{\infty}$ is the cusp neighbourhood $D=\tilde{F}_{\infty} \cap\{\tau \in \mathbb{H}:|\tau-1|<\varepsilon\}$ for a small enough $\varepsilon>0$. Since $V$ and $V^{-1}$ fix 1 while $W$ sends 1 to $1 / 3$, the multiplicity of $\varphi$ at $\rho(1)=c$ is 3 and that is 1 at $\rho(1 / 3)=\infty$. We write $(\varphi)_{\infty}=3 \cdot c+1 \cdot \infty$ as a divisor for short In the same way, we have $(\varphi)_{0}=3 \cdot b+1 \cdot 0$ and $(\varphi)_{1}=1 \cdot d+3 \cdot 1$. In particular, $\varphi$ may be expressed by

$$
\varphi(z)=e \frac{z(z-b)^{3}}{(z-c)^{3}} \quad \text { and } \quad \varphi(z)-1=e^{\prime} \frac{(z-d)(z-1)^{3}}{(z-c)^{3}}
$$

for constants $e$ and $e^{\prime}$. Since $b, c, d$ are different from 1, we have the unique solution $b=-2, c=-1 / 2, d=-1$ and $e=e^{\prime}=1 / 8$. Hence,

$$
\alpha=\varphi(z)=\frac{z(z+2)^{3}}{(2 z+1)^{3}} .
$$

Next we determine the form of $\omega$ given in Lemma 3.4 Since $S M_{3}$ swaps 0 and $\infty$ (respectively $1 / 3$ and -1 ), $\omega$ swaps $\rho(0)=1$ and $\rho(\infty)=0$ (respectively, $\rho(1 / 3)=\infty$ and $\rho(-1)=\rho(1)=-1 / 2)$. Hence, $\omega(z)=(1-z) /(1+2 z)$. By Lemma 3.4, we obtain

$$
\beta=\psi(z)=1-\varphi(\omega(z))=\frac{z^{3}(z+2)}{2 z+1} .
$$

[^1]We compute

$$
\alpha \beta=\frac{z^{4}(z+2)^{4}}{(2 z+1)^{4}} \quad \text { and } \quad(1-\alpha)(1-\beta)=\frac{\left(1-z^{2}\right)^{4}}{(2 z+1)^{4}}
$$

Note that $\varphi$ and $\psi$ both map the interval $[0,1]$ onto itself homeomorphically. Hence, for $\alpha, \beta \in[0,1]$, we obtain the relation

$$
\begin{equation*}
(\alpha \beta)^{1 / 4}+\{(1-\alpha)(1-\beta)\}^{1 / 4}=1 \tag{4.2}
\end{equation*}
$$

This is known as Legendre's modular equation (see (5.37) in [5] and (4.1.16) in [12]). Formula (4.2) may be transformed to the polynomial equation $P(\alpha, \beta)=0$ as in Theorem 1.8, where

$$
P(x, y)=y^{4}+2 x^{3} y^{3}-2 x y-x^{4} .
$$

This is known as the modular equation of third order in Jacobi's form (see (3.42) in [24]).

## 5. Case of degree 3 in the theory of signature 3

When $q=3$, the standard generators of $G_{3}$ are

$$
T:=T_{6}=\left(\begin{array}{cc}
1 & \sqrt{3} \\
0 & 1
\end{array}\right) \quad \text { and } \quad V:=V_{3}=\left(\begin{array}{cc}
2 & -\sqrt{3} \\
\sqrt{3} & -1
\end{array}\right) .
$$

Recall that $V$ is an elliptic element of order 3 with fixed point at $\tau_{0}:=e^{\pi i / 6}=(\sqrt{3}+i) / 2$. Recall also that the canonical projection $\pi_{3}: \mathbb{H} \rightarrow X=\widehat{\mathbb{C}} \backslash\{0,1\}$ satisfies

$$
\begin{equation*}
\pi_{3}(0)=1, \quad \pi_{3}(\infty)=0 \quad \text { and } \quad \pi_{3}\left(\tau_{0}\right)=\infty \tag{5.1}
\end{equation*}
$$

by (2.1). The following result is useful.
Lemma 5.2. $A \in \operatorname{PSL}(2, \mathbb{R})$ belongs to $G_{3}$ precisely when $A$ is represented by a matrix of the form

$$
\left(\begin{array}{cc}
a & b \sqrt{3}  \tag{5.3}\\
c \sqrt{3} & d
\end{array}\right), \quad a, b, c, d \in \mathbb{Z}, a d-3 b c=1
$$

Proof. We denote by $G$ the Möbius transformations represented by the matrices in (5.3). Then it is well known that $G$ is a proper subgroup of $H_{6}$ (see [17]). On the other hand, it is obvious that $G_{3}$ is contained in $G$. Since $\left|H_{6}: G_{3}\right|=2$, we have $G=G_{3}$ as required.

Figure 5. Fundamental domain $F$ of $K=G_{3} \cap G_{3}^{M_{3}}$.
5.1. Case $p=3$. Since the case of $p=3$ is simpler than that of $p=2$, we start with this case. Let $F=\tilde{F}_{3} \cup V\left(\tilde{F}_{3}\right) \cup V^{2}\left(\tilde{F}_{3}\right)$. Then $F$ is a hyperbolic polygon with six vertices at $0, \sqrt{3} / 3, \sqrt{3} / 2,2 \sqrt{3} / 3, \sqrt{3}, \infty$. Let $K$ be the group generated by the side pairing transformations

$$
A_{1}=T, \quad A_{2}=V T V^{-1}=\left(\begin{array}{cc}
-5 & 4 \sqrt{3} \\
-3 \sqrt{3} & 7
\end{array}\right), \quad A_{3}=V^{-1} T V=\left(\begin{array}{cc}
-2 & \sqrt{3} \\
-3 \sqrt{3} & 4
\end{array}\right)
$$

of $F$ (see Figure 5).
It is easy to see that $K=G_{3} \cap G_{3}^{M_{3}}$ by Lemma 5.2 and that $K$ is torsion-free and satisfies $\left|G_{3}: K\right|=3$. Since the quotient surface $Z=K \backslash \mathbb{H}$ is a four-times punctured sphere, we may normalize $\rho: \mathbb{H} \rightarrow Z$ so that $\rho(\infty)=1, \rho(\sqrt{3} / 3)=a, \rho(2 \sqrt{3} / 3)=b, \rho(0)=$ $\rho(\sqrt{3} / 2)=\rho(\sqrt{3})=0$ and $\rho\left(\tau_{0}\right)=\infty$. By the form of $K$, the element $V$ normalizes $K$; that is, $V^{-1} K V=K$. Thus $V$ induces an analytic automorphism $v: Z \rightarrow Z$. We recall that $V$ is a rotation about $\tau_{0}$ of angle $-2 \pi / 3$. It is clear that $v(0)=0$ and $v(\infty)=\infty$. Since $V$ satisfies $V(\infty)=2 \sqrt{3} / 3, V(2 \sqrt{3} / 3)=\sqrt{3} / 3$ and $V(\sqrt{3} / 3)=\infty$, the map $v$ should have the form $v(z)=e^{-2 \pi i / 3} z$. Hence, $b=e^{-2 \pi i / 3}=-(1+i \sqrt{3}) / 2$ and $a=\bar{b}=(-1+i \sqrt{3}) / 2$. We will determine the forms of rational maps $\varphi, \psi: \hat{Z}=\widehat{\mathbb{C}} \rightarrow \hat{X}=\widehat{\mathbb{C}}$ of degree 3 . Since $\varphi$ has a branch point at $\infty$ of order 3 , we have $\varphi^{-1}(\infty)=\{\infty\}$. In particular, $\varphi$ is a polynomial of degree 3 . We also have $\varphi^{-1}(1)=\{0\}$. Therefore, $\varphi$ should be of the form $1+c z^{3}$ for a constant $c$. Since $\varphi(1)=\pi_{3}(\infty)=0$, we obtain $c=-1$. Next we determine $\omega$ in Lemma 3.4. Since $S M_{3}$ swaps 0 and $\infty$ (respectively $\sqrt{3} / 3$ and $-\sqrt{3} / 3 \equiv 2 \sqrt{3} / 3(\bmod K), \omega$ swaps 1 and 0 (respectively, $a$ and $b$ ), Hence, after some
computations, we get the form $\omega(z)=(1-z) /(1+2 z)$. We now apply Lemma 3.4 to obtain $\psi(z)=1-\varphi(\omega(z))=\omega(z)^{3}=(1-z)^{3} /(1+2 z)^{3}$. In summary, we have

$$
\alpha=\varphi(z)=1-z^{3} \quad \text { and } \quad \beta=\psi(z)=\frac{(1-z)^{3}}{(1+2 z)^{3}} .
$$

We are now able to show Theorem 1.5 easily. The polynomial $P(x, y)$ in Theorem 1.8 is computed as

$$
\begin{aligned}
P(x, y)= & (8 x-9)^{3} y^{3}+3\left(64 x^{3}+504 x^{2}-1053 x+486\right) y^{2} \\
& +3\left(8 x^{3}-171 x^{2}+405 x-243\right) y+x^{3} .
\end{aligned}
$$

5.2. Case $p=2$. Let $F$ be the same as in the previous subsection. We choose side-pairing transformations $A_{1}, A_{2}, A_{3}$ of $F$ at this time as follows:

$$
A_{1}=T, \quad A_{2}=V^{2} T V^{2}=\left(\begin{array}{cc}
1 & -\sqrt{3} \\
2 \sqrt{3} & -5
\end{array}\right), \quad A_{3}=(S V)^{-1} T S V=\left(\begin{array}{cc}
5 & -3 \sqrt{3} \\
4 \sqrt{3} & -7
\end{array}\right) .
$$

Then $A_{1}, A_{2}$ and $A_{3}$ generate the torsion-free group $K=G_{3} \cap G_{3}^{M_{2}}$ and the relation $\left|G_{3}: K\right|=3$ follows (see Figure 6).

Figure 6. Fundamental domain $F$ of $K=G_{3} \cap G_{3}^{M_{2}}$.
We also see that $Z=K \backslash \mathbb{H}$ is a four-times punctured sphere. We normalize the map $\rho: \mathbb{H} \rightarrow Z$ so that $\rho(\infty)=0, \rho(0)=\rho(\sqrt{3})=1$ and $\rho\left(\tau_{0}\right)=-1$. Let $b=\rho(\sqrt{3} / 3)=$ $\rho(2 \sqrt{3} / 3)$ and $c=\rho(\sqrt{3} / 2)$. Since $\pi_{3}(\tau)=\varphi(\rho(\tau))$ has a branch point of order 3 at $\tau=\tau_{0}$, the map $\varphi(z)$ has a branch point of order 3 at $z=-1$; that is, $\varphi^{-1}(\infty)=\{-1\}$. Since
$V(\infty)=2 \sqrt{3} / 3, V^{2}(\infty)=\sqrt{3} / 3$, we have $(\varphi)_{0}=1 \cdot 0+2 \cdot b$. Therefore, the rational map $\varphi$ of degree 3 should have the form

$$
\varphi(z)=\frac{m z(z-b)^{2}}{(z+1)^{3}}
$$

for a constant $m \neq 0$. Observe that $V\left(\tilde{F}_{3}\right)$ and $V^{2}\left(\tilde{F}_{3}\right)$ share the cusps at $\sqrt{3}$ and 0 , respectively, with $\tilde{F}_{3}$. Hence, we see that $(\varphi)_{1}=2 \cdot 1+1 \cdot c$ and

$$
\varphi(z)-1=\frac{m^{\prime}(z-c)(z-1)^{2}}{(z+1)^{3}}
$$

for a constant $m^{\prime} \neq 0$. Then we have $b=-3, c=-2, m=1 / 2$ and $m^{\prime}=-1 / 2$ so that $\varphi(z)=z(z+3)^{2} /\left[2(z+1)^{3}\right]$. Next we will determine $\omega$ in Lemma 3.4. Since $S M_{2}$ swaps 0 and $\infty($ respectively, $\sqrt{3} / 3$ and $-\sqrt{3} / 2 \equiv \sqrt{3} / 2 \bmod K), \omega$ swaps 1 and 0 (respectively, $b=-3$ and $c=-2)$, the form of $\omega$ is $(1-z) /(1+z)$. Now Lemma 3.4 yields $\psi(z)=$ $1-\varphi(\omega(z))=z^{2}(z+3) / 4$. We summarize the results as

$$
\alpha=\varphi(z)=\frac{z(z+3)^{2}}{2(z+1)^{3}} \quad \text { and } \quad \beta=\psi(z)=\frac{z^{2}(z+3)}{4} .
$$

We remark that these expressions of $\alpha$ and $\beta$ are found in Ramanujan's notebook (see [11, Theorem 6.1]). Since

$$
\alpha \beta=\frac{z^{3}(z+3)^{3}}{8(z+1)^{3}} \quad \text { and } \quad(1-\alpha)(1-\beta)=\frac{(1-z)^{3}(z+2)^{3}}{8(z+1)^{3}},
$$

it is now easy to obtain the formula in Theorem 1.3. We also obtain the polynomial $P(x, y)$ in Theorem 1.8 as

$$
P(x, y)=(2 x-1)^{3} y^{3}-3 x\left(4 x^{2}-13 x+10\right) y^{2}+3 x\left(2 x^{2}-10 x+9\right) y-x^{3},
$$

which is equivalent to (1.4).
