

POSITIVE CLUSTER COMPLEXES AND τ -TILTING SIMPLICIAL COMPLEXES OF CLUSTER-TILTED ALGEBRAS OF FINITE TYPE

YASUAKI GYODA

ABSTRACT. In this study, we consider the positive cluster complex, a full subcomplex of a cluster complex the vertices of which are all non-initial cluster variables. In particular, we provide a formula for the difference in face vectors of positive cluster complexes caused by a mutation for finite type. Moreover, we explicitly describe specific positive cluster complexes of finite type and calculate their face vectors. We also provide a method to compute the face vector of an arbitrary positive cluster complex of finite type using these results. Furthermore, we apply our results to the τ -tilting theory of cluster-tilted algebras of finite representation type using the correspondence between clusters and support τ -tilting modules.

1. INTRODUCTION

Cluster algebras are a class of commutative algebras generated by some elements called *cluster variables*, which are given by transformations called *mutations*. The combinatorial structure of cluster variables and mutations is a subject of active research owing to its applications in various mathematical fields. In this study, we consider cluster complexes. These simplicial complexes are combinatorial structures comprising clusters and mutations introduced by Fomin-Zelevinsky [FZ03a]. More precisely, a cluster complex $\Delta(\mathbf{x}, B)$ is a simplicial complex the vertex set of which comprises cluster variables and the simplicial set of which comprises subsets of clusters in a cluster algebra (Definition 2.6). When a cluster algebra arises from a triangulation of a marked surface, the cluster complex is now known to coincide with the *arc complex*, the maximal simplicial set of which consists of triangulations on the marked surface (see [FST08, FT18]). Further, when a cluster algebra arises from a non-valued quiver, its cluster complex coincides with the *support τ -tilting simplicial complex*, the simplicial set of which comprises special modules of the cluster-tilted algebra of the quiver (see [BMR⁺06, AIR14]). Cluster algebras have been applied to hyperbolic geometry and representation theory of algebras, respectively, through these correspondences.

In this study, we focus on the positive cluster complex and the full subcomplex of the cluster complex, the vertices of which are non-initial cluster variables. This work is motivated by the representation theory of algebras. The positive cluster complex appears naturally as a *τ -tilting simplicial complex*, in which maximal simplices are τ -tilting modules. When Λ is hereditary, the τ -tilting Λ -module coincides with the tilting Λ -module. The tilting module is a generalization of the progenerator in the Morita theory and an essential element in the tilting theory. A tilting module T gives rise to an equivalence between a certain torsion class (resp. torsion-free class) of Λ and a certain torsion-free class (resp. torsion class) of $(\text{End}_\Lambda T)^{\text{op}}$ (see [BB80]). The tilting simplicial complex was studied by Riedtmann-Schofield and Unger [RS91, Ung99]. In particular, Riedtmann-Schofield introduced the mutation of tilting modules.

The primary purpose of this paper is to investigate the shape of the positive cluster complex of finite type and apply it to the τ -tilting simplicial complex by using an isomorphism between the cluster and support τ -tilting modules given by Adachi-Iyama-Reiten [AIR14].

We begin with the theory of cluster complexes, by investigating enumerative properties of face vectors of positive cluster complexes of finite type. The face vector is essential in understanding the structure of a simplicial complex. Let (\mathbf{x}, B) be a cluster seed and $\Delta(\mathbf{x}, B)$ a cluster complex associated with (\mathbf{x}, B) . We denote by $\Delta^+(\mathbf{x}, B)$ a positive cluster complex with respect to the initial seed (\mathbf{x}, B) (Definition 3.1). For $v \in \mathbb{Z}^n$, we denote by $[v]_k$ the vector the i th component of which is $(i - k)$ th component of v (and if $i \leq k$, it is 0).

Theorem 1.1 (Theorem 3.5). *We provide the formula for the difference of the face vectors of positive cluster complexes $\Delta^+(\mathbf{x}, B)$ and $\Delta^+(\mathbf{x}', B')$ when (\mathbf{x}', B') is obtained from (\mathbf{x}, B) by a mutation. More precisely, if $x \in \mathbf{x}$ is exchanged with $x' \in \mathbf{x}'$ by the mutation, we have*

$$(1.1) \quad f(\Delta^+(\mathbf{x}, B)) - f(\Delta^+(\mathbf{x}', B')) = [f(\Delta^+(\mathbf{x}' - \{x'\}, B_{\setminus\{x'\}}))]_1 - [f(\Delta^+(\mathbf{x} - \{x\}, B_{\setminus\{x\}}))]_1,$$

where $f(\Delta^+(\mathbf{x}, B))$ is the face vector of $\Delta^+(\mathbf{x}, B)$.

Equation (1.1) implies that the difference between two face vectors of positive cluster complexes obtained by a mutation equals that of lower ranks. Moreover, by using Theorem 1.1, we provide a sufficient condition for the invariance of face vectors under a mutation.

Corollary 1.2 (Corollary 3.8). *If B' is obtained from B by a sink or source mutation, then the face vectors of $\Delta^+(\mathbf{x}, B)$ and $\Delta^+(\mathbf{x}', B')$ coincide.*

Moreover, the following corollary follows immediately from Corollary 1.2.

Corollary 1.3 (Corollary 3.9). *Let B and B' be skew-symmetrizable matrices. If corresponding valued quivers Q_B and $Q_{B'}$ have the same Dynkin diagram as the underlying graph, then the face vectors of $\Delta^+(\mathbf{x}, B)$ and $\Delta^+(\mathbf{x}', B')$ coincide.*

An “initial condition” is required along with the difference between two face vectors by a mutation to calculate the face vector of a positive cluster complex. Therefore, we need to know the face vectors of specific positive cluster complexes. For the classical finite type, we solve this problem by providing explicit descriptions of positive cluster complexes in a particular case.

Theorem 1.4 (Theorems 4.4, 4.15, 4.28). *We give an explicit description of a positive cluster complex $\Delta^+(\mathbf{x}, B)$ when the corresponding valued quiver Q_B of B is a linearly oriented Dynkin quiver of type A, B, C, D . Specifically, if Q_B is a linearly oriented A_n type, $\Delta^+(\mathbf{x}, B)$ is isomorphic to a cone of the (dual) associahedron with the rank $n - 1$.*

We calculate face vectors of positive cluster complexes of classical type from the explicit descriptions in Theorem 1.4.

Theorem 1.5 (Theorem 5.1). *Suppose that the underlying graph of the valued quiver Q_B is A_n, B_n, C_n or D_n type. Then, the k th entry of $f^+(\Delta(\mathbf{x}, B))$ is given by the following list:*

$$(A_n) \frac{1}{k+2} \binom{n}{k+1} \binom{n+k+1}{k+1},$$

$$(B_n) \binom{n}{k+1} \binom{n+k}{k+1},$$

(C_n) same as B_n type,

$$(D_n) \binom{n}{k+1} \binom{n+k-1}{k+1} + \binom{n-1}{k} \binom{n-k-2}{k} - \frac{1}{n-1} \binom{n-1}{k} \binom{n+k-1}{k+1}.$$

For exceptional finite type, we calculate face vectors directly by using a calculator.

Theorem 1.6 (Theorem 5.2). *Suppose that the underlying graph of the valued quiver Q_B is E_6, E_7, E_8, F_4 , or G_2 type. Then, $f^+(\Delta(\mathbf{x}, B))$ is given by the following list:*

$$(E_6) (1, 36, 300, 1035, 1720, 1368, 418),$$

$$(E_7) (1, 63, 777, 3927, 9933, 13299, 9009, 2431),$$

$$(E_8) (1, 120, 2135, 15120, 54327, 108360, 121555, 71760, 17342),$$

$$(F_4) (1, 24, 101, 144, 66),$$

$$(G_2) (1, 6, 5).$$

By Theorems 1.5, 1.6 and Theorem 1.1, we can obtain the face vector of any positive cluster complex of finite type by summing the differences by mutations to the face vector of a computable such complex. We explain this point precisely in Section 5 with a concrete example.

By applying these results to positive cluster complexes of skew-symmetric finite type and identifying positive cluster complexes with τ -tilting simplicial complexes, we provide some results on τ -tilting theory. First, we have the counterpart of Theorem 1.1.

Theorem 1.7 (Corollary 6.8). *Let Λ and Λ' be cluster-tilted algebras such that $Q_{\Lambda'}$ is obtained from Q_{Λ} by a quiver mutation. Then, we provide a formula for the difference of the numbers of basic τ -rigid modules of Λ and Λ' with k direct summands.*

As the counterpart of Corollary 1.2, we have the following corollary.

Corollary 1.8 (Corollary 6.9). *Let Λ and Λ' be cluster-tilted algebras such that Q'_{Λ} is obtained from Q_{Λ} by a sink or source mutation. Then, Λ and Λ' have the same number of basic τ -rigid modules with k direct summands for any $0 \leq k \leq |Q_{\Lambda}|$.*

The following corollary is a special case of Corollary 1.8, which has been given in several works [MRZ03, Eno20].

Corollary 1.9 (Corollary 6.10). *Let Q be a simply laced Dynkin quiver. For any $0 \leq k \leq |Q|$, the number of basic rigid KQ -modules with k direct summands depends only on the underlying graph of Q .*

Next, by applying Theorem 1.4 to A_n or D_n type, we have the following.

Theorem 1.10 (Corollaries 6.11, 6.14). *We describe a τ -tilting simplicial complex of kQ when Q is a linearly oriented quiver of Dynkin A_n or D_n type. Specifically, if Q is linearly oriented Dynkin A_n type, then the τ -tilting simplicial complex of KQ is isomorphic to a cone of the support τ -tilting simplicial complex of KQ' , where Q' is of the Dynkin A_{n-1} type.*

Moreover, by using the h -vector and the shellability of the τ -tilting complex, we prove a theorem on the Hasse quiver $\text{Hasse}(\tau\text{-tilt}\Lambda)$ of a τ -tilting module along with an associated corollary. For an algebra Λ , let $T(M)$ be the number of arrows that end at $M \in \text{Hasse}(\tau\text{-tilt}\Lambda)$. Set

$$(1.2) \quad h_i(\Lambda) = \#\{M \in \tau\text{-tilt}\Lambda \mid T(M) = i\}.$$

Theorem 1.11 (Corollary 6.21). *Let Λ and Λ' be cluster-tilted algebras of finite representation type. If $Q_{\Lambda'}$ is obtained from Q_{Λ} by a sink or source quiver mutation, then $h_i(\Lambda) = h_i(\Lambda')$ holds for any i .*

Corollary 1.12 (Corollary 6.22). *Let Λ and Λ' be finite dimensional hereditary algebras. If Q_{Λ} and $Q_{\Lambda'}$ have the same underlying graph, then $h_i(\Lambda) = h_i(\Lambda')$ holds for any i .*

In Appendix A, we provide another proof of the A_n case of Theorem 1.4 directly, without identifying a positive cluster complex with a τ -tilting simplicial complex.

Organization. The remainder of this work is organized as follows. In Section 2, we describe the basics of cluster algebra. In Section 3, we discuss the properties of positive cluster complexes. In Section 4, we provide specific descriptions of some special positive cluster complexes of finite type. Building on these results, we provide a method for computing the face vectors of general finite type positive cluster complexes in Section 5. In Section 6, we apply the results of Sections 3, 4, and 5 to the representation theory of algebras.

Acknowledgments. The author thanks Haruhisa Enomoto for the discussion on positive complexes. The author also thanks Osamu Iyama, Sota Asai, and Aaron Chan for their helpful comments at the Tokyo-Nagoya Algebra Seminar. Iyama also checked the paper and commented on its structure. The author would also like to thank Tomoki Nakanishi. This work was supported by JSPS KAKENHI Grant number JP20J12675.

2. CLUSTER STRUCTURES AND THEIR PROPERTIES

2.1. Cluster patterns and cluster complexes. We start by recalling the definitions of seed mutation and cluster patterns according to [FZ07]. Let $n \in \mathbb{Z}_{\geq 0}$ and \mathcal{F} be a rational function field of n indeterminates. A *labeled seed* is a pair (\mathbf{x}, B) , where

- $\mathbf{x} = (x_1, \dots, x_n)$ is an n -tuple of elements of \mathcal{F} forming a free generating set of \mathcal{F} ,
- $B = (b_{ij})$ is a *skew-symmetrizable* $n \times n$ integer matrix which is. Then, there exists a positive integer diagonal matrix S such that SB is skew-symmetric. Also, we call S a *skew-symmetrizer* of B .

We say that \mathbf{x} is a *cluster*, and we refer to x_i and B as the *cluster variables* and the *exchange matrix*, respectively.

We adopt the notation $[b]_+ = \max(b, 0)$ for an integer b . Let (\mathbf{x}, B) be a labeled seed, and let $k \in \{1, \dots, n\}$. The *seed mutation μ_k in direction k* transforms (\mathbf{x}, B) into another labeled seed $\mu_k(\mathbf{x}, B) = (\mathbf{x}', B')$ defined as follows.

- The entries of $B' = (b'_{ij})$ are given by

$$(2.1) \quad b'_{ij} = \begin{cases} -b_{ij} & \text{if } i = k \text{ or } j = k, \\ b_{ij} + [b_{ik}]_+ b_{kj} + b_{ik} [-b_{kj}]_+ & \text{otherwise.} \end{cases}$$

- The cluster variables $\mathbf{x}' = (x'_1, \dots, x'_n)$ are given by

$$(2.2) \quad x'_j = \begin{cases} \frac{\prod_{i=1}^n x_i^{[b_{ik}]_+} + \prod_{i=1}^n x_i^{[-b_{ik}]_+}}{x_k} & \text{if } j = k, \\ x_j & \text{otherwise.} \end{cases}$$

Specially, if $b_{jk} \geq 0$ (resp. $b_{jk} \leq 0$) for all j , then we say that μ_k is a *sink mutation* (resp. *source mutation*). Let \mathbb{T}_n be the n -regular tree in which edges are labeled by the numbers $1, \dots, n$ such that the n edges emanating from each vertex have different labels. We write $t \xrightarrow{k} t'$ to indicate that vertices $t, t' \in \mathbb{T}_n$ are joined by an edge labeled by k . We fix an arbitrary vertex $t_0 \in \mathbb{T}_n$, which is referred to as the *rooted vertex*.

A *cluster pattern* is an assignment of a labeled seed $\Sigma_t = (\mathbf{x}_t, B_t)$ to every vertex $t \in \mathbb{T}_n$ such that the labeled seeds Σ_t and $\Sigma_{t'}$ assigned to the endpoints of any edge $t \xrightarrow{k} t'$ are obtained from each other by the seed mutation in direction k . We denote by $P: t \mapsto \Sigma_t$ in this assignment. The elements of Σ_t are denoted as follows:

$$(2.3) \quad \mathbf{x}_t = (x_{1;t}, \dots, x_{n;t}), \quad B_t = (b_{ij;t}).$$

In particular, at t_0 , we denote

$$(2.4) \quad \mathbf{x} = \mathbf{x}_{t_0} = (x_1, \dots, x_n), \quad B = B_{t_0} = (b_{ij}).$$

The degree n of the regular tree \mathbb{T}_n is called the *rank* of a cluster pattern P . We also denote by $P(\mathbf{x}, B)$ the cluster pattern with the initial seed (\mathbf{x}, B) .

Example 2.1. An example of mutations in the case of A_2 is provided below. Let $n = 2$. We consider a tree \mathbb{T}_2 with edges labeled as follows:

$$(2.5) \quad \cdots \xrightarrow{1} t_0 \xrightarrow{2} t_1 \xrightarrow{1} t_2 \xrightarrow{2} t_3 \xrightarrow{1} t_4 \xrightarrow{2} t_5 \xrightarrow{1} \cdots .$$

We set $B = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}$ as the initial exchange matrix at t_0 . Then, coefficients and cluster variables are given as in Table 1 [FZ07, Example 2.10].

t	B_t	\mathbf{x}_t
0	$\begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}$	$x_1 \quad x_2$
1	$\begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}$	$x_1 \quad \frac{x_1 + 1}{x_2}$
2	$\begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}$	$\frac{x_1 + x_2 + 1}{x_1 x_2} \quad \frac{x_1 + 1}{x_2}$
3	$\begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}$	$\frac{x_1 + x_2 + 1}{x_1 x_2} \quad \frac{x_2 + 1}{x_1}$
4	$\begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}$	$x_2 \quad \frac{x_2 + 1}{x_1}$
5	$\begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}$	$x_2 \quad x_1$

TABLE 1. Exchange matrices and cluster variables in type A_2

To define the class of cluster patterns of finite type, we define the non-labeled seeds according to [FZ07]. For a cluster pattern P , we introduce the following equivalence relations of labeled seeds. We say that

$$\Sigma_t = (\mathbf{x}_t, B_t), \quad \mathbf{x}_t = (x_{1;t}, \dots, x_{n;t}), \quad B_t = (b_{ij;t})$$

and

$$\Sigma_s = (\mathbf{x}_s, B_s), \quad \mathbf{x}_s = (x_{1;s}, \dots, x_{n;s}), \quad B_s = (b_{ij;s})$$

are equivalent if there exists a permutation σ of indices $1, \dots, n$ such that

$$(2.6) \quad x_{i;s} = x_{\sigma(i);t}, \quad b_{ij;s} = b_{\sigma(i),\sigma(j);t}$$

for all i and j . We denote by $[\Sigma]$ the equivalence classes represented by a labeled seed Σ and refer to this as the *non-labeled seed*. We define a (*non-labeled*) *clusters* $[\mathbf{x}]$ as the set ignoring the order of a labeled cluster. Abusing notation, we abbreviate $[\mathbf{x}]$ to \mathbf{x} . We can define the *mutation*, the *sink mutation*, and the *source mutation* μ_x of a non-labeled seed in the direction of a cluster variable x by using a mutation of a labeled seed.

Remark 2.2. By [CL20, Proposition 3], if we assume that the first equation in (2.6) holds, then we have the second equation in (2.6). Therefore, non-labeled clusters can be regarded as clusters of non-labeled seeds. Furthermore, “an exchange matrix B associated with \mathbf{x} ” is well-defined.

Definition 2.3. The *exchange graph* of a cluster pattern is the connected regular graph the vertices of which are the non-labeled seeds of the cluster pattern and the edges of which connect the non-labeled seeds related by a single mutation.

Using the exchange graph, we define cluster patterns of finite type.

Definition 2.4. A cluster pattern P is of *finite type* if the exchange graph of P is finite.

Remark 2.5. If P is of finite type, the initial non-labeled seed $[(\mathbf{x}, B)]$ is mutation equivalent to $[(\mathbf{x}', B')]$ such that $A(B')$ is a finite Cartan matrix ([FZ03a, Theorem 1.4]), where $A(B') = (a_{ij})$ is defined as

$$a_{ij} = \begin{cases} 2 & \text{if } i = j; \\ -|b'_{ij}| & \text{if } i \neq j. \end{cases}$$

We call B' an exchange matrix of *tree finite type*.

Let us introduce cluster complexes as defined in [FZ03a].

Definition 2.6. Let $P(\mathbf{x}, B)$ be a cluster pattern. We define a *cluster complex* $\Delta(\mathbf{x}, B)$ as a simplicial complex the vertex set of which consists of cluster variables and in which simplices are subsets of each cluster.

If $P(\mathbf{x}, B)$ is of finite type, then we say that the cluster complex $\Delta(\mathbf{x}, B)$ is of *finite type*. A cluster complex of finite type has finitely many simplices. We say that x is *compatible* with x' if $\{x, x'\}$ is a simplex of $\Delta(\mathbf{x}, B)$.

Example 2.7. We consider the cluster pattern in Example 2.1 and provide a cluster complex corresponding to this cluster pattern in Figure 1.

FIGURE 1. Cluster complex of A_2 type

We note that, if $[(\mathbf{x}, B)]$ is mutation equivalent to $[(\mathbf{x}', B')]$ as non-labeled seeds, then we have $\Delta(\mathbf{x}, B) \cong \Delta(\mathbf{x}', B')$. Hence, we can define the *cluster complex of X_n type* as a cluster complex $\Delta(\mathbf{x}, B)$, where B is mutation equivalent to an exchange matrix of tree X_n type under an appropriate permutation of indices. We denote by $\Delta(X_n)$ the cluster complex of X_n type.

2.2. Quiver mutations. A cluster pattern can be constructed using a quiver Q instead of an exchange matrix B ; we explain this construction along the lines of [Kel10] and [Kel12]. First, we consider the case in which B is skew-symmetric. For an $n \times n$ skew-symmetric integer matrix $B = (b_{ij})$, we define a quiver Q_B as follows.

- The cardinality of the set of vertices for Q_B is n , and these vertices are numbered from 1 to n .
- The number of arrows from i to j in Q_B is b_{ij} . If negative, we assume that there are $-b_{ij}$ arrows from j to i .

Let $Q' = \mu_k(Q)$ be a quiver obtained from Q by the following steps.

- (1) For any path $i \rightarrow k \rightarrow j$, add an arrow $i \rightarrow j$,
- (2) reverse all arrows incident to k ,
- (3) remove a maximal set of disjoint 2-cycles.

We refer to this transformation from Q to Q' as the *quiver mutation in direction k* . Then, we have $Q_{\mu_k(B)} = \mu_k(Q_B)$. Therefore, quivers and quiver mutations can be used rather than of skew-symmetric exchange matrices and matrix mutations.

Example 2.8. A quiver Q_B corresponding to $B = \begin{bmatrix} 0 & -1 & -2 \\ 1 & 0 & 4 \\ 2 & -4 & 0 \end{bmatrix}$ is

where the numbers on the arrows represent the number of arrows; values of 1 arrow are omitted for simplicity. Then, we obtain the following quiver from Q_B by mutating in direction 3:

Next, we generalize quivers and quiver mutations to a form that can be used even when the corresponding matrix B is skew-symmetrizable. Let Q_0 be the set of vertices of Q and Q_1 the set of arrows of Q . For an $n \times n$ skew-symmetrizable integer matrix B , we define a *valued quiver* $Q_B = (Q_B, v, d)$ as follows.

- The cardinality of the set of vertices for Q_B is n , and these vertices are numbered from 1 to n .
- The quiver Q_B has an arrow from i to j if $b_{ij} > 0$.
- A function $v: (Q_B)_1 \rightarrow \mathbb{Z}^2$ transfers $(\alpha: i \rightarrow j) \mapsto (b_{ij}, -b_{ji})$.
- A function $d: (Q_B)_0 \rightarrow \mathbb{Z}_{>0}$ satisfies the following condition: for each arrow $\alpha: i \rightarrow j$, we have

$$d(i)v(\alpha)_1 = v(\alpha)_2d(j),$$

$$\text{where } v(\alpha) = (v(\alpha)_1, v(\alpha)_2).$$

We define $\mu_k(Q_B) := Q_{\mu_k(B)}$ and refer to this construction as the *valued quiver mutation in direction k* .

Example 2.9. A valued quiver Q_B corresponding to $B = \begin{bmatrix} 0 & -2 & -4 \\ 1 & 0 & 4 \\ 2 & -4 & 0 \end{bmatrix}$ is

where the pair of integers on the arrow α is $v(\alpha)$, and $d(1) = 1, d(2) = 2, d(3) = 2$. Then, we obtain the following quiver from Q_B by mutating in direction 3.

$$1 \begin{array}{c} \xleftarrow{(4,2)} \\ \xleftarrow{(9,18)} \end{array} 2 \begin{array}{c} \xleftarrow{(4,4)} \\ \xleftarrow{(4,4)} \end{array} 3 .$$

By definition, $d(i)$ of Q_B corresponds with the (i, i) entry of the skew-symmetrizer S of B . Moreover, by Remark 2.5, if a cluster pattern $P(\mathbf{x}, B)$ is of finite type, then Q_B is mutation equivalent to a valued quiver in which the underlying graph is that shown in Figure 2 (we omit labels $(1,1)$). We note that a sink (resp. source)

FIGURE 2. Underlying graph of finite type

mutation, which is defined in Subsection 2.1, is a mutation in direction i , which is a sink (resp. source) vertex in Q_B .

2.3. Basic properties of cluster complexes. Here, we introduce some basic and useful properties of cluster complexes.

First, we recall the definition of closed stars and links and cones.

Definition 2.10. Let K be a simplicial complex and v a vertex of K .

- (1) The *closed star of v* is a (not necessarily full) subcomplex $\text{st}_K(v)$ of K the simplices of which are all the simplices σ of K such that $\sigma \cup \{v\}$ is a simplex of K .
- (2) The *link of v* is a (not necessarily full) subcomplex $\text{lk}_K(v)$ of K defined by $\text{lk}_K(v) = \{\sigma \in \text{st}_K(v) \mid v \notin \sigma\}$; that is, simplices of $\text{lk}_K(v)$ are all the simplices σ of K with $v \notin \sigma$ such that $\sigma \cup \{v\}$ is a simplex of K .
- (3) Let K be a simplicial complex and v a vertex of K . Let $*$ be a vertex disjoint from K . The *cone of K* is a simplicial complex $\text{cone}(K)$ in which simplices are σ and $\sigma \cup \{*\}$ for each simplex σ of K .

The following property can be verified straightforwardly from Definition 2.10.

Lemma 2.11. *Let K be a simplicial complex and v a vertex of K . Then, $\text{st}_K(v)$ is isomorphic to $\text{cone}(\text{lk}_K(v))$ as simplicial complexes.*

The following property is fundamental:

Lemma 2.12. *Let $\Delta(\mathbf{x}, B)$ be a cluster complex and v a vertex of $\Delta(\mathbf{x}, B)$. Then, $\text{st}_{\Delta(\mathbf{x}, B)}(v)$ and $\text{lk}_{\Delta(\mathbf{x}, B)}(v)$ are full subcomplexes of $\Delta(\mathbf{x}, B)$.*

This lemma is proven using the following lemma.

Lemma 2.13 ([CL20, Corollary 5]). *Let X be a set of cluster variables satisfying the following condition.*

$$(2.7) \quad \text{For any pair } x, x' \in X, \text{ there exists a cluster } \mathbf{x} \text{ such that } x, x' \in \mathbf{x}.$$

Then, there exists a cluster such that it contains X .

Proof of Lemma 2.12. Here, we prove that $\text{st}_{\Delta(\mathbf{x}, B)}(v)$ is a full subcomplex of $\Delta(\mathbf{x}, B)$. It suffices to show that if X and X' are simplices of $\text{st}_{\Delta(\mathbf{x}, B)}(v)$, and $X \cup X'$ is a simplex of $\Delta(\mathbf{x}, B)$, then $X \cup X'$ is a simplex of $\text{st}_{\Delta(\mathbf{x}, B)}(v)$. By definition of the closed star, $X \cup X' \cup \{v\}$ satisfies (2.7). Therefore, by Lemma 2.13, $X \cup X' \cup \{v\}$ is a simplex of $\Delta(\mathbf{x}, B)$ and $X \cup X'$ is a simplex of $\text{st}_{\Delta(\mathbf{x}, B)}(v)$. Similarly, we can prove the fullness of $\text{lk}_{\Delta(\mathbf{x}, B)}(v)$. \square

Now, we generalize the definition of the cone.

Definition 2.14. Let K, L be simplicial complexes with a disjoint vertex set. The *join of K and L* is a simplicial complex $\text{join}(K, L)$ the vertex set of which is $K \cup L$ and the simplices of which are all disjoint unions of a simplex of K and that of L .

We note that $\text{join}(K, L, M)$ is well-defined by the associativity of joining. We remark that, if $B = B_1 \oplus B_2$ (i.e., $Q_B = Q_{B_1} \cup Q_{B_2}$), then we have

$$(2.8) \quad \Delta(\mathbf{x}, B) \cong \text{join}(\Delta(\mathbf{x}_1, B_1), \Delta(\mathbf{x}_2, B_2)),$$

where $\mathbf{x}_1, \mathbf{x}_2$ are subsets of \mathbf{x} corresponding to B_1, B_2 , respectively.

3. POSITIVE CLUSTER COMPLEXES

3.1. Positive cluster complexes and basic property. In this section, we define the special subcomplex of a cluster complex called the *positive cluster complex*.

Definition 3.1. Let $\Delta(\mathbf{x}, B)$ be a cluster complex. We define a *positive cluster complex* $\Delta^+(\mathbf{x}, B)$ as a full subcomplex of $\Delta(\mathbf{x}, B)$ the vertex set of which consists of all non-initial cluster variables.

The term ‘‘positive’’ comes from the positive roots of a finite root system. If B is a bipartite matrix of tree finite type, then there is a canonical bijection between $\Delta^+(\mathbf{x}, B)$ and simplices consisting of positive roots of a *generalized associahedron* [FZ03a, Theorem 1.9]. In fact, [Arm09, FKT13] use the term the ‘‘positive cluster complex’’ in this sense. In this paper, we use this term more generally, even if B is not bipartite or not of tree finite type. By the definition of the positive cluster complex, if $B = B_1 \oplus B_2$, then we have

$$(3.1) \quad \Delta^+(\mathbf{x}, B) \cong \text{join}(\Delta^+(\mathbf{x}_1, B_1), \Delta^+(\mathbf{x}_2, B_2)).$$

Example 3.2. In Example 2.7, the set of positive simplices associated with the initial cluster \mathbf{x} is given as follows.

$$\left\{ \emptyset, \left\{ \frac{x_2 + 1}{x_1} \right\}, \left\{ \frac{x_1 + x_2 + 1}{x_1 x_2} \right\}, \left\{ \frac{x_1 + 1}{x_2} \right\}, \right. \\ \left. \left\{ \frac{x_2 + 1}{x_1}, \frac{x_1 + x_2 + 1}{x_1 x_2} \right\}, \left\{ \frac{x_1 + 1}{x_2}, \frac{x_1 + x_2 + 1}{x_1 x_2} \right\} \right\}$$

We recall the *face vector*¹, $f(\Delta) = (f_{-1}, f_0, \dots, f_n)$. This vector is associated with a simplicial complex Δ , and f_i represents the number of i -dimensional simplices. We also consider the face vector associated with a set of simplices (necessarily not a simplicial complex) herein. In this case, since the empty set may not be included in a set of simplices, f_{-1} is not always equal to 1. This vector can be defined when a simplicial complex or a set of simplices is finite.

We remark that if

$$(3.2) \quad \Delta \cong \text{join}(\Delta', \Delta''),$$

$f(\Delta') = (1, a_0, a_1, \dots, a_n)$ and $f(\Delta'') = (1, b_0, b_1, \dots, b_m)$, then we have

$$(3.3) \quad f(\Delta) = \left(1, \sum_{i+j=-1} a_i b_j, \sum_{i+j=0} a_i b_j, \dots, \sum_{i+j=m+n} a_i b_j \right),$$

where $-1 \leq i \leq n$, $-1 \leq j \leq m$, and $a_{-1} = b_{-1} = 1$.

A proof of a fundamental property of positive cluster complexes is given below.

Proposition 3.3. *Positive cluster complexes are pure.*

This property is proven by the following lemma:

Lemma 3.4. *Let (\mathbf{x}_t, B_t) be a seed in which cluster contains the initial cluster variable x_i . By a seed mutation of (\mathbf{x}_t, B_t) into a direction corresponding to x_i , x_i is exchanged with a non-initial cluster variable.*

Proof. We use the d -compatibility degree or f -compatibility degree, which are introduced in [CL20] and [FG19], respectively. As there is no significant difference in the proofs between the two, we prove the statement using the f -compatibility degree. Let x be a cluster variable exchanged with x_i by the mutation in the statement. We assume x is an initial cluster variable. Then, since both x_i and x are contained in the initial cluster, the compatibility degree $(x_i \parallel x) = 0$ by [FG19, Theorem 4.18]. However, since x_i is exchanged with x by a mutation, we have $(x_i \parallel x) = 1$ by [FG19, Theorem 4.22], which is a contradiction. \square

Proof of Proposition 3.3. It suffices to show that for any subset X consisting of non-initial cluster variables of a cluster \mathbf{x}_t , there exists a cluster \mathbf{x}_s such that $X \subset \mathbf{x}_s$ and \mathbf{x}_s do not contain initial cluster variables. Lemma 3.4 shows that \mathbf{x}_s satisfying this condition can be obtained by replacing all the initial cluster variables in \mathbf{x}_t with mutations. \square

3.2. Difference of face vectors by mutation. We use the following notation to describe the main theorem of this section. Let (\mathbf{x}, B) be a seed, and X a subset of \mathbf{x} . Then, we denote by $B_{\setminus X}$ the submatrix of B obtained by removing all entries in positions corresponding to X from B . The main theorem of this subsection is the following one.

¹In cluster algebra theory, the term “ f -vector” is used to refer to the exponential vector of the principal term of a F -polynomial. Therefore, we use this name throughout to avoid confusion.

Theorem 3.5. *Let $\Delta(\mathbf{x}, B)$ be a cluster complex of finite type. We assume that $[(\mathbf{x}', B')]$ is obtained from $[(\mathbf{x}, B)]$ by a mutation in direction x (and $x \mapsto x'$). Then, we have*

$$(3.4) \quad f(\Delta^+(\mathbf{x}, B)) - f(\Delta^+(\mathbf{x}', B')) = [f(\Delta^+(\mathbf{x}' - \{x'\}, B_{\setminus\{x'\}}))]_1 - [f(\Delta^+(\mathbf{x} - \{x\}, B_{\setminus\{x\}}))]_1.$$

This theorem indicates an amount of increase of positive faces by a mutation.

The complement of the set of simplices of a positive cluster complex is the set of simplices such that each simplex contains at least one element in the initial cluster. We cite some useful lemmas below.

Lemma 3.6 ([FZ03b, Proposition 3.5.3]). *For any cluster complex $\Delta(\mathbf{x}, B)$ of finite type and $x \in \mathbf{x}$, $\text{st}_{\Delta(\mathbf{x}, B)}(x)$ is isomorphic to a cone of $\Delta(\mathbf{x} - \{x\}, B_{\setminus\{x\}})$. In particular, we have a bijection between the set of simplices of $\Delta(\mathbf{x}, B)$ including $\{x\}$ and that of $\Delta(\mathbf{x} - \{x\}, B_{\setminus\{x\}})$. Furthermore, if the face vector of the former can be defined and is f , then that of the latter is $[f]_{-1}$.*

Furthermore, Lemma 3.6 can be generalized as follows.

Lemma 3.7 ([FZ03b, Proposition 3.6]). *For any cluster complex $\Delta(\mathbf{x}, B)$ of finite type and $X \subset \mathbf{x}$ such that $|X| = k$, we have a bijection between the set of simplices of $\Delta(\mathbf{x}, B)$ including X and that of $\Delta(\mathbf{x} - X, B_{\setminus X})$. Furthermore, if the face vector of the former can be defined and is f , then that of the latter is $[f]_{-k}$.*

This allows us to prove Theorem 3.5.

Proof of Theorem 3.5. We may assume that $\mathbf{x} = X \sqcup x$, $\mathbf{x}' = X \sqcup x'$, and $X = \{x_1, \dots, x_{n-1}\}$. For any set $Y \subset \mathbf{x}$, let $\widehat{\Delta}_Y$ be the set of simplices of $\Delta(\mathbf{x}, B)$ such that each simplex contains at least one element in Y . Moreover, for any subset $Y' \subset Y$, let $\underline{\Delta}_{Y' \subset Y}$ be the set of simplices of $\Delta(\mathbf{x}, B)$ such that each simplex contains all elements in Y' and does not contain any elements in $Y \setminus Y'$. Since (\mathbf{x}, B) is mutation equivalent to (\mathbf{x}', B') , we have $\Delta(\mathbf{x}, B) \cong \Delta(\mathbf{x}', B')$. Since $\Delta^+(\mathbf{x}, B) = \Delta(\mathbf{x}, B) - \widehat{\Delta}_{\mathbf{x}}$ and $\Delta^+(\mathbf{x}', B') = \Delta(\mathbf{x}', B') - \widehat{\Delta}_{\mathbf{x}'}$ and

$$(3.5) \quad \widehat{\Delta}_{\mathbf{x}} = \widehat{\Delta}_X \sqcup \underline{\Delta}_{\{x\} \subset \mathbf{x}},$$

$$(3.6) \quad \widehat{\Delta}_{\mathbf{x}'} = \widehat{\Delta}_X \sqcup \underline{\Delta}_{\{x'\} \subset \mathbf{x}'},$$

the difference of face vectors of $\Delta^+(\mathbf{x}, B)$ and $\Delta^+(\mathbf{x}', B')$ is

$$f(\underline{\Delta}_{\{x'\} \subset \mathbf{x}'}) - f(\underline{\Delta}_{\{x\} \subset \mathbf{x}}).$$

Therefore, by Lemma 3.6, we have a bijection between simplices of $\underline{\Delta}_{\{x\} \subset \mathbf{x}}$ and that of $\text{cone}(\Delta^+(\mathbf{x} - \{x\}, B_{\setminus\{x\}}))$. This suffices to complete the proof. \square

By Theorem 3.5, we have the following corollary.

Corollary 3.8. *Let $\Delta(\mathbf{x}, B)$ be a cluster complex of finite type. If $[\Sigma_{t'}]$ is obtained from $[\Sigma_t]$ by a sink or source mutation, then for any $-1 \leq k \leq n - 1$, $\Delta^+(\mathbf{x}_t, B_t)$ and $\Delta^+(\mathbf{x}_{t'}, B_{t'})$ have the same number of k -simplices.*

We also have the following corollary.

Corollary 3.9. *Let B and B' be skew-symmetrizable matrices. If Q_B and $Q_{B'}$ have the same underlying graph in Figure 2, then, for any $-1 \leq k \leq n - 1$, $\Delta^+(\mathbf{x}_t, B_t)$ and $\Delta^+(\mathbf{x}_{t'}, B_{t'})$ have the same number of k -simplices.*

Proof. We can obtain B' from B by a sequence of sink or source mutations and a permutation of indices ([FZ03a, Proposition 9.2]). Therefore, we have the statement using Corollary 3.8. \square

Example 3.10. We set

$$B = \begin{bmatrix} 0 & -1 & 1 \\ 1 & 0 & 0 \\ -1 & 0 & 0 \end{bmatrix}, \quad Q_B = 1 \overset{\curvearrowright}{\rightarrow} 2 \rightarrow 3,$$

and consider a cluster pattern with the initial seed $(\mathbf{x} = (x_1, x_2, x_3), Q_B)$. This is of A_3 type. Figure 3 provides a cluster complex of this cluster pattern. In Figure

FIGURE 3. Cluster complex of A_3 type

3, vertices are represented by the diagonals of a hexagon. This is an identification of a cluster complex with the corresponding *arc complex* (see Subsection 4.1). We consider a mutation of $(\mathbf{x} = (x_1, x_2, x_3), Q_B)$ in direction 3. A non-labeled seed obtained by this mutation is given as

$$\left(\mathbf{x}' = \left(x_1, x_2, \frac{x_1 + 1}{x_3} \right), Q_B = 1 \overset{\curvearrowright}{\rightarrow} 2 \rightarrow 3, \right).$$

In Figure 3, a simplex corresponding to \mathbf{x} is a triangle that is the right-hand neighbor of the central triangle, and \mathbf{x}' is the right-hand neighbor of \mathbf{x} . In Figure 4, the left-hand side is a complex $\Delta^+(\mathbf{x}, B)$ and the right-hand side is $\Delta^+(\mathbf{x}', B')$. Since mutation from (\mathbf{x}, B) to (\mathbf{x}', B') is a source mutation, we have $f(\Delta^+(\mathbf{x}, B)) = f(\Delta^+(\mathbf{x}', B'))$ by Corollary 3.8. Indeed, from Figure 4, both $f(\Delta^+(\mathbf{x}, B))$ and $f(\Delta^+(\mathbf{x}', B'))$ are $(1, 6, 10, 5)$.

Remark 3.11. As in Example 3.10, although $f(\Delta^+(\mathbf{x}, B)) = f(\Delta^+(\mathbf{x}', B'))$, $\Delta^+(\mathbf{x}, B) \cong \Delta^+(\mathbf{x}', B')$ does not necessarily hold.

We also consider the case in which the face vector of $\Delta^+(\mathbf{x}, B)$ does not coincide with that of $\Delta^+(\mathbf{x}', B')$.

FIGURE 4. Complexes $\Delta^+(\mathbf{x}, B)$ and $\Delta^+(\mathbf{x}', B')$ 

Example 3.12. We consider the same situation in Example 3.10 and a mutation of $(\mathbf{x} = (x_1, x_2, x_3), B)$ in direction 1. A non-labeled seed obtained by this mutation is

$$\left(\mathbf{x}'' = \left(\frac{x_2 + x_3}{x_1}, x_2, x_3 \right), Q_B'' = 1 \overset{\curvearrowright}{\longleftarrow} 2 \overset{\curvearrowright}{\longleftarrow} 3 \right).$$

This is neither a sink nor a source mutation. In Figure 3, a simplex corresponding to \mathbf{x}'' is a triangle of the center. In Figure 5, the left-hand side is a complex $\Delta^+(\mathbf{x}, B)$, and the right-hand side is $\Delta^+(\mathbf{x}'', B'')$.

FIGURE 5. Complexes $\Delta^+(\mathbf{x}, B)$ and $\Delta^+(\mathbf{x}'', B'')$ 

Then, we have the face vectors $f(\Delta^+(\mathbf{x}, B))$ and $f(\Delta^+(\mathbf{x}'', B''))$ as follows:

$$f(\Delta^+(\mathbf{x}, B)) = (1, 6, 10, 5), \quad f(\Delta^+(\mathbf{x}'', B'')) = (1, 6, 9, 4).$$

Thus, the difference between the two is $(0, 0, 1, 1)$. We can also calculate this value using Theorem 3.5. However, we need face vectors of positive cluster complexes of

subquivers to do so. In Section 5, we provide face vectors of positive cluster complex in special cases and thereby calculate this example.

Remark 3.13. We consider an example such that $f(\Delta^+(\mathbf{x}_t, B_t)) = f(\Delta^+(\mathbf{x}_{t'}, B_{t'}))$ and $(\mathbf{x}_{t'}, B_{t'})$ are obtained from (\mathbf{x}_t, B_t) by a mutation that is neither a sink nor a source mutation. We give Q_{B_t} and $Q_{B_{t'}}$ as

$$Q_{B_t} = \begin{array}{ccc} 1 & \longleftarrow & 2 \\ & \searrow & \nearrow \\ & 3 & \\ & \swarrow & \nwarrow \\ 4 & \longrightarrow & 5 \end{array}, \quad Q_{B_{t'}} = \begin{array}{ccc} 1 & & 2 \\ & \swarrow & \nwarrow \\ & 3 & \\ & \swarrow & \nwarrow \\ 4 & & 5 \end{array}.$$

A seed $(\mathbf{x}_{t'}, B_{t'})$ is obtained from (\mathbf{x}_t, B_t) by a mutation in direction 3. We note that B_t and $B_{t'}$ are A_5 type. Thus, $\Delta^+(\mathbf{x}_t, B_t)$ and $\Delta^+(\mathbf{x}_{t'}, B_{t'})$ are finite type. Since full subquivers of Q_{B_t} and $Q_{B_{t'}}$ whose vertices are $\{1, 2, 4, 5\}$ are the same quiver, which consists of two A_2 type quivers, $\Delta^+(\mathbf{x}_t, B_t)$ and $\Delta^+(\mathbf{x}_{t'}, B_{t'})$ have the same face vectors. In fact, since $Q_{B_{t'}}$ is the same shape as Q_{B_t} , we have $\Delta^+(\mathbf{x}_t, B_t) \cong \Delta^+(\mathbf{x}_{t'}, B_{t'})$.

By using the above results of face vectors, we obtain properties of h -vectors. These vectors are defined, for example, in [BH98, Section 5.1].

Definition 3.14. Let K be a simplicial complex and $f(K) = (f_{-1}, f_0, \dots, f_{n-1})$ the face vector of K . We define the h -vector as $h(K) = (h_0, \dots, h_n)$, where

$$(3.7) \quad \sum_{i=0}^n f_{i-1}(x-1)^{n-i} = \sum_{i=0}^n h_i x^{n-i}.$$

By Corollaries 3.8 and 3.9, we have the following corollaries.

Corollary 3.15. *Let $\Delta(\mathbf{x}, B)$ be a cluster complex of finite type. If (\mathbf{x}', B') is obtained from (\mathbf{x}, B) by a sink or source mutation, then we have $h(\Delta^+(\mathbf{x}, B)) = h(\Delta^+(\mathbf{x}', B'))$.*

Corollary 3.16. *Let B and B' be skew-symmetrizable matrices. If Q_B and $Q_{B'}$ have the same underlying graph in Figure 2, then $h(\Delta^+(\mathbf{x}, B)) = h(\Delta^+(\mathbf{x}', B'))$.*

When a simplicial complex is pure and shellable, the h -vector has a special meaning; see Section 6.4.

4. EXPLICIT DESCRIPTIONS OF POSITIVE CLUSTER COMPLEXES OF THE CLASSICAL FINITE TYPE

In this section, we explicitly describe some positive cluster complexes of finite type.

4.1. Type A_n . In this subsection, we focus on a cluster complex of A_n type, that is, a cluster complex $\Delta(\mathbf{x}, B)$ such that the initial exchange matrix B is mutation equivalent to an exchange matrix of the tree A_n type. Notably, we consider the case in which B is an exchange matrix of tree finite type of A_n (i.e., Q_B has a diagram of A_n type in Figure 2 as its underlying diagram).

First, we explain the realization of cluster structure by marked surfaces, which is given by [FZ03a, Section 12.2] and [FST08]. Let S be a regular $(n+3)$ -gon. We say that a diagonal ℓ is *compatible* with ℓ' if ℓ and ℓ' do not cross at the interior of S , and a set of pairwise compatible diagonals is a *compatible set*. We note that a maximal

compatible set of S gives a triangulation of S ; let T be a maximal compatible set. We label these diagonals by (ℓ_1, \dots, ℓ_n) and we call the result a *labeled maximal compatible set*. We define a matrix B_T as that obtained from T as follows. For each triangle Δ in a triangulation of S given by T , we define the $n \times n$ integer matrix $B^\Delta = (b_{ij}^\Delta)$ by setting

$$b_{ij}^\Delta = \begin{cases} 1 & \text{if } \Delta \text{ has diagonals labeled } \ell_i \text{ and } \ell_j, \\ & \text{with } \ell_j \text{ following } \ell_i \text{ in the clockwise order,} \\ -1 & \text{if the same holds, with the counterclockwise order,} \\ 0 & \text{otherwise.} \end{cases}$$

The matrix $B = B_T = (b_{ij})$ is then defined by

$$B = \sum_{\Delta} B^\Delta,$$

where the summation runs over all triangles Δ in a triangulation of S given by T .

Example 4.1. Let $T = (\ell_1, \ell_2, \ell_3)$ be a labeled maximal compatible set given as in Figure 6. Then, we have $B_T = \begin{bmatrix} 0 & -1 & 1 \\ 1 & 0 & -1 \\ -1 & 1 & 0 \end{bmatrix}$. The corresponding quiver is

FIGURE 6. Labeled maximal compatible set of a hexagon

For $i \in \{1, \dots, n\}$ and a maximal compatible set T , we define a *flip* $\varphi_i(T)$ in direction i as a transformation that obtains the unique maximal compatible set T' from T by removing ℓ_i and adding the other diagonal ℓ'_i to $T \setminus \{\ell_i\}$. We explain that flips establish the same structure as seed mutations. We say that a pair (T, B_T) of labeled a maximal compatible set and an exchange matrix B_T given by T as described above is a *labeled triangulation pair*. Abusing notation, we denote $\varphi_i(T, B_T) := (\varphi_i(T), B_{\varphi_i(T)})$ and we refer to this operation as a *flip of a labeled triangulation pair*. We define a *triangulation pattern* as an assignment $\Xi_t = (T_t, B_{T_t})$ to every vertex $t \in \mathbb{T}_n$ such that labeled triangulation pairs Ξ_t and $\Xi_{t'}$ assigned to the endpoints of any edge $t \xrightarrow{k} t'$ are obtained from each other by a flip of a labeled triangulation pair in direction k . We denote by $P: t \mapsto \Xi_t$ this assignment. To distinguish a cluster pattern from a triangulation pattern, we use the notation P^Σ for the former and P^Ξ for the latter. We call a triangulation pair associated with the rooted vertex t_0 the *initial triangulation pair*. We denote by $P(T, B_T)$ a triangulation pattern with the initial triangulation pair (T, B_T) . We use the notation $\ell_{i,t}$ as the i th diagonal in T_t . We define a *non-labeled triangulation pair* $[\Xi]$ as the equivalence classes represented by a labeled triangulation pair Ξ in the same way

as a non-labeled seed. We define a *flip* φ_ℓ of non-labeled triangulation pair, an *arc complex* $\Delta(T, B_T)$ in the same way as a mutation of non-labeled seed and a cluster complex, respectively. Thus, we have the following basic property.

Theorem 4.2 ([FST08, Proposition 4.8, Theorem 7.11]). *Let S be a regular $(n+3)$ -gon and T a labeled maximal compatible set.*

- (1) *We have $B_{\varphi_i(T)} = \mu_i(B_T)$, where μ_i is a mutation in direction i of an exchange matrix.*
- (2) *We have the canonical bijection between the sets of all diagonals of S and the set of cluster variables in $\{\mathbf{x}_t\}_{t \in \mathbb{T}_n}$ by the correspondence $\ell_{i;t} \mapsto x_{i;t}$. Furthermore, this bijection induces an isomorphism between the arc complex $\Delta(T, B_T)$ and the cluster complex $\Delta(\mathbf{x}, B_T)$.*

We note that B_T is a skew-symmetric matrix which is mutation equivalent to an exchange matrix of tree A_n type. Therefore, by using the canonical bijection in Theorem 4.2, we identify diagonals of $(n+3)$ -gon with cluster variables of a cluster pattern of A_n type. In particular, ℓ is compatible with ℓ' if and only if x_ℓ is compatible with $x_{\ell'}$, where x_ℓ and $x_{\ell'}$ are corresponding cluster variables to ℓ and ℓ' .

Example 4.3. Let $B = \begin{bmatrix} 0 & -1 & 0 \\ 1 & 0 & -1 \\ 0 & 1 & 0 \end{bmatrix}$ of type A_3 . The corresponding quiver is

$1 \leftarrow 2 \leftarrow 3$. Let T be a set $\left\{ \ell_1 = \text{diag}_1, \ell_2 = \text{diag}_2, \ell_3 = \text{diag}_3 \right\}$ of diagonals of a hexagon. Then, we have $B = B_T$. We consider a cluster pattern $P^\Sigma(\mathbf{x}, B)$ and a triangulation pattern $P^\Xi(T, B_T)$. Then, we have $\mu_{x_3}[(x_1, x_2, x_3)] = \left[\left(x_1, x_2, \frac{x_2+1}{x_3} \right) \right]$

by a mutation in direction x_3 . On the other hand, we have $\varphi_{\ell_3}(\text{diag}_3) = \text{diag}_1$ by a

flip in direction ℓ_3 . Therefore, $\frac{x_2+1}{x_3}$ corresponds to diag_1 by the canonical bijection.

The canonical bijection between the set of cluster variables and the diagonal set is given in Table 2.

		cluster variable x diagonal corresponding to x			
x_1		$\frac{x_2+1}{x_1}$		$\frac{x_1+x_3+x_2x_3}{x_1x_2}$	
x_2		$\frac{x_1+x_3}{x_2}$		$\frac{x_1+x_3+x_1x_2}{x_2x_3}$	
x_3		$\frac{x_2+1}{x_3}$		$\frac{x_1+x_3+x_1x_2+x_2x_3}{x_1x_2x_3}$	

TABLE 2. Canonical bijection between the set of cluster variables and diagonal set of A_3 type

The main theorem in this subsection is the following, in which we refer to Definition 2.10 for the definition of the cone.

Theorem 4.4. *Let $\Delta(\mathbf{x}, B)$ be a cluster complex of A_n type. Suppose that quiver Q_B has the following form.*

$$(4.1) \quad \circ \longrightarrow \circ \longrightarrow \circ \longrightarrow \circ \cdots \longrightarrow \circ \longrightarrow \circ$$

Then $\Delta^+(\mathbf{x}, B)$ is isomorphic to the cone of $\Delta(A_{n-1})$.

Remark 4.5. A matrix B satisfies the assumption in Theorem 4.4 if and only if it has the following property: for a triangulation of an $(n+3)$ -gon S obtained by a maximal compatible set T which gives $B_T = B$, there exists a vertex v of S such that all diagonals in T share v (see Figure 7).

FIGURE 7. Example of triangulation corresponding to B satisfying the assumption in Theorem 4.4

Definition 4.6. Let K be a simplicial complex and V a vertex subset of K . For a vertex x in K , we say that x is *non-linked to V* when $\{x, v\}$ is not a simplex of K for all $v \in V$.

We denote by I the vertex set consisting of all cluster variables in the initial cluster \mathbf{x} .

The following lemma can be applied to exchange matrices of tree A_n type, which contains the case (4.1).

Lemma 4.7. *Let $B = (b_{ij})$ be an exchange matrix of tree A_n type. For a cluster complex $\Delta(\mathbf{x}, B)$, there exists a unique vertex x such that x is non-linked to I .*

Proof. By the canonical bijection between cluster variables and diagonals of a regular $(n+3)$ -gon S , it suffices to show that there is a unique diagonal ℓ such that for all diagonals ℓ_i in the initial maximal compatible set T , ℓ_i intersects with ℓ at the interior of S . Since the initial exchange matrix B is of the tree A_n type, two vertices of S are shared by only one triangle in the initial triangulation T . A diagonal of S combining these two vertices is the desired diagonal. \square

Lemma 4.8. *Let $\Delta(\mathbf{x}, B)$ be a cluster complex satisfying the assumption in Theorem 4.4 and x the (unique) non-linked vertex to I . Then, $\text{lk}_{\Delta(\mathbf{x}, B)}(x)$ is isomorphic to $\Delta(A_{n-1})$. Furthermore, $\text{st}_{\Delta(\mathbf{x}, B)}(x)$ is isomorphic to $\text{cone}(\Delta(A_{n-1}))$.*

Proof. We show the first statement. By Lemma 2.12 and discussion of the proof of Lemma 3.6, it suffices to show that x has the following property.

- We fix a non-labeled seed $[(\mathbf{x}_t, B_t)]$ containing x . Then, $B_{\setminus\{x\}}$ (this notation is defined in Lemma 3.6) is mutation equivalent to a matrix of tree A_{n-1} type.

By the canonical bijection between cluster variables and diagonals of a regular $(n+3)$ -gon S , it suffices to show that a diagonal ℓ_x , which corresponds to x , cut out a triangle from S . From the assumption in B , a vertex v of S is shared by all the diagonals in the initial maximal compatible set T . Therefore, ℓ_x is a diagonal that combines both neighbor vertices of v by the proof of Lemma 4.7. Therefore, ℓ_x cuts a triangle out of S . The second statement follows from the first and Lemma 2.11. \square

Proof of Theorem 4.4. From Lemma 4.8, it suffices to show $\text{st}_{\Delta(\mathbf{x},B)}(x) = \Delta^+(\mathbf{x}, B)$. First, we prove $\text{st}_{\Delta(\mathbf{x},B)}(x) \subset \Delta^+(\mathbf{x}, B)$. Of a non-linked vertex, all vertices of $\text{st}_{\Delta(\mathbf{x},B)}(x)$ are in $\Delta^+(\mathbf{x}, B)$. Since $\Delta^+(\mathbf{x}, B)$ is a full subcomplex of $\Delta(\mathbf{x}, B)$, we have the desired inclusion. Second, let us prove that $\Delta^+(\mathbf{x}, B) \subset \text{st}_{\Delta(\mathbf{x},B)}(x)$. It suffices to show that for any simplex F of $\Delta^+(\mathbf{x}, B)$, $F \cup \{x\}$ is a simplex of $\Delta(\mathbf{x}, B)$. We assume that there exists a simplex F of $\Delta^+(\mathbf{x}, B)$ such that $F \cup \{x\}$ is not a simplex of $\Delta(\mathbf{x}, B)$. From the canonical bijection between cluster variables and diagonals of a regular $(n+3)$ -gon S , we can assume that a compatible set T_F corresponding to F contains ℓ' intersecting with the corresponding diagonal ℓ_x of x at the interior of S . However, all diagonals intersecting with ℓ_x at the interior of S are in a diagonal set T corresponding to the initial cluster \mathbf{x} . This contradicts the fact that F is a simplex of $\Delta^+(\mathbf{x}, B)$. \square

By using Theorem 4.4, we can calculate the number of simplices in $\Delta^+(\mathbf{x}, B)$ using $f(\Delta(A_{n-1}))$. We provide a conceptual proof of the following corollary given by Chapoton.

Corollary 4.9 ([Cha04, (34)]). *Let B be an exchange matrix the quiver Q_B of which has a diagram of A_n type in Figure 2 as its underlying graph. Let $f_{n,k}$ be the number of k -dimensional simplices of $\Delta(A_n)$, and $f_{n,k}^+$ the number of k -dimensional simplices of $\Delta^+(\mathbf{x}, B)$. Then, we have*

$$(4.2) \quad f_{n,k}^+ = f_{n-1,k} + f_{n-1,k-1} = \frac{1}{k+2} \binom{n}{k+1} \binom{n+k+1}{k+1}.$$

Proof. By Theorem 4.4 and Corollary 3.9, we have

$$(4.3) \quad f(\Delta^+(\mathbf{x}, B)) = f(\Delta(A_{n-1})) + [f(\Delta(A_{n-1}))]_1.$$

By [Cha04, (33)], we have

$$(4.4) \quad f_{n,k} = \frac{1}{k+2} \binom{n}{k+1} \binom{n+k+3}{k+1}.$$

By (4.3) and (4.4), we have the desired equation (4.2). \square

Remark 4.10. In [Cha04, (34)], the formula is given more generally. The equation (4.2) corresponds with [Cha04, (34)] in the case that $\ell = 0$.

Example 4.11. Let (\mathbf{x}, B) be a seed which is the same as in Example 4.3. Then, $\Delta^+(\mathbf{x}, B)$ is a domain that is shown filled with gray in Figure 8.

4.2. Type B_n and C_n . We focus on cluster complexes of B_n and C_n type, that is, cluster complexes $\Delta(\mathbf{x}, B)$ such that B is mutation equivalent to an exchange matrix of tree B_n or C_n type in this subsection. In particular, we consider the case in which B is an exchange matrix of tree B_n or C_n (i.e., Q_B has a diagram of B_n or C_n type as shown in Figure 2 as its underlying diagram).

First, we explain the realization of the cluster structure by marked surfaces, which is given by [FZ03a, Subsection 12.3]. Let S be a regular $(2n+2)$ -gon. We consider orbits of diagonals by a π rotation Θ . We say that, for any orbits $\bar{\ell}$ and $\bar{\ell}'$, $\bar{\ell}$

FIGURE 8. positive cluster complex of A_3 

is *compatible* with $\bar{\ell}'$ if $\bar{\ell}$ and $\bar{\ell}'$ do not cross at the interior of S , and the set of pairwise compatible orbits of diagonals is a *compatible set*. We note that a maximal compatible set T consists of $n - 1$ orbits composed of two diagonals and a single diameter. We label these orbits by $(\bar{\ell}_1, \dots, \bar{\ell}_n)$. We call T the *labeled maximal compatible set* as in the case with A_n type. We define a matrix B_T as a matrix obtained from T in the following manner. We assume that $\bar{\ell}_n$ is a diameter in T . Let S_{ℓ_n} be one of $(n + 2)$ -gon cut out by a diameter ℓ_n . For each triangle Δ in a triangulation of S_{ℓ_n} given by T , we define the $n \times n$ integer matrix $B^\Delta = (b_{ij}^\Delta)$ by setting

$$b_{ij}^\Delta = \begin{cases} 1 & \text{for any } i \in [1, n], j \in [1, n - 1], \text{ if } \Delta \text{ has diagonals labeled } \bar{\ell}_i \text{ and } \bar{\ell}_j, \\ & \text{with } \bar{\ell}_j \text{ following } \bar{\ell}_i \text{ in the clockwise order,} \\ -1 & \text{if the same holds as above, with the counterclockwise order,} \\ 2 & \text{for any } i \in [1, n - 1], \text{ if } j = n \text{ and } \Delta \text{ has diagonals labeled } \bar{\ell}_i \text{ and } \bar{\ell}_n, \\ & \text{with } \bar{\ell}_n \text{ following } \bar{\ell}_i \text{ in the clockwise order,} \\ -2 & \text{if the same holds as the above, with the counterclockwise order} \\ 0 & \text{otherwise,} \end{cases}$$

where $[1, n]$ means $\{1, \dots, n\}$. The matrix $B = B_T = (b_{ij})$ is then defined by

$$B = \sum_{\Delta} B^\Delta,$$

where the summation runs over all triangles Δ in a triangulation of S_{ℓ_n} given by T .

Example 4.12. Let $T = (\bar{\ell}_1, \bar{\ell}_2, \bar{\ell}_3)$ be a labeled maximal compatible set given as in Figure 9. Then, we have $B_T = \begin{bmatrix} 0 & -1 & 2 \\ 1 & 0 & -2 \\ -1 & 1 & 0 \end{bmatrix}$ and the corresponding valued

quiver is $1 \overset{(2,1)}{\longleftarrow} 2 \overset{(1,2)}{\longleftarrow} 3$ and $d(1) = d(2) = 1, d(3) = 2$.

FIGURE 9. Labeled maximal compatible set of an octagon

For $i \in \{1, \dots, n\}$ and a maximal compatible set T , we define a *flip* $\varphi_i(T)$ in direction i as a transformation that obtains the unique maximal compatible set T' from T by removing $\bar{\ell}_i$ and adding the other diagonal $\bar{\ell}'_i$ to $T \setminus \{\bar{\ell}_i\}$. We explain that flips establish the same structure as seed mutations of B_n type, and define a *labeled triangulation pair* (T, B_T) , a *flip of labeled triangulation pair* $\varphi_i(T, B_T) := (\varphi_i(T), B_{\varphi_i(T)})$, a *triangulation pattern* $P: t \mapsto \Xi_t$, a *non-labeled triangulation pair* $[\Xi]$, and an *arc complex* $\Delta(T, B_T)$ in the same manner as in Subsection 4.1. In parallel with A_n type, we have the following property by [FZ03a, Subsection 12.3] and checking exchange relations [FZ03a, (12.6),(12.7),(12.8)].

Theorem 4.13. *Let S be a regular $(2n + 2)$ -gon and T be a maximal compatible set. Let $P_{(T, B_T)}^\Xi$ be a triangulation pattern and we consider a cluster pattern $P_{(\mathbf{x}, B_T)}^\Sigma$ the initial exchange matrix of which is B_T .*

- (1) *We have $B_{\varphi_i(T)} = \mu_i(B_T)$, where μ_i is a mutation in direction i of an exchange matrix.*
- (2) *We have the canonical bijection between the set of all orbits of diagonals of S and the set of cluster variables in $\{\mathbf{x}_t\}_{t \in \mathbb{T}_n}$ by the correspondence $\bar{\ell}_{i,t} \mapsto x_{i,t}$. Furthermore, this bijection induces an isomorphism between an arc complex $\Delta(T, B_T)$ and a cluster complex $\Delta(\mathbf{x}, B_T)$.*

We note that B_T is a skew-symmetrizable matrix, which is mutation equivalent to an exchange matrix of tree B_n type.

To obtain the geometric realization of a cluster structure of C_n type, we replace b_{ij}^Δ in the above discussion with

$$b_{ij}^\Delta = \begin{cases} 1 & \text{for any } i \in [1, n-1], j \in [1, n], \text{ if } \Delta \text{ has diagonals labeled } \bar{\ell}_i \text{ and } \bar{\ell}_j, \\ & \text{with } \bar{\ell}_j \text{ following } \bar{\ell}_i \text{ in the clockwise order,} \\ -1 & \text{if the same holds as the above, with the counterclockwise order,} \\ 2 & \text{for any } j \in [1, n-1], \text{ if } i = n \text{ and } \Delta \text{ has diagonals labeled } \bar{\ell}_i \text{ and } \bar{\ell}_n, \\ & \text{with } \bar{\ell}_n \text{ following } \bar{\ell}_i \text{ in the clockwise order,} \\ -2 & \text{if the same holds as the above, with the counterclockwise order,} \\ 0 & \text{otherwise.} \end{cases}$$

For a maximal compatible set T of a $(2n+2)$ -gon S , if B is the corresponding matrix to T of the B_n type, then that of C_n type is given by the transpose of $-B$.

By the construction method of arc complexes B_n and C_n type, we have $\Delta(B_n) \cong \Delta(C_n)$.

Example 4.14. Let $B = \begin{bmatrix} 0 & -1 & 0 \\ 1 & 0 & -2 \\ 0 & 1 & 0 \end{bmatrix}$ of type B_3 . The corresponding valued quiver is $1 \xleftarrow{(1,1)} 2 \xleftarrow{(1,2)} 3$, and $d(1) = d(2) = 1, d(3) = 2$.

Let T be a set $\left\{ \bar{\ell}_1 = \text{⬡}, \bar{\ell}_2 = \text{⬡}, \bar{\ell}_3 = \text{⬡} \right\}$ of an octagon. Then, we have $B = B_T$. For example, we consider a cluster pattern $P^\Sigma(\mathbf{x}, B)$ and a triangulation pattern $P^\Xi(T, B_T)$. Then, we have $\mu_{x_3}[(x_1, x_2, x_3)] = \left[\left(x_1, x_2, \frac{x_2^2 + 1}{x_3} \right) \right]$ by a mutation in direction x_3 . In contrast, we have $\varphi_{\ell_3}(\text{⬡}) = \text{⬡}$ by a flip in direction ℓ_3 . Therefore, $\frac{x_2^2 + 1}{x_3}$ corresponds to  by the canonical bijection. The canonical bijection between the set of cluster variables and the orbit set is given in Table 3, and the cluster complex of B_3 type is given in Figure 10.

Cluster variable x | diagonal corresponding to x

x_1		$\frac{x_2 + 1}{x_1}$		$\frac{x_1 + x_3 + x_2x_3}{x_1x_2}$	
x_2		$\frac{x_1 + x_3}{x_2}$		$\frac{x_1 + x_3 + x_1x_2^2}{x_2x_3}$	
x_3		$\frac{x_2^2 + 1}{x_3}$		$\frac{x_1^2x_2^2 + x_1^2 + 2x_1x_3 + x_3^2}{x_2^2x_3}$	
		$\frac{x_1 + x_3 + x_1x_2^2 + x_2x_3}{x_1x_2x_3}$			
		$\frac{x_1^2x_2^2 + x_1x_2x_3 + x_2x_3^2 + x_1^2 + 2x_1x_3 + x_3^2}{x_1x_2^2x_3}$			
		$\frac{x_1^2x_2^2 + x_2^2x_3^2 + 2x_1x_2x_3 + 2x_2x_3^2 + x_1^2 + 2x_1x_3 + x_3^2}{x_1^2x_2^2x_3}$			

TABLE 3. Canonical bijection between the set of cluster variables and the set of orbits of diagonals of B_3 type

Here, we investigate a positive cluster complex of B_n (and C_n) type. First, we give a generalization of the closed star. Let K be a simplicial complex and v a vertex of K . For any subset V of a vertex set of K , we denote by

$$\text{st}_K(V) = \bigcup_{v \in V} \text{st}_K(v).$$

the union of closed stars of v .

FIGURE 10. Cluster complex of B_3 type

We denote by I the vertex set consisting of all cluster variables in the initial cluster \mathbf{x} . The main theorem in this subsection is the following.

Theorem 4.15. *Let $\Delta(\mathbf{x}, B)$ be a cluster complex of B_n or C_n type. Suppose that Q_B has one of the following forms:*

$$(4.5) \quad \circ \longrightarrow \circ \longrightarrow \circ \longrightarrow \circ \longrightarrow \cdots \circ \xrightarrow{(1,2)} \circ$$

$$(4.6) \quad \circ \longleftarrow \circ \longleftarrow \circ \longleftarrow \circ \longleftarrow \cdots \circ \xleftarrow{(2,1)} \circ$$

$$(4.7) \quad \circ \longrightarrow \circ \longrightarrow \circ \longrightarrow \circ \longrightarrow \cdots \circ \xrightarrow{(2,1)} \circ$$

$$(4.8) \quad \circ \longleftarrow \circ \longleftarrow \circ \longleftarrow \circ \longleftarrow \cdots \circ \xleftarrow{(1,2)} \circ$$

Then, $\Delta^+(\mathbf{x}, B)$ is isomorphic to $\text{st}_{\Delta(\mathbf{x}, B)}(I)$.

Remark 4.16. A matrix B satisfies the assumption in Theorem 4.15 if and only if a matrix B has the following property: for a triangulation of a $(2n + 2)$ -gon S obtained by a maximal compatible set T which gives $B_T = B$ and a diameter $\bar{\ell}_n$ of T , there exists a vertex v of $S_{\bar{\ell}_n}$ such that all diagonals of T in $S_{\bar{\ell}_n}$ share v (see Figure 11). The shape shown at left in Figure 11 corresponds with a valued quiver (4.5) and (4.7), and the shape shown at right corresponds to (4.6) and (4.8). Because of symmetry, we may assume the left shape in Figure 11 without loss of generality.

FIGURE 11. Triangulation corresponding to B satisfying the assumption in Theorem 4.15

The following lemma can be applied to an exchange matrix of tree B_n or C_n type, which contains the case (4.5)–(4.8).

Lemma 4.17. *Let $B = (b_{ij})$ be an exchange matrix of tree B_n or C_n type. For a cluster complex $\Delta(\mathbf{x}, B)$, there exist just n vertices that are each non-linked to I .*

Proof. By the canonical bijection between cluster variables and orbits of diagonals of a regular $(2n + 2)$ -gon S , it suffices to show that there exist n orbits of diagonals such that each orbit intersects with all the orbits of diagonals corresponding to the initial cluster variables at the interior of S . Let T be a maximal compatible orbit set corresponding to \mathbf{x} . There are just two vertices of S shared by only a single triangle in the triangulation induced by T since the initial exchange matrix B is of the tree B_n type. We fix a vertex w in these two and consider an $(n + 2)$ -gon S_{ℓ_n} cut by a diameter ℓ_n and not including w . Let v_1, \dots, v_n be the vertices of an $(n + 2)$ -gon S_{ℓ_n} which are not endpoints of ℓ_n , and $\ell_{v_1}, \dots, \ell_{v_n}$ be diagonals combining w with v_1, \dots, v_n , respectively. Then, orbits of $\ell_{v_1}, \dots, \ell_{v_n}$ by Θ are the desired orbits. \square

We denote by $I' = \{x'_1, \dots, x'_n\}$ the unique set of n vertices that are non-linked to I .

Lemma 4.18. *For a cluster complex $\Delta(\mathbf{x}, B)$ satisfying the condition in Theorem 4.15, $\text{st}_{\Delta(\mathbf{x}, B)}(I')$ is isomorphic to $\text{st}_{\Delta(\mathbf{x}, B)}(I)$.*

Proof. We prove that I' forms a cluster, and an exchange matrix B' associated with this cluster equals B up to the permutation of indices. By the canonical bijection between cluster variables and orbits of diagonals of a regular $(2n + 2)$ -gon S , it suffices to show that the set of orbits corresponding to I' satisfies the condition in Remark 4.16. For one orbit to intersect all orbits corresponding to I , it must have a vertex shared by one triangle as one of its endpoints in the triangulation by I . Thus, if the orbit set corresponding to I is that shown at left in Figure 11, then that corresponding to I' is that shown at right. Therefore, there exists an isomorphism and a permutation σ such that

$$(4.9) \quad \text{st}_{\Delta(\mathbf{x}, B)}(I') \rightarrow \text{st}_{\Delta(\mathbf{x}, B)}(I), \quad \{x'_{\sigma(i)}\} \mapsto \{x_i\},$$

where $1 \leq i \leq n$. \square

Proof of Theorem 4.15. Because of Lemma 4.18, it suffices to show $\text{st}_{\Delta(\mathbf{x}, B)}(I') = \Delta^+(\mathbf{x}, B)$.

First, we prove that $\text{st}_{\Delta(\mathbf{x}, B)}(I') \subset \Delta^+(\mathbf{x}, B)$. It suffices to show that $\text{st}_{\Delta(\mathbf{x}, B)}(x'_i) \subset \Delta^+(\mathbf{x}, B)$ for all i . This follows from the same discussion as in the proof of Theorem 4.4.

Second, let us prove that $\Delta^+(\mathbf{x}, B) \subset \mathbf{st}_{\Delta(\mathbf{x}, B)}(I')$. It suffices to show that, for any simplex F of $\Delta^+(\mathbf{x}, B)$, there is $x'_i \in I'$ such that $F \cup \{x'_i\}$ is a simplex of $\Delta(\mathbf{x}, B)$. We assume that there exists a simplex F of $\Delta^+(\mathbf{x}, B)$ such that $F \cup \{x'_i\}$ is not a simplex of $\Delta(\mathbf{x}, B)$ for all x'_i . By the canonical bijection between cluster variables and orbits of diagonals of a regular $(2n + 2)$ -gon S , we can assume that the set T_F of orbits corresponding to F contains orbits $\bar{m}_1, \dots, \bar{m}_n$ (which may be duplicated) of diagonals such that \bar{m}_i intersects with $\bar{\ell}'_i$, which is an orbit corresponding to x'_i , at the interior of S . We note that $\{\bar{\ell}'_1, \dots, \bar{\ell}'_n\}$ satisfies the condition in Remark 4.16 by Lemma 4.18. Then, we can find an orbit \bar{m} of diagonals in T_F intersecting all $\bar{\ell}'_i$ at the interior of S by the following algorithm (see Figure 12):

- (1) We assume that labels of orbits $\{\bar{\ell}'_1, \dots, \bar{\ell}'_n\}$ are numbered from the outside in order, and denote by u a vertex sharing only one triangle in a triangulation given by $\{\bar{\ell}'_1, \dots, \bar{\ell}'_n\}$.
- (2) We choose an orbit \bar{m}_1 in T_F intersecting with $\bar{\ell}'_1$. Then, one of the diagonals in \bar{m}_1 must have an endpoint at u . If \bar{m}_1 intersects with $\bar{\ell}'_n$, then we have $\bar{m} = \bar{m}_1$. If not, we proceed with the next step.
- (3) We assume that \bar{m}_1 intersects with $\bar{\ell}'_i$ and does not intersect with $\bar{\ell}'_{i+1}$. We choose an orbit \bar{m}_{i+1} in T_F intersecting with $\bar{\ell}'_{i+1}$. Then, one of the diagonals in \bar{m}_{i+1} must have an endpoint at u since if it did not, \bar{m}_{i+1} would intersect with \bar{m}_1 at the interior of S . If \bar{m}_{i+1} intersects with $\bar{\ell}'_n$ at the interior of S , then we have $\bar{m} = \bar{m}_{i+1}$. If not, we repeat to choose \bar{m}_j in the same manner as choosing \bar{m}_{i+1} until \bar{m}_j intersects with $\bar{\ell}'_n$. Since one of the diagonals in \bar{m}_j must have an endpoint at u , \bar{m}_j intersects with all $\bar{\ell}'_i$ at the interior of S . Therefore, we have $\bar{m} = \bar{m}_j$.

FIGURE 12. Algorithm for finding \bar{m} ($n = 4$).

Since an orbit of diagonals is in the initial maximal compatible set if and only if an orbit of diagonals crossing all $\bar{\ell}'_i$, this contradicts the fact that F is a simplex of $\Delta^+(\mathbf{x}, B)$. \square

Let K be a simplicial complex and V a vertex subset of K . The *link* of V is a (not necessarily full) subcomplex of K defined by $\mathbf{lk}(V) = \{\sigma \in \mathbf{st}_K(V) \mid \sigma \cap V = \emptyset\}$; that is, simplices of $\mathbf{lk}_K(V)$ are all the simplices σ of K with $v \notin \sigma$ for all $v \in V$ such that there exists $v \in V$ such that $\sigma \cup \{v\}$ is a simplex of K .

Corollary 4.19. *For a cluster complex $\Delta(\mathbf{x}, B)$ satisfying the assumption in Theorem 4.15, we have $\mathbf{lk}_{\Delta(\mathbf{x}, B)}(I) = \mathbf{lk}_{\Delta(\mathbf{x}, B)}(I')$. Furthermore, it is isomorphic to $\Delta(B_{n-1})$.*

Proof. Here, we prove $\mathbf{lk}_{\Delta(\mathbf{x}, B)}(I) \subset \mathbf{lk}_{\Delta(\mathbf{x}, B)}(I')$. Let F be a simplex of $\mathbf{lk}_{\Delta(\mathbf{x}, B)}(I)$. For all $x_i \in I$, we have $x_i \notin F$. Therefore, F is a simplex of $\Delta^+(\mathbf{x}, B)$. By Theorem

4.15, F is also a simplex of $\text{st}_{\Delta(\mathbf{x},B)}(I')$. Furthermore, for all $x'_i \in I'$, we have $x'_i \notin F$ since each x'_i is non-linked to I . Therefore, F is a simplex of $\text{lk}_{\Delta(\mathbf{x},B)}(I')$. The converse follows from the symmetry of $\text{lk}_{\Delta(\mathbf{x},B)}(I)$ and $\text{lk}_{\Delta(\mathbf{x},B)}(I')$. Indeed, I is a unique set of n non-linked vertex to I' .

Next, we prove the second statement. By using geometric realization, we identify $\text{lk}_{\Delta(\mathbf{x},B)}(I)$ with $\Delta(B_{n-1})$ as follows. Let S be a $(2n+2)$ -gon and let T and T' maximal compatible sets corresponding to \mathbf{x} and \mathbf{x}' (see Figure 13). Let $\{v_1, v_2\}$ and $\{v_3, v_4\}$

FIGURE 13. $T \cup T'$ (left), D (right) in the case that $n = 3$

be pairs of vertices of S sharing only a single triangle in a triangulation given by T and T' , respectively. We assume the edges (v_1, v_3) and (v_2, v_4) are diagonals of S , and v_1 is a neighbor of v_3 . We name the remainder of the vertices v_5, \dots, v_{2n+2} in the clockwise order from the right neighbor of v_1 . Let S' be a $2n$ -gon obtained by reducing (v_1, v_3) and (v_2, v_4) to points respectively. Let D be the set of all diagonals of S except for those contained in T or T' (see Figure 13), and D' the set of all diagonals of S' . We consider the surjection $\psi: D \rightarrow D', (v_i, v_j) \mapsto \overline{(v_i, v_j)}$ (see Figure 14). We show that ψ provides a bijection $\bar{\psi}: D/\Theta \rightarrow D'/\Theta, \overline{(v_i, v_j)} \mapsto \overline{(v_i, v_j)}$

FIGURE 14. Surjection D to D' ($n = 3$)

of orbits by Θ by induction on n . When $n = 2$, we can obtain this fact by direct calculation. We assume that $\bar{\psi}$ is bijective when the rank is $n - 1$. We prove this for rank n . Let \tilde{S} be a $2n$ -gon obtained by the convex hull of vertices of S except for v_5 and its antipodal vertex v_{n+4} . We consider subsets \tilde{T} and \tilde{T}' , which are obtained by removing diagonals with v_5 or v_{n+4} as endpoints from T and T' , respectively. Then, we can consider \tilde{T} and \tilde{T}' as a triangulation of \tilde{S} satisfying the condition in Remark 4.16, and \tilde{T}'/Θ is an orbit set such that each orbit crosses all orbits of \tilde{T}/Θ at the interior of \tilde{S} . Therefore, by the assumption of induction and a correspondence $\overline{(v_1, v_6)} \mapsto \overline{(v_1, v_6)}$, we have a bijection $\bar{\psi}|_{\tilde{D}}: \tilde{D}/\Theta \rightarrow \tilde{D}'/\Theta$, where \tilde{D} is the set of all

diagonals of \tilde{S} , except for those contained in \tilde{T} or \tilde{T}' , and \tilde{D}' is the set of all diagonals of S' except for those with v_5 or v_{n+4} as endpoints (see Figure 15). Moreover, we

FIGURE 15. $\tilde{T} \cup \tilde{T}'$ (left), \tilde{D} (center), \tilde{D}' (right) in the case that $n = 3$

have

$$D \setminus \tilde{D} = \{(v_5, v_i) \mid i \neq 1, 2, 3, 6\} \cup \{(v_{n+4}, v_j) \mid j \neq 1, 2, 4, n+5\}.$$

Therefore, $\psi|_{D \setminus \tilde{D}}: D \setminus \tilde{D} \rightarrow D' \setminus \tilde{D}'$ is bijective. Thus, $\bar{\psi}|_{D \setminus \tilde{D}}$ is bijective as well. This implies that $\bar{\psi}$ is a bijection. Furthermore, $\bar{\psi}$ preserves the compatibility of orbits; that is, if (v_i, v_j) intersects with (v_k, v_ℓ) at the interior of S , then they also do at the interior S' , and vice versa. We note that $\text{lk}_{\Delta(\mathbf{x}, B)}(I)$ is a full subcomplex of $\Delta(\mathbf{x}, B)$ since $\text{lk}_{\Delta(\mathbf{x}, B)}(I)$ is the intersection of full subcomplexes $\Delta^+(\mathbf{x}, B)$ and $\Delta^+(\mathbf{x}', B')$. Therefore, $\bar{\psi}$ can be lifted to an isomorphism between $\text{lk}_{\Delta(\mathbf{x}, B)}(I)$ and $\Delta(B_{n-1})$. \square

Corollary 4.20. *For a cluster complex $\Delta(\mathbf{x}, B)$ satisfying the assumption in Theorem 4.15, we have*

$$\Delta(\mathbf{x}, B) = \text{st}_{\Delta(\mathbf{x}, B)}(I) \cup \text{st}_{\Delta(\mathbf{x}, B)}(I')$$

and

$$\text{lk}_{\Delta(\mathbf{x}, B)}(I) = \text{st}_{\Delta(\mathbf{x}, B)}(I) \cap \text{st}_{\Delta(\mathbf{x}, B)}(I').$$

Proof. The first equation follows from Lemma 4.17, and we provide a proof for the second here. For any $F \in \text{lk}_{\Delta(\mathbf{x}, B)}(I)$, F is in $\text{st}_{\Delta(\mathbf{x}, B)}(I)$, and by Corollary 4.19, F is also in $\text{st}_{\Delta(\mathbf{x}, B)}(I')$. Therefore, we have $\text{lk}_{\Delta(\mathbf{x}, B)}(I) \subset \text{st}_{\Delta(\mathbf{x}, B)}(I) \cap \text{st}_{\Delta(\mathbf{x}, B)}(I')$. Let $F \in \text{st}_{\Delta(\mathbf{x}, B)}(I) \cap \text{st}_{\Delta(\mathbf{x}, B)}(I')$. Since $F \in \text{st}_{\Delta(\mathbf{x}, B)}(I)$, we have $F \cap I' = \emptyset$. By this fact and the assumption $F \in \text{st}_{\Delta(\mathbf{x}, B)}(I')$, we have $F \in \text{lk}_{\Delta(\mathbf{x}, B)}(I')$. Therefore, by Corollary 4.19, we have $F \in \text{lk}_{\Delta(\mathbf{x}, B)}(I)$. \square

By using Corollary 4.20, we can calculate the number of simplices in $\Delta^+(\mathbf{x}, B)$ where B is an exchange matrix of tree B_n or C_n type from cluster complexes of B_n type and B_{n-1} type as in Corollary 4.9.

Corollary 4.21 ([Cha04, (46)]). *Let B be an exchange matrix the quiver Q_B of which has a diagram of B_n or C_n type in Figure 2 as its underlying graph. Let $f_{n,k}$ be the number of k -dimensional simplices of $\Delta(B_n)$, and $f_{n,k}^+$ the number of k -dimensional simplices of $\Delta^+(\mathbf{x}, B)$. Then, we have*

$$(4.10) \quad f_{n,k}^+ = \frac{1}{2}(f_{n,k} + f_{n-1,k}) = \binom{n}{k+1} \binom{n+k}{k+1}.$$

Proof. By Corollary 4.20 and Corollary 3.9, we have the difference of face vectors of $\Delta^+(\mathbf{x}, B)$ and $\Delta(\mathbf{x}, B) \setminus \Delta^+(\mathbf{x}, B)$ equals the face vector of $\Delta(B_{n-1})$. Therefore, we have

$$f(\Delta(B_n)) = f(\Delta^+(\mathbf{x}, B)) + (f(\Delta^+(\mathbf{x}, B)) - f(\Delta(B_{n-1}))),$$

and by simplifying this equation, we obtain

$$(4.11) \quad f(\Delta^+(\mathbf{x}, B)) = \frac{1}{2}(f(\Delta(B_n)) + f(\Delta(B_{n-1}))).$$

By [Cha04, (44)], we have

$$(4.12) \quad f_{n,k} = \binom{n}{k+1} \binom{n+k+1}{k+1}$$

By (4.11) and (4.12), we obtain the desired equation (4.10). \square

Example 4.22. Let (\mathbf{x}, B) be a seed which is the same as in Example 4.14. Then, $\Delta^+(\mathbf{x}, B)$ is a domain shown filled in with gray in Figure 16.

FIGURE 16. positive cluster complex of B_3 type

4.3. Type D_n . In this subsection, we focus on cluster complexes of D_n type, a cluster complex $\Delta(\mathbf{x}, B)$ such that B is mutation equivalent to an exchange matrix of the tree D_n type. Notably, we consider the case that B is an exchange matrix of the tree D_n type (in other words, Q_B has a diagram of D_n type in Figure 2 as its underlying diagram).

Similar to A_n type or B_n, C_n type, we begin by explaining the realization of cluster structure by marked surfaces, which is given by [FZ03a, Subsection 12.4]. Let S be a regular $2n$ -gon. We consider orbits of their diagonals by a π rotation Θ as B_n and C_n type. However, we provide two distinguished orbits for (an orbit of) a diameter. In this work, we distinguish these two by the diameter labels 1 and 2. We say that, for orbits, $\bar{\ell}$ is *compatible* with $\bar{\ell}'$ if they are diagonals falling under any of the following:

- $\bar{\ell}$ and $\bar{\ell}'$ are diameters with the same diameter label,
- $\bar{\ell}$ and $\bar{\ell}'$ are the same diameters with different diameter labels,
- $\bar{\ell}$ and $\bar{\ell}'$ do not cross each other in the interior of S .

We refer to a set of pairwise compatible orbits of diagonals a *compatible set*. We label these orbits by $\{\bar{\ell}_1, \dots, \bar{\ell}_n\}$, and define the *labeled maximal compatible set* in the same way as A_n or B_n, C_n type. We note that a maximal compatible set T consists of $n - 2$ orbits composed of two diagonals and 2 (distinguished) diameters. We assume that these 2 diameters are $\bar{\ell}_{n-1} = \{\ell_{n-1}\}, \bar{\ell}_n = \{\ell_n\}$. We define a matrix B_T as the matrix defined from T as follows. Let S_{ℓ_n} be one of $(n + 2)$ -gon cut out by a diameter ℓ_n . For each triangle Δ in a triangulation of S_{ℓ_n} given by T , we define the $n \times n$ integer matrix $B^\Delta = (b_{ij}^\Delta)$ by setting

$$b_{ij}^\Delta = \begin{cases} 1 & \text{if } \Delta \text{ has diagonals labeled } \bar{\ell}_i \text{ and } \bar{\ell}_j, \text{ with } \bar{\ell}_j \text{ following } \bar{\ell}_i \text{ in clockwise order,} \\ -1 & \text{if the same holds as the above, in counterclockwise order,} \\ 0 & \text{otherwise.} \end{cases}$$

The matrix $B = B_T = (b_{ij})$ is then defined by

$$B = \sum_{\Delta} B^\Delta,$$

where the summation runs over all triangles Δ in a triangulation of S_{ℓ_n} given by T . This matrix is independent of the choice of diameter ℓ_n in T . Therefore, we can use ℓ_{n-1} instead of ℓ_n .

Example 4.23. Let $T = (\bar{\ell}_1, \bar{\ell}_2, \bar{\ell}_3, \bar{\ell}_4)$ be a labeled maximal compatible set given as

in Figure 17. Then, we have $B_T = \begin{bmatrix} 0 & 0 & 1 & -1 \\ 0 & 0 & -1 & 1 \\ -1 & 1 & 0 & 0 \\ 1 & -1 & 0 & 0 \end{bmatrix}$. The corresponding quiver

FIGURE 17. Labeled maximal compatible set of an octagon

For $i \in \{1, \dots, n\}$ and a maximal compatible set T , we define a *flip* $\varphi_i(T)$ in *direction* i as a transformation that obtains the unique maximal compatible set T' from T by removing $\bar{\ell}_i$ and adding the other diagonal $\bar{\ell}'_i$ to $T \setminus \{\bar{\ell}_i\}$. We explain that flips establish the same structure as seed mutations of D_n type. We define a *labeled triangulation pair* (T, B_T) , a *flip of a labeled triangulation pair* $\varphi_i(T, B_T) := (\varphi_i(T), B_{\varphi_i(T)})$, a *triangulation pattern* $P: t \mapsto \Xi_t$, and *arc complex* $\Delta(T, B_T)$ in the same way as Subsection 4.1. In parallel with A_n and B_n, C_n type, the following property can be easily obtained by [FZ03a, Subsection 12.4] and checking exchange relations [FZ03a, (12.19)–(12.23)].

Theorem 4.24. *Let S be a regular $2n$ -gon and T be a maximal compatible set.*

- (1) *We have $B_{\varphi_i(T)} = \mu_i(B_T)$, where μ_i is a mutation in direction i of an exchange matrix.*
- (2) *We have the canonical bijection between the sets of all orbits of diagonals of S and the set of cluster variables in $\{\mathbf{x}_t\}_{t \in \mathbb{T}_n}$ by the correspondence $\bar{\ell}_{i,t} \mapsto x_{i,t}$. Furthermore, this bijection induces an isomorphism between an arc complex $\Delta(T, B_T)$ and a cluster complex $\Delta(\mathbf{x}, B_T)$.*

We note that B_T is a skew-symmetric matrix which is mutation equivalent to an exchange matrix of tree D_n type.

Remark 4.25. For convenience, we regard D_2 type as $A_1 \times A_1$ type. Further, the Dynkin diagram of the D_3 type has the same shape as that of A_3 . However, they differ in terms of the order of their vertices. In the A_3 type, a vertex indexed by 1 is an end of one of the diagrams. Conversely, in the D_3 type, it is the central vertex of the diagrams.

Example 4.26. Let $B = \begin{bmatrix} 0 & -1 & -1 \\ 1 & 0 & 0 \\ 1 & 0 & 0 \end{bmatrix}$ of type D_3 . The corresponding quiver is

. Let T be a set $\{\bar{\ell}_1 = \text{hexagon with diagonal 1-2}, \bar{\ell}_2 = \text{hexagon with diagonal 1-3}, \bar{\ell}_3 = \text{hexagon with diagonal 2-3}\}$ of orbits of diagonals. Then,

we have $B = B_T$. For example, we consider a cluster pattern $P^\Sigma(\mathbf{x}, B)$ and a triangulation pattern $P^\Xi(T, B_T)$. Then, we have $\mu_{x_3}[(x_1, x_2, x_3)] = \left[\left(x_1, x_2, \frac{x_2 + 1}{x_3} \right) \right]$

by a mutation in direction x_3 . Meanwhile, we have $\varphi_{\ell_3} \left(\text{hexagon with diagonal 1-2} \right) = \text{hexagon with diagonal 1-3}$ by a flip in

direction ℓ_3 . Therefore, for the canonical bijection, $\frac{x_1 + 1}{x_3}$ corresponds to $\text{hexagon with diagonal 1-3}$. The

canonical bijection between the set of cluster variables and the set of all orbits of diagonals is given in Table 4, and the cluster complex of D_3 type is given in Figure 18.

By using the canonical bijection given by Theorem 4.24, we identify orbits of diagonal of a $2n$ -gon with cluster variables of a cluster pattern of D_n type.

Definition 4.27. Let K and L be simplicial complexes the vertex sets of which are disjoint, and M and N be subcomplexes of K and L , respectively, such that $M \cong N$. We define a *complex G obtained by gluing K and L together along M and N* as $G = K' \cup L'$, where $K' \cong K$, $L' \cong L$ and $K' \cap L' \cong M \cong N$.

TABLE 4. Canonical bijection between the set of cluster variables and the set of orbits of diagonal of D_3 type

FIGURE 18. Cluster complex of D_3 type

We denote by I the vertex set consisting of all cluster variables in the initial cluster \mathbf{x} . We define Δ_{glue} as a full subcomplex of $\Delta(\mathbf{x}, B)$ the vertex set of which consists of all vertices of $\text{st}_{\Delta(\mathbf{x}, B)}(I \setminus \{x_{n-1}, x_n\})$ which are not in $\{x_1, \dots, x_{n-2}\}$ and compatible with both x_{n-1} and x_n . The main theorem in the subsection is given below.

Theorem 4.28. *Let $\Delta(\mathbf{x}, B)$ be a cluster complex of D_n type. Suppose Q_B has one of the following forms.*

(4.13) 

(4.14) 

Then, $\Delta^+(\mathbf{x}, B)$ is isomorphic to a complex obtained by gluing $\text{join}(\Delta_0, \Delta_1, \Delta(A_{n-3}))$ and $\text{st}_{\Delta(\mathbf{x}, B)}(I \setminus \{x_{n-1}, x_n\})$ together along $\text{join}(\Delta_1, \Delta(A_{n-3}))$ and Δ_{glue} , where Δ_i is the i -dimensional simplex.

Remark 4.29. A matrix B satisfies the assumption in Theorem 4.28 if and only if the matrix has the following property. For an orbit set of an $2n$ -gon S obtained by a maximal compatible set T which gives $B_T = B$ and diameters $\bar{\ell}_{n-1}$ and $\bar{\ell}_n$ of T , $\bar{\ell}_{n-1}$ and $\bar{\ell}_n$ are the same diameter with different diameter labels, and there is a vertex v of $S_{\bar{\ell}_n}$ such that all diagonals in T in $S_{\bar{\ell}_n}$ share v (see Figure 19). The shape shown at left in Figure 19 corresponds to the quiver (4.13), and that at right corresponds to (4.14). Because of symmetry, we may assume the version at left in Figure 19 without loss of generality.

FIGURE 19. Triangulation corresponding to B satisfying the assumption in Theorem 4.28

Lemma 4.30. Let $B = (b_{ij})$ be an exchange matrix of tree D_n type. For a cluster complex $\Delta(\mathbf{x}, B)$, there exist just $n - 2$ vertices non-linked to I .

Proof. By the canonical bijection between cluster variables and orbits of diagonals of a regular $2n$ -gon S , it suffices to show that there are just $n - 2$ orbits of diagonals such that each of them is not compatible with any orbits of diagonals corresponding to the initial cluster variables at the interior of S . Since the initial exchange matrix B is of tree D_n type, the initial maximal compatible set T in which there are only two vertices of S shared by only one triangle. Let v, v' be vertices of these two, and we consider an $(n + 1)$ -gon $S_{\bar{\ell}_n}$, which is cut out by a diameter $\bar{\ell}_n$ and not including v . Let v_1, \dots, v_{n-2} be the vertices of an $(n + 1)$ -gon $S_{\bar{\ell}_n}$, which are not endpoints of $\bar{\ell}_n$ or v' , and $\bar{\ell}_{v_1}, \dots, \bar{\ell}_{v_{n-2}}$ diagonals combining v with v_1, \dots, v_{n-2} , respectively. Then, orbits of $\bar{\ell}_{v_1}, \dots, \bar{\ell}_{v_{n-2}}$ by Θ are the desired orbits. \square

We denote by $I' = \{x'_1, \dots, x'_{n-2}\}$ the unique set of n vertices non-linked to I . We introduce some additional notation for convenience. Let S be a regular $2n$ -gon and T a maximal compatible set corresponding to I and T' a compatible set corresponding to I' . We name four vertices v_1, v_2, v_3, v_4 such that $\{v_1, v_2\}$ and $\{v_3, v_4\}$ are pairs of vertices of S sharing only one triangle in a triangulation given by T and T' , respectively. Hereafter, let (v, v') denote the edge connecting v and v' . We assume the edges (v_1, v_3) and (v_2, v_4) are diagonals of S . We name the rest of vertices v_5, \dots, v_{2n} from the right neighbor of v_1 in clockwise order. (See Figure 20.)

Lemma 4.31. For a cluster complex $\Delta(\mathbf{x}, B)$ satisfying the assumption in Theorem 4.28, $\text{st}_{\Delta(\mathbf{x}, B)}(I')$ is isomorphic to $\text{st}_{\Delta(\mathbf{x}, B)}(I \setminus \{x_{n-1}, x_n\})$.

Proof. The situation is the same as in Lemma 4.18. \square

FIGURE 20. T (left) and T' (right) in the case that $n = 4$

Unlike A_n or B_n, C_n type, the closed star of non-linked vertices to I does not coincide with $\Delta^+(\mathbf{x}, B)$. However, the link of non-linked vertices is isomorphic to $\Delta(D_{n-1})$; we provide a proof below.

Lemma 4.32. *For a cluster complex $\Delta(\mathbf{x}, B)$ satisfying the assumption in Theorem 4.28, we have $\text{lk}_{\Delta(\mathbf{x}, B)}(I') \cong \Delta(D_{n-1})$.*

Proof. Let S' be a $2n$ -gon obtained by reducing (v_1, v_3) and (v_2, v_4) to points, respectively. Let D be the set of diagonals of S which are compatible with at least one orbit of T' and not in T' (we distinguish two labeled diameters with the same edge). These are diagonals corresponding to a vertex set of $\text{lk}_{\Delta(\mathbf{x}, B)}(I')$. Let D' be the set of all diagonals of S' . We consider the surjection $\psi: D \rightarrow D', (v_i, v_j) \mapsto (v_i, v_j)$ (see Figure 21). For diameters (v_i, v_j) labeled 1 and 2, we note that ψ gives a correspondence between diameters with the same label. As in the proof of Lemma 4.19, we

 FIGURE 21. Surjection D to D' ($n = 4$)

can show that ψ gives a bijection $\bar{\psi}: D/\Theta \rightarrow D'/\Theta, \overline{(v_i, v_j)} \mapsto \overline{(v_i, v_j)}$ of orbits by Θ by using the induction of n . Furthermore, $\bar{\psi}$ preserves the compatibility of orbits; that is, if $\overline{(v_i, v_j)}$ intersects with $\overline{(v_k, v_\ell)}$ at the interior of S , then they do so at the interior of S' , and vice versa. Next, we show that $\text{lk}_{\Delta(\mathbf{x}, B)}(I')$ is a full subcomplex of $\Delta(\mathbf{x}, B)$. It suffices to show that, for any compatible set F of D/Θ , an orbit of T' is compatible with all orbits of F . We assume that there exists a compatible set F of D/Θ such that each orbit of T' is not compatible with at least one orbit of F . We can assume that labels of orbits $\{\bar{\ell}'_1, \dots, \bar{\ell}'_{n-2}\}$ are numbered in order from the outside without loss of generality, and denote by u a vertex sharing only one triangle in a triangulation given by $\{\bar{\ell}'_1, \dots, \bar{\ell}'_n\}$ (see the first figure in Figure 22). Since F has an orbit which is not compatible with $\bar{\ell}'_1$, we can choose one and refer to this as \bar{n}_1 (see the third figure in Figure 22). Then, one of endpoints of \bar{n}_1 is u . We assume

FIGURE 22. Orbits of T' , D , and \bar{n}_1, \bar{n}_2 in the case that $n = 5$ 

\bar{n}_1 is not compatible with $\bar{\ell}'_1, \dots, \bar{\ell}'_{k_1}$. Then, we note that $k_1 \neq n - 2$ since there is no orbit in D/Θ which is not compatible with $\bar{\ell}'_{n-2}$ and one of the endpoints of which is u . If $k_1 < n - 3$. Then, we can choose \bar{n}_2 an orbit of D/Θ , which is not compatible with $\bar{\ell}'_{k_1+1}$ and compatible with \bar{n}_1 (See the fourth figure in Figure 22). We note that one of endpoints of \bar{n}_2 is u . We assume \bar{n}_2 is not compatible with $\bar{\ell}'_1, \dots, \bar{\ell}'_{k_2}$. If $k_2 < n - 3$, we choose n_i repeatedly in the same as above. We can repeat this operation until $k_i = n - 3$. Then, all orbits which are not compatible with $\bar{\ell}'_{n-2}$ are also not compatible with \bar{n}_{i-1} , which conflicts with the assumption. Therefore, D/Θ is a full subcomplex of $\Delta(\mathbf{x}, B)$ and $\bar{\psi}$ can be lifted to an isomorphism between $\text{lk}_{\Delta(\mathbf{x}, B)}(I')$ and $\Delta(D_{n-1})$. \square

It follows from the next lemma that $\text{st}_{\Delta(\mathbf{x}, B)}(I')$ does not coincide with $\Delta^+(\mathbf{x}, B)$.

Lemma 4.33. *For a cluster complex $\Delta(\mathbf{x}, B)$ satisfying the assumption in Theorem 4.28, there exists a unique cluster variable x^* such that it is neither in $\text{st}_{\Delta(\mathbf{x}, B)}(I')$ as a vertex nor in I .*

Proof. The number of cluster variables of cluster algebras of D_n type is n^2 since this number corresponds with that of almost positive roots by [FZ03a, Theorem 1.9]. By lemmas 4.30 and 4.32, the number of 0-dimensional simplices of $\text{st}_{\Delta(\mathbf{x}, B)}(I')$ is $(n - 2) + (n - 1)^2 = n^2 - n - 1$. Since the initial cluster variables are not in $\text{st}_{\Delta(\mathbf{x}, B)}(I')$, the number of cluster variables which is neither in $\text{st}_{\Delta(\mathbf{x}, B)}(I)$ as a 0-dimensional simplex nor in I is $n^2 - (n^2 - n - 1) - n = 1$. Indeed, the orbit of $\{(v_1, v_4), (v_2, v_3)\}$ is the unique orbit satisfying this condition. \square

Clearly, we have $\text{st}_{\Delta(\mathbf{x}, B)}(I') \subset \Delta^+(\mathbf{x}, B)$. Therefore, $\Delta^+(\mathbf{x}, B)$ is a complex obtained by gluing a cone into $\text{st}_{\Delta(\mathbf{x}, B)}(I')$ by Lemma 4.33, and this cone is described by $\text{join}(\{x^*\}, \text{lk}_{\Delta(\mathbf{x}, B)}(x^*) \cap \text{st}_{\Delta(\mathbf{x}, B)}(I'))$, where x^* is the same notation in Lemma 4.33. We consider determining the shape of this cone and begin by characterizing the cone. We denote by x'_{n-1} and x'_n cluster variables corresponding to diameters (v_3, v_4) with diameter labels 1 and 2 of $2n$ -gon S respectively.

Lemma 4.34. *We assume the same situation as in Lemma 4.33. The complex*

$$\text{join}(\{x^*\}, \text{lk}_{\Delta(\mathbf{x}, B)}(x^*) \cap \text{st}_{\Delta(\mathbf{x}, B)}(I'))$$

is a full subcomplex of $\Delta(\mathbf{x}, B)$ the vertex set of which is

$$(4.15) \quad V = \{y \in \mathcal{X}(\mathbf{x}, B) \mid y \notin I' \text{ and } y \text{ is compatible with both } x'_{n-1} \text{ and } x'_n\},$$

where $\mathcal{X}(\mathbf{x}, B)$ is the vertex set of $\Delta(\mathbf{x}, B)$.

Proof. We abbreviate $\text{lk}_{\Delta(\mathbf{x}, B)}(x^*) \cap \text{st}_{\Delta(\mathbf{x}, B)}(I')$ to $\text{lk} \cap \text{st}$. We denote by Δ_V a full subcomplex of $\Delta(\mathbf{x}, B)$ in which the vertex set is V .

First, we prove $\text{join}(\{x^*\}, \text{lk} \cap \text{st}) \subset \Delta_V$. Since Δ_V is a full subcomplex, it suffices to show that Δ_V contains all 0-dimensional simplices of $\text{join}(\{x^*\}, \text{lk} \cap \text{st})$. We fix any vertex $\{y\}$ of $\text{join}(\{x^*\}, \text{lk} \cap \text{st})$. If $y = x^*$, then Δ_V clearly contains $\{y\}$ since x^* corresponds to the orbit of diagonals $\{(v_1, v_4), (v_2, v_3)\}$ of S by the proof of Lemma 4.33. We assume $y \neq x^*$ and show that $\{y\} \in \Delta_V$. By this assumption, $\{y\}$ is a 0-dimensional simplex of $\text{lk} \cap \text{st}$. Since $\{x^*\} \notin \text{st}_{\Delta(\mathbf{x}, B)}(I')$ and $\{y\} \in \text{lk}_{\Delta(\mathbf{x}, B)}(x^*)$, we have $y \notin I'$. We assume that y is not compatible with x'_{n-1} or x'_n . Then, the corresponding orbit of diagonal $\bar{\ell}_y$ must cross (v_3, v_4) at interior of S . Moreover, since $\{y\} \in \text{lk}_{\Delta(\mathbf{x}, B)}(x^*)$, $\bar{\ell}_y$ is compatible with $\{(v_1, v_4), (v_2, v_3)\}$. An orbit satisfying this condition has a diameter of only (v_1, v_2) . Therefore, $\bar{\ell}_y$ is a diameter (v_1, v_2) in which the diameter label is 1 or 2. In either case, we have $y \in I$. This contradicts $\{y\} \in \text{st}_{\Delta(\mathbf{x}, B)}(I')$.

Next, we show converse inclusion. The complex $\text{join}(\{x^*\}, \text{lk} \cap \text{st})$ is also a full subcomplex since $\text{lk}_{\Delta(\mathbf{x}, B)}(x^*)$ is full by Lemma 2.12, $\text{lk}_{\Delta(\mathbf{x}, B)}(I')$ is also full by Lemma 4.32, and we have

$$(4.16) \quad \text{lk}_{\Delta(\mathbf{x}, B)}(x^*) \cap \text{st}_{\Delta(\mathbf{x}, B)}(I') = \text{lk}_{\Delta(\mathbf{x}, B)}(x^*) \cap \text{lk}_{\Delta(\mathbf{x}, B)}(I').$$

Therefore, it suffices to show that $\text{join}(\{x^*\}, \text{lk} \cap \text{st})$ contains all 0-dimensional simplices of Δ_V . We fix any 0-dimensional simplex $\{y\} \in \Delta_V$. If $y = x^*$, then $\{y\}$ is in $\text{join}(\{x^*\}, \text{lk} \cap \text{st})$ clearly. We assume $y \neq x^*$, and show that $\{y\} \in \text{lk} \cap \text{st}$. First, cluster variables which are compatible with both x'_{n-1} and x'_n , and not with x^* are only x'_1, \dots, x'_{n-2} . Since $y \notin I'$, we have $\{y\} \in \text{lk}_{\Delta(\mathbf{x}, B)}(x^*)$. We prove $\{y\} \in \text{st}_{\Delta(\mathbf{x}, B)}(I')$. We assume y is not compatible with any elements in I' . Then, we have $y \in \{x_1, x_2, \dots, x_n, x^*\}$, but since $y \neq x^*$, we have $y \in \{x_1, x_2, \dots, x_n\}$. Any x_i are not compatible with x'_{n-1} or x'_n . This is a contradiction. \square

The following lemma determines the shape of the cone.

Lemma 4.35. *We assume the same situation as Lemma 4.33. The complex $\text{lk}_{\Delta(\mathbf{x}, B)}(x^*) \cap \text{st}_{\Delta(\mathbf{x}, B)}(I')$ is isomorphic to $\text{join}(\Delta_1, \Delta(A_{n-3}))$.*

Proof. Let $\bar{\ell}_{x^*}$ be an orbit corresponding to x^* . Let E be the set of diagonals of S corresponding to a vertex set of $\text{lk}_{\Delta(\mathbf{x}, B)}(x^*) \cap \text{st}_{\Delta(\mathbf{x}, B)}(I')$ (as D in the proof of Lemma 4.32, we distinguish two labeled diameters with the same edge). By the characterization of Lemma 4.34, E consists of two labeled diameters obtained by an edge (v_3, v_4) , all diagonals of the $(n-3)$ -gon cut out by (v_1, v_4) , and all diagonals of the $(n-3)$ -gon cut out by (v_2, v_3) (see the subfigure shown at left in Figure 23). By (4.16), E is a subset of D in Lemma 4.32, and E/Θ is a subset of D/Θ . We consider a restriction $\psi|_E$ of ψ to E , where ψ is the same function as that in Lemma 4.32. The map $\psi|_E$ induces an injection $\bar{\psi}|_E: E/\Theta \rightarrow D'/\Theta$, and by the fullness of $\text{lk}_{\Delta(\mathbf{x}, B)}(x^*) \cap \text{st}_{\Delta(\mathbf{x}, B)}(I')$, it is lifted to isomorphism between $\text{lk}_{\Delta(\mathbf{x}, B)}(x^*) \cap \text{st}_{\Delta(\mathbf{x}, B)}(I')$ and a full subcomplex of $\Delta(D_{n-1})$ (see Figure 23). Furthermore, this subcomplex is isomorphic to $\text{join}(\Delta_1, \Delta(A_{n-3}))$. We will confirm this fact. We denote by $E' = \psi(E)$ the image of $\psi|_E$. Let S'' be an n -gon obtained by cutting out S' at a diameter (v_1, v_2) . By symmetry, we can assume S'' has v_5 as a vertex without loss of generality. Let E'_\circ be a subset of E' consists of all diagonals of S except for two labeled diameters obtained by an edge (v_1, v_2) . Let E'' be all diagonals of S'' . We consider a map $\eta: E'' \rightarrow E'_\circ/\Theta, (v_i, v_j) \mapsto \overline{(v_i, v_j)}$, which is a bijection by the construction of E , which is lifted to the isomorphism of complexes. Moreover, two labeled diameters obtained by an edge (v_1, v_2) are compatible with all orbits of E'_\circ/Θ . Since two labeled diameters are compatible with each other, the full subcomplex the vertex set of which is E' is isomorphic to $\text{join}(\Delta_1, \Delta(A_{n-3}))$. \square

FIGURE 23. Restriction ψ to E ($n = 4$)FIGURE 24. Map η ($n = 4$)

Proof of Theorem 4.28. First, we prove the equation

$$\Delta^+(\mathbf{x}, B) = \text{join}(\{x^*\}, \text{lk}_{\Delta(\mathbf{x}, B)}(x^*) \cap \text{st}_{\Delta(\mathbf{x}, B)}(I')) \cup \text{st}_{\Delta(\mathbf{x}, B)}(I'),$$

We abbreviate $\text{join}(\{x^*\}, \text{lk}_{\Delta(\mathbf{x}, B)}(x^*) \cap \text{st}_{\Delta(\mathbf{x}, B)}(I'))$ to $\text{join}(\{x^*\}, \text{lk} \cap \text{st})$ again. The right-hand side is included in the left. We prove the converse inclusion. We denote by J a vertex set of $\text{st}_{\Delta(\mathbf{x}, B)}(I')$. Let F be a simplex of $\Delta^+(\mathbf{x}, B)$. Since F consists of cluster variables which are not initial variables, F is a subset of $\{x^*\} \cup J$ by Lemma 4.33. Since $\text{lk}_{\Delta(\mathbf{x}, B)}(I')$ is a full subcomplex of $\Delta(\mathbf{x}, B)$, $\text{st}_{\Delta(\mathbf{x}, B)}(I')$ is also a full subcomplex of $\Delta(\mathbf{x}, B)$. Therefore, if F does not contain x^* , then F is a simplex of $\text{st}_{\Delta(\mathbf{x}, B)}(I')$. If F contains x^* , then each 0-dimensional simplices of F are simplices of $\text{join}(\{x^*\}, \text{lk} \cap \text{st})$. By the fullness of $\text{join}(\{x^*\}, \text{lk} \cap \text{st})$, F belongs to $\text{join}(\{x^*\}, \text{lk} \cap \text{st})$. To complete the proof of Theorem 4.28, we verify the following three.

- (1) $\text{lk} \cap \text{st} \cong \text{join}(\Delta_1, \Delta(A_{n-3}))$.
- (2) $\text{join}(\{x^*\}, \text{lk} \cap \text{st}) \cong \text{join}(\Delta_0, \Delta_1, \Delta(A_{n-3}))$,
- (3) there exists an isomorphism $\text{st}_{\Delta(\mathbf{x}, B)}(I') \cong \text{st}_{\Delta(\mathbf{x}, B)}(I \setminus \{x_{n-1}, x_n\})$ such that it induces $\text{lk} \cap \text{st} \cong \Delta_{\text{glue}}$.

The statement (1) follows from Lemma 4.35 and (2) follows from (1). We show (3). The existence of an isomorphism follows from Lemma 4.31. We show that it induces $\text{lk} \cap \text{st} \cong \Delta_{\text{glue}}$. We can assume σ in the proof of Lemma 4.31 is the identity without loss of generality. Owing to $\text{lk} \cap \text{st} = \text{join}(\{x^*\}, \text{lk} \cap \text{st}) \cap \text{st}_{\Delta(\mathbf{x}, B)}(I')$ and Lemma 4.34, $\text{lk} \cap \text{st}$ is a full subcomplex the vertex set of which is $V \cap \text{st}_{\Delta(\mathbf{x}, B)}(I')$, where V is that of (4.15). Since x'_i corresponds to x_i by the isomorphism in the proof of

Lemma 4.31, $V \cap \text{st}_{\Delta(\mathbf{x}, B)}(I')$ corresponds to $V' \cap \text{st}_{\Delta(\mathbf{x}, B)}(I \setminus \{x_{n-1}, x_n\})$, where

$$V' = \{y \in \mathcal{X}(\mathbf{x}, B) \mid y \notin I \text{ and } y \text{ is compatible with both } x_{n-1} \text{ and } x_n\}.$$

Since Δ_{glue} is a full subcomplex of $\Delta(\mathbf{x}, B)$ in which the vertex set is $V' \cap \text{st}_{\Delta(\mathbf{x}, B)}(I \setminus \{x_{n-1}, x_n\})$, this completes the proof. \square

Similar to A_n, B_n and C_n type, we give a conceptual proof of the following corollary given by Krattenthaler.

Corollary 4.36 ([Kra06, Theorem FD]). *Let B be an exchange matrix whose quiver Q_B has a diagram of D_n type in Figure 2 as its underlying graph. Let $f_{D_n, k}$ be the number of k -dimensional simplices of $\Delta(D_n)$, $f_{A_n, k}$ be the number of k -dimensional simplices of $\Delta(A_n)$ and $f_{n, k}^+$ the number of k -dimensional simplices of $\Delta^+(\mathbf{x}, B)$. If $k = -1$, then we have $f_{n, -1}^+ = 1$. If $k \neq -1$, then we obtain*

$$(4.17) \quad \begin{aligned} f_{n, k}^+ &= \frac{1}{2}(f_{D_n, k} + f_{D_{n-1}, k} + f_{A_{n-3}, k-1} + f_{A_{n-3}, k-2}) - f_{A_{n-2}, k-1} - f_{A_{n-2}, k-1} \\ &= \binom{n}{k+1} \binom{n+k-1}{k+1} + \binom{n-1}{k} \binom{n-k-2}{k} - \frac{1}{n-1} \binom{n-1}{k} \binom{n+k-1}{k+1}. \end{aligned}$$

Proof. When $k = -1$, the claim is clear. We consider the case of $k \neq -1$. By Corollary 3.9, it suffices to consider the linearly oriented case. First, we show the following equation:

$$(4.18) \quad \begin{aligned} f(\Delta^+(\mathbf{x}, B)) &= \frac{1}{2}f(\Delta(D_n)) + \frac{1}{2}f(\Delta(D_{n-1})) - [f(\Delta(A_{n-2}))]_1 - [f(\Delta(A_{n-2}))]_2 \\ &\quad + \frac{1}{2}[f(\Delta(A_{n-3}))]_1 + \frac{1}{2}[f(\Delta(A_{n-3}))]_2. \end{aligned}$$

We note that

$$\begin{aligned} &\text{st}_{\Delta(\mathbf{x}, B)}(I - \{x_{n-1}, x_n\}) \\ &= \widehat{\Delta}_{\mathbf{x}} \setminus (\underline{\Delta}_{\{x_{n-1}\} \subset \mathbf{x}} \cup \underline{\Delta}_{\{x_n\} \subset \mathbf{x}} \cup \underline{\Delta}_{\{x_{n-1}, x_n\} \subset \mathbf{x}}) \cup \text{lk}_{\Delta(\mathbf{x}, B)}(I - \{x_{n-1}, x_n\}), \end{aligned}$$

and by Lemmas 4.31 and 4.32, we have $\text{lk}_{\Delta(\mathbf{x}, B)}(I - \{x_{n-1}, x_n\}) \cong \text{lk}_{\Delta(\mathbf{x}, B)}(I') \cong \Delta(D_{n-1})$. By Theorem 4.28 and the above argument, we obtain

$$\begin{aligned} f(\Delta(D_n)) &= f(\widehat{\Delta}_{\mathbf{x}}) + f(\Delta^+(\mathbf{x}, B)) \\ &= f(\widehat{\Delta}_{\mathbf{x}}) + f(\text{st}_{\Delta(\mathbf{x}, B)}(I - \{x_{n-1}, x_n\})) + [f(\text{join}(\Delta_1, \Delta(A_3)))]_1 \\ &= 2f(\widehat{\Delta}_{\mathbf{x}}) - f(\underline{\Delta}_{\{x_{n-1}\} \subset \mathbf{x}}) - f(\underline{\Delta}_{\{x_n\} \subset \mathbf{x}}) - f(\underline{\Delta}_{\{x_{n-1}, x_n\} \subset \mathbf{x}}) \\ &\quad + f(\Delta(D_{n-1})) + [f(\text{join}(\Delta_1, \Delta(A_3)))]_1, \end{aligned}$$

where the notation is the same in the proof of Theorem 3.5. Then, we have

$$\begin{aligned} f(\underline{\Delta}_{\{x_{n-1}\} \subset \mathbf{x}}) &= f(\underline{\Delta}_{\{x_n\} \subset \mathbf{x}}) = [f(\Delta^+(\mathbf{x} - \{x_n\}, B_{\setminus \{x_n\}}))]_1, \\ f(\underline{\Delta}_{\{x_{n-1}, x_n\} \subset \mathbf{x}}) &= [f(\Delta^+(\mathbf{x} - \{x_{n-1}, x_n\}, B_{\setminus \{x_{n-1}, x_n\}}))]_2 \end{aligned}$$

by using the discussion in the proof of Theorem 3.5 and Lemma 3.7. Furthermore, since $B_{\setminus\{x_{n-1}\}}, B_{\setminus\{x_n\}}, B_{\setminus\{x_{n-1}, x_n\}}$ is of tree A_n type, we have

$$\begin{aligned} [f(\Delta^+(\mathbf{x} - \{x_n\}, B_{\setminus\{x_n\}}))]_1 &= [f(\text{cone}(\Delta(A_{n-2})))]_1 \\ &= [f(\Delta(A_{n-2}))]_1 + [f(\Delta(A_{n-2}))]_2, \\ [f(\Delta^+(\mathbf{x} - \{x_{n-1}, x_n\}, B_{\setminus\{x_{n-1}, x_n\}}))]_2 &= [f(\text{cone}(\Delta(A_{n-3})))]_2 \\ &= [f(\Delta(A_{n-3}))]_2 + [f(\Delta(A_{n-3}))]_3 \end{aligned}$$

by Corollary 4.9. Finally, we have

$$[f(\text{join}(\Delta_1, \Delta(A_{n-3})))]_1 = [f(\Delta(A_{n-3}))]_1 + 2[f(\Delta(A_{n-3}))]_2 + [f(\Delta(A_{n-3}))]_3$$

by (3.3). By substituting and simplifying the above equations, we have (4.18). The combinatorial formula of $f_{D_n, k}$ has already given by [Slo, A080721], and it is

$$(4.19) \quad f_{D_n, k} = \binom{n}{k+1} \left(\binom{n+k+1}{k+1} - \binom{n+k-1}{k} \right).$$

By (4.18) and (4.19), if $k \neq 0$, we have

$$(4.20) \quad \begin{aligned} f_{D_n, k}^+ &= \frac{1}{2}(f_{D_n, k} + f_{D_{n-1}, k} + f_{A_{n-3}, k-1} + f_{A_{n-3}, k-2}) - f_{A_{n-2}, k-1} - f_{A_{n-2}, k-2} \\ &= \frac{1}{2} \binom{n}{k+1} \left(\binom{n+k+1}{k+1} - \binom{n+k-1}{k} \right) + \frac{1}{2} \binom{n-1}{k+1} \left(\binom{n+k}{k+1} - \binom{n+k-2}{k} \right) \\ &\quad - \frac{1}{k+1} \binom{n-2}{k} \binom{n+k}{k} - \frac{1}{k} \binom{n-2}{k-1} \binom{n+k-1}{k-1} + \frac{1}{2k+2} \binom{n-3}{k} \binom{n+k-1}{k} \\ &\quad + \frac{1}{2k} \binom{n-3}{k-1} \binom{n+k-2}{k-1}. \end{aligned}$$

If $k = 0$, we have $f_{D_n, 0}^+ = n^2 - n$. By organizing (4.19), we obtain the desired equation (4.17). This equation is also correct in the case that $k = 0$. \square

Remark 4.37. The formula is given more generally in [Kra06, Theorem FD]. The equation (4.17) corresponds with [Kra06, Theorem FD] in the case that $m = 1, \ell = 0$.

Example 4.38. Let (\mathbf{x}, B) be a seed, which is the same as in Example 4.26. Then, $\Delta^+(\mathbf{x}, B)$ is a domain which is filled with gray in Figure 25.

5. ALGORITHM TO CALCULATE FACE VECTORS OF POSITIVE CLUSTER COMPLEXES

In this section, we provide an algorithm to calculate face vectors of positive cluster complexes along with a concrete example. First, we give face vectors of positive cluster complexes of tree Dynkin type under a specific condition. We have already obtained the formula of face vectors for the classical type in Section 4.

Theorem 5.1. *Let B be an exchange matrix of tree $A_n, B_n, C_n,$ or D_n type. Then, $f(\Delta^+(\mathbf{x}, B))$ is given by the following list.*

$$(A_n) \quad \frac{1}{k+2} \binom{n}{k+1} \binom{n+k+1}{k+1},$$

$$(B_n) \quad \binom{n}{k+1} \binom{n+k}{k+1},$$

FIGURE 25. positive cluster complex of D_3 type

(C_n) same as B_n type,

$$(D_n) \binom{n}{k+1} \binom{n+k-1}{k+1} + \binom{n-1}{k} \binom{n-k-2}{k} - \frac{1}{n-1} \binom{n-1}{k} \binom{n+k-1}{k+1}.$$

Proof. It follows from Corollaries 4.9, 4.21, and 4.36. □

For exceptional type, we calculate face vectors using SageMath and the software package ClusterSeed.

Theorem 5.2. *Let B be an exchange matrix of tree E_6, E_7, E_8, F_4 , or G_2 type. Then, $f(\Delta^+(\mathbf{x}, B))$ is given by the following list.*

- (E_6) (1, 36, 300, 1035, 1720, 1368, 418),
- (E_7) (1, 63, 777, 3927, 9933, 13299, 9009, 2431),
- (E_8) (1, 120, 2135, 15120, 54327, 108360, 121555, 71760, 17342),
- (F_4) (1, 24, 101, 144, 66),
- (G_2) (1, 6, 5).

Combining Theorem 5.1 with Theorem 5.2, we have the following corollary.

Corollary 5.3. *Let B be an exchange matrix of tree Dynkin type. Then, $f(\Delta^+(\mathbf{x}, B))$ is given by the list in Theorem 5.1 and 5.2.*

By using these facts and Theorem 3.5, we calculate Example 3.12 again.

Let (\mathbf{x}, B) and (\mathbf{x}'', B'') be the same as in Example 3.12. The vector $f(\Delta^+(\mathbf{x}, B)) - f(\Delta^+(\mathbf{x}'', B''))$ is given by the following steps:

- (1) Since $(\mathbf{x}'', B'') = \mu_1(\mathbf{x}, B)$, we consider full subquivers of Q_B and $Q_{B''}$ excluded vertices labeled by 1. We denote these quivers as \hat{Q}_B and $\hat{Q}_{B''}$, and they are as follows.

$$\hat{Q}_B = 2 \quad 3, \quad \hat{Q}_{B''} = 2 \leftarrow 3.$$

We note that they are products of quivers that are mutation equivalent to Dynkin quivers.

- (2) Let \hat{B} and \hat{B}'' be the corresponding exchange matrices of \hat{Q}_B and $\hat{Q}_{B''}$. We calculate $f(\Delta^+((x_2, x_3), \hat{B}))$ and $f(\Delta^+((x_2, x_3), \hat{B}''))$. Since \hat{Q}_B is Dynkin $A_1 \times A_1$ diagram and $\hat{Q}_{B''}$ is Dynkin A_2 diagram, we have

$$\begin{aligned} f(\Delta^+((x_2, x_3), \hat{B})) &= (1, 2, 1) \\ f(\Delta^+((x_2, x_3), \hat{B}'')) &= (1, 3, 2). \end{aligned}$$

by (3.1), (3.3) and Theorem 5.1.

- (3) We calculate the shift to the right by 1 of the difference of $f(\Delta^+((x_2, x_3), \hat{B}))$ and $f(\Delta^+((x_2, x_3), \hat{B}''))$; that is,

$$[f(\Delta^+((x_2, x_3), \hat{B}''))]_1 - [f(\Delta^+((x_2, x_3), \hat{B}))]_1 = (0, 0, 1, 1).$$

By Theorem 3.5, it corresponds with $f(\Delta^+(\mathbf{x}, B)) - f(\Delta^+(\mathbf{x}'', B''))$.

Furthermore, we can calculate $f(\Delta^+(B, \mathbf{x}))$ using Theorem 5.1 (and Corollary 5.3), and the value is $(1, 6, 10, 5)$. Therefore, we have

$$f(\Delta^+(\mathbf{x}'', B'')) = (1, 6, 10, 5) + (0, 0, -1, -1) = (1, 6, 9, 4).$$

By repeating this algorithm, we can calculate face vectors of all positive cluster complexes of A_n type. In the case of other type, we can also calculate the same way as the above. If a non-Dynkin quiver Q' appears when step (1) is complete, we need to calculate the face vector of a positive cluster complex associated with Q' by applying this algorithm to Q' .

6. APPLICATION TO τ -TILTING THEORY OF CLUSTER-TILTED ALGEBRAS

6.1. τ -tilting simplicial complexes. In this section, we describe applications to the representation theory of algebras. We begin by introducing some notations and definitions. Through this section, K is an algebraically closed field. Let Λ be a finite dimensional basic K -algebra. We denote by $\mathbf{mod} \Lambda$ a category of finitely generated modules of Λ , and by $\mathbf{proj} \Lambda$ the full subcategory of $\mathbf{mod} \Lambda$ the objects of which are projective modules. We consider that a module $M \in \mathbf{mod} \Lambda$ is a τ -rigid module if $\mathrm{Hom}_{\mathcal{C}}(M, \tau M) = 0$, where τ is the AR-translation in Λ . Let $|M|$ be the number of non-isomorphic indecomposable direct summands of M . If M is a τ -rigid module and satisfies $|M| = |\Lambda|$, we say that M is a τ -tilting module. We denote by $\tau\text{-tilt} \Lambda$ the set of isomorphism classes of basic τ -tilting modules of Λ .

Next, we introduce a generalization of τ -rigid, or τ -tilting modules given by [AIR14].

Definition 6.1. Let (M, P) be a pair with $M \in \mathbf{mod} \Lambda$ and $P \in \mathbf{proj} \Lambda$.

- (1) We say that (M, P) is a τ -rigid pair of Λ if M is τ -rigid and $\mathrm{Hom}_{\Lambda}(P, M) = 0$,
- (2) We say that (M, P) is a τ -tilting pair of Λ if (M, P) is a τ -rigid pair and $|M| + |P| = |\Lambda|$.

We say that a τ -rigid pair (M, P) is *indecomposable* (resp. *basic*) if $M \oplus P$ is indecomposable (resp. basic). Note that, if (M, P) is indecomposable, then either M or P is 0. We consider the following simplicial complexes induced by τ -rigid pairs and τ -rigid modules.

Definition 6.2.

- (1) We define a *support τ -tilting simplicial complex* $\Delta(s\Lambda)$ of Λ as a complex the vertex set of which comprises isomorphism classes of indecomposable τ -rigid pairs and simplices of which are isomorphism classes of basic τ -rigid pairs of Λ .

- (2) We define a τ -tilting simplicial complex $\Delta(\Lambda)$ of Λ as a complex the vertex set of which is of isomorphism classes of indecomposable τ -rigid modules and simplices of which are isomorphism classes of basic τ -rigid modules of Λ .

For a finite dimensional basic K -algebra Λ , we denote by Q_Λ a quiver, which satisfies $\Lambda \cong KQ_\Lambda/I$, where I is an admissible ideal. In parallel with seed mutation, we define a τ -tilting mutation.

Definition & Proposition 6.3 ([AIR14, Theorem 2.18]). *Let Λ be a finite dimensional K -algebra and $(M \oplus N, P \oplus Q)$ a τ -tilting pair of Λ , where (N, Q) is an indecomposable τ -rigid pair. There exists a unique indecomposable τ -rigid pair (N', Q') such that $(N, Q) \neq (N', Q')$ and $(M \oplus N', P \oplus Q')$ is a τ -tilting pair. We say that $(M \oplus N', P \oplus Q')$ is the τ -tilting mutation of (M, P) in direction (N, Q) , and we denote by $(M \oplus N', P \oplus Q') = \mu_{(N, P)}(M \oplus N, P \oplus Q)$.*

On $\Delta(s\Lambda)$ or $\Delta(\Lambda)$, the mutation is the operation of moving from a maximal simplex to a neighboring maximal simplex. We also introduce the support τ -tilting modules.

Definition 6.4. Let $M \in \text{mod } \Lambda$. We say that M is a *support τ -tilting module* if there exists an idempotent $e \in \Lambda$ such that M is a τ -tilting $\Lambda/\Lambda e\Lambda$ -module.

Let $M \in \text{mod } \Lambda$. If M is a τ -tilting $\Lambda/\Lambda e\Lambda$ -module, then $(M, \Lambda e)$ is a τ -tilting pair of Λ . Conversely, if $(M, \Lambda e)$ is a τ -tilting pair of Λ , then M is a τ -tilting $\Lambda/\Lambda e\Lambda$ -module. We can identify the support τ -tilting modules with τ -tilting pairs through this correspondence. When Λ has finitely many isomorphism classes of basic τ -tilting modules, we say that Λ is of *finite τ -tilting type* or *τ -tilting-finite algebra*.

6.2. Cluster categories and cluster-tilted algebras. Let Q be an acyclic (non-valued) quiver and $\mathcal{C}_Q = \mathcal{D}^b(KQ)/\tau^{-1}[1]$ a cluster category of Q . For an additive category \mathcal{C} , we say that $T \in \mathcal{C}$ is a *cluster tilting object* of \mathcal{C} if T satisfies the following two conditions:

- $\text{Hom}_{\mathcal{C}}(T, T[1]) = 0$,
- $\text{Hom}_{\mathcal{C}}(T, Y[1]) = 0$ implies $Y \in \text{add } T$,

where $\text{add } T$ is the full subcategory of \mathcal{C} whose objects are direct summands of direct sums of T . We define a cluster tilting mutation parallel to a seed mutation or a τ -tilting mutation.

Definition & Proposition 6.5 ([IY08, Theorem 5.3]). *Let \mathcal{C}_Q be a cluster category and $T = U \oplus X$ a cluster tilting object in \mathcal{C}_Q , where X is an indecomposable object. There is a unique indecomposable X' such that $X \neq X'$ holds and $T = U \oplus X'$ is cluster tilting objects. We say that $T \oplus U'$ is the cluster tilting mutation of $T \oplus U$ in direction U , and we denote by $T \oplus U' = \mu_U(T \oplus U)$.*

We consider algebras with a connection with cluster categories. We say that Λ is a *cluster-tilted algebra* if there exists an acyclic quiver Q and a cluster tilting object T in \mathcal{C}_Q such that $\Lambda \cong (\text{End}_{\mathcal{C}_Q} T)^{\text{op}}$. Let T, T' be a cluster tilting objects and $\Lambda = (\text{End}_{\mathcal{C}_Q} T)^{\text{op}}$, $\Lambda' = (\text{End}_{\mathcal{C}_Q} T')^{\text{op}}$. We note that if T' is obtained from T by a cluster tilting mutation, then $Q_{\Lambda'}$ is obtained from Q_Λ by a quiver mutation ([BIRS09, Theorem I.1,6]). The object $T = KQ$ is a cluster tilting object in \mathcal{C}_Q , and then we have $Q_\Lambda = Q$. Therefore, for any cluster-tilted algebra Λ of \mathcal{C}_Q , Q_Λ is mutation equivalent to Q . Moreover, for any quiver Q which is mutation equivalent to an acyclic quiver, the corresponding cluster-tilted algebra $\Lambda = KQ/I$ is uniquely determined (see [BIRS11, Theorem 2.3]).

We can identify τ -tilting simplicial complexes with positive cluster complexes by the following theorem.

Theorem 6.6. *Let Q_Λ be a quiver which is mutation equivalent to a Dynkin quiver, and B_Λ a skew-symmetric matrix whose associated quiver is Q_Λ . Then, we have $\Delta(s\Lambda) \cong \Delta(\mathbf{x}, B_\Lambda)$ and its restriction gives $\Delta(\Lambda) \cong \Delta^+(\mathbf{x}, B_\Lambda)$.*

Proof. By [AIR14, Theorem 4.1], we have a bijection between indecomposable rigid objects in \mathcal{C}_Q and indecomposable τ -rigid pairs of Λ , which is lifted to a bijection between basic rigid objects in \mathcal{C}_Q (resp. basic rigid objects in \mathcal{C}_Q , which do not have direct summand of non-zero direct summands in $\mathbf{add} T[1]$) and summands of basic τ -tilting pairs (resp. basic τ -rigid modules) of Λ . In contrast, by [FK10, Proposition 2.3] and [CKLP13, Corollary 3.5], the compositions of shift function and the inverse map of the cluster character $[1] \circ CC_T^{-1}$ gives a bijection between cluster variables in $P(\mathbf{x}, B)$ and indecomposable objects in \mathcal{C}_Q . It is lifted to a bijection between subsets of clusters in $P(\mathbf{x}, B)$ (resp. subsets of clusters in $P(\mathbf{x}, B)$ not containing initial variables) and rigid objects in \mathcal{C}_Q (resp. rigid objects in \mathcal{C}_Q which do not have direct summand of non-zero direct summands in $\mathbf{add} T[1]$). Therefore, we have the desired isomorphism. \square

We remark that the isomorphism in Theorem 6.6 is compatible with τ -tilting/seed mutations. Therefore, we obtain the following proposition.

Proposition 6.7. *A cluster-tilted algebra Λ is finite representation type if and only if $\Delta(\mathbf{x}, B_\Lambda)$ is of finite type.*

Proof. From the above discussion, Λ is finite τ -tilting type if and only if $\Delta(\mathbf{x}, B_\Lambda)$ is of finite type. Moreover, we have the equivalence of finite τ -tilting type and finite representation type by [Zit20, Theorem 3.1]. \square

By Theorem 6.6, $\Delta(s\Lambda)$ and $\Delta(\Lambda)$ depend only on their quiver Q_Λ . In particular, $\Delta(s\Lambda)$ depends only on its mutation equivalence class.

6.3. Corollaries in representation theory. Using an isomorphism in Theorem 6.6 and results from Section 3, we have some corollaries on the cluster-tilted algebra of finite representation type. Let $T = U \oplus X$ be a cluster tilting object in \mathcal{C}_Q , where X is indecomposable.

We denote by $e_X \in \Lambda$ an idempotent corresponding X and $Q_\Lambda \setminus X$ a full subquiver of Q consisting of all vertices of Q except that corresponding to X . The following corollaries are analogs of Theorem 3.5 and its corollaries.

Corollary 6.8. *Let $\Lambda = (\text{End}_{\mathcal{C}_Q} T)^{\text{op}}$, $\Lambda' = (\text{End}_{\mathcal{C}_Q} T')^{\text{op}}$ be cluster-tilted algebras of finite representation type. We assume that T' is obtained from T by a mutation in direction X . Conversely, we assume that T is obtained from T' by a mutation in direction X' . We denote by $\Lambda_- = \Lambda/\Lambda e_X \Lambda$ and $\Lambda'_- = \Lambda'/\Lambda e_{X'} \Lambda'$. Then, we have*

$$(6.1) \quad f(\Delta(\Lambda)) - f(\Delta(\Lambda')) = [f(\Delta(\Lambda'_-))]_1 - [f(\Delta(\Lambda_-))]_1.$$

Proof. By [BMR08, Theorem 2.13], $\Lambda/\Lambda e_X \Lambda$ is the cluster-tilted algebra associated with a quiver $Q_\Lambda \setminus X$. Therefore, the statement follows from Theorems 3.5 and 6.6. \square

Corollary 6.9. *Let Λ and Λ' be cluster-tilted algebras of finite representation type. If $Q_{\Lambda'}$ is obtained from Q_Λ by a sink or source quiver mutation, then we have a bijection between the simplicial set of $\Delta(\Lambda)$ and that of $\Delta(\Lambda')$. Furthermore, this bijection induces a bijection between simplices of $\Delta(\Lambda)$ and $\Delta(\Lambda')$ in each dimension.*

In particular, Λ and Λ' have the same numbers of isomorphism classes of basic τ -rigid modules.

Proof. It follows Corollary 3.8 and Theorem 6.6. \square

Particularly, the following corollary has been given by [MRZ03, Proposition 6.1] and [Eno20, Theorem A.3] in other manners.

Corollary 6.10. *Let Λ and Λ' be finite dimensional hereditary algebras. If Q_Λ and $Q_{\Lambda'}$ have the same underlying graph, then we have a bijection between the simplicial set of $\Delta(\Lambda)$ and that of $\Delta(\Lambda')$. Furthermore, this bijection induces a bijection between simplices of $\Delta(\Lambda)$ and $\Delta(\Lambda')$ in each dimension.*

Proof. The above follows from Corollary 3.9 and Theorem 6.6. \square

Using the result in Section 4, we have explicit descriptions of $\Delta(\Lambda)$ in some special cases. The following corollary is an explicit description of a (τ -)tilting simplicial complex of special A_n type.

Corollary 6.11. *Let Λ_{A_n} be a n -dimensional hereditary algebra whose quiver is given by (4.1). Then $\Delta(\Lambda_{A_n})$ is isomorphic to a cone of $\Delta(s\Lambda_{A_{n-1}})$.*

Proof. The statement follows from Theorems 4.4 and 6.6. \square

Remark 6.12. We also provide a proof of Corollary 6.11 using τ -tilting reduction. (See Appendix A.)

Before describing a (τ -)tilting simplicial complex of special D_n type, we define the compatibility of indecomposable modules.

Definition 6.13. For indecomposable modules T, S of Λ , we say that T is *compatible* with S if $T \oplus S$ is τ -rigid.

Corollary 6.14. *Let Λ_{D_n} be a n -dimensional hereditary algebra whose quiver is given by (4.13) or (4.14). Let $I = \{T_1, \dots, T_n\}$ be the set of indecomposable summands of T and Δ_{glue} a full subcomplex of $\Delta(s\Lambda_{D_n})$ whose vertex set consists of all 0-dimensional simplices of $\text{st}_{\Delta(s\Lambda_{D_n})}(I \setminus \{T_{n-1}, T_n\})$, which are not in $\{T_1, \dots, T_{n-2}\}$ and compatible with both T_{n-1} and T_n . Then, $\Delta(\Lambda_{D_n})$ is isomorphic to a complex obtained by gluing $\text{join}(\Delta_0, \Delta_1, \Delta(s\Lambda_{A_{n-3}}))$ and $\text{st}_{\Delta(s\Lambda_{D_n})}(I \setminus \{T_{n-1}, T_n\})$ together along $\text{join}(\Delta_1, \Delta(s\Lambda_{A_{n-3}}))$ and Δ_{glue} , where Δ_i is the i -dimensional simplex.*

Proof. The statement follows from Theorems 4.28 and 6.6. \square

Example 6.15. Let Q be a quiver $Q = 1 \begin{array}{c} \curvearrowright \\ \longrightarrow \end{array} 2 \begin{array}{c} \curvearrowright \\ \longrightarrow \end{array} 3$. We consider a cluster category \mathcal{C}_Q and its cluster tilting object $T = \frac{1}{2} \oplus 2 \oplus \frac{3}{2}$. Then $\Lambda := (\text{End}_{\mathcal{C}_Q} T)^{\text{op}} \cong KQ$ and $\Delta(s\Lambda)$ and $\Delta(\Lambda)$ of Λ are shown in Figure 26. Let T' be a cluster tilting object obtained from T by a mutation in direction $\frac{3}{2}$. Then, we have $T' = \frac{1}{2} \oplus 2 \oplus \frac{3}{2} [1]$ and $\Lambda' := (\text{End}_{\mathcal{C}_Q} T')^{\text{op}} \cong KQ'$, where $Q' = 1 \begin{array}{c} \curvearrowright \\ \longrightarrow \end{array} 2 \begin{array}{c} \curvearrowright \\ \longrightarrow \end{array} 3$. Complexes $\Delta(s\Lambda')$ and $\Delta(\Lambda')$ of Λ' are in Figure 27. On the other hand, let T'' be a cluster tilting object obtained from T by a mutation in direction $\frac{1}{2}$. Then, we have $T'' = 3 \oplus 2 \oplus \frac{3}{2}$ and

$\Lambda'' := (\text{End}_{\mathcal{C}_Q} T'')^{\text{op}} \cong KQ''/I$, where $Q'' = 1 \begin{array}{c} \xrightarrow{\alpha} \\ \xleftarrow{\beta} \end{array} 2 \begin{array}{c} \xrightarrow{\alpha} \\ \xleftarrow{\gamma} \end{array} 3$ and $I = \langle \alpha\beta, \beta\gamma, \gamma\alpha \rangle$. The complexes $\Delta(s\Lambda'')$ and $\Delta(\Lambda'')$ of Λ'' are in Figure 28.

By Theorem 6.6, we have $\Delta(s\Lambda) \cong \Delta(s\Lambda') \cong \Delta(s\Lambda'') \cong \Delta(\mathbf{x}, B)$, $\Delta(\Lambda) \cong \Delta^+(\mathbf{x}, B)$, $\Delta(\Lambda') \cong \Delta^+(\mathbf{x}', B')$, and $\Delta(\Lambda'') \cong \Delta^+(\mathbf{x}'', B'')$, where $\Delta^+(\mathbf{x}, B)$, $\Delta(\mathbf{x}, B)$, $\Delta^+(\mathbf{x}', B')$, and $\Delta^+(\mathbf{x}'', B'')$ is the same notation as those in Examples 3.10 and 3.12.

FIGURE 27. Support τ -tilting simplicial complex and τ -tilting simplicial complex of Λ'

6.4. **h -vectors and Hasse quivers.** We consider the application of h -vectors of τ -tilting simplicial complexes.

Definition 6.16. Let K be a pure simplicial complex and K_{\max} the set of all maximal simplices in K . We say that K is *shellable* if there exists a total order \preceq in K_{\max} such that $(\cup_{S' \prec S} S') \cap S$ is a pure proper maximal simplicial complex for all $S \in K_{\max}$.

FIGURE 28. Support τ -tilting simplicial complex and τ -tilting simplicial complex of Λ''

We prove the shellability of τ -tilting simplicial complexes.

Theorem 6.17. *For a τ -tilting-finite algebra Λ , $\Delta(\Lambda)$ is shellable.*

Let $s\tau\text{-tilt}\Lambda$ be the set of all isomorphism classes of basic support τ -tilting modules in $\text{mod } \Lambda$. To prove Theorem 6.17, we introduce the partial order \preceq in $s\tau\text{-tilt}\Lambda$. For $M, N \in s\tau\text{-tilt}\Lambda$, we define $M \preceq N$ if $\text{Fac}M \subset \text{Fac}N$. The *Hasse quiver* $\text{Hasse}(s\tau\text{-tilt}\Lambda)$ of Λ is the following quiver:

- The vertex set is $s\tau\text{-tilt}\Lambda$.
- Let M, N be support τ -tilting modules in Λ . We draw an arrow $M \rightarrow N$ if $M \succ N$ and there is no support τ -tilting module L such that $M \succ L \succ N$.

We denote by $\text{Hasse}(\tau\text{-tilt}\Lambda)$ the full subquiver of $\text{Hasse}(s\tau\text{-tilt}\Lambda)$ whose vertex set consists of τ -tilting module of Λ .

Example 6.18. Let Λ_{A_3} be a cluster-tilted algebra associated with the linearly oriented quiver of A_3 type. Then, $\text{Hasse}(s\tau\text{-tilt}\Lambda)$ and $\text{Hasse}(\tau\text{-tilt}\Lambda)$ are as in Figure 29.

We use the following characterization of the Hasse quiver of $s\tau\text{-tilt}\Lambda$.

Theorem 6.19 ([AIR14, Theorem 2.33]). *For τ -tilting pairs (M, P) and (M', P') , the following conditions are equivalent.*

- (i) (M, P) is a mutation of (M', P') ,
- (ii) M is connected to M' by an edge in $\text{Hasse}(s\tau\text{-tilt}\Lambda)$.

Lemma 6.20. *Let Λ be a τ -tilting-finite algebra. For any basic support τ -tilting Λ -modules M, N , if there is an arrow $M \rightarrow N$ in $\text{Hasse}(s\tau\text{-tilt}\Lambda)$, then we have $|M| \geq |N|$.*

Proof. Let (M, P) and (N, Q) be the corresponding τ -tilting pair of M and N . By Theorem 6.19, there exist indecomposable modules X and X' such that $((M \setminus X) \oplus$

FIGURE 29. $\text{Hasse}(s\tau\text{-tilt}\Lambda_{A_3})$ and $\text{Hasse}(\tau\text{-tilt}\Lambda_{A_3})$ 

$(M \oplus X', P \setminus X) = (N, Q)$, $(M \setminus X, P \oplus X') = (N, Q)$, or $(M \oplus X', P \setminus X) = (N, Q)$. If $(M \oplus X', P \setminus X) = (N, Q)$, then we have $\text{Fac}M \subset \text{Fac}N$. This contradicts $M \rightarrow N$. Therefore, we have $((M \setminus X) \oplus X', P) = (N, Q)$ or $(M \setminus X, P \oplus X') = (N, Q)$ and $|M| \geq |N|$. \square

For support τ -tilting simplicial complexes, the following theorem is known.

Theorem 6.21 ([DIJ19, Theorem 5.4]). *Let Λ be a τ -tilting-finite algebra. Then, $\Delta(s\Lambda)$ is shellable for a total order preserving the partial orders \preceq or \preceq^{op} .*

Proof of Theorem 6.17. We set $|\Lambda| = n$. It suffices to construct a total order preserving the partial order \preceq^{op} such that every τ -tilting module is smaller than every non- τ -tilting support τ -tilting module. We prove the dual; that is, there is a total order preserving the partial order \preceq such that every τ -tilting module is larger than all non- τ -tilting support τ -tilting modules. Choose the maximal element in $\Delta(s\Lambda)_{\max}$ in the partial order \preceq , remove the chosen element from the whole, and then choose one of the maximal elements for \preceq from the set, and so on, until the set is empty. In this case, for any two support τ -tilting modules, if we determine the order under the rule that the one which is chosen earlier is greater, then this order is the total order such that the original partial order is preserved. Now, we can make the order of choosing support τ -tilting modules such that all τ -tilting modules are chosen before choosing the others. Assuming that this is impossible, there will be arrows from supporting τ -tilting modules with less than n direct commutations to support τ -tilting modules with n , which contradicts Lemma 6.20. \square

Let K be a shellable simplicial complex for the order \preceq of K_{\max} . We set $\{F_1, \dots, F_m\} = K_{\max}$, where $F_i \preceq F_j$ if and only if $i \leq j$. Let $N(F_j)$ be the number of vertices x of F_j such that at least one face of codimension 1 of F_j not containing x is contained

in F_1, F_2, \dots, F_{j-1} . Let $h = (h_0, h_1, \dots, h_n)$ be the h -vector of K . Then, we have

$$h_i = \#\{1 \leq j \leq m \mid N(F_j) = i\}.$$

For further details, see [Zie95, Section 8.3]. Let Λ be a τ -tilting-finite algebra. Since every codimension 1 simplex in $\Delta(\Lambda)$ is contained in 1 or 2 maximal simplices, $N(F_j)$ coincides with the number of F_k such that $k < j$ and the codimension of $F_k \cap F_j$ is 1. Furthermore, this is the number of arrows the terminals of which are the support tilting module corresponding to F_j in $\text{Hasse}(\tau\text{-tilt}\Lambda)$. For $M \in \tau\text{-tilt}\Lambda$, we denote by $T(M)$ the number of arrows whose terminal is M in $\text{Hasse}(\tau\text{-tilt}\Lambda)$. Set

$$(6.2) \quad h_i(\Lambda) = \#\{M \in \tau\text{-tilt}\Lambda \mid T(M) = i\}.$$

By Theorem 6.17, $(h_0(\Lambda), h_1(\Lambda), \dots, h_n(\Lambda))$ is the h -vector of $\Delta(\Lambda)$. Therefore, when $\Delta(\Lambda)$ is a cluster-tilted algebra of finite representation type, we have the following corollaries by Corollaries 3.15, 3.16 and Theorem 6.6.

Corollary 6.22. *Let Λ and Λ' be cluster-tilted algebras of the finite representation type. If $Q_{\Lambda'}$ is obtained from Q_{Λ} by a sink or source quiver mutation, then $h_i(\Lambda)$ coincide with $h_i(\Lambda')$ for any i .*

Corollary 6.23. *Let Λ and Λ' be finite dimensional hereditary algebras. If Q_{Λ} and $Q_{\Lambda'}$ have the same underlying graph, then $h_i(\Lambda)$ coincide with $h_i(\Lambda')$ for any i .*

Example 6.24. Let $Q = 1 \leftarrow 2 \leftarrow 3 \leftarrow 4$ and $Q' = 1 \leftarrow 2 \leftarrow 3 \rightarrow 4$. Let Λ, Λ' be cluster-tilted algebras associated with Q and Q' , respectively. The h -vector of both $\Delta(\Lambda)$ and $\Delta(\Lambda')$ are $h = (1, 6, 6, 1)$ (see Figure 30).

APPENDIX A. PROOF OF COROLLARY 6.11 USING τ -TILTING REDUCTION

In this section, we provide another proof of Corollary 6.11 without using cluster algebra theory. Through this section, we abbreviate Λ_{A_n} to Λ and $\Lambda_{A_{n-1}}$ to Λ' . Moreover, we denote by $P_1 \oplus \dots \oplus P_n$ the indecomposable decomposition of ${}_{\Lambda}\Lambda$, where P_n is the unique indecomposable projective-injective module of Λ .

First, we begin with the following proposition.

Proposition A.1. $\Delta(\Lambda) = \text{st}_{\Delta(s\Lambda)}(P_n, 0)$.

Proof. First, we prove $\text{st}_{\Delta(s\Lambda)}(P_n, 0) \subset \Delta(\Lambda)$. Let $X = (M, P) \in \text{st}_{\Delta(s\Lambda)}(P_n, 0)$. It suffices to show that $(P_n \oplus M, P)$ is not a τ -rigid pair if $P \neq 0$. We assume $P \neq 0$. Since there exists an injection from P_i to P_n for any $1 \leq i \leq n$, we have $\text{Hom}_{\Lambda}(P, P_n \oplus M) \neq 0$. Therefore, $(P_n \oplus M, P)$ is not τ -rigid pair. Next, we prove $\Delta(\Lambda) \subset \text{st}_{\Delta(s\Lambda)}(P_n, 0)$. For any basic τ -rigid module M , it suffices to show $\text{Hom}_{\Lambda}(P_n \oplus M, \tau(P_n \oplus M)) = 0$. Since P_n is projective, we have $\tau(P_n \oplus M) = \tau M$. By using the Auslander-Reiten formula, we have $\text{Hom}_{\Lambda}(P_n, \tau M) = \text{Ext}_{\Lambda}(M, P_n) = 0$ since P_n is injective. Therefore, we have

$$\text{Hom}_{\Lambda}(P_n \oplus M, \tau(P_n \oplus M)) = \text{Hom}_{\Lambda}(M, \tau M) = 0$$

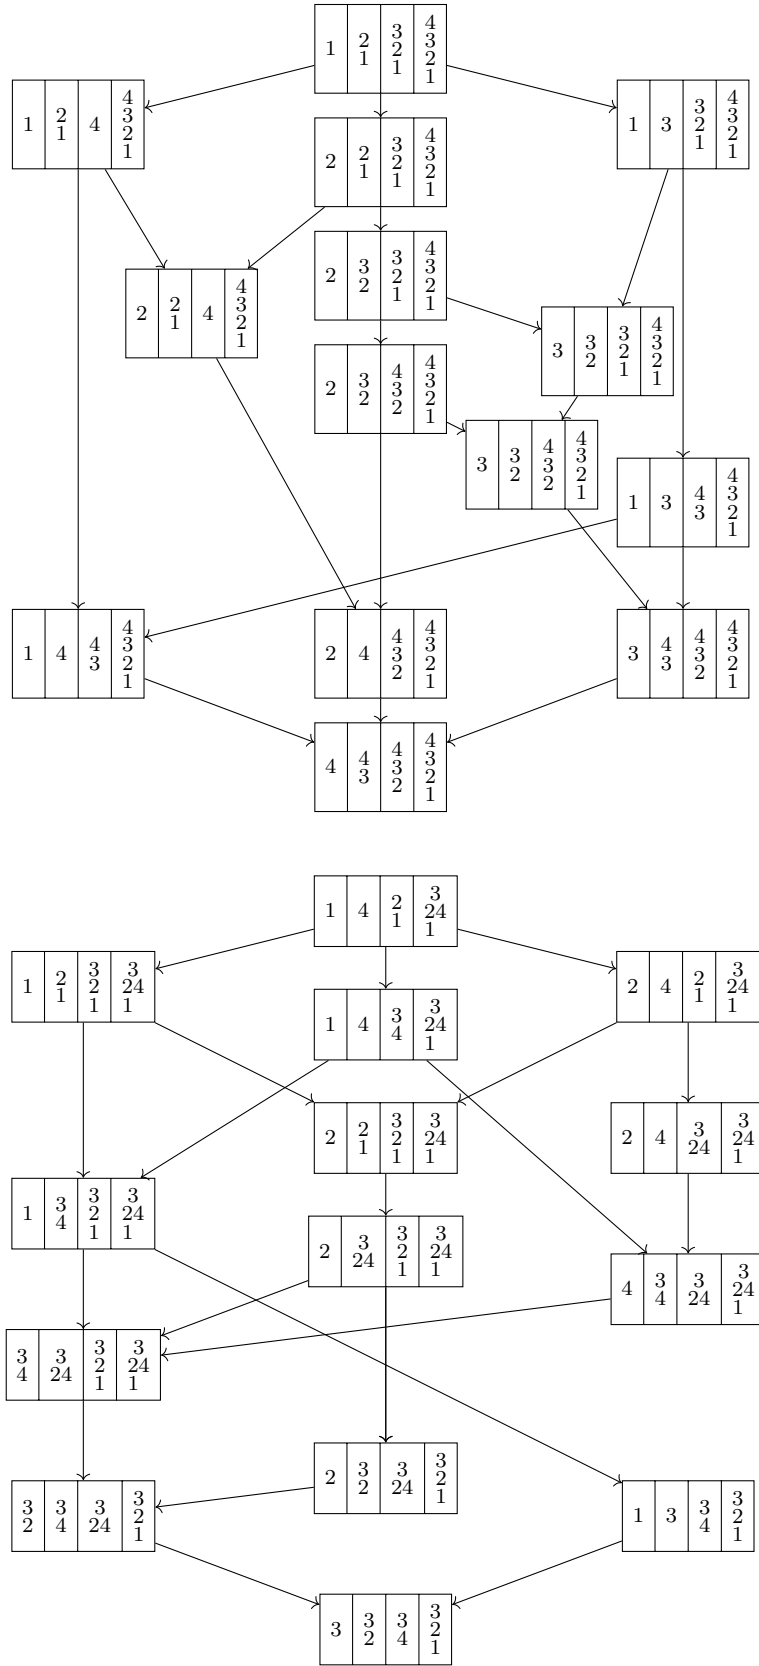

Therefore, we have $\Delta(\Lambda) \subset \text{st}_{\Delta(s\Lambda)}(P_n, 0)$. \square

We use τ -tilting reduction instead of Lemma 3.6. We fix A as a finite dimensional algebra, U is a τ -tilting module of A , and T_U is the Bongartz completion of U . Let $B = \text{End}_A T_U$ and $C = B/\langle e_U \rangle$, where e_U is the idempotent corresponding $\text{Hom}_A(T_U, U)$. For $M \in \text{mod } A$, we denote by

$$0 \rightarrow \text{t}M \rightarrow M \rightarrow \text{f}M \rightarrow 0$$

the canonical sequence associated with a torsion pair $(\text{Fac}U, U^{\perp})$. Then, we have the following theorem.

FIGURE 30. $\text{Hasse}(\tau\text{-tilt}\Lambda)$ and $\text{Hasse}(\tau\text{-tilt}\Lambda')$

Theorem A.2 ([Jas15, Theorem 3.15, Corollary 3.16]). *The map*

$$\mathrm{Hom}_{\Lambda}(T_U, f(-)): s\tau\text{-tilt}_U A \rightarrow s\tau\text{-tilt } C$$

is a bijection. Moreover, this bijection is compatible with support τ -tilting mutations.

Proof of Corollary 6.11. By Proposition A.1 and Lemma 2.11, it suffices to show that

$$(A.1) \quad \mathrm{lk}_{\Delta(s\Lambda)}(P_n, 0) \cong \Delta(s\Lambda').$$

We set $A = \Lambda$ and $U = P_n$. Then, we have $T = \Lambda$, $B = \mathrm{End}_{\Lambda} \Lambda \cong \Lambda$ and $C \cong \Lambda'$. Therefore, by applying the above setting to Theorem A.2, we have a bijection

$$f(-): s\text{-tilt}_{P_n} \Lambda \rightarrow s\text{-tilt } \Lambda'.$$

Moreover, this bijection is compatible with support τ -tilting mutations. Therefore, we obtain (A.1) as desired. \square
