#### Invariant Gorenstein Rings On 3-Dimensional Vector Spaces

#### Tamir Buqaie

#### Supervised by: Prof. Amiram Braun

#### Abstract

For a finite subgroup  $G \subset SL(V)$ , let  $S(V)^G$  denote the subring of G-invariants, where V is a 3- dimensional G - module over F and S(V) the symmetric algebra of V. In this thesis we discuss the modular case of invariant theory, that is, when charF = p divides |G|. The aim of this work is to classify **Gorenstein** ring of the form  $S(V)^G$ .

A.Braun in [2] and Fleischmann-Woodcock in [6] proved that if  $S(V)^G$  is Cohen-Macaulay ring and  $S(V)^{W(G)}$  is a polynomial ring then  $S(V)^G$  is Gorenstein if and only if  $G/W(G) \subseteq SL(m/m^2)$ , where W(G) is the G-subgroup generated by all pseudo-reflections and m is the maximal homogenous ideal of  $S(V)^{W(G)}$ . (See [Theorem 1.2]).

Here, since  $G \subset SL(V)$ , we have one kind of pseudo-reflection ,called transvection, in other words W(G) = T(G), where T(G) denote the G- subgroup generated by all transvections of G. This work is divide into 7 chapters, the classification of  $S(V)^G$ , in each chapter, depends on the previous theorem which provides a necessary and sufficient condition for G such that  $S(V)^G$  is Gorenstein. So to apply this theorem we might ask ourselves, whether  $S(V)^{T(G)}$  is polynomial ring and what are the T(G)-invariants of this ring? Or at least, what are the degrees of the T(G)-invariants ? Since  $\dim_F V = 3$ , the Cohen-Macaulay property of  $S(V)^G$  holds [9, Proposition 5.6.10]. These are some of the classical questions that invariant theorists have studied in the modular case.

We prove the following theorem : Let  $G \subset SL(3, \mathbb{F}_p)$  be a finite group and  $V = \mathbb{F}_p^3$  is a reducible *G*-module, then  $S(V)^G$  is Gorenstein. (See [Theorem 1.3]).

#### We explain now how this work is organized.

As mentioned above, we divide our work into 7 chapters. In chapters A, B, D, E, Fand G we fix a basis for V, and represent each  $g \in G$ , by matrices, with respect to this basis. Then we compute the ring of T(G)—invariants. We are mainly concered with the case of  $S(V)^{T(G)}$  being a polynomial ring. Under the assumptions of each chapter we prove that  $S(V)^{T(G)}$  is a polynomial ring. Generally, we can not confirm in chapter D that the polynomial property of  $S(V)^{T(G)}$  holds. We provide in chapters A, B, D, and G, a sufficient and necessary condition on G such that  $S(V)^G$  is Gorenstein ,when  $G \subset SL(3, F)$ . However, in chapter E and F, we exclusively consider the case  $G \subset SL(3, \mathbb{F}_p)$ . The technique in this work will be to exhibit the action of the group G on  $m/m^2$  and using [Theorem 1.2].

In order to prove that  $S(V)^{T(G)}$  is a polynomial ring ,in most cases, we use Kemper's theorem [4, Theorem 3.7.5].

In chapter A, we consider V, a reducible G - module of the form  $V = Fv \oplus W$ and Fv, W are G-submodules with  $\dim_F W = 2$ . This is a special chapter, since by **Proposition 2.3**, the Gorenstein property of  $S(V)^G$  depends on W. So we use the computation of [3], and proceed our proof in steps by dividing it into 3 cases, which are:

- 1. W is an irreducible and primitive T(G) module.
- 2. W is a reducible T(G) module.
- 3. W is an irreducible and imprimitive T(G) module.

In fact, the results in chapter A are obtained from the discussion in [3]. The difference between the situation here and the situation of [3], is that in [3],  $G \subset SL(2, F)$  and here  $\overline{G} = G|W \subset GL(2, F)$ .

In chapter B, we consider V, a reducible, indecomposable G – module which has at least two G-submodules  $W_1, W_2$  where  $dimW_i = 2$  for i = 1, 2. In addition to the main theorem, we prove, under specific condition, that  $S(V)^G$  is Gorenstein in the following cases (see [Theorem 3.5]) :

(i) 
$$p = 3$$
.

- (ii) |G| is prime to 3.
- (iii)  $F = \mathbb{F}_q$ , where  $q = p^s$  and g.c.d(3, s) = 1.

We define a F-vector space X, where  $dim_F X \in \{1, 2\}$ , and separate this chapter into two cases. In the first case, we deal with  $dim(span_F X) = 1$ . In the second case, we deal with  $dim(span_F X) = 2$ , where T(G) is a direct product of two transvection groups  $T_1(G), T_2(G)$ . In Lemma 3.7,Lemma 3.8, and Proposition 3.9 we examine the normality of  $T_1(G), T_2(G)$ . However this is not needed for Proposition 3.10 ,Proposition 3.13, and Corollary 3.14.

Chapter C is different, we provide in this chapter preliminaries to chapters D, E, F and G.

In chapter D, we consider V, a reducible and indecomposable G-module which has a unique G-submodule W with  $\dim_F W = 2$ , and V contains no 1-dimensional G-submodules. In this chapter, we can not conclude that  $S(V)^{T(G)}$  is always polynomial ring. So we make specific assumption (see **Assumption 5.2** )to prove [Theorem 1.3]. This is applicable in case  $F = \mathbb{F}_p$ .

In chapter E, we consider V, a reducible and indecomposable G – module which has a unique 1-dimensional G-submodule  $U = Fv_0$  and V contains no 2-dimensional G-submodules.Hence W = V/U is an irreducible G- module. We exclusively consider here the case  $F = \mathbb{F}_p$ .

There are two cases of W that **Lemma 6.2** have provided .The first case is when W is an unfaithful irreducible T(G)-module, and the second one is when W is a faithful irreducible T(G)-module.

In chapter F, we consider V, a reducible and indecomposable G-module which has a unique G-submodule W with  $dim_F W = 2$ , and a unique 1-dimensional G-submodule  $Fv_0$ , and  $Fv_0 \subset W \subset V$ . We exclusively consider here the case  $F = \mathbb{F}_p$ .

Finally, in chapter G, we consider V, a reducible and indecomposable G – module and contains (at least) two 1-dimensional G-submodules. By using **Proposition 4.3**, we provide a sufficient and necessary condition on G for the Gorenstein property of  $S(V)^G$ , and present the main result in **Corollary 8.1**.

## Index of notations

- $\mathbb{F}_p$  The prime field of order p.
- |G| The order of group G.
- F-A finite field with charF = p.
- $\overline{F}$  The algebraic closure of F.
- S(V) The symmetric algebra of V.
- $S(V)^G$  The subring of G invariants.
- T(G) The G-subgroup generated by all transvections.
- W(G) The G-subgroup generated by all pseudoreflections.
- m- The unique homogenous maximal ideal of  $S(V)^{T(G)}$ .
- $V^*$  The hom-dual  $hom_F(V, F)$ .
- GL(V) The general linear group of V.
- GL(n, F) The linear automorphisms of  $F^n$ .
- SL(V) The special linear group of V.
- SL(n, F) The linear automorphisms of  $F^n$  of determinant 1.
- G|W- The restriction of G to W.
- $<\sigma_1,...,\sigma_s>$  The subgroup generated by  $\{\sigma_1,...,\sigma_s\}$ .
- $Fix_G(W)$  The elements of G, that acts trivially on subspace W.

#### 1 Introduction

Let  $G \subset SL(V)$  be a finite subgroup of SL(V). Let F be a field with charF = p > 0, V a 3- dimensional F- vector space and S(V) the symmetric algebra of V. We denote by  $S(V)^G$  the subring of G-invariants. One of the main purposes of this thesis is to classify Gorenstein rings of the form  $S(V)^G$ , when p divides |G|.

The following are results of K.Watanabe, Fleischmann-Woodcock and A.Braun.

**Theorem 1.1.** (K. Watanabe [10], [11])

Suppose that (|G|, p) = 1 and G contains no pseudo-reflection. Then the following are equivalent:

1.  $G \subset SL(V)$ .

2.  $S(V)^G$  is a Gorenstein ring.

Theorem 1.2. (A.Braun [2], Fleischmann-Woodcock [6])

Suppose that  $S(V)^G$  is Cohen-Macaulay and  $S(V)^{W(G)}$  is a polynomial ring. Then  $S(V)^G$  is Gorenstein iff  $G/W(G) \subseteq SL(m/m^2)$ , where m is the unique homogenous maximal ideal of  $S(V)^{W(G)}$  and W(G) is the G-subgroup generated by all pseudo-reflections(of all types).

Here an element  $g \in G$  is called pseudoreflection if rank(g-I) = 1. If (|G|, p) = 1 then every pseudoreflection is diagonalizable with one's on all but a single diagonal entry. In the modular case, that is if p divides |G| we have a new type of pseudoreflection, called transvection, having the additional property  $(g-I)^2 = 0$ , so it is not diagonalizable.Denote by T(G) the G-subgroup generated by all transvections.

Eagon and Hochster proved in [5] that  $S(V)^G$  is Cohen-Macaulay for all nonmodular groups G, i.e when (|G|, p) = 1. But there are finite p - groups, such that  $S(V)^G$  is not Cohen-Macaulay.

**Example 1.1.** Let F be a field of characteristic p and V is a faithful representation of a non-trivial p-group P and mV denote the faithful representation of G formed by taking the direct sum of m copies of V. Then  $S(mV)^P$  is not Cohen-Maculay when  $m \ge 3./12$ , Theorem 1.2

However in this thesis we assume that  $\dim_F V = 3$  and by [9, Proposition 5.6.10]  $S(V)^G$  is always Cohen-Macaulay ring.

It is shown in [3, Section 2] that  $S(V)^G$  can fail to be Gorenstein even if  $G \subset SL(V)$  and  $\dim V = 2$ . Moreover, [3] provides necessary and sufficient conditions to ensure the Gorenstein property of  $S(V)^G$  in case  $\dim_F V = 2$  and  $G \subset SL(V)$ . We mostly examine here the case of  $\dim_F V = 3, G \subset SL(V)$  and V is a reducible G-module. The analysis is carried out by separation into different cases. A noteworthy consequence is perhaps the following:

**Theorem 1.3.** Let  $G \subset SL(3, \mathbb{F}_p)$  be a finite group and  $V = \mathbb{F}_p^3$  is a reducible *G*-module. Then  $S(V)^G$  is Gorenstein.

This extends a similar result in [3, Corollary (C)]. The separation into cases is summed up in the following table.

Table						
Chapter	V is a reducible $G$ -module.					
A	$V = Fv \oplus W$ and $Fv, W$ are G-submodules.					
В	V is indecomposable and contains (at least) two 2- dimensional					
	$G-$ submodules $W_1, W_2$ .					
D	V is indecomposable, contains a unique 2- dimensional $G$ - sub-					
	module, but no $1-$ dimensional $G-$ submodule.					
E	V is indecomposable, contains a unique 1- dimensional $G$ - sub-					
	module $U$ , but no 2- dimensional $G$ - submodule.					
F	V is indecomposable and $\mathbb{F}_p v_0 \subset W \subset V$ , where $\mathbb{F}_p v_0, W$ are $G$ -					
	submodules and $dim_{\mathbb{F}_p}W = 2$ .					
G	V is indecomposable and contains (at least) two 1- dimensional					
	G- submodules.					

**<u>Convention</u>:** Given a basis  $\{v_1, ..., v_n\}$  of V, and  $g \in G$ . Then  $g(v_i) = \sum_{j=1}^n a_{ij}v_j, a_{ij} \in F$  and the matrix  $A := (a_{ij})$ , representing g, acts on coordinates (=row vectors) from the <u>right</u>.

## **2** Chapter $(A): V = Fv \oplus W$ , and Fv, W are *G*-submodules.

In this chapter we consider V, a reducible G - module of the form  $V = Fv \oplus W$  and Fv, W are G - modules with  $dim_F W = 2$ . **Proposition 2.3** provides a sufficient and necessary condition for G as above, to ensure the Gorenstein property of  $S(V)^G$ . Our proof will proceed in steps by dividing it into 3 cases:

- 1. W is an irreducible and primitive T(G) module.
- 2. W is a reducible T(G) module.
- 3. W is an irreducible and imprimitive T(G) module.

The next two results are usefull in this chapter.

Lemma 2.1. W is a faithful G-module.

*Proof.* Let  $1_G \neq g \in G$ , with g|W = Id. Then

$$g = \left( \begin{array}{ccc} \lambda(g) & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{array} \right).$$

Where  $g(v) = \lambda(g)v$ , for all  $g \in G$ . Since  $G \subset SL(V)$ ,  $\lambda(g) = 1$  and therefore

$$g = \left( \begin{array}{rrr} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{array} \right).$$

A contradiction.

The next result does not require the assumption  $V = Fv \oplus W$ .

**Lemma 2.2.** Suppose that  $G \subset SL(V)$  and U a 1-dimensional G-submodule. Then  $U \subseteq ker(\sigma - I)$  for all transvection  $\sigma$  in G. Equivalently, T(G) acts trivially on U.

Proof. Let  $\sigma \in T(G)$  be a transvection  $, \sigma \neq I$ , and  $M = ker(\sigma - I)$ . Suppose that  $Fu = U \not\subset M$ . Then with respect to a basis  $\{u, m_1, m_2\}, m_1, m_2 \in M$ , we have :  $\sigma = \begin{pmatrix} \lambda(\sigma) & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$ , where  $\sigma(u) = \lambda(\sigma)u$  and  $\sigma|M = Id$ . But  $G \subset SL(V)$ , therefore  $\lambda(\sigma) = 1$ , implying that  $\sigma = I$ , a contardiction.

**Proposition 2.3.** Let  $G \subset SL(V)$  be a finite group and  $V = Fv \oplus W$  a decomposition of V into G - submodules with  $\dim_F W = 2$ . Then the following are equivalent:

- 1.  $S(V)^G$  is Gorenstein.
- 2.  $det(g|W) = det(g|m/m^2)$ , for each  $g \in G$  where m is the unique homogenous maximal ideal of  $S(W)^{T(G)}$ .

Proof. By Lemma 2.2  $S(V)^{T(G)} = S(W)^{T(G)}[v]$ . Now by [8],  $S(W)^{T(G)} = F[a_1, a_2]$  is a polynomial ring, where  $m = (a_1, a_2)$ . Let P be the unique homogenous maximal ideal of  $S(V)^{T(G)}$ , then  $P = (a_1, a_2, v)$ . By [Theorem 1.2]  $S(V)^G$  is Gorenstein if and only if  $1 = det(g|P/P^2) = \lambda(g)det(g|m/m^2)$ , where  $g(v) = \lambda(g)v$ , for all  $g \in G$ . Since  $G \subset SL(V)$ ,  $det(g|W) = \lambda(g)^{-1}$ , hence  $S(V)^G$  is Gorenstein if and only if  $det(g|W) = det(g|m/m^2)$ , for each  $g \in G$ .

The transvections group T(G)|W had been classified by Kantor whenever T(G)|W is an irreducible primitive linear group [7, Theorem 1.5]. So with the above notation one of the following holds:

(i)  $T(G)|W = SL(2, \mathbb{F}_q)$ , where p|q.

(ii) 
$$T(G)|W \cong SL(2, \mathbb{F}_5), T(G)|W \subset SL(2, \mathbb{F}_9)$$
 and  $\mathbb{F}_9 \subseteq F$ .

We now consider the above case (i).

**Proposition 2.4.** Suppose  $G \subset SL(V)$  is a finite group with  $T(G)|W = SL(2, \mathbb{F}_q)$ , where  $q = p^s$  and  $\mathbb{F}_q \subseteq F$ . Let  $V = F^3 = Fv \oplus W$  be the natural SL(3, F) – module. Then  $S(V)^G$  is Gorenstein if and only if  $G|W \subset GL(2, \mathbb{F}_{q^2})$ .

Proof. Recall as in [3, Proposition 3.5] that  $S(W)^{T(G)} = S(W)^{SL(2,\mathbb{F}_q)} = F[u, c_{21}], deg(u) = q + 1, deg(c_{21}) = q^2 - q$ . Let  $g \in G$  be arbitrary and set  $g|W = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$  with respect to the basis  $\{x, y\}$ . So  $g^{-1}|W = \frac{1}{det(g|W)} \begin{pmatrix} d & -b \\ c & d \end{pmatrix}$ . Since  $gT(G)g^{-1} = T(G)$ , we get after restriction to W that  $(g|W) \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} (g^{-1}|W) = \frac{1}{det(g|W)} \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} d & -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\ c & d \end{pmatrix} = \frac{1}{det(g|W)} \begin{pmatrix} a -b \\$ 

Similarly,  $(g|W) \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} (g^{-1}|W) = \frac{1}{det(g|W)} \begin{pmatrix} ad-bc+bd & -b^2 \\ ad-bc-bd \end{pmatrix} \in SL(2, \mathbb{F}_q).$  Set e = det(g|W) = ad - bc. Then  $\frac{ac}{e}, \frac{a^2}{e}, \frac{c^2}{e}, \frac{b^2}{e}, \frac{d^2}{e}, \frac{bd}{e} \in \mathbb{F}_q$ . Assume firstly that  $a \neq 0$ . Then  $\gamma := \frac{c}{a} = \frac{\left(\frac{c^2}{a}\right)}{\left(\frac{ac}{e}\right)} \in \mathbb{F}_q$ . If  $b \neq 0$  then  $\mu := \frac{d}{b} = \frac{\left(\frac{bd}{e}\right)}{\left(\frac{b^2}{e}\right)} \in \mathbb{F}_q$ . Hence  $e = ad - bc = ab\mu - ba\gamma = ab(\mu - \gamma)$  and therefore  $\beta := \frac{b}{a} = \frac{ab(\mu - \gamma)}{a^2(\mu - \gamma)} = \frac{e}{a^2} \in \mathbb{F}_q$ , as well as  $\delta := \frac{d}{a} = \frac{\mu b}{a} = \mu \beta \in \mathbb{F}_q$ . If b = 0 then take  $\beta = 0$  and  $\delta := \frac{d}{a} = \frac{ad}{a^2} = \frac{e}{a^2} \in \mathbb{F}_q$ . So in both cases  $b = a\beta, c = a\gamma, d = a\delta, \beta, \gamma, \delta \in \mathbb{F}_q$ . Therefore  $g|W = \begin{pmatrix} a & 0 \\ 0 & a \end{pmatrix} \begin{pmatrix} 1 & \beta \\ \gamma & \delta \end{pmatrix}$ , with  $h := \begin{pmatrix} 1 & \beta \\ \gamma & \delta \end{pmatrix} \in GL(2, \mathbb{F}_q)$ .

If a = 0 then e = det(g|W) = -bc implies  $b \neq 0 \neq c$ . So we get equality  $g|W = \begin{pmatrix} c & 0 \\ 0 & c \end{pmatrix} \begin{pmatrix} 0 & \beta \\ 1 & \delta \end{pmatrix}$  with c replacing a and  $\beta, \delta \in \mathbb{F}_q$ . Consequently if  $a \neq 0$  we get:  $g(c_{21}) = (aI_W)(h(c_{21})) = a^{q^2-q}c_{21}$ , and as in the proof of [3, Proposition 3.5] we get that  $g(u) = (aI_W)(h(u)) = det(h)a^{degu}u = det(h)a^{q+1}u$ . But  $det(g|W) = a^2det(h)$ , hence  $g(u) = det(g|W)a^{q-1}u$ .

Let  $M = Fu + Fc_{21}$  be the 2-dimensional subspace of the polynomial ring  $S(W)^{T(G)} = F[u, c_{21}], m = (u, c_{21})$ , so  $m/m^2 \cong M$ . Then the matrix representing g|M with respect to the basis  $\{u, c_{21}\}$  is  $\begin{pmatrix} a^{q^{-1}det(g|W)} & 0 \\ 0 & a^{q^2-q} \end{pmatrix}$ . Therefore the condition of **Proposition 2.3** :  $det(g|W) = det(g|m/m^2) = det(g|M)$  is equivalent to:  $det(g|W) = a^{q-1}det(g|W)a^{q^2-q} = a^{q^2-1}det(g|W)$ . Hence it is equivalent to  $a^{q^2-1} = 1$ , namely  $a \in \mathbb{F}_{q^2}$ . Using  $h \in GL(2, \mathbb{F}_q)$ , this is also equivalent to  $g|W = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in GL(2, \mathbb{F}_{q^2})$ . A similar conclusion is obtained if a = 0.

We next consider the above case (ii).

**Proposition 2.5.** Suppose  $G \subset SL(3, F)$  is a finite group with  $T(G)|W \cong SL(2, \mathbb{F}_5), T(G)|W \subseteq SL(2, \mathbb{F}_9)$  and  $\mathbb{F}_9 \subseteq F$  (here p = 3).Let  $V = F^3 = Fv \oplus W$  be the natural SL(3, F) – module. Then  $S(V)^G$  is Gorenstein iff  $G|W \subseteq \langle T(G)|W, \eta I_W \rangle$ , where  $\eta$  is a 20<sup>th</sup>-primitive root of unity.

Proof. Let  $g \in G$ , choose  $\xi \in \overline{F}$  such that  $\xi^2 det(g|W) = 1$ . Hence  $\hat{g} := \xi I_W g|W \in SL(2, \overline{F})$  where  $\overline{F}$  is the algebraic closure of F. Clearly  $\hat{g}(T(G)|W)\hat{g}^{-1} = T(G)|W$ . Therefore the computation in [3, Proposition 3.7], with  $\hat{g}$  instead of g|W, shows that  $\hat{g} \in T(G)|W$ . Hence  $\begin{pmatrix} \xi & 0 \\ 0 & \xi \end{pmatrix} = \hat{g}(g^{-1}|W) \in (T(G)|W)(G|W) = G|W$ . Consequently  $G|W \subseteq \langle T(G)|W, \begin{pmatrix} \lambda & 0 \\ 0 & \lambda \end{pmatrix} |\lambda \in \overline{F} > .$ 

Now  $\binom{\xi \ 0}{0 \ \xi} g|W = \hat{g}|W \in T(G)|W$ . Recall from [3, Proposition 6.6.] that  $S(W)^{SL(2,\mathbb{F}_5)} = F[f_{10}, f_{12}]$ , where  $f_{10} = x_1^9 x_2 - x_1 x_2^9$  and  $f_{12} = x_1^{12} + x_1^{10} x_2^2 - x_1^6 x_2^6 + x_1^2 x_2^{10} - x_2^{12}$ . Hence  $\hat{g}(f_{10}) = f_{10}, \hat{g}(f_{12}) = f_{12}$  implying that  $g(f_{10}) = \xi^{-10} f_{10}, g(f_{12}) = \xi^{-12} f_{12}$ . Let  $U = Ff_{10} + Ff_{12}$  be the 2-dimensional subspace of the polynomial ring  $S(W)^{SL(2,\mathbb{F}_5)} = F[f_{10}, f_{12}] = f_{10} + Ff_{12}$ .

Let  $U = Ff_{10} + Ff_{12}$  be the 2-dimensional subspace of the polynomial ring  $S(W)^{\otimes D(4,2)} = F[f_{10}, f_{12}], m = (f_{10}, f_{12})$ , so  $m/m^2 \cong U$ . Then the matrix representing g|U with respect to the basis  $\{f_{10}, f_{12}\}$  is  $\binom{\xi^{-10} \quad 0}{0 \quad \xi^{-12}}$ . Therefore, by **Proposition 2.3**  $det(g|W) = det(g|m/m^2) = det(g|U)$  is translated into  $\xi^{-2} = \xi^{-22}$  or  $\xi^{20} = 1$ . Therefore  $S(V)^G$  is Gorenstein iff  $G|W \subseteq \langle T(G)|W, \eta I_W \rangle$  where  $\eta \in \overline{F}$  is a primitive 20 - th root of unity.

We now consider case 2, namely the possibility of W being a reducible T(G) - module.

**Proposition 2.6.** Let  $G \subset SL(3, F)$  be a finite group.Let  $V = F^3 = Fv \oplus W$  be the natural SL(3, F)-module and suppose W is a **reducible** T(G)-submodule. Then  $S(V)^G$  is Gorenstein if and only if  $G|W \subseteq \{ \begin{pmatrix} a & b \\ 0 & d \end{pmatrix} | a^{p^n-1} = 1, a, b, d \in F \}.$ 

Proof. Set  $\hat{g} := \xi I_W g | W$ , with  $det(\hat{g}) = \xi^2 det(g | W) = 1$ . Since W is a reducible T(G) | W - module, there exists a basis  $\{x_1, x_2\}$  of W with respect to which  $T(G) | W \subseteq \begin{pmatrix} F & F \\ 0 & F \end{pmatrix}$ . Every transvection acts trivially on every one dimensional submodule of W by **Lemma 2.2**. Hence it must stabilize  $Fx_2$ . Therefore since  $T(G) | W \subset SL(W), T(G) | W \subseteq \begin{pmatrix} 1 & F \\ 0 & I \end{pmatrix}$ . Consequently T(G) | W is elementary abelian

group.So  $T(G)|W = \langle \sigma_1 \rangle \times \cdots \times \langle \sigma_n \rangle$ , where  $\sigma_i = \begin{pmatrix} 1 & \alpha_i \\ 0 & 1 \end{pmatrix}$ , for i = 1, ..., n, and  $\{\alpha_1, ..., \alpha_n\}$  are linearly independent over  $\mathbb{F}_p$ . Let  $g|W = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ . Now the computation in the proof of [3, Theorem 3.1] with  $\hat{g}$  instead of g|W shows that  $\xi c = 0$ , hence c = 0,  $\hat{g} = \begin{pmatrix} \lambda & \pi \\ 0 & \lambda^{-1} \end{pmatrix}$ .

Hence  $\hat{g}|m/m^2 = \begin{pmatrix} \lambda^{p^n} & 0 \\ 0 & \lambda^{-1} \end{pmatrix}$ , where  $\xi a = \lambda$ ,  $\xi d = \lambda^{-1}, \pi \in F$  and  $m = (b, x_2)$ , where b which is of degree  $p^n$  is defined as in the proof of [3, Theorem 3.1]. Hence  $\hat{g}(b) = \lambda^{p^n} b = (\xi a)^{p^n} b = (\xi)^{p^n} g(b)$  and  $\hat{g}(x_2) = \lambda^{-1}x_2 = (\xi d)x_2 = \xi g(x_2)$ . Therefore  $g|m/m^2 = \begin{pmatrix} a^{p^n} & 0 \\ 0 & d \end{pmatrix}$ . Consequently  $det(g|m/m^2) = a^{p^n}d = a^{p^n-1}(ad) = a^{p^n-1}det(g|W)$ . Hence, by **Proposition 2.3**  $S(V)^G$  is Gorenstein if and only if  $a^{p^n-1} = 1$ . In other words  $S(V)^G$  is Gorenstein if and only if  $G|W \subseteq \{\begin{pmatrix} a & b \\ 0 & d \end{pmatrix}|a^{p^n-1} = 1, b, d \in F\}$ .

Our next objective is to handle case 3, i.e when T(G)|W acts irreducibly and imprimitively on W. It is well known(e.g.[13]) that T(G)|W is a monomial subgroup.Recall that  $H \subset GL(W)$  is called monomial if W has a basis with respect to which the matrix of each element of H has exactly one non-zero entry in each row and column. If  $charF \neq 2$ , then by [3, Lemma 3.9.] T(G)|W = 1.This contradicts the assumption that W is an irreducible T(G)|W-module.Hence we only deal with p = 2.

**Proposition 2.7.** Assume that charF = 2. Let  $G \subset SL(3, F)$  be a finite group with T(G)|W acting imprimitively and irreducibly on the submodule W and  $V = Fv \oplus W$ . Then  $S(V)^G$  is Gorenstein iff  $G|W \subseteq \langle T(G)|W, \delta I_W \rangle$ , where  $\delta$  is a primitive d – th root of unity and d defined in the proof.

Proof. Let  $\{x_1, x_2\}$  be the basis of W with respect to which T(G)|W is irreducible and monomial.Let  $\{g_1, ..., g_n\}$  be the set of transvections generating T(G)|W.The T(G)|W- irreducibility of W forces  $n \geq 2$ . So either  $g_i = \begin{pmatrix} * & 0 \\ 0 & * \end{pmatrix}$  or  $\begin{pmatrix} 0 & * \\ * & 0 \end{pmatrix}$ . The first possibility leads , as in [3, Lemma 3.9.] to  $g_i|W = I_W$ . So  $g_i = \begin{pmatrix} 0 & \alpha_i \\ \alpha_i^{-1} & 0 \end{pmatrix}$ , for i = 1, ..., n, with respect to the basis  $\{x_1, x_2\}$  of W. Let  $n_{ij}$  be the minimal number such that  $(g_i g_j)^{n_{ij}} = 1$ , where  $i \neq j$ , clearly  $g_i^{-1} = g_i$  for i = 1, ..., n. Also  $n_{ij} = n_{ji} > 1$  and since charF = 2,  $n_{ij}$  is odd. Recall that  $S(W)^{T(G)}$  is a polynomial ring [8, Theorem 2.4].We next compute the actual generators of  $S(W)^{T(G)}$ .

 $\begin{array}{l} \text{Let } [(T(G)|W), (T(G)|W)] = &< g_i g_j g_i g_j > \text{be the commutator subgroup of } T(G)|W. \text{ We have } \\ (g_1g_2)^{n_{12}} = 1. \text{ Therefore } g_2 = (g_1g_2)^{n_{12}}g_2 = (g_1g_2)^{n_{12}-1}(g_1g_2)g_2 = (g_1g_2)^{n_{21}-1}g_1. \text{ But } n_{12}-1 \text{ is even, } \\ \text{since } n_{12} \text{ is odd .Hence } g_2 = (g_1g_2g_1g_2)^{\frac{n_{12}-1}{2}}g_1 \in [T(G)|W, T(G)|W]g_1. \text{ This similarly holds for } g_i, i \geq \\ 3, \text{ hence } \frac{|(T(G)|W)|}{|([T(G)|W,T(G)|W])|} = 2. \text{ Let } d = l.c.m\{n_{ij}|i < j\}. \text{ Since } g_ig_jg_ig_j = \binom{\alpha_i\alpha_j^{-1}\alpha_i\alpha_j^{-1} & 0}{0 \quad \alpha_i^{-1}\alpha_j\alpha_i^{-1}\alpha_j} \Big), \\ \text{it follows that } [(T(G)|W), (T(G)|W)] = \{\binom{\zeta \ 0 \ 0 \ \zeta^{-1}}{0 \quad \zeta^{-1}} |\zeta^d = 1\}. \text{ Since } (\alpha_i\alpha_j^{-1})^{n_{ij}} = 1 \text{ it follows that } \\ \alpha_i^{n_{ij}} = \alpha_j^{n_{ij}}. \text{ Consequently } \alpha_i^d := \beta \text{ for } i = \{1, 2, 3, ..., n\}. \end{array}$ 

Now we have:

1.  $g_i(x_1^d + \alpha_i^d x_2^d) = g_i(x_1)^d + \alpha_i^d g_i(x_2)^d = \alpha_i^d x_2^d + \alpha_i^d (\alpha_i^{-1} x_1)^d = x_1^d + \alpha_i^d x_2^d.$ 2.  $g_i(x_1 x_2) = g_i(x_1)g_i(x_2) = \alpha_i x_2 \cdot \alpha_i^{-1} x_1 = x_1 x_2.$ 

Hence  $\{x_1x_2, x_1^d + \beta x_2^d\} \in S(W)^{T(G)}$  and  $deg(x_1x_2)deg(x_1^d + \beta x_2^d) = 2d = |T(G)|W|$ . So by [4, Theorem 3.7.5] we get that  $S(W)^{T(G)} = F[x_1x_2, x_1^d + \beta x_2^d]$ . Let  $g|W = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ . Set  $\hat{g} = \xi I_W g|W$ , where  $\xi^2 det(g|W) = 1$ . Now the computation of [3, Theorem 3.10], with  $\hat{g}$  instead of g|W, shows that  $\hat{g} \in T(G)|W$ .

We have:

(i) 
$$g(x_1x_2) = \begin{pmatrix} \xi^{-1} & 0 \\ 0 & \xi^{-1} \end{pmatrix} \hat{g}(x_1x_2) = \xi^{-2}x_1x_2.$$
  
(ii)  $g(x_1^d + \beta x_2^d) = \begin{pmatrix} \xi^{-1} & 0 \\ 0 & \xi^{-1} \end{pmatrix} \hat{g}(x_1^d + \beta x_2^d) = \begin{pmatrix} \xi^{-1} & 0 \\ 0 & \xi^{-1} \end{pmatrix} (x_1^d + \beta x_2^d) = \xi^{-d}(x_1^d + \beta x_2^d).$ 

Consequently,  $g|m/m^2 = \begin{pmatrix} \xi^{-2} & 0 \\ 0 & \xi^{-d} \end{pmatrix}$ , where  $m/m^2 = U = F(x_1x_2) + F(x_1^d + \beta x_2^d)$ . So  $det(g|m/m^2) = \xi^{-2}\xi^{-d} = det(g|W)\xi^{-d}$ , and  $det(g|W) = det(g|m/m^2)$  if and only if  $\xi^{-d} = 1$ . Consequently, by **Proposition 2.3**  $S(V)^G$  is Gorenstein if and only if  $G|W \subseteq \langle T(G)|W, \delta I_W \rangle$  where  $\delta$  is a primitive d - th root of unity.

**Corollary 2.8.** Suppose  $G \subset SL(3, \mathbb{F}_p)$ , and  $V = \mathbb{F}_p v \oplus W$  a decomposition of  $V = \mathbb{F}_p^3$  into G-submodules. Then  $S(V)^G$  is Gorenstein.

*Proof.* This is a consequence of **Proposition 2.4**, **Proposition 2.6** and **Proposition 2.7**.  $\Box$ 

## 3 Chapter(B): V is indecomposable and contains (at least) two 2- dimensional G- submodules $W_1, W_2$ .

In this chapter we consider V, a reducible, indecomposable G-module which has at least two Gsubmodules  $W_1, W_2$  where  $dimW_i = 2$  for i = 1, 2. Fix a basis  $\{w_2, w_1, v\}$  such that  $W_i = Fw_i + Fv$ . Then  $W_1 \cap W_2 = Fv$  is 1-dimensional G-submodule of V. Therefore for every  $g \in G$  we have a matrix representation with respect to this basis.

$$g = \begin{pmatrix} \lambda_2(g) & 0 & \delta_{13}(g) \\ 0 & \lambda_1(g) & \delta_{23}(g) \\ 0 & 0 & \lambda(g) \end{pmatrix}$$

Let  $\sigma \in T(G)$  be a transvection .  $\sigma: W_i \to W_i$  for i = 1, 2. So  $\sigma(w_i) = \alpha_i w_i + \beta_i v$  where  $\alpha_i, \beta_i \in F$ . Since  $|\langle \sigma \rangle| = p$  and  $\sigma$  acts trivially on Fv by **Lemma 2.2**,  $w_i = \sigma^p(w_i) = \alpha_i^p w_i + \gamma_i v$ , hence  $\gamma_i = 0$  and  $\alpha_i^p = 1$ , then  $\alpha_i = 1$ , for i = 1, 2. As a result,  $\sigma$  is represented by the matrix :

$$\left(\begin{array}{rrrr} 1 & 0 & a \\ 0 & 1 & b \\ 0 & 0 & 1 \end{array}\right)$$

with respect the basis  $\{w_2, w_1, v\}$ .

**Corollary 3.1.** T(G) is an elementary abelian group.

*Proof.* Suppose that  $\tau$  is another transvection where

$$\tau = \left(\begin{array}{rrr} 1 & 0 & a_1 \\ 0 & 1 & b_1 \\ 0 & 0 & 1 \end{array}\right).$$

Then it easy to see that  $\tau \sigma = \sigma \tau$ . Therefore T(G) is an elementary abelian group. Say it is minimaly generated by  $\{\sigma_1, ..., \sigma_n\}$ , where

$$\sigma_i = \left( \begin{array}{rrr} 1 & 0 & a_i \\ 0 & 1 & b_i \\ 0 & 0 & 1 \end{array} \right)$$

for i = 1, ..., n. So  $|T(G)| = p^n$ .

Let  $X := \{ \begin{pmatrix} a_i \\ b_i \end{pmatrix} \in {F \choose F} | i = 1, ..., n \}$ , then the elements of X are linearly independent over  $\mathbb{F}_p$ . Clearly  $dim(span_F X) \in \{1, 2\}$ .

#### Case 1: $dim(span_F X) = 1$

Assume that  $dim(span_F X) = 1$ .So  $\binom{a_i}{b_i} = \mu_i \binom{a}{b}$  for i = 1, ..., n. Where  $\binom{a_1}{b_1} = \binom{a}{b}, \mu_1 = 1$  and  $\mu_i \in F$  for i = 2, ..., n. Since the elements of X are linearly independent over  $\mathbb{F}_p$ , this is equivalent to  $\{1, \mu_2, ..., \mu_n\}$  being of linearly independent over  $\mathbb{F}_p$ .

**Lemma 3.2.**  $S(V)^{T(G)}$  is a polynomial ring.

*Proof.* We shall firstly change the basis of V. We have  $\sigma_1(w_1) = w_1 + bv$  and  $\sigma_1(w_2) = w_2 + av$ , where  $a = a_1$  and  $b = b_1$ . Hence  $\sigma_1(aw_1 - bw_2) = a\sigma(w_1) - b\sigma(w_2) = a(w_1 + bv) - b(w_2 + av) = aw_1 - bw_2$ . So  $0 \neq (aw_1 - bw_2) \in S(V)^{<\sigma_1>}$ . We therefore change the basis of V into  $\{w_2, aw_1 - bw_2, v\}$ , and then  $\sigma_1$  is represented by the matrix:

$$\left(\begin{array}{rrrr} 1 & 0 & a \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{array}\right).$$

We also have:

 $\sigma_i(aw_1 - bw_2) = a\sigma_i(w_1) - b\sigma_i(w_2) = a(w_1 + b_iv) - b(w_2 + av_i) = aw_1 - bw_2 + (ab_i - ba_i)v.$  But  $\binom{a_i}{b_i} = \mu_i\binom{a}{b}$ , and therefore  $(ab_i - ba_i) = 0$ . Hence  $0 \neq (aw_1 - bw_2) \in S(V)^{<\sigma_i>}$ , for i = 1, ..., n. So each  $\sigma_i$  is represented by the matrix:

$$\left(\begin{array}{rrrr} 1 & 0 & a_i \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{array}\right)$$

where  $a_i = \mu_i a$ . So we are in the same situation as in the modular binary case (see [3]).Consequently, by [3, Lemma 3.13]  $S(V)^{T(G)} = F[x, aw_1 - bw_2, v]$  is a polynomial ring, and x is an homogenous polynomial in  $\{v, aw_1 - bw_2\}$  of degree  $p^n$  having  $w_2^{p^n}$  as one of its monomial.

We now need to shift to the action of G on  $S(V)^{T(G)}$ .

**Proposition 3.3.**  $S(V)^G$  is Gorenstein if and only if every element of G/T(G) has order dividing  $|T(G)| - 1 = p^n - 1$ .

*Proof.* If a = 0 or b = 0 we argue exactly as in the binary form paper (see[3]). So we may assume that  $a \neq 0$  and  $b \neq 0$ . Since  $T(G) \triangleleft G, g\sigma_i g^{-1} \in T(G), \forall i = 1, ..., n$ . Hence

$$g\sigma_i g^{-1} = \varphi_i = \begin{pmatrix} 1 & 0 & \epsilon_i a \\ 0 & 1 & \epsilon_i b \\ 0 & 0 & 1 \end{pmatrix}, \epsilon_i \in \mathbb{F}_p 1 + \mathbb{F}_p \mu_2 \dots + \mathbb{F}_p \mu_n$$

So  $g\sigma_i = \varphi_i g$  is written explicitly by:

$$\begin{pmatrix} \lambda_2(g) & 0 & \delta_{13}(g) \\ 0 & \lambda_1(g) & \delta_{23}(g) \\ 0 & 0 & \lambda(g) \end{pmatrix} \begin{pmatrix} 1 & 0 & \mu_i a \\ 0 & 1 & \mu_i b \\ 0 & 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 0 & \epsilon_i a \\ 0 & 1 & \epsilon_i b \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} \lambda_2(g) & 0 & \delta_{13}(g) \\ 0 & \lambda_1(g) & \delta_{23}(g) \\ 0 & 0 & \lambda(g) \end{pmatrix}.$$

By equating the (1,3) and (2,3) entries in both sides, we get :

$$\begin{cases} \lambda_2(g)\mu_i a = \epsilon_i a\lambda(g) \\ \lambda_1(g)\mu_i b = \epsilon_i b\lambda(g) \end{cases}$$

Since  $a \neq 0 \neq b$  we get in particular that  $\lambda_1(g) = \lambda_2(g)$  for each  $g \in G$ . Recall that  $G \subset SL(V)$ , hence  $\lambda_1(g) \cdot \lambda_2(g) \cdot \lambda(g) = 1$ . Let  $m = \langle x, aw_1 - bw_2, v \rangle$  be the unique graded maximal ideal of  $S(V)^{T(G)} = F[x, aw_1 - bw_2, v]$ . Then,

$$g|m/m^{2} = \begin{pmatrix} \lambda_{2}(g)^{p^{n}} & 0 & 0\\ 0 & \lambda_{1}(g) & a\delta_{23}(g) - b\delta_{13}(g)\\ 0 & 0 & \lambda(g) \end{pmatrix}.$$

So by [Theorem 1.2]  $S(V)^G$  is Gorenstein iff  $\lambda_2(g)^{p^n} \cdot \lambda_1(g) \cdot \lambda(g) = 1$ . Since  $\lambda_2(g) = \lambda_1(g)$  and  $\lambda_1(g) \cdot \lambda_2(g) \cdot \lambda(g) = 1$ , then  $S(V)^G$  is Gorenstein if and only if  $\lambda_1(g)^{p^n-1} = 1$ . Since  $\lambda_1(g) = \lambda_2(g), |T(G)| = p^n$ , then  $|gT(G)| = |g|m/m^2| = |\lambda_1(g)|$ , for  $g \in G$ . So  $S(V)^G$  is Gorenstein if and only if every  $gT(G) \in G/T(G)$  has order dividing  $|T(G)| - 1 = p^n - 1$ .

**Remark 3.4.** The difference between the previous result and the results of [3], is that in [3], G/T(G) was a cyclic group and here it is not necessarily so.

#### Case 2: $dim(span_F X) = 2$

We also assume that  $T(G) = \langle \sigma_1, ..., \sigma_{n_1}, \tau_1, ..., \tau_{n_2} \rangle$ , where

$$\sigma_i = \left( \begin{array}{ccc} 1 & 0 & a\mu_i \\ 0 & 1 & b\mu_i \\ 0 & 0 & 1 \end{array} \right)$$

and

$$\tau_i = \left( \begin{array}{ccc} 1 & 0 & c\alpha_i \\ 0 & 1 & d\alpha_i \\ 0 & 0 & 1 \end{array} \right),$$

where  $\binom{a}{b}, \binom{c}{d} \in \binom{F}{F}$  are *F*-linearly independent. Also  $\{\mu_1, ..., \mu_{n_1}\} \subset F$  are  $\mathbb{F}_p$ -linearly independent and  $\{\alpha_1, ..., \alpha_{n_2}\} \subset F$  are  $\mathbb{F}_p$ -linearly independent. Let  $T_1(G) = \langle \sigma_1, ..., \sigma_{n_1} \rangle$  and  $T_2(G) = \langle \tau_1, ..., \tau_{n_2} \rangle$ .

We shall prove the following result.

**Theorem 3.5.** Let F be a field with charF = p > 0. Let  $G \subset SL(3, F)$  be a finite subgroup and  $V = F^3$ , the natural SL(3, F)-module with the above notation, assumption and  $\lambda_1(g) = \lambda_2(g) \ \forall g \in G$ . Then  $S(V)^G$  is Gorenstein in the following cases:

- (*i*) p = 3.
- (ii) |G| is prime to 3.
- (iii)  $F = \mathbb{F}_q$ , where  $q = p^s$  and g.c.d(3, s) = 1.

**Lemma 3.6.**  $S(V)^{T(G)}$  is a polynomial ring.

Proof.  $\sigma_i(w_1) = w_1 + b\mu_i v$  and  $\sigma_i(w_2) = w_2 + a\mu_i v$ , implying that :  $\sigma_i(aw_1 - bw_2) = aw_1 - bw_2$ , for  $i = 1, ..., n_1$ . Similarly,  $\tau_i(cw_1 - dw_2) = cw_1 - dw_2$ , for  $i = 1, ..., n_2$ . Since  $\{aw_1 - bw_2, cw_1 - dw_2\}$  are linearly independent (otherwise  $\binom{a}{b} = \lambda \binom{c}{d}$ ), in contradiction to their *F*-linear independence),  $\{aw_1 - bw_2, cw_1 - dw_2, v\}$  is a basis of *V* and they are *F*-algebraically independent.Now  $\tau_i(aw_1 - bw_2) = a\tau_i(w_1) - b\tau_i(w_2) = a(w_1 + d\alpha_i v) - b(w_2 + c\alpha_i v) = (aw_1 - bw_2) + (ad - bc)\alpha_i v$ . Hence by [3, Lemma 3.13]  $S(F(aw_1 - bw_2) + Fv)^{T(G)} = F[x, v]$  is a polynomial ring, where *x* is homogenous polynomial (in  $(aw_1 - bw_2), v$ ) of degree  $p^{n_2}$ , having  $(aw_1 - bw_2)^{p^{n_2}}$  as one of its monomials.Similarly  $\sigma_i(cw_1 - dw_2) = (cw_1 - dw_2) + (cb - da)\mu_i v$ , and again  $S(F(cw_1 - dw_2) + Fv)^{T(G)} = F[y, v]$ , is a polynomial ring, where *y* is homogenous polynomial (in  $(cw_1 - dw_2), v$ ) of degree  $p^{n_1}$ , having  $(cw_1 - dw_2)v^{p^{n_1}}$  as one of its monomials. Since  $\{aw_1 - bw_2, cw_1 - dw_2, v\}$  are algebraic independent , then  $\{x, y, v\}$  are algebraically independent.Since  $(degx) \cdot (degy) \cdot (degv) = p^{n_2} \cdot p^{n_1} \cdot 1 = |T(G)|$ , we have by [4, Theorem 3.9.4] that  $S(V)^{T(G)} = F[x, y, v]$  is a polynomial ring.

In the next three results we examine the normality of  $T_1(G)$ ,  $T_2(G)$ . This is not needed for **Proposition 3.10**, **Proposition 3.13**, and **Corollary 3.14**.

**Lemma 3.7.** Let  $G \subset GL(V)$  be a finite subgroup,  $T(G) = T_1(G) \times T_2(G)$  and suppose that  $T_k(G) \triangleleft G$  for k = 1, 2. Then one of the following holds:

- (a)  $\lambda_2(g) = \lambda_1(g) \ \forall g \in G.$
- (b)  $\lambda_2(g) = \delta(g)\lambda_1(g)$ , where  $\delta(g) \in \mathbb{F}_p \ \forall g \in G$ .

*Proof.* Since g normalizes  $T_1(G) \ \forall g \in G$ , we have for each  $i = 1, ..., n_1$ :

$$\gamma_i = g\sigma_i g^{-1} = \begin{pmatrix} 1 & 0 & \sum_{j=1}^{n_1} a\mu_j r_{ji} \\ 0 & 1 & \sum_{j=1}^{n_1} b\mu_j r_{ji} \\ 0 & 0 & 1 \end{pmatrix},$$

where  $r_{ji} \in \mathbb{F}_p$ . Since  $g\sigma_i = \gamma_i g$  we get by equating the (1,3) and (2,3) entries in both sides:

(1)  

$$\begin{cases} \lambda_2(g)a\mu_i = \lambda(g)(\sum_{j=1}^{n_1} \mu_j r_{ji})a\\ \lambda_1(g)b\mu_i = \lambda(g)(\sum_{j=1}^{n_1} \mu_j r_{ji})b \end{cases}$$

Similarly, since g normalizes  $T_2(G) \forall g \in G$ , we have for each  $i = 1, ..., n_2$ :

(2)

$$\begin{cases} \lambda_2(g)c\alpha_i = \lambda(g)(\sum_{j=1}^{n_2} \alpha_j r_{ji})c\\ \lambda_1(g)d\alpha_i = \lambda(g)(\sum_{j=1}^{n_2} \alpha_j r_{ji})d \end{cases}$$

Recall that  $\binom{a}{b}, \binom{c}{d} \in \binom{F}{F}$  are *F*-linearly independent. If  $a \neq 0 \neq b$  (or  $c \neq 0 \neq d$ ) then we get by (1)(or (2)) that:  $\lambda_1(g) = \lambda_2(g) \forall g \in G$ . On the other hand, if  $\binom{a}{b} \binom{c}{d} = \binom{a}{0} \binom{0}{d}$ , then from (1) and (2) we get that  $\delta(g) = \frac{\lambda_2(g)}{\lambda_1(g)} = \frac{\alpha_i \sum_{j=1}^{n_1} \mu_j r_{ji}}{\mu_i \sum_{j=1}^{n_2} \alpha_j r_{ji}}$ , and if  $\binom{a}{b} \binom{c}{d} = \binom{0}{b} \binom{c}{0}$ , then from (1) and (2) we get that  $\delta(g) = \frac{\lambda_2(g)}{\lambda_1(g)} = \frac{\mu_i \sum_{j=1}^{n_2} \alpha_j r_{ji}}{\alpha_i \sum_{j=1}^{n_1} \mu_j r_{ji}}$ . Since  $\mu_i, \alpha_i, r_{ji} \in \mathbb{F}_p$  then  $\delta(g) \in \mathbb{F}_p$ .

**Lemma 3.8.**  $T_k(G) \triangleleft G$  for k = 1, 2 in the two following cases:

- (a)  $\lambda_2(g) = \lambda_1(g) \ \forall g \in G.$
- $(b) \ \left(\begin{smallmatrix} a & c \\ b & d \end{smallmatrix}\right) \in \{\left(\begin{smallmatrix} 0 & c \\ b & 0 \end{smallmatrix}\right), \left(\begin{smallmatrix} a & 0 \\ 0 & d \end{smallmatrix}\right)\}.$

*Proof.* Suppose to the contrary that  $T_1(G) \not \subset G$ . Then  $gT(G)g^{-1} = T(G)$  implies that  $g\sigma_i g^{-1} = \sigma_1^{e_1} \cdot \ldots \cdot \sigma_{n_1}^{e_{n_1}} \cdot \tau_1^{f_1} \cdot \ldots \cdot \tau_{n_2}^{f_{n_2}}$ , where not all of the  $f'_i s$  are 0. By a simple calculation we have:

$$g\sigma_i g^{-1} = \begin{pmatrix} 1 & 0 & \lambda(g)^{-1} \mu_i \lambda_2(g) a \\ 0 & 1 & \lambda(g)^{-1} \mu_i \lambda_1(g) b \\ 0 & 0 & 1 \end{pmatrix}.$$

On the other hand we have :

$$\sigma_1^{e_1} \cdot \ldots \cdot \sigma_{n_1}^{e_{n_1}} = \left(\begin{array}{ccc} 1 & 0 & \sum_{i=1}^{n_1} a\mu_i e_i \\ 0 & 1 & \sum_{i=1}^{n_1} b\mu_i e_i \\ 0 & 0 & 1 \end{array}\right).$$

as well as

$$\tau_1^{f_1} \cdot \ldots \cdot \tau_{n_2}^{f_{n_2}} = \begin{pmatrix} 1 & 0 & \sum_{i=1}^{n_2} c\alpha_i f_i \\ 0 & 1 & \sum_{i=1}^{n_2} d\alpha_i f_i \\ 0 & 0 & 1 \end{pmatrix}$$

Hence by equating the (1,3) and (2,3) entries in both sides :

$$\begin{cases} \lambda(g)^{-1}\mu_i\lambda_2(g)a = \sum_{j=1}^{n_1} a\mu_j e_j + \sum_{j=1}^{n_2} c\alpha_j f_j \\ \lambda(g)^{-1}\mu_i\lambda_1(g)b = \sum_{j=1}^{n_1} b\mu_j e_j + \sum_{j=1}^{n_2} d\alpha_j f_j \end{cases}$$

We firstly assume that  $\lambda_2(g) = \lambda_1(g)$ . Then  $\lambda_2(g)\lambda(g)^{-1}\mu_i({a \atop b}) = (\sum_{j=1}^{n_1} \mu_j e_j)({a \atop b}) + (\sum_{j=1}^{n_2} \alpha_j f_j)({c \atop d})$ . So since  ${a \atop b}, {c \atop d}$  are *F*-linearly independent we get that  $\sum_{j=1}^{n_2} \alpha_j f_j = 0$ . Since  $\{\alpha_1, ..., \alpha_{n_2}\}$  are  $\mathbb{F}_{p}$ -linearly independent,  $f_j = 0$  for  $j = 1, ..., n_2$ . A contradiction, hence  $T_1(G) \lhd G$ .

Assume now that item (b) holds. Say  $\begin{pmatrix} a & c \\ b & d \end{pmatrix} = \begin{pmatrix} a & 0 \\ 0 & d \end{pmatrix}$ , hence  $\begin{pmatrix} \lambda(g)^{-1}\mu_i\lambda_2(g)a \\ 0 \end{pmatrix} = (\sum_{j=1}^{n_1}\mu_je_j)\begin{pmatrix} a \\ 0 \end{pmatrix} + (\sum_{j=1}^{n_2}\alpha_jf_j)\begin{pmatrix} 0 \\ d \end{pmatrix}$ , so  $(\sum_{j=1}^{n_2}\alpha_jf_j) = 0$ . Since  $\{\alpha_1, ..., \alpha_{n_2}\}$  are  $\mathbb{F}_p$ -linearly independent,  $f_j = 0$  for  $j = 1, ..., n_2$ , a contradiction. If  $\begin{pmatrix} a & c \\ b & d \end{pmatrix} = \begin{pmatrix} 0 & c \\ b & 0 \end{pmatrix}$ , then by the same steps above we get that  $(\sum_{j=1}^{n_2}\alpha_jf_j) = 0$ , again  $f_j = 0$  for  $j = 1, ..., n_2$ , again a contradiction. By a similar discussion we get that  $T_2(G) \lhd G$ .

The combination of Lemma 3.7 and Lemma 3.8 yields.

Proposition 3.9. The following conditions are equivalent.

- (a)  $T_k(G) \triangleleft G$ , for k = 1, 2.
- (b) one of the following holds:
- 1.  $\begin{pmatrix} a & c \\ b & d \end{pmatrix} \in \{\begin{pmatrix} 0 & c \\ b & 0 \end{pmatrix}, \begin{pmatrix} a & 0 \\ 0 & d \end{pmatrix}\}$
- 2.  $\lambda_2(g) = \lambda_1(g)$ , for all  $g \in G$ .

*Proof.* That (b) implies (a) is a consequence of Lemma 3.8. That (a) implies (b) follows from the proof of Lemma 3.7.

We can now give a necessary and sufficient condition for a subgroup G such that  $S(V)^G$  is Gorenstein.

**Proposition 3.10.** Suppose  $n_1 < n_2$ . Then  $S(V)^G$  is Gorenstein if and only if :

- 1.  $\lambda_1(q)^{p^{n_1}+p^{n_2}}\lambda(q) = 1$ , in case  $c \neq 0 \neq d$ .
- 2.  $\lambda_1(g)^{p^{n_2}}\lambda_2(g)^{p^{n_1}}\lambda(g) = 1$ , in case  $c = 0 \neq d$ .
- 3.  $\lambda_2(q)^{p^{n_2}}\lambda_1(q)^{p^{n_1}}\lambda(q) = 1$ , in case  $c \neq 0 = d$ .

The case  $n_2 < n_1$  is similar. Note that we do not assume any normality assumption on  $T_k(G)$ .

*Proof.* By Lemma 3.6 , we have that  $S(V)^{T(G)} = F[x, y, v], deg(y) = p^{n_1}, deg(x) = p^{n_2}$ . Since  $g^{-1}T(G)g = T(G)$  we have  $g(y) \in S(V)^{T(G)}$ . Therefore, since g preserve degrees,  $g(y) = \alpha y + \beta v^{p^{n_1}}$ . Recall that  $(cw_1 - dw_2)^{p^{n_1}}$  appears as a monomial in y and all other monomials involve v in addition.

We have :

 $g(cw_1 - dw_2) = cg(w_1) - dg(w_2) = c(\lambda_1(g)w_1 + \delta_{23}(g)v) - d(\lambda_2(g)w_2 + \delta_{13}(g)v) = (c\lambda_1(g)w_1 - \delta_{13}(g)v_1 - \delta_{13}($  $d\lambda_2(g)w_2) + \chi v$ , where  $\chi = c\delta_{23}(g) - d\delta_{13}(g)$ . Hence  $g((cw_1 - dw_2)^{p^{n_1}}) = c^{p^{n_1}}\lambda_1(g)^{p^{n_1}}w_1^{p^{n_1}} - d^{p^{n_1}}\lambda_2(g)^{p^{n_1}}w_2^{p^{n_1}} + \chi^{p^{n_1}}v^{p^{n_1}}$ . So by comparing coefficients of y in g(y) we get:

$$c^{p^{n_1}}\lambda_1(g)^{p^{n_1}}w_1^{p^{n_1}} - d^{p^{n_1}}\lambda_2(g)^{p^{n_1}}w_2^{p^{n_1}} = \alpha(cw_1 - dw_2)^{p^{n_1}}.$$
 Consequently  
(1)  $c^{p^{n_1}}\lambda_1(g)^{p^{n_1}} = \alpha c^{p^{n_1}}, d^{p^{n_1}}\lambda_2(g)^{p^{n_1}} = \alpha d^{p^{n_1}}.$ 

Similarly  $g(x) = \delta x + \varepsilon y^{p^{n_2-n_1}} + \text{mixed terms (in } y, v) + \xi v^{p^{n_2}}$ . Recall that  $(aw_1 - bw_2)^{p^{n_2}}$  appears as a monomial in x and all other monomials involve v in addition. So the contribution to the terms with  $w_1^{p^{n_2}}$  in the right hand side of the last equation are  $\delta(aw_1 - bw_2)^{p^{n_2}} + \varepsilon((cw_1 - dw_2)^{p^{n_1}})^{p^{n_2-n_1}} = \delta(aw_1 - bw_2)^{p^{n_2}} + \varepsilon(cw_1 - dw_2)^{p^{n_2}}.$ 

The contribution of the left hand side are from  $g((aw_1 - bw_2)^{p^{n_2}}) = a^{p^{n_2}}(\lambda_1(g)w_1 + \delta_{23}(g)v)^{p^{n_2}} - \delta_{23}(g)v)^{p^{n_2}}$  $b^{p^{n_2}}(\lambda_2(g)w_2+\delta_{13}(g)v)^{p^{n_2}}$ . Consequently we get :

(2) 
$$a^{p^{n_2}}\lambda_1(g)^{p^{n_2}} = \delta a^{p^{n_2}} + \varepsilon c^{p^{n_2}}, b^{p^{n_2}}\lambda_2(g)^{p^{n_2}} = \delta b^{p^{n_2}} + \varepsilon d^{p^{n_2}}.$$

If  $c \neq 0 \neq d$ , then (1) shows that  $\lambda_1(g)^{p^{n_1}} = \alpha = \lambda_2(g)^{p^{n_1}}$ , so  $\lambda_1(g) = \lambda_2(g)$ . Now (2) shows that  $a^{p^{n_2}}(\lambda_1(g)^{p^{n_2}} - \delta) = \varepsilon c^{p^{n_2}}, b^{p^{n_2}}(\lambda_2(g)^{p^{n_2}} - \delta) = \varepsilon d^{p^{n_2}}$ . So if  $\varepsilon \neq 0$  then  $\frac{a^{p^{n_2}}}{\varepsilon c^{p^{n_2}}} = \frac{b^{p^{n_2}}}{\varepsilon d^{p^{n_2}}}$ . Hence  $\frac{a}{c} = \frac{b}{d}$  or  $\frac{a}{b} = \frac{c}{d}$ , which is a contradiction, so  $\varepsilon = 0$  in case  $c \neq 0 \neq d$ . Therefore  $\lambda_1(g)^{p^{n_2}} = \delta = \lambda_2(g)^{p^{n_2}}$ . Let  $m = \langle x, y, v \rangle$  be the unique homogenous  $z \neq 0$ . maximal ideal of  $S(V)^{T(G)} = F[x, y, v]$ . The matrix representing q on  $m/m^2$  whenever  $c \neq 0 \neq d$  is

$$\left(\begin{array}{ccc} \lambda_1(g)^{p^{n_2}} & 0 & 0\\ 0 & \lambda_1(g)^{p^{n_1}} & 0\\ 0 & 0 & \lambda(g) \end{array}\right),\,$$

so the condition for  $S(V)^G$  to be Gorenstein is  $\lambda_1(g)^{p^{n_2}+p^{n_1}}\lambda(g) = 1$ . Since  $G \subset SL(V), \lambda_1(g) = \lambda(g)^{-2}$ . Hence  $S(V)^G$  is Gorenstein if and only if  $\lambda_1(g)^{p^{n_2}+p^{n_1}-2} = 1$ . Moreover, by **Lemma 3.8**,  $T_k(G) \triangleleft G$  for k = 1, 2.

Assume now that  $c = 0 \neq d$ , hence from (1) we get  $\lambda_2(g)^{p^{n_1}} = \alpha$  and from (2), since  $a \neq 0$  in this case,  $\lambda_1(g)^{p^{n_2}} = \delta$ . So the matrix representing g on  $m/m^2$  is

$$\begin{pmatrix} \lambda_1(g)^{p^{n_2}} & 0 & 0\\ 0 & \lambda_2(g)^{p^{n_1}} & 0\\ 0 & 0 & \lambda(g) \end{pmatrix},\,$$

and  $S(V)^G$  is Gorenstein if and only if  $\lambda_1(g)^{p^{n_2}}\lambda_2(g)^{p^{n_1}}\lambda(g) = 1$ .

Assume now that  $c \neq 0 = d$ . Then from (1) we get  $\lambda_1(g)^{p^{n_1}} = \alpha$  and from (2), since  $b \neq 0$  in this case,  $\lambda_2(g)^{p^{n_2}} = \delta$ . So the matrix representing g on  $m/m^2$  is

$$\begin{pmatrix} \lambda_2(g)^{p^{n_2}} & 0 & 0\\ 0 & \lambda_1(g)^{p^{n_1}} & 0\\ 0 & 0 & \lambda(g) \end{pmatrix},\,$$

and  $S(V)^G$  is Gorenstein if and only if  $\lambda_2(g)^{p^{n_2}}\lambda_1(g)^{p^{n_1}}\lambda(g) = 1$ . This settles the case  $n_1 < n_2$ . If  $n_1 > n_2$  then we do the same analysis but with  $\{a, b\}$  instead of  $\{c, d\}$ .

Our next result will be used in the proof of Theorem 3.5.

**Lemma 3.11.** Suppose  $T_k(G) \triangleleft G$ . Then  $\left(\frac{\lambda_2(g)}{\lambda(g)}\right)^{p^{n_k}-1} = \left(\frac{\lambda_1(g)}{\lambda(g)}\right)^{p^{n_k}-1} = 1$ , for k = 1, 2.

*Proof.* We have by **Lemma 3.6** that  $S(F(aw_1 - bw_2) + Fv)^{T_2(G)} = F[x, v]$ , where x is homogenous polynomial (in  $(aw_1 - bw_2), v$ ) of degree  $p^{n_2}$ , having  $(aw_1 - bw_2)^{p^{n_2}}$  as one of its monomials and all other monomials involve v. In other words  $x = (aw_1 - bw_2)^{p^{n_2}} + v^{p^{n_2}-1}(aw_1 - bw_2) + \text{monomials}$  involve v. By a simple calculating we get that :

$$\begin{cases} g(aw_1 - bw_2)^{p^{n_2}} = a^{p^{n_2}}\lambda_1(g)^{p^{n_2}}w_1^{p^{n_2}} - b^{p^{n_2}}\lambda_2(g)^{p^{n_2}}w_2^{p^{n_2}} + (a\delta_{23}(g) - b\delta_{13}(g))^{p^{n_2}}v^{p^{n_2}}.\\ g(v^{p^{n_2}-1}(aw_1 - bw_2)) = a\lambda(g)^{p^{n_2}-1}\lambda_1(g)w_1v^{p^{n_2}-1} - b\lambda(g)^{p^{n_2}-1}\lambda_2(g)w_2v^{p^{n_2}-1} + \lambda(g)^{p^{n_2}-1}v^{p^{n_2}}(a\delta_{23}(g) - b\delta_{13}(g)). \end{cases}$$

Now  $T_2(G) \triangleleft G$  imply that F[x, v] is g-stable. Therefore, since g preserve degrees, we get  $g(x) = \rho x + \kappa v^{p^{n_2}}, \rho, \kappa \in F$ . Assume firstly, using **Lemma 3.7**, that  $\lambda_1(g) = \lambda_2(g)$ . Hence, if  $a \neq 0$  then by comparing coefficients of  $w_1^{p^{n_2}}$  and  $v^{p^{n_2}-1}w_1$  in g(x) we get  $\rho = \lambda_1(g)^{p^{n_2}} = \lambda(g)^{p^{n_2}-1}\lambda_1(g)$ . So  $(\frac{\lambda_1(g)}{\lambda(g)})^{p^{n_2}-1} = 1$ , and if  $b \neq 0$  then by comparing coefficients of  $w_2^{p^{n_2}-1}w_2$  in g(x) we get  $\rho = \lambda_2(g)^{p^{n_2}-1}w_2$  in g(x) we get  $\rho = \lambda_2(g)^{p^{n_2}-1}\lambda_2(g)$ . So  $(\frac{\lambda_2(g)}{\lambda(g)})^{p^{n_2}-1} = 1$ .

Assume now, using **Lemma 3.7**, that  $\lambda_2(g) = \delta(g)\lambda_1(g)$ , where  $\delta(g) \in \mathbb{F}_p$ . Consequently, by **Proposition 3.9**,  $\begin{pmatrix} a & c \\ b & d \end{pmatrix} \in \{\begin{pmatrix} 0 & c \\ b & 0 \end{pmatrix}, \begin{pmatrix} a & 0 \\ 0 & d \end{pmatrix}\}$ . Hence if  $a \neq 0 = b$ , then by comparing coefficient of  $w_1^{p^{n_2}}$  and  $v^{p^{n_2}-1}w_1$  in g(x) we get  $\rho = \lambda_1(g)^{p^{n_2}} = \lambda(g)^{p^{n_2}-1}\lambda_1(g)$ . So  $(\frac{\lambda_1(g)}{\lambda(g)})^{p^{n_2}-1} = 1$ , hence  $(\frac{\delta(g)^{-1}\lambda_2(g)}{\lambda(g)})^{p^{n_2}-1} = 1$ . By little Fermat's theorem we get that  $\delta(g)^{p^{n_2}-1} = 1$ , then  $(\frac{\lambda_2(g)}{\lambda(g)})^{p^{n_2}-1} = 1$ . If  $b \neq 0 = a$ , then by comparing coefficient of  $w_2^{p^{n_2}}$  and  $v^{p^{n_2}-1}w_2$  in g(x) we get  $\rho = \lambda_2(g)^{p^{n_2}} = \lambda(g)^{p^{n_2}-1}\lambda_2(g)$ . So  $(\frac{\lambda_2(g)}{\lambda(g)})^{p^{n_2}-1} = 1$ , hence  $(\frac{\delta(g)\lambda_1(g)}{\lambda(g)})^{p^{n_2}-1} = 1$ . By little Fermat's theorem we get that  $\delta(g)^{p^{n_2}-1} = 1$ , then  $(\frac{\lambda_2(g)}{\lambda(g)})^{p^{n_2}-1} = 1$ . Similarly, if we look at  $S(F(cw_1 - dw_2) + Fv)^{T_1(G)} = F[y, v]$  from **Lemma 3.6**, then the above reasoning shows again that  $(\frac{\lambda_k(g)}{\lambda(g)})^{p^{n_1}-1} = 1$ , for k = 1, 2.

**Lemma 3.12.** (|G|/|T(G)|, p) = 1, and if  $\lambda_1(g) = \lambda_2(g) \ \forall g \in G$  then G/T(G) is a cyclic group. Proof. Since  $G \subset SL(V), \lambda(g) = \lambda_1(g)^{-1}\lambda_2(g)^{-1}$ . We have:

$$g^{p} = \begin{pmatrix} \lambda_{2}(g)^{p} & 0 & * \\ 0 & \lambda_{1}(g)^{p} & * \\ 0 & 0 & \lambda_{1}(g)^{-p}\lambda_{2}(g)^{-p} \end{pmatrix}$$

If  $g^p \in T(G)$  then  $\lambda_1(g)^p = \lambda_2(g)^p = 1$ , and then  $\lambda_1(g) = \lambda_2(g) = 1$ , so :

$$g = \begin{pmatrix} 1 & 0 & * \\ 0 & 1 & * \\ 0 & 0 & 1 \end{pmatrix} \in T(G).$$

This shows that (|G|/|T(G)|, p) = 1. Assume now that  $\lambda_1(g) = \lambda_2(g) \forall g \in G$ . Set  $U = \mathbb{F}_p \mu_1 + \cdots \mathbb{F}_p \mu_{n_1}$ . By **Lemma 3.8**,  $T_1(G) \triangleleft G$  then  $g\sigma_i g^{-1} \in T_1(G)$ . Now since

$$g\sigma_i g^{-1} = \left(\begin{array}{rrr} 1 & 0 & \lambda(g)^{-1} \mu_i \lambda_2(g) a \\ 0 & 1 & \lambda(g)^{-1} \mu_i \lambda_1(g) b \\ 0 & 0 & 1 \end{array}\right)$$

for  $i = 1, ..., n_1$ , we get that  $\lambda(g)^{-1}\lambda_1(g)\mu_i \in U$ , hence  $\lambda(g)^{-1}\lambda_1(g)U \subseteq U$  Since  $G \subset SL(V)$  and  $\lambda_1(g) = \lambda_2(g)$  then  $\lambda(g)^{-1}\lambda_1(g) = \lambda_1(g)^3$ . Consequently by [3, Lemma 3.12.]  $|\lambda_1(g)^3|$  divides  $(p^{n_1}-1)$ . By a similar discussion on  $T_2(G)$  we get that  $|\lambda_1(g)^3|$  divides  $(p^{n_2}-1)$ . Let  $H = \{\epsilon \in F | \epsilon^{3(p^{n_1}-1)} = 1\}$ . Define  $\Phi: G/T(G) \longrightarrow H$ , by  $\Phi(gT(G)) = \lambda_1(g)$ , for each  $g \in G$ . Since

$$gT(G) = g|m/m^2 = \begin{pmatrix} \lambda_1(g)^{p^{n_2}} & 0 & 0\\ 0 & \lambda_1(g)^{p^{n_1}} & 0\\ 0 & 0 & \lambda_1(g)^{-2} \end{pmatrix},$$

it follows that  $\Phi$  is an injective homomorphism with its image in H since  $|gT(G)| = |\lambda_1(g)|$  divides  $3(p^{n_1} - 1)$ . Since H is cyclic group it follows that G/T(G) is cyclic.

Recall that  $n_1$  and  $n_2$  are the numbers of the generators of  $T_1(G)$  and  $T_2(G)$  respectively. The next result considers the case  $n_1 = n_2$  which was omitted from **Proposition 3.10**.

**Proposition 3.13.** Suppose that  $n_1 = n_2$ . Then  $S(V)^G$  is Gorenstein iff  $\lambda_2(g)^{p^{n_1}}\lambda_1(g)^{p^{n_1}}\lambda(g) = 1$ .

*Proof.* We have by **Lemma 3.6** that  $S(V)^{T(G)} = F[x, y, v], deg(y) = p^{n_1}, deg(x) = p^{n_2}$ . Since  $g^{-1}T(G)g = T(G)$  we have  $g(y), g(x) \in S(V)^{T(G)}$ . Hence, since g preserve degrees, we get :

(1)  $g(y) = \alpha y + \gamma x + \beta v^{p^{n_1}}, \alpha, \gamma, \beta \in F.$ 

(2) 
$$g(x) = \delta x + \varepsilon y + \chi v^{p^{n_1}}, \delta, \varepsilon, \chi \in F.$$

Therefore,  $S(V)^G = [S(V)^{T(G)}]^{G/T(G)}$ . Let m = (x, y, v) be the unique graded maximal ideal of  $S(V)^{T(G)} = F[y, x, v]$ , then the matrix of  $\bar{g} \in G/T(G)$  on  $m/m^2 = F\bar{y} + F\bar{x} + F\bar{v}$  is :

$$\left(\begin{array}{ccc} \alpha & \gamma & 0 \\ \varepsilon & \delta & 0 \\ 0 & 0 & \lambda(g) \end{array}\right).$$

So by [Theorem 1.2]  $S(V)^G$  is Gorenstein if and only if  $(\alpha \delta - \varepsilon \gamma)\lambda(g) = 1 \quad \forall g \in G$ .

#### The computation of $\alpha\delta - \varepsilon\gamma$ :

We shall assume that  $c \neq 0 \neq d$  and  $a \neq 0 \neq b$ . We know that  $(cw_1 - dw_2)^{p^{n_1}}$  appears as a monomial in y,  $(aw_1 - bw_2)^{p^{n_1}}$  appears as a monomial in x, and all other monomials involve also v. Therefore the coefficients of  $w_1^{p^{n_1}}$  in (1) are :

Therefore the coefficients of  $w_1^{p^{n_1}}$  in (1) are :  $c^{p^{n_1}}\lambda_1(g)^{p^{n_1}}$  in the left hand side and  $\alpha c^{p^{n_1}} + \gamma a^{p^{n_1}}$  in the right hand side. Hence  $c^{p^{n_1}}\lambda_1(g)^{p^{n_1}} = \alpha c^{p^{n_1}} + \gamma a^{p^{n_1}}$ . Similarly, for the coefficients of  $w_2^{p^{n_1}}$ , we have  $d^{p^{n_1}}\lambda_2(g)^{p^{n_1}} = \alpha d^{p^{n_1}} + \gamma b^{p^{n_1}}$ . From (2) we similarly have:

$$\begin{cases} a^{p^{n_1}} \lambda_1(g)^{p^{n_1}} = \delta a^{p^{n_1}} + \varepsilon c^{p^{n_1}} \\ b^{p^{n_1}} \lambda_2(g)^{p^{n_1}} = \delta b^{p^{n_1}} + \varepsilon d^{p^{n_1}} \end{cases}$$

Hence from (1) and (2) we have :

$$\begin{cases} \lambda_1(g)^{p^{n_1}} = \alpha + \gamma(\frac{a}{c})^{p^{n_1}} \\ \lambda_2(g)^{p^{n_1}} = \alpha + \gamma(\frac{b}{d})^{p^{n_1}} \\ \lambda_1(g)^{p^{n_1}} = \delta + \varepsilon(\frac{c}{c})^{p^{n_1}} \\ \lambda_2(g)^{p^{n_1}} = \delta + \varepsilon(\frac{d}{d})^{p^{n_1}} \end{cases}$$

Hence,

$$\begin{cases} (\lambda_1(g) - \lambda_2(g))^{p^{n_1}} = \gamma(\frac{a}{c} - \frac{b}{d})^{p^{n_1}} \\ (\lambda_1(g) - \lambda_2(g))^{p^{n_1}} = \varepsilon(\frac{c}{a} - \frac{d}{b})^{p^{n_1}} \end{cases}$$

It follows that:

(A) := 
$$(\lambda_1(g) - \lambda_2(g))^{2p^{n_1}} = \gamma \varepsilon ((\frac{a}{c} - \frac{b}{d})(\frac{c}{a} - \frac{d}{b}))^{p^{n_1}}$$

Also we have :

$$\begin{cases} \left(\frac{c}{a}\lambda_1(g) - \frac{d}{b}\lambda_2(g)\right)^{p^{n_1}} = \alpha\left(\frac{c}{a} - \frac{d}{b}\right)^{p^{n_1}} \\ \left(\frac{a}{c}\lambda_1(g) - \frac{b}{d}\lambda_2(g)\right)^{p^{n_1}} = \delta\left(\frac{a}{c} - \frac{d}{b}\right)^{p^{n_1}} \end{cases}$$

And it follows that :

(B) := 
$$(\frac{c}{a}\lambda_1(g) - \frac{d}{b}\lambda_2(g))^{p^{n_1}}(\frac{a}{c}\lambda_1(g) - \frac{b}{d}\lambda_2(g))^{p^{n_1}} = \alpha\delta[(\frac{c}{a} - \frac{d}{b})(\frac{a}{c} - \frac{b}{d})]^{p^{n_1}}.$$

So **(B)-(A)** =  $(\alpha\delta - \varepsilon\gamma)[(\frac{c}{a} - \frac{d}{b})(\frac{a}{c} - \frac{b}{d})]^{p^{n_1}}$ . Observe that  $(\frac{c}{a} - \frac{d}{b})(\frac{a}{c} - \frac{b}{d}) = 2 - (\frac{cb}{ad} + \frac{ad}{bc})$ . Also **(B)-(A)** =  $(\lambda_1(g)^2 + \lambda_2(g)^2 - (\frac{cb}{ad} + \frac{ad}{bc})\lambda_1(g)\lambda_2(g))^{p^{n_1}} - (\lambda_1(g)^2 + \lambda_2(g)^2 - 2\lambda_1(g)\lambda_2(g))^{p^{n_1}} = (\lambda_1(g))^{p^{n_1}}(\lambda_2(g))^{p^{n_1}}[2 - (\frac{cb}{ad} + \frac{ad}{bc})]^{p^{n_1}}.$ 

Hence  $\frac{(B)-(A)}{((\frac{c}{a}-\frac{d}{b})(\frac{a}{c}-\frac{b}{a}))^{p^{n_1}}} = (\alpha\delta - \varepsilon\gamma)$ . Therefore  $\alpha\delta - \varepsilon\gamma = \lambda_1(g)^{p^{n_1}}\lambda_2(g)^{p^{n_1}}$ , hence  $S(V)^G$  is Gorenstein if and only if  $\lambda_2(g)^{p^{n_1}}\lambda_1(g)^{p^{n_1}}\lambda(g) = 1$ .

The cases where one of  $\{a, b, c, d\}$  is 0 are easier. For example, if a = 0, hence since  $\binom{a}{b}, \binom{c}{d}$  are *F*-linearly independent,  $c \neq 0$ , .Hence  $\lambda_1(g)^{p^{n_1}} = \alpha$  and  $\varepsilon = 0$ , therefore  $\delta = \lambda_2(g)^{p^{n_1}}$ . Hence  $\alpha \delta - \varepsilon \gamma = \alpha \delta = \lambda_1(g)^{p^{n_1}} \lambda_2(g)^{p^{n_1}} \lambda_2(g)^{p^{n_1}}$ . So again  $S(V)^G$  Gorenstein if and only if  $\lambda_2(g)^{p^{n_1}} \lambda_1(g)^{p^{n_1}} \lambda(g) = 1$ . Equivalently  $\lambda(g)^{p^{n_1}-1} = 1$ .

We finally arrive at: The proof of Theorem 3.5.

*Proof.* We have by **Lemma 3.12** that (|G|/|T(G)|, p) = 1 and  $G/T(G) \cong \langle \lambda_1(g) \rangle$  is a cyclic group. Let  $\frac{|G|}{|T(G)|} = |\lambda_1(g)| \equiv k$ , since  $G \subset SL(V)$ ,  $\frac{\lambda_1(g)}{\lambda(g)} = \frac{\lambda_1(g)}{\lambda_1(g)^{-1}\lambda_2(g)^{-1}} = \frac{\lambda_1(g)}{\lambda_1(g)^{-1}\lambda_1(g)^{-1}} = \lambda_1(g)^3$ . Hence, by **Lemma 3.11**,  $(\lambda_1(g)^3)^{p^{n_1}-1} = (\lambda_1(g)^3)^{p^{n_2}-1} = 1$ . So  $(\lambda_1(g)^3)^{p^{n_1}+p^{n_2}-2} = 1$ , which means that k divides  $[3 \cdot (p^{n_1} + p^{n_2} - 2)]$ .

If p = 3 then since (3, k) = 1, k divides  $(p^{n_1} + p^{n_2} - 2)$ , consequently by **Proposition 3.10** and **Proposition 3.13**,  $S(V)^G$  is Gorenstein. This settles item (i).

Assume now that  $3 \nmid |G|$ . The action of  $g^3$  on  $m/m^2$  where m is the unique maximal ideal of  $S(V)^{T(G)}$  is :

$$\begin{pmatrix} \lambda_1(g)^{3 \cdot p^{n_2}} & 0 & 0\\ 0 & \lambda_1(g)^{3 \cdot p^{n_1}} & 0\\ 0 & 0 & \lambda_1(g)^{-6} \end{pmatrix}.$$

Since  $|\lambda_1(g)^3|$  divides  $p^{n_1} + p^{n_2} - 2$ , the above reasoning shows that  $S(V)^{\langle g^3, T(G) \rangle} = S(m/m^2)^{\langle g^3|m/m^2 \rangle}$  is Gorenstein. Consequently if  $3 \nmid |G|$ , then  $G = \langle g^3, T(G) \rangle$  and  $S(V)^G$  is therefore Gorenstein, so item (*ii*) is verified.

We have by **Lemma 3.8** that  $T_k(G) \triangleleft G$  for k = 1, 2, hence by using the proof of **Lemma 3.7** we get :

(1)

$$\begin{cases} \lambda_2(g)a\mu_i = \lambda(g)(\sum_{j=1}^{n_1} \mu_j r_{ji})a\\ \lambda_1(g)b\mu_i = \lambda(g)(\sum_{j=1}^{n_1} \mu_j r_{ji})b \end{cases}$$

(2)

$$\begin{cases} \lambda_2(g)c\alpha_i = \lambda(g)(\sum_{j=1}^{n_2} \alpha_j r_{ji})c\\ \lambda_1(g)d\alpha_i = \lambda(g)(\sum_{j=1}^{n_2} \alpha_j r_{ji})d \end{cases}$$

Given the assumption of item (*iii*).Since  $\lambda_1(g) = \lambda_2(g)$ , it follows that  $(a \neq 0 \neq b)$  or  $(c \neq 0 \neq d)$ . Say  $a, c, d \neq 0$ , the equations above imply that  $\frac{\lambda(g)}{\lambda_1(g)}(\sum_{j=1}^{n_1} \mu_j r_{ji}) = \mu_i$  and  $\frac{\lambda(g)}{\lambda_1(g)}(\sum_{j=1}^{n_2} \alpha_j r_{ji}) = \alpha_i$ . Set  $M_1 = \mathbb{F}_p \mu_1 + \ldots + \mathbb{F}_p \mu_{n_1}$  and  $M_2 = \mathbb{F}_p \alpha_1 + \ldots + \mathbb{F}_p \alpha_{n_2}$ , so  $\dim_{\mathbb{F}_p} M_1 = n_1$  and  $\dim_{\mathbb{F}_p} M_2 = n_2$ . Thus  $\frac{\lambda_1(g)}{\lambda(g)}M_1 = \lambda_1(g)^3M_1 \subseteq M_1$  and  $\frac{\lambda_1(g)}{\lambda(g)}M_2 = \lambda_1(g)^3M_2 \subseteq M_2$ . Suppose to the contrary that  $\lambda_1(g) \notin \mathbb{F}_p(\lambda_1(g)^3)$ , then  $[\mathbb{F}_p(\lambda_1(g)) : \mathbb{F}_p(\lambda_1(g)^3)] = 3$ . But  $[F : \mathbb{F}_p] = s$  is relatively prime to 3, a contradiction.Thus  $\lambda_1(g) \in \mathbb{F}_p(\lambda_1(g)^3)$ , hence  $\lambda_1(g)M_1 \subseteq M_1$ , similarly,we get that  $\lambda_2(g)M_2 \subseteq M_2$ . Therefore, by [3, Lemma 3.12.]  $k \mid (p^{n_1}-1)$  and  $k \mid (p^{n_2}-1)$ , hence  $k \mid (p^{n_1}+p^{n_2}-2)$ . Consequently,by **Proposition 3.10** item (1),  $S(V)^G$  is Gorenstein and item (*iii*) holds.

We also have here the following.

**Corollary 3.14.** Suppose  $G \subset SL(3, \mathbb{F}_p)$  and  $V = \mathbb{F}_p^3$  contains two 2-dimensional G-submodules. Then  $S(V)^G$  is Gorenstein.

Proof. Since  $F = \mathbb{F}_p$ ,  $\dim_{F_p}(spanX) \in \{1, 2\}$ , and either  $T(G) = T_1(G) \times T_2(G)$  or  $T(G) = T_1(G)$ . If  $\dim_{\mathbb{F}_p}(spanX) = 2$ , then  $n_1 = n_2 = 1$ . So by **Proposition 3.13** the condition for being Gorenstein is  $\lambda_2(g)^p \lambda_1(g)^p \lambda(g) = 1$ , for each  $g \in G$ . Since  $\lambda(g) = \lambda_1(g)^{-1} \lambda_2(g)^{-1}$ , it follows that it is equivalent to  $\lambda_2(g)^{p-1}\lambda_1(g)^{p-1} = 1$ . Now since  $\lambda_1(g), \lambda_2(g) \in \mathbb{F}_p \setminus \{0\}$  it follows that  $\lambda_1(g)^{p-1} = 1 = \lambda_2(g)^{p-1}$ , and the condition is fullfilled. If  $\dim_{\mathbb{F}_p}(spanX) = 1$ , then n = 1, that is |T(G)| = p, so since  $|gT(G)| = |\lambda_1(g)|$ , it follows from  $\lambda_1(g) \in \mathbb{F}_p \setminus \{0\}$  that |gT(G)| divides |T(G)| - 1, and again the Gorenstein property holds.

# 4 Chapter(C): Preliminaries to Chapters D,E,F and G.

Let  $G \subset GL(V)$  be a group and  $W \subset V$  a G-submodule with  $\dim_F W = \dim_F V - 1$ . With respect to a fixed basis, each  $g \in G$  is represented by the matrix :

$$g = \begin{pmatrix} g_{11} & g_{12} & \dots & g_{1n} \\ 0 & g_{22} & \dots & g_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & g_{n2} & \dots & g_{nn} \end{pmatrix}$$

**Lemma 4.1.** Suppose  $g \in G \cap SL(V)$ . Then

$$g^{-1}hg = \begin{pmatrix} 1 & G_{11}(\alpha_1, \dots, \alpha_{n-1})g|W & & & \\ 0 & 1 & 0 & \dots & \dots & 0 & 0 \\ \vdots & \vdots & 0 & \vdots & \vdots & \vdots \\ 0 & & \dots & \vdots & 0 & \dots & 0 & 1 & 0 \\ 0 & & 0 & 0 & \dots & \dots & \dots & 0 & 1 \end{pmatrix} = \\ = \begin{pmatrix} 1 & G_{11}(\alpha_1, \dots, \alpha_{n-1})g|W \\ \vdots & & I_{n-1} \\ 0 & & & \vdots & \vdots \\ g_{n2} & \dots & g_{nn} \end{pmatrix}, where \\ g|W = \begin{pmatrix} g_{22} & g_{23} & \dots & g_{2n} \\ g_{32} & \dots & g_{3n} \\ \vdots & \vdots & \ddots & \vdots \\ g_{n2} & \dots & g_{nn} \end{pmatrix}, G_{11} = det(g|W), and \\ = \begin{pmatrix} 1 & \alpha_1 & \dots & \dots & \alpha_{n-1} \\ 0 & 1 & 0 & \dots & \dots & 0 & 0 \\ \vdots & \vdots & 0 & \dots & \vdots & \vdots \\ 0 & \dots & \vdots & 0 & \dots & 0 & 1 & 0 \\ 0 & 0 & 0 & \dots & \dots & 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & \alpha_1 & \dots & \alpha_{n-1} \\ 0 \\ \vdots & I_{n-1} \\ 0 \end{pmatrix}.$$

Proof.

$$g^{-1} = \begin{pmatrix} G_{11} & -G_{21} & \dots & (-1)^{n+1}G_{n1} \\ & & \\ & (-1)^{i+j}G_{ji} & & \end{pmatrix} = \\ = \begin{pmatrix} G_{11} & -G_{21} & \dots & (-1)^{n+1}G_{n1} \\ 0 & & \\ \vdots & g^{-1}|W & & \\ 0 & & \end{pmatrix}.$$

He

ence,  

$$g^{-1}\begin{pmatrix} 1 & \alpha_{1} & \dots & \dots & \alpha_{n-1} \\ 0 & 1 & 0 & \dots & \dots & 0 & 0 \\ \vdots & \vdots & 0 & & \vdots & \vdots & \vdots \\ 0 & \dots & \vdots & 0 & \dots & 0 & 1 & 0 \\ 0 & 0 & 0 & \dots & \dots & \dots & 0 & 1 \end{pmatrix} g = g^{-1}hg =$$

$$\begin{pmatrix} G_{11} & -G_{21} & \dots & (-1)^{n+1}G_{n1} \\ 0 & g^{-1}|W & \\ 0$$

as claimed.

**Corollary 4.2.** Suppose  $g \in G$  is a transvection. Then

$$g^{-1}hg = \begin{pmatrix} 1 & (\alpha_1, \dots, \alpha_{n-1})g|W & & & \\ 0 & 1 & 0 & \dots & \dots & 0 \\ 0 & 0 & 1 & 0 & \dots & \dots & 0 & 0 \\ \vdots & \vdots & 0 & \vdots & & \vdots & \vdots \\ 0 & & \dots & & \vdots & 0 & \dots & 0 & 1 & 0 \\ 0 & & 0 & 0 & \dots & \dots & \dots & 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & (\alpha_1, \dots, \alpha_{n-1})g|W & \\ 0 & \vdots & & I_{n-1} \\ 0 & & & I_{n-1} \end{pmatrix}$$

*Proof.* Since g is transvection we have  $g \in SL(V)$ . Now g|W is either the identity or a transvection on W. Hence in the 1<sup>st</sup> case there is nothing to prove and in the 2<sup>nd</sup> case det(g|W) = 1 and  $g_{11} = 1$ . Since  $G_{11} = det(g|W)$ , the result follows from **Lemma 4.1**.

Let V be a G-module and W a G-submodule. Recall that  $Fix_G(W) := \{g \in G | g | W = id\}$ .

**Proposition 4.3.** Suppose G is generated by transvections and  $\dim_F W = \dim_F V - 1$ . Then  $S(V)^{Fix_G(W)} = S(W)[z]$ , where  $z = v^{p^t} + q_1v^{p^{t-1}} + \ldots + q_tv$ ,  $q_i \in S(W)^{G|W}$  is homogenous of degree  $p^t - p^{t-i}$  and  $|Fix_G(W)| = p^t$ .

*Proof.* We fix a basis  $\{v, w_{n-1}, ..., w_1\}$  of V and  $\{w_{n-1}, ..., w_1\}$  a basis of W. The action of all elements of G are given by matrices with respect to this basis. So  $Fix_G(W) = \langle \sigma_1, ..., \sigma_t \rangle$ , where  $\{\sigma_1, ..., \sigma_t\}$  is a minimal generating set and

$$\sigma_{i} = \begin{pmatrix} 1 & \alpha_{1}^{(i)} & \dots & \dots & \dots & \alpha_{n-1}^{(i)} \\ 0 & 1 & 0 & \dots & \dots & 0 & 0 \\ 0 & 0 & 1 & 0 & \dots & \dots & 0 & 0 \\ \vdots & \vdots & 0 & & & \vdots & \vdots \\ 0 & \dots & \vdots & 0 & \dots & 0 & 1 & 0 \\ 0 & 0 & 0 & \dots & \dots & \dots & 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & \alpha_{1}^{(i)} & \dots & \alpha_{n-1}^{(i)} \\ 0 & & & & \\ \vdots & & & I_{n-1} \\ 0 & & & & \end{pmatrix}, i = 1, \dots, t.$$

Hence  $\{(\alpha_1^{(i)},...,\alpha_{n-1}^{(i)})|i=1,...,t\}$  is a  $\mathbb{F}_p$ -linearly independent set. Since, by **Corollary 4.2**,  $Fix_G(W)$  is a normal subgroup of G, then for a transvection  $g \in G, \{g^{-1}\sigma_1g,...,g^{-1}\sigma_tg\}$  is also a minimal generating set of  $Fix_G(W)$ . Consequently,  $span_{\mathbb{F}_p}\{(\alpha_1^{(i)},...,\alpha_{n-1}^{(i)})|i=1,...,t\} = span_{\mathbb{F}_p}\{(\alpha_1^{(i)},...,\alpha_{n-1}^{(i)})(g|W)|i=1,...,t\}.$ 

Recall that  $S(V)^{Fix_G(W)} = S(W)[z]$ , where z is obtained via the following procedure:

$$\begin{cases} z_1 = v^p - (\sigma_1 - I)(v)^{p-1}v = v^p - (\alpha_1^{(1)}w_{n-1} + \dots + \alpha_{n-1}^{(1)}w_1)^{p-1}v.\\ z_i = z_{i-1}^p - (\sigma_i - I)(z_{i-1})^{p-1}z_{i-1}, i = 2, \dots, t.\\ z = z_t. \end{cases}$$

Similarly, set

$$\sigma_{i,g} = \begin{pmatrix} 1 & & (\alpha_1^{(i)}, \dots, \alpha_{n-1}^{(i)})g|W & & & \\ 0 & & 1 & 0 & \dots & \dots & 0 \\ 0 & & 0 & & 1 & 0 & \dots & \dots & 0 & 0 \\ \vdots & & \vdots & & 0 & \vdots & & \vdots & \vdots \\ 0 & & & \dots & & \vdots & 0 & \dots & 0 & 1 & 0 \\ 0 & & & & 0 & \dots & \dots & \dots & 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & & (\alpha_1^{(i)}, \dots, \alpha_{n-1}^{(i)})g|W \\ \vdots & & & I_{n-1} \\ 0 & & & & I_{n-1} \end{pmatrix}$$

for i = 1, ..., t. Hence  $z'_1 = v^p - (\sigma_{1,g} - I)(v)^{p-1}v = v^p - (\beta_1^{(1)}w_{n-1} + ... + \beta_{n-1}^{(1)}w_1)^{p-1}v$ , where  $(\beta_1^{(i)}, ..., \beta_{n-1}^{(i)}) = (\alpha_1^{(i)}, ..., \alpha_{n-1}^{(i)})(g|W)$ . Hence  $g((\sigma_i - I)(v)) = g(\alpha_1^{(i)}w_{n-1} + ... + \alpha_{n-1}^{(i)}w_1) = \beta_1^{(i)}w_{n-1} + ... + \beta_{n-1}^{(i)}w_1$ , for i = 1, ..., t. If  $z'_i = (z'_{i-1})^p - [(\sigma_{i,g} - I)(z'_{i-1})]^{p-1}z'_{i-1}$  and  $z' = z'_t$ , then, by induction, starting with i = 1, we have :

$$\begin{array}{l} z_{i} = v^{p^{i}} + \gamma_{1i}v^{p^{i-1}} + \ldots + \gamma_{ii}v, \gamma_{ji} \in S(W), 1 \leq j \leq i. \\ z_{i}^{'} = v^{p^{i}} + \delta_{1i}v^{p^{i-1}} + \ldots + \delta_{ii}v, \delta_{ji} \in S(W), 1 \leq j \leq i. \\ g(\gamma_{ji}) = \delta_{ji}, \forall j = 1, \ldots, i. \end{array}$$

Since  $S(V)^{Fix_G(W)} = S(W)[z] = S(W)[z']$  and z, z' are monic polynomials in v with 0 as the free coefficient, it follows that z' = z and consequently  $\delta_{jt} = \gamma_{jt}$ , for j = 1, ..., t. Therefore  $g(\gamma_{jt}) = \gamma_{jt}$  for  $1 \le j \le t$ , and all transvections  $g \in G$ . Hence  $q_j := \gamma_{jt} \in S(W)^{G|W}$  for j = 1, ..., t.

Let V be a F-finite dimensional G-module, then  $V^* = Hom_F(V, F)$  is a G-module by the action  $(g \cdot f)(v) = f(g^{-1}v)$ , for  $f \in V^*, g \in G$  and  $v \in V$ . Let  $W \subset V$  be a G-submodule. Set  $W^{\perp} = \{f \in V^* | f(W) = 0\}$ . Clearly  $W^{\perp}$  is a G-submodule of  $V^*$  and  $dim_F W^{\perp} = dim_F V - dim_F W$ .

Lemma 4.4.  $V^*/W^{\perp} \cong W^*$  as G-modules.

Proof. Consider the map  $\pi : V^* \longrightarrow W^*$  given by  $\pi(f) = f|W$ , that is the restriction of f to  $W.Ker(\pi) = \{f \in V^* | f|W = 0\} = W^{\perp}$ . Hence the induced map  $\overline{\pi} : V^*/W^{\perp} \longrightarrow W^*$  is injective. Since  $\dim_F V^* - \dim_F W^{\perp} = \dim_F V - \dim_F W^{\perp} = \dim_F W$  we get that  $\overline{\pi}$  is an isomorphism. It is also easy to cheak that  $\pi$  and hence  $\overline{\pi}$  are G-module maps.

We also have the following results.

Corollary 4.5.  $V/W \cong (W^{\perp})^*$ .

Proof.  $(W^{\perp})^{\perp} = \{v \in V | g(v) = 0, \forall g \in W^{\perp}\}$ . Hence  $W \subset (W^{\perp})^{\perp}$ . Since  $\dim_F(W^{\perp})^{\perp} = \dim_F V^* - \dim_F W^* - \dim_F V^* - \dim_F V - \dim_F W$  we get that  $(W^{\perp})^{\perp} = W$ . We now apply Lemma 4.4 to the pair  $W^{\perp} \subset V^*$ . Hence  $V/W = (V^*)^*/(W^{\perp})^{\perp} \cong (W^{\perp})^*$ .

**Corollary 4.6.**  $\{g \in G | g(V) \subseteq W\} = \{g \in G | (g | W^{\perp}) = 0\}.$ 

*Proof.* This is a consequence of **Corollary 4.5**, since  $\{g \in G | g(V) \subseteq W\} = Ann_G V/W = Ann_G (W^{\perp})^* = Ann_G W^{\perp} = \{g \in G | g|W^{\perp} = 0\}.$ 

**Corollary 4.7.** Let  $W \subset V$  be a G-submodule. Then

- 1. W is faithful G-module iff  $W^*$  is a faithful G-module iff  $V^*/W^{\perp}$  is a faithful G-module.
- 2. W is an irreducible G-module iff  $W^*$  is an irreducible G-module iff  $V^*/W^{\perp}$  is an irreducible G-module.

Proof. This follows from Lemma 4.4.

# 5 Chapter(D): V is indecomposable, contains a unique 2- dimensional G- submodule, but no 1- dimensional G- submodule.

In this chapter we consider V, a reducible and indecomposable G – module which has a unique G-submodule W with  $dim_F W = 2$ , and V contains no 1-dimensional G-submodules, hence W is an irreducible G – module.

Lemma 5.1. One of the following holds:

- 1. W is a reducible T(G)-module and  $\sigma | W = id, \forall \sigma \in T(G)$ .
- 2. W is an irreducible T(G) module.

*Proof.* Assume that W is a reducible T(G)- module. Then there exists  $w \in W$  such that Fw is a T(G)- module, and it follows, using **Lemma 2.2**, that  $\sigma(w) = w \,\forall \sigma \in T(G)$ . Let  $g \in G$ , since  $T(G) \triangleleft G$ ,  $(g^{-1}\sigma g) = \tau$  for some  $\tau \in T(G)$ , hence  $\sigma(g(w)) = g(\tau(w)) = g(w)$ . If  $g(w) \notin Fw$  then  $\{w, g(w)\}$  is a basis for W and  $\sigma$  acts trivially on  $W \,\forall \sigma \in T(G)$  so (1) is established. On the other hand if  $g(w) \in Fw \,\forall g \in G$ , then Fw is 1-dimensional G-module. This contradicts the assumption that V contains no 1-dimensional G-modules.

For W an irreducible T(G) – module, the transvection group T(G)|W had been classified by Kantor whenever T(G)|W is an irreducible primitive linear group, see e.g [7, Theorem 1.5]. So one of the following holds in this case :

- (i)  $T(G)|W = SL(2, \mathbb{F}_q)$ , where p|q.
- (ii)  $T(G)|W \cong SL(2,\mathbb{F}_5), T(G)|W \subset SL(2,\mathbb{F}_9)$  and  $\mathbb{F}_9 \subseteq F$ .

Let  $\{v, w_2, w_1\}$  be a basis of  $V = F^3$  where  $\{w_1, w_2\}$  is a basis of W. So every  $g \in G$  is represented with respect to this basis, by the matrix:

(5.a) 
$$\begin{pmatrix} \lambda(g) & \delta_{12}(g) & \delta_{13}(g) \\ 0 & \delta_{22}(g) & \delta_{23}(g) \\ 0 & \delta_{32}(g) & \delta_{33}(g) \end{pmatrix}$$
.

We shall make the following assumption:

**Assumption 5.2.** Let  $\alpha : T(G) \longrightarrow (T(G)|W)$  be the map defined by  $\alpha(\tau) = (\tau|W)$  and let  $N := ker(\alpha)$ . Then  $S(V)^{T(G)}$  is a polynomial ring,  $S(V)^{T(G)} = S(W)^{T(G)}[n] = F[n, m_1, m_2]$  where  $m = (m_1, m_2)$  is the homogenous maximal ideal of  $S(W)^{T(G)} = F[m_1, m_2]$ , and  $S(V)^N = S(W)[n]$ .

The next result provides a necessary and sufficient condition on G to make  $S(V)^G$  into a Gorenstein ring .

**Proposition 5.3.** We keep the above notation and Assumption 5.2. Let  $G \subset SL(V)$  be a finite group. Then the following are equivalent:

1.  $S(V)^G$  is Gorenstein.

2. 
$$det(g|m/m^2) = \lambda(g)^{1-d}det(g|W)$$
, where  $d = deg(n) = \frac{|T(G)|}{deg(m_1) \cdot deg(m_2)}$  and  $m = (m_1, m_2)$ .

*Proof.* Suppose firstly that  $S(V)^G$  is Gorenstein. Then by [Theorem 1.2]  $det(g|p/p^2) = 1$ , where  $p = (n, m_1, m_2)$  is the homogenous maximal ideal of  $S(V)^{T(G)}$ . Clearly g acts linearly on  $p/p^2$  and is represented by the matrix:

$$\begin{bmatrix} \lambda(g)^d & * & * \\ \hline 0 & \\ 0 & g|m/m^2 \end{bmatrix}$$

So  $det(g|p/p^2) = \lambda(g)^d det(g|m/m^2) = 1$ . Since  $G \subset SL(V), \lambda(g)det(g|W) = 1$ . Consequently,  $\lambda(g)^d det(g|m/m^2) = \lambda(g)det(g|W)$ , hence  $det(g|m/m^2) = \lambda(g)^{1-d}det(g|W)$ . Suppose now that  $det(g|m/m^2) = \lambda(g)^{1-d}det(g|W)$ . Hence, using  $G \subset SL(V), \lambda(g)^d det(g|m/m^2) = \lambda(g)det(g|W) = 1$ . So  $det(g|p/p^2) = 1$ , then by [Theorem 1.2]  $S(V)^G$  is Gorenstein .

**Theorem 5.4.** Suppose  $W \subset V$  is an irreducible G-submodule and  $\sigma | W = Id$ , for all  $\sigma \in T(G)$  (as in Lemma 5.1 (1)). Then  $S(V)^G$  is Gorenstein iff  $\lambda(g)^{1-d} = 1$ . Consequently if  $V = \mathbb{F}_p^3$  then  $S(V)^G$  is always Gorenstein.

Proof. By assumption  $T(G) = ker(\alpha)$ , where  $\alpha : T(G) \longrightarrow (T(G)|W)$  is the restriction map. Therefore by **Proposition 4.3**  $S(V)^{T(G)} = S(W)[n]$ , where  $d = deg(n) = p^t$ . Hence **Assumption 5.2** holds here with  $m_1 = w_1, m_2 = w_2, m = (w_1, w_2), p = (n, w_1, w_2)$ . Since  $m/m^2 = Fw_1 + Fw_2 = W$ we have that  $det(g|m/m^2) = det(g|W)$ , implying by **Proposition 5.3** that  $S(V)^G$  is Gorenstein if and pnly if  $\lambda(g)^{1-d} = 1$ . Consequently, if  $V = \mathbb{F}_p^3$  then , since  $\lambda(g) \in \mathbb{F}_p, \lambda(g)^{1-d} = 1$ .

The next result applies in case (i), where W is an irreducible primitive T(G)-module.

**Proposition 5.5.** Suppose  $G \subset SL(V)$  is a finite group with  $T(G)|W = SL(2, \mathbb{F}_q)$ , where  $q = p^s$ ,  $\mathbb{F}_q \subseteq F$  and satisfies **Assumption 5.2**. Let  $V = F^3$  be the natural SL(3, F) – module.Let  $g \in G$  be arbitrary and set  $g|W = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$  with respect to the  $\mathbb{F}_q$  – basis  $\{w_1, w_2\}$ . Then  $S(V)^G$  is Gorenstein if and only if  $a^{q^2-1} = \lambda(q)^{1-d}$ .

*Proof.* The computation in **Proposition 2.4** shows that the matrix representing  $g|m/m^2$  is  $\begin{pmatrix} a^{q^{-1}det(g|W)} & 0 \\ 0 & a^{q^2-q} \end{pmatrix}$ , hence  $det(g|m/m^2) = a^{q^2-1}det(g|W)$ . Hence, by **Proposition 5.3**,  $S(V)^G$  is Gorenstein if and only if  $a^{q^2-1}det(g|W) = det(g|W)\lambda(g)^{1-d}$ . Thus  $S(V)^G$  is Gorenstein if and only if  $a^{q^2-1} = \lambda(g)^{1-d}$ .

**Remark 5.6.** For W an irreducible and imprimitive T(G)-module, T(G)|W is a monomial subgroup (e.g.[13]). In this case, if char  $F \neq 2$ , then by [3, Lemma 3.9.] T(G)|W = 1, which contradicts the assumption that W is an irreducible T(G)-module. On the other hand, if p = 2, then  $T(G)|W = < \sigma >$ , where  $\sigma = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ . This implies that  $(w_2 + w_1) \in S(V)^G$ . Hence  $\mathbb{F}_2(w_2 + w_1)$  is G-module, which contradicts the assumption that W is an irreducible G-module. Hence we deal only with the case when W is an irreducible primitive T(G)-module.

**Proposition 5.7.** Suppose  $F = \mathbb{F}_p$  and W is an irreducible T(G)-module. Then Assumption 5.2 holds for G.

Proof. Clearly

$$N = ker(\alpha) \subseteq \begin{pmatrix} 1 & \mathbb{F}_p & \mathbb{F}_p \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$

Since  $F = \mathbb{F}_p$ , we have by **Remark 5.6** that W is a primitive T(G)-module, and therefore  $T(G)|W = SL(2, \mathbb{F}_p)$ . If  $N \neq 1$  then there exists

$$\sigma := \begin{pmatrix} 1 & \alpha & \beta \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, (\alpha, \beta) \neq (0, 0), \sigma \in N.$$

Consequently by Corollary 4.2 we have :

$$\left(\begin{array}{ccc} 1 & (\alpha,\beta)SL(2,\mathbb{F}_p)\\ 0 & 1 & 0\\ 0 & 0 & 1 \end{array}\right) \subseteq N,$$

and therefore since  $(\alpha, \beta)SL(2, \mathbb{F}_p) = (\mathbb{F}_p, \mathbb{F}_p)$  we conclude that

$$N = \left(\begin{array}{ccc} 1 & \mathbb{F}_p & \mathbb{F}_p \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{array}\right).$$

Let

$$g = \begin{pmatrix} 1 & \delta_{12}(g) & \delta_{13}(g) \\ 0 & \delta_{22}(g) & \delta_{23}(g) \\ 0 & \delta_{32}(g) & \delta_{33}(g) \end{pmatrix} \in T(G),$$

be an arbitrary element. Then

$$\begin{pmatrix} 1 & \delta_{12}(g) & \delta_{13}(g) \\ 0 & \delta_{22}(g) & \delta_{23}(g) \\ 0 & \delta_{32}(g) & \delta_{33}(g) \end{pmatrix} \begin{pmatrix} 1 & -\delta_{12}(g) & -\delta_{13}(g) \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \delta_{22}(g) & \delta_{23}(g) \\ 0 & \delta_{32}(g) & \delta_{33}(g) \end{pmatrix} \in T(G)N = T(G).$$

Consequently, since  $T(G)|W = \{g|W = \begin{pmatrix} \delta_{22}(g) & \delta_{23}(g) \\ \delta_{32}(g) & \delta_{33}(g) \end{pmatrix}|g \in T(G)\}$  and  $SL(2, \mathbb{F}_p) = T(G)|W$ , then

$$H := \left(\begin{array}{c|c} 1 & 0 & 0 \\ \hline 0 & SL(2, \mathbb{F}_p) \\ 0 & SL(2, \mathbb{F}_p) \end{array}\right) \subseteq T(G).$$

Moreover  $H \cap N = \{1\}$ . Hence  $|HN| = |H| \cdot |N| = (p^2 - p) \cdot (p+1) \cdot |N| = |T(G)|W| \cdot |N| = \frac{|T(G)|}{|N|} \cdot |N| = |T(G)|$ , implying that T(G) = HN. Let  $\{v, w_2, w_1\}$  be the basis representing the matrices above, where  $W = span_{\mathbb{F}_p}\{w_1, w_2\}$ . Now by **Proposition 4.3**, there exists  $n = v^{p^2} + q_1v^p + q_2v$ ,  $q_i \in S(W)^{T(G)|W}$ , with  $S(V)^N = S(W)[n]$ . Since h(v) = v for each  $h \in H$ , it follows that  $n \in S(V)^H$ , and therefore  $S(V)^{T(G)} = S(W)[n]^{T(G)/N} = S(W)^H[n] = S(W)^{SL(2,\mathbb{F}_p)}[n] = F[d_1, d_2, n]$ , where  $\{d_1, d_2\}$  are the Dickson invariants of degrees  $\{p + 1, p^2 - p\}$  respectively.

Suppose  $N = \{1\}$ . Hence  $T(G) \cong T(G)|W = SL(2, \mathbb{F}_p)$ . Now  $T(G) = \langle \phi_1, ..., \phi_k \rangle$ , where  $\phi_i$ , is a transvection, for i = 1, ..., k. Moreover  $k \ge 2$  (since  $T(G) \cong SL(2, \mathbb{F}_p)$ ), and we may assume that at least two out of  $\{\phi_1|W, ..., \phi_k|W\}$  do not commute, say  $\{\phi_1|W, \phi_2|W\}$ . Therefore  $\langle \phi_1|W, \phi_2|W \rangle \cong SL(2, \mathbb{F}_p)$ , implying that  $\phi_i|W \in \langle \phi_1|W, \phi_2|W \rangle$ , for each  $i \ge 3$ . Therefore, since  $\alpha$  is injective, we have:  $\phi_i \in \langle \phi_1, \phi_2 \rangle$ , for  $i \ge 3$ , that is  $T(G) = \langle \phi_1, \phi_2 \rangle$ . Hence  $ker(\phi_1 - I) \cap ker(\phi_2 - I) := Fv$ , is a one dimensional trivial T(G)-module. Moreover, since W is an irreducible T(G)-module,  $v \notin W$ , hence  $V = Fv \oplus W$  as T(G)-modules. Consequently with respect to the basis  $\{v, w_1, w_2\}$  (where  $\{w_1, w_2\}$  is any basis of W), T(G) is represent by matrices of the form :

$$H := \left( \begin{array}{c|c} 1 & 0 & 0 \\ \hline 0 & SL(2, \mathbb{F}_p) \\ \hline 0 & SL(2, \mathbb{F}_p) \end{array} \right),$$

and since  $|H| = |SL(2, \mathbb{F}_p)| = |T(G)|W| = |T(G)|$  we have H = T(G). Hence  $S(V)^{T(G)} = S(W)^{SL(2, \mathbb{F}_p)}[v] = F[d_1, d_2, v]$  and we take n = v.

**Theorem 5.8.** Suppose  $G \subset SL(3, \mathbb{F}_p)$  and W is an irreducible T(G)-submodule of  $V = \mathbb{F}_p^3$ . Then  $S(V)^G$  is Gorenstein.

*Proof.* By **Proposition 5.5** and **Proposition 5.7**, we have to check that  $a^{p^2-1} = \lambda(g)^{1-d}$ , where  $d = deg(n) \in \{1, p^2\}$  and  $g|W = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ . If N = 1 then d = 1, and if  $N \neq 1$ , then  $d = p^2$ . Since  $a, \lambda(g) \in \mathbb{F}_p$  we have  $a^{p-1} = \lambda(g)^{p-1} = 1$ . Hence  $a^{p^2-1} = 1 = \lambda(g)^{1-d}$  for  $d \in \{1, p^2\}$ .

**Corollary 5.9.** Suppose  $G \subset SL(3, \mathbb{F}_p), W \subset V = \mathbb{F}_p^3$  is an irreducible G-submodule and  $\dim_{\mathbb{F}_p} W = 2$ . Then  $S(V)^G$  is Gorenstein.

*Proof.* This is a combination of Lemma 5.1, Theorem 5.4 and Theorem 5.8

# 6 Chapter(E): V is indecomposable, contains a unique 1- dimensional G- submodule U, but no 2- dimensional Gsubmodule.

In this chapter we consider V, a 3-dimensional reducible and indecomposable G - module which has a unique 1-dimensional G-submodule  $U = Fv_0$  and V contains no 2-dimensional G-submodules.Hence W = V/U is an irreducible G- module. We shall exclusively consider here the case  $F = \mathbb{F}_p$ .

Let  $\{w_1, w_2, v_0\}$  be any basis of  $V = F^3$ . So every  $g \in G$  is represented with respect to this basis, by the matrix:

(6.a) 
$$g = \begin{pmatrix} \delta_{11}(g) & \delta_{12}(g) & \delta_{13}(g) \\ \delta_{21}(g) & \delta_{22}(g) & \delta_{23}(g) \\ 0 & 0 & \lambda(g) \end{pmatrix}.$$

Let  $\alpha : T(G) \longrightarrow (T(G)|W)$  be the map which is defined by  $\alpha(\tau) = \tau |W$ , hence  $ker(\alpha) = \{\sigma \in T(G) | \sigma(x) - x \in Fv_0, \forall x \in V\}$ . Consequently,

$$ker(\alpha) \subseteq \left(\begin{array}{rrr} 1 & 0 & * \\ 0 & 1 & * \\ 0 & 0 & 1 \end{array}\right)$$

We shall firstly consider the case that  $W = V/\mathbb{F}_p v_0$  is an irreducible T(G) - module (on top of being *G*-irreducible). Since  $F = \mathbb{F}_p$ , it follows from **Remark 5.6**, that  $T(G)|W = SL(2, \mathbb{F}_p)$ .

**Proposition 6.1.** Suppose  $V = \mathbb{F}_p^3$ , and  $V/\mathbb{F}_p v_0$  is an unfaithful, irreducible T(G)-module. Then  $S(V)^{T(G)}$  is a polynomial ring.

Proof. Clearly  $T(G) \subset SL(V)$ .Let  $N := ker(\alpha)$ , then by assumption  $N \neq 1$ . Set  $U = \mathbb{F}_p v_0$ . Then by Corollary 4.6,  $N = Ann_{T(G)}V/U = Ann_{T(G)}U^{\perp}$ .

V/U is an irreducible T(G)-module hence by **Corollary 4.7**,  $U^{\perp}$  is a 2-dimensional irreducible T(G)- submodule of  $V^*$ . Therefore by the proof of the early part of **Proposition 5.7**,  $|N| = p^2$ .

Hence,

with generators

$$N = \begin{pmatrix} 1 & 0 & \mathbb{F}_p \\ 0 & 1 & \mathbb{F}_p \\ 0 & 0 & 1 \end{pmatrix},$$
$$\{ \begin{pmatrix} 1 & 0 & 1 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{pmatrix} \}.$$

Let

$$g = \begin{pmatrix} \delta_{11}(g) & \delta_{12}(g) & \delta_{13}(g) \\ \delta_{21}(g) & \delta_{22}(g) & \delta_{23}(g) \\ 0 & 0 & 1 \end{pmatrix},$$

be a transvection in T(G). Then

$$\begin{pmatrix} 1 & 0 & -\delta_{13}(g) \\ 0 & 1 & -\delta_{23}(g) \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} \delta_{11}(g) & \delta_{12}(g) & \delta_{13}(g) \\ \delta_{21}(g) & \delta_{22}(g) & \delta_{23}(g) \\ 0 & 0 & 1 \end{pmatrix} = \begin{pmatrix} \delta_{11}(g) & \delta_{12}(g) & 0 \\ \delta_{21}(g) & \delta_{22}(g) & 0 \\ 0 & 0 & 1 \end{pmatrix} \in NT(G) = T(G).$$

Since  $\left\{ \begin{pmatrix} \delta_{11}(g) & \delta_{12}(g) \\ \delta_{21}(g) & \delta_{22}(g) \end{pmatrix} | g \in T(G) \right\} = SL(2, \mathbb{F}_p) = T(G) | W$  then

$$H := \left( \begin{array}{c|c} SL(2, \mathbb{F}_p) & 0\\ \hline 0 & 0 & 1 \end{array} \right) \subseteq T(G).$$

Since  $|T(G)| = |SL(2, \mathbb{F}_p)| \cdot |N| = (p+1)(p^2 - p)p^2$ , then  $T(G) = \langle H, N \rangle$ . We have  $S(V)^N = \mathbb{F}_p[v_0, a, b]$  where  $a = w_1^p - v_0^{p-1}w_1$  and  $b = w_2^p - v_0^{p-1}w_2$ . Consider  $\{\sigma, \tau\}$ , generators of H, where

$$\tau = \left(\begin{array}{rrr} 1 & 1 & 0\\ 0 & 1 & 0\\ 0 & 0 & 1 \end{array}\right), \sigma = \left(\begin{array}{rrr} 1 & 0 & 0\\ 1 & 1 & 0\\ 0 & 0 & 1 \end{array}\right).$$

Then  $\tau(b) = b, \tau(a) = a + b, \sigma(a) = a, \sigma(b) = a + b$ . Hence  $A = a^p b - b^p a$  and  $B = \frac{a^{p^2} b - b^{p^2} a}{A}$ , are Dickson invariants of  $(S(V)^N)^H = S(V)^{T(G)}$ . So  $deg(A) \cdot deg(B) \cdot deg(v_0) = p(p+1) \cdot p(p^2 - p) = |T(G)|$ . Hence by [4, Theorem 3.7.5]  $S(V)^{T(G)} = \mathbb{F}_p[v_0, A, B]$  is a polynomial ring.

**Lemma 6.2.** Suppose  $V = \mathbb{F}_p^3$ , and  $W = V/\mathbb{F}_p v_0$  is an irreducible T(G)-module. Then one of the following holds.

- 1. W is an unfaithful irreducible T(G)-module and  $T(G) = \langle H, N \rangle$ .
- 2. W is a faithful irreducible T(G)-module and T(G) = H, where H is defined in **Proposition** 6.1.

Proof. If item (1) holds then by **Proposition 6.1** the result follows. So we may assume that W is a faithful irreducible T(G)-module. Let  $T(G) = \langle \phi_1, ..., \phi_k \rangle$ , so  $(T(G)|W) = \langle \phi_1|W, ..., \phi_k|W \rangle$ . If  $\phi_i|W = Id$  then  $\phi_i \in N = 1$ . Hence  $\phi_i|W$  are non trivial transvections for i = 1, ..., k. Since W is an irreducible T(G)-module then there exist at least two transvections that do not commute, say  $(\phi_1|W)$  and  $(\phi_2|W)$ . But then W is an irreducible  $\langle \phi_1|W, \phi_2|W \rangle$  -module. Hence  $\langle \phi_1|W, \phi_2|W \rangle \cong SL(2, \mathbb{F}_p)$ . Since  $|(T(G)|W)| = |SL(2, \mathbb{F}_p)|$  then  $\langle \phi_1|W, \phi_2|W \rangle = (T(G)|W)$ . Therefore,  $\forall \phi_i \in T(G)$  with  $i \geq 3$ ,  $(\phi_i|W)$  is generated by  $(\phi_1|W)$  and  $(\phi_2|W)$ . So  $\phi_i = h \cdot Z$  where  $h \in \langle \phi_1, \phi_2 \rangle$  and  $Z \in N = ker(\alpha)$ . Since  $N = 1, \phi_i = h$ . Therefore  $T(G) = \langle \phi_1, \phi_2 \rangle$ .

Consider  $U^{\perp} \subset V^*$ . Since W = V/U is a faithful and irreducible T(G)-module it follows from **Corollary 4.5,Corollary 4.7** that  $U^{\perp}$  is a faithful and irreducible T(G)-submodule of  $V^*$ .

Consider  $ker(\phi_1 - I) \cap ker(\phi_2 - I) \subset V^*$ . It is a 1-dimensional subspace (since  $\phi_1, \phi_2$  are transvections on  $V^*$ ). Let  $Fg = ker(\phi_1 - I) \cap ker(\phi_2 - I) \subset V^*$ . Since  $T(G) = \langle \phi_1, \phi_2 \rangle$  it follows that Fg is a trivial T(G)-submodule of  $V^*$ . Since  $U^{\perp}$  is irreducible it follows that  $Fg \oplus U^{\perp} = V^*$ , a direct sum decomposition of  $V^*$  as T(G)-modules. Since  $U^{\perp}$  is irreducible and faithful we have , as in **Proposition 5.7**, a representation of T(G) as matrices of the form :

$$\left(\begin{array}{c|c} 1 & 0 & 0 \\ \hline 0 & SL(2, \mathbb{F}_p) \\ \hline \end{array}\right),$$

with respect to the basis  $\{g, h_1, h_2\}$ , where  $\{h_1, h_2\}$  is any basis of  $U^{\perp}$ . Let  $\{x, w_1, w_2\}$  be the dual basis of  $\{g, h_1, h_2\}$ . So  $g(x) = 1, h_1(x) = h_2(x) = 0, h_i(w_j) = \delta_{ij}$  and  $g(w_1) = g(w_2) = 0$ . Hence  $x \in (Fh_1 + Fh_2)^{\perp} = (U^{\perp})^{\perp} = U$  and  $\mathbb{F}_p x = \mathbb{F}_p v_0$ .

 $(Fg)^{\perp} = Fw_1 + Fw_2$  is a 2-dimensional T(G)-submodule of V and  $(Fg)^{\perp} \oplus (U^{\perp})^{\perp} = V$ . Hence the matrices representing T(G) with respect to the basis  $\{w_1, w_2, v_0\}$  are

$$H := \left( \begin{array}{c|c} SL(2, \mathbb{F}_p) & 0\\ \hline 0 & 0 & 1 \end{array} \right).$$

The following theorem deals with the special case, when  $W = V/\mathbb{F}_p v_0$  is an irreducible primitive T(G)-module and  $F = \mathbb{F}_p$ . Since  $F = \mathbb{F}_p$ , by [7, Theorem 1.5]  $(T(G)|W) = SL(2,\mathbb{F}_p)$  and  $p \neq 2$ .

**Theorem 6.3.** Suppose that  $G \subset SL(3, \mathbb{F}_p), W = V/\mathbb{F}_p v_0$  is an irreducible T(G)-module. Then  $S(V)^G$  is Gorenstein.

Proof. Assume firstly that W is a faithful irreducible T(G)-module.By Lemma 6.2 (2),  $S(V)^{T(G)} = S(V)^H = \mathbb{F}_p[u, y, v_0]$  is a polynomial ring where  $u = w_1 w_2^p - w_2 w_1^p$ ,  $y = \frac{w_1 w_2^{p^2} - w_2 w_1^{p^2}}{u}$  are the Dickson's invariants.Now for  $g \in G$  since  $gT(G)g^{-1} = T(G)$ ,  $\mathbb{F}_p[u, y, v_0]$  is g-stable and since g preserve degrees we get  $g(u) = \alpha u + \beta v_0^{p+1}$  with  $\alpha, \beta \in \mathbb{F}_p$ . By Fermat' little theorem and formula (6.a) we get:

$$\begin{split} g(u) &= (\delta_{11}(g)w_1 + \delta_{12}(g)w_2 + \delta_{13}(g)v_0)(\delta_{21}(g)w_1^p + \delta_{22}(g)w_2^p + \delta_{23}(g)v_0^p) - (\delta_{21}(g)w_1 + \delta_{22}(g)w_2 + \\ \delta_{23}(g)v_0)(\delta_{11}(g)w_1^p + \delta_{12}(g)w_2^p + \delta_{13}(g)v_0^p) &= \delta_{11}(g)\delta_{22}(g)(w_1w_2^p - w_2w_1^p) + \\ \delta_{12}(g)\delta_{23}(g)(w_2v_0^p - v_0w_2^p) + \\ \delta_{13}(g)\delta_{22}(g)(w_2^pv_0 - w_2v_0^p) + \\ \delta_{12}(g)\delta_{23}(g)(w_2v_0^p - v_0w_2^p) + \\ \delta_{13}(g)\delta_{22}(g)(w_1w_2^p - w_2w_0^p) + \\ \delta_{12}(g)\delta_{23}(g) - \delta_{13}(g)\delta_{21}(g))(w_1w_2^p - w_2w_1^p) + \\ (\delta_{12}(g)\delta_{23}(g) - \delta_{13}(g)\delta_{22}(g))(w_2v_0^p - v_0^pw_2). \end{split}$$

Now by comparing coefficients of g(u) we get:

(6.b) 
$$\begin{cases} \alpha = \delta_{11}(g)\delta_{22}(g) - \delta_{12}(g)\delta_{21}(g) \\ \beta = 0 \\ \delta_{11}(g)\delta_{23}(g) - \delta_{13}(g)\delta_{21}(g) = 0 \\ \delta_{12}(g)\delta_{23}(g) - \delta_{13}(g)\delta_{22}(g) = 0 \end{cases}$$

Since  $G \subset SL(V), \lambda(g)^{-1} = \delta_{11}(g)\delta_{22}(g) - \delta_{12}(g)\delta_{21}(g)$ , then  $g(u) = \lambda(g)^{-1}u$ . Similarly,  $g(y) = \gamma y + q(u, v_0)$ , where  $\gamma \in \mathbb{F}_p$  and  $q(u, v_0)$  is a homogenous polynomial (in  $u, v_0$ ) with  $deg(q) = deg(y) = p^2 - p$ .

By Fermat' little theorem, formula (6.a) and (6.b) we get:

$$\begin{aligned} g(w_1 w_2^{p^2} - w_2 w_1^{p^2}) &= (\delta_{11}(g) \delta_{22}(g) - \delta_{12}(g) \delta_{21}(g))(w_1 w_2^{p^2} - w_2 w_1^{p^2}) + (\delta_{11}(g) \delta_{23}(g) - \delta_{13}(g) \delta_{21}(g))(w_1 v_0^{p^2} - w_0 w_1^{p^2}) + (\delta_{12}(g) \delta_{23}(g) - \delta_{13}(g) \delta_{22}(g))(w_2 v_0^{p^2} - v_0^{p^2} w_2) \\ &= \lambda(g)^{-1}(w_1 w_2^{p^2} - w_2 w_1^{p^2}) + 0 + 0, \\ &\text{using } \delta_{11}(g) \delta_{22}(g) - \delta_{12}(g) \delta_{21}(g) \\ &= \lambda(g)^{-1}. \text{ Since } uy \\ &= w_1 w_2^{p^2} - w_2 w_1^{p^2} \text{ we get } g(y) \\ &= \frac{g(w_1 w_2^{p^2} - w_2 w_1^{p^2})}{g(u)} \\ &= \frac{\lambda(g)^{-1}(w_1 w_2^{p^2} - w_2 w_1^{p^2})}{\lambda(g)^{-1}u} \\ &= \frac{w_1 w_2^{p^2} - w_2 w_1^{p^2}}{u} \\ &= y. \text{ So by comparing coefficients we get that } \gamma \\ &= 1 \text{ and } q(u, v_0) \\ &= 0. \end{aligned}$$

Clearly, g acts linearly on  $\mathbb{F}_p u + \mathbb{F}_p y + \mathbb{F}_p v_0$  and is represented by the matrix :

1	$\lambda(g)^{-1}$	0	0		
	0	1	0		
	0	0	$\lambda(g)$	]	

Therefore, by [Theorem 1.2]  $S(V)^G$  is Gorenstein.

Assume now that W is an unfaithful irreducible T(G)-module.By **Proposition 6.1**  $S(V)^{T(G)} = \mathbb{F}_p[A, B, v_0]$  is a polynomial ring where  $A = a^p b - b^p a$ ,  $B = \frac{a^{p^2} b - b^{p^2} a}{A}$  and  $deg(A) = p^2 + p$ ,  $deg(B) = p(p^2 - p)$ . We have :

$$\begin{split} A &= a^p b - b^p a = (w_1^{p^2} - v_0^{p(p-1)} w_1^p)(w_2^p - v_0^{p(p-1)} w_2) - (w_2^{p^2} - v_0^{p(p-1)})w_2^p(w_1^p - v_0^{p-1} w_1) = (w_1^{p^2} w_2^p - w_2^{p^2} w_1^p) - v_0^{p-1}(w_1^{p^2} w_2 - w_2^{p^2} w_1) + v_0^{p^{2-1}}(w_1^p w_2 - w_2^p w_1) = (-u)^p - v_0^{p-1}(w_1^{p^2} w_2 - w_2^{p^2} w_1) + v_0^{p^{2-1}}(-u), \\ \text{where } u = w_1 w_2^p - w_2 w_1^p. \text{ We get in the previous calculation that :} \end{split}$$

 $\begin{cases} g(u) = \lambda(g)^{-1}u.\\ g(w_1^{p^2}w_2 - w_2^{p^2}w_1) = \lambda(g)^{-1}(w_1^{p^2}w_2 - w_2^{p^2}w_1). \end{cases}$ Since  $g(v_0^{p^2-1}) = (\lambda(g)^{-1})^{p^2-1}v_0^{p^2-1} = v_0^{p^2-1}$ , then  $g(A) = \lambda(g)^{-1}A.$  We also have :

$$\begin{aligned} &a^{p^2}b - b^{p^2}a = (w_1^{p^3} - v_0^{p^2(p-1)}w_1^{p^2})(w_2^p - v_0^{p-1}w_2) - (w_2^{p^3}v_0^{p^2(p-1)}w_2^{p^2})(w_1 - v_0^{p-1}w_1) = (w_1^{p^3}w_2^{p^2} - w_2^{p^3}w_1^p) - v_0^{(p-1)}(w_1^{p^3}w_2 - w_2^{p^3}w_1) + v_0^{p^2(p-1)}(w_2^{p^2}w_1^p - w_2^{p^2}w_2^p) + v_0^{(p^2+1)(p-1)}(w_1^{p^2}w_2 - w_2^{p^2}w_1) = (-u)^{p^2} - v_0^{(p-1)}(w_1^{p^3}w_2 - w_2^{p^3}w_1) + v_0^{p^2(p-1)}(u)^p + v_0^{(p^2+1)(p-1)}(-uy). \end{aligned}$$

We get in the previous calculation that  $g(u) = \lambda(g)u$  and g(y) = 1. On the other hand we have :

$$g(v_0^{(p-1)}(w_1^{p^3}w_2 - w_2^{p^3}w_1)) = (\delta_{11}(g)\delta_{22}(g) - \delta_{12}(g)\delta_{21}(g))(w_1^{p^3}w_2 - w_2^{p^3}w_1) + (\delta_{23}(g)\delta_{11}(g) - \delta_{13}(g)\delta_{21}(g))(w_0^{p^3}w_2 - w_2^{p^3}w_0) + (\delta_{22}(g)\delta_{13}(g) - \delta_{12}(g)\delta_{23}(g))(w_1^{p^3}v_0 - w_2^{p^3}v_0).$$
 Hence by **(6.b)**,  $g(v_0^{(p-1)}(w_1^{p^3}w_2 - w_2^{p^3}w_1)) = \lambda(g)^{-1}(v_0^{(p-1)}(w_1^{p^3}w_2 - w_2^{p^3}w_1).$ 

Consequently  $g(a^{p^2}b - b^{p^2}a) = \lambda(g)^{-1}(a^{p^2}b - b^{p^2}a)$ , hence  $g(B) = \frac{g(a^{\nu} \ b - b^{\nu} \ a)}{g(A)} = \frac{\lambda(g)^{-1}(a^{\nu} \ b - b^{\nu} \ a)}{\lambda(g)^{-1}A} = B$ . So g acts linearly on  $\mathbb{F}_pA + \mathbb{F}_pB + \mathbb{F}_pv_0$  and is represented by the matrix :

$$\left(\begin{array}{ccc} \lambda(g)^{-1} & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & \lambda(g) \end{array}\right).$$

Again,<br/>by [Theorem 1.2]  $S(V)^G$  is Gorenstein .

We shall now consider the possibility that W is a reducible T(G)-module.

**Lemma 6.4.** Suppose W = V/Fv is a reducible T(G)-module. Then W is a trivial T(G)-module, that is  $ker(\alpha) = T(G)$ .

Proof. Let  $F\bar{w}_1$  be a T(G)- submodule of W. Hence  $\phi(\bar{w}_1) = \bar{w}_1, \forall \phi \in T(G)$ . Since W is irreducible G-submodule,  $F\bar{w}_1$  is not a G-submodule. Consequently, there exists  $g \in G$  such that  $g(\bar{w}_1) = \bar{w}_2 \notin F\bar{w}_1$ . Since  $T(G) \triangleleft G, \forall \sigma \in T(G), g^{-1}\sigma g = \tau$ , for some  $\tau \in T(G)$ . Hence  $(g^{-1}\sigma g)(\bar{w}_1) = \tau(\bar{w}_1) = \bar{w}_1$ , and therefore  $\sigma(g(\bar{w}_1)) = g(\bar{w}_1)$ , hence  $\sigma(\bar{w}_2) = \bar{w}_2$ . But  $\{\bar{w}_1, \bar{w}_2\}$  is a basis of W. Consequently W is a trivial T(G)-module.

**Corollary 6.5.** Suppose  $W = V/\mathbb{F}_p v_0$  is a reducible T(G)-module, then  $S(V)^{T(G)}$  is a polynomial ring.

Proof.

$$ker(\alpha) = T(G) \subseteq \left(\begin{array}{ccc} 1 & 0 & \mathbb{F}_p \\ 0 & 1 & \mathbb{F}_p \\ 0 & 0 & 1 \end{array}\right).$$

Hence  $|T(G)| \in \{p, p^2\}$ . If  $|T(G)| = p^2$ , then

$$T(G) = \begin{pmatrix} 1 & 0 & \mathbb{F}_p \\ 0 & 1 & \mathbb{F}_p \\ 0 & 0 & 1 \end{pmatrix},$$

with generators :

$$\left(\begin{array}{rrrr}1 & 0 & 1\\0 & 1 & 0\\0 & 0 & 1\end{array}\right), \left(\begin{array}{rrrr}1 & 0 & 0\\0 & 1 & 1\\0 & 0 & 1\end{array}\right).$$

Hence  $S(V)^{T(G)} = \mathbb{F}_p[v_0, x, y]$ , where  $x = w_1^p - v_0^{p-1}w_1, y = w_2^p - v_0^{p-1}w_2$ . If |T(G)| = p, then T(G) is generated by :

$$\left(\begin{array}{rrr}1&0&\alpha\\0&1&\beta\\0&0&1\end{array}\right),\alpha,\beta\in\mathbb{F}_p.$$

Then as in Lemma 3.2  $S(V)^{T(G)} = \mathbb{F}_p[v_0, \alpha w_2 - \beta w_1, z]$  is a polynomial ring and  $z = w_1^p - (\alpha v_0)^{p-1} w_1$ .

**Corollary 6.6.** Suppose  $W = V/\mathbb{F}_p v_0$  is a reducible T(G)-module and an irreducible G-module. Then  $|T(G)| = p^2$ .

*Proof.* Suppose as in Corollary 6.5, that |T(G)| = p, so

$$T(G) = < \begin{pmatrix} 1 & 0 & \alpha \\ 0 & 1 & \beta \\ 0 & 0 & 1 \end{pmatrix} > .$$

Since  $\mathbb{F}_p v_0$ ,  $\mathbb{F}_p(\alpha w_1 - \beta w_2)$  are trivial T(G)- modules we have that  $A = \mathbb{F}_p v_0 + \mathbb{F}_p(\alpha w_1 - \beta w_2) = ker(\sigma - I)$  for each transvection  $\sigma \in T(G)$ . Let  $g \in G$  and  $\sigma$  a transvection in G. Then  $g^{-1}\sigma g = \tau$  for some transvection  $\tau$ . Then for each  $a \in A$  we have  $(g^{-1}\sigma g)(a) = \tau(a) = a$  and hence  $\sigma(g(a)) = g(a)$ , implying that  $g(a) \in A$  for each  $g \in G$ . Hence A is a 2-dimensional G-submodule of V. This contradicts the assumption on V.

**Theorem 6.7.** Suppose  $W = V/\mathbb{F}_p v_0$  is a reducible T(G) – module and an irreducible G – module. Then  $S(V)^G$  is Gorenstein.

*Proof.* We follow here the argument in **Proposition 3.13** with  $\binom{a}{b} = \binom{1}{0}, \binom{c}{d} = \binom{0}{1}$ . Recall that by **Corollary 6.5** and **Corollary 6.6**,

$$T(G) = \begin{pmatrix} 1 & 0 & \mathbb{F}_p \\ 0 & 1 & \mathbb{F}_p \\ 0 & 0 & 1 \end{pmatrix},$$

with generators :

$$\left(\begin{array}{rrrr}1 & 0 & 1\\0 & 1 & 0\\0 & 0 & 1\end{array}\right), \left(\begin{array}{rrrr}1 & 0 & 0\\0 & 1 & 1\\0 & 0 & 1\end{array}\right)$$

Hence  $S(V)^{T(G)} = \mathbb{F}_p[v_0, x, y]$ , where  $x = w_1^p - v_0^{p-1}w_1, y = w_2^p - v_0^{p-1}w_2$ . So if  $m = (v_0, x, y)$  then  $\bar{g} \in G/T(G)$  is represented on  $m/m^2 = \mathbb{F}_p \bar{y} + \mathbb{F}_p \bar{x} + \mathbb{F}_p v_0$  by the matrix :

$$\left(\begin{array}{ccc} \alpha & \gamma & 0 \\ \varepsilon & \delta & 0 \\ 0 & 0 & \lambda(g) \end{array}\right),$$

and  $g \in G$  is represented on  $V = \mathbb{F}_p w_2 + \mathbb{F}_p w_1 + \mathbb{F}_p v_0$ , by the matrix :

$$\left(\begin{array}{ccc} \lambda_2(g) & \delta_{12}(g) & \delta_{13}(g) \\ \delta_{21}(g) & \lambda_1(g) & \delta_{23}(g) \\ 0 & 0 & \lambda(g) \end{array}\right).$$

We shall show that  $det(\bar{g}) = 1$ , for each  $\bar{g} \in G/T(G)$ , implying by [Theorem 1.2] that  $S(V)^G$  is Gorenstein. Now  $g(y) = \alpha y + \gamma x + \beta v_0^p$  and  $g(x) = \delta x + \varepsilon y + \chi v_0^p$  (keeping the notation in **Lemma 3.13**). Since  $g(w_2) = \lambda_2(g)w_2 + \delta_{12}(g)w_1 + \delta_{13}(g)v_0$ , we have  $g(y) = g(w_2)^p - (\lambda(g)v_0)^{p-1}g(w_2) = (\lambda_2(g)w_2 + \delta_{12}(g)w_1 + \delta_{13}(g)v_0)^p - (\lambda(g)v_0)^{p-1}(\lambda_2(g)w_2 + \delta_{12}(g)w_1 + \delta_{13}(g)v_0) = (\lambda_2(g)^p w_2^p - \lambda(g)^{p-1}\lambda_2(g)v_0^{p-1}w_2) + (\delta_{12}(g)^p w_1^p - \lambda(g)^{p-1}\delta_{12}(g)v_0^{p-1}w_1) + (\delta_{13}(g)^p - \lambda(g)^{p-1}\delta_{13}(g))v_0^p.$ 

Consequently  $\alpha = \lambda_2(g)^p = \lambda(g)^{p-1}\lambda_2(g), \gamma = \delta_{12}(g)^p = \lambda(g)^{p-1}\delta_{12}(g)$ . Consequently, since  $\lambda_2(g), \delta_{12}(g) \in \mathbb{F}_p$ , it follows that  $\alpha = \lambda_2(g)$  and  $\gamma = \delta_{12}(g)$ .

Similarly using  $g(w_1) = \delta_{21}(g)w_2 + \lambda_1(g)w_1 + \delta_{23}(g)v_0$ , we have  $g(x) = g(w_1)^p - (\lambda(g)v_0)^{p-1}g(w_1) = (\delta_{21}(g)w_2 + \lambda_1(g)w_1 + \delta_{23}(g)v_0)^p - (\lambda(g)v_0)^{p-1}(\delta_{21}(g)w_2 + \lambda_1(g)w_1 + \delta_{23}(g)v_0) = (\delta_{21}(g)^p w_2^p - \lambda(g)^{p-1}\delta_{21}(g)v_0^{p-1}w_2) + (\lambda_1(g)^p w_1^p - \lambda(g)^{p-1}\lambda_1(g)v_0^{p-1}w_1) + (\delta_{23}(g)^p - \lambda(g)^{p-1}\delta_{23}(g))v_0^p.$ Therefore  $\varepsilon = \delta_{21}(g)^p, \delta = \lambda_1(g)^p$ , and since  $\lambda_1(g), \delta_{21}(g) \in \mathbb{F}_p$ , we have  $\varepsilon = \delta_{21}(g), \delta = \lambda_1(g)$ . Therefore  $det(\bar{g}) = (\alpha\delta - \varepsilon\gamma)\lambda(g) = (\lambda_2(g)\lambda_1(g) - \delta_{21}(g)\delta_{12}(g))\lambda(g) = det(g) = 1$  (since  $G \subset SL(3, \mathbb{F}_p)$ ).

As a consequence of **Theorem 6.3** and **Theorem 6.7** we have :

**Corollary 6.8.** Suppose  $W = V/\mathbb{F}_p v_0$  is an irreducible G-module. Then  $S(V)^G$  is Gorenstein.

# 7 Chapter(F): V is indecomposable and contains two G- submodules $\mathbb{F}_p v_0, W$ , where $\mathbb{F}_p v_0 \subset W \subset V$ , and $dim_{\mathbb{F}_p} W = 2$ .

In this chapter we conside V, a reducible indecomposable G-module, which has a unique 1-dimensional G- submodule  $Fv_0$ , and a unique 2-dimensional G- submodule W, and  $Fv_0 \subset W \subset V$ . We shall exclusively consider the case  $F = \mathbb{F}_p$ .

exclusively consider the case  $F = \mathbb{F}_p$ . Let  $\{w_2, w_1, v_0\}$  be a basis of  $V = \mathbb{F}_p^3$ , where  $W = \mathbb{F}_p w_1 + \mathbb{F}_p v_0$ . So every  $g \in G$  is represented with respect to this basis , by the matrix :

$$g = \begin{pmatrix} \lambda_2(g) & \delta_{12}(g) & \delta_{13}(g) \\ 0 & \lambda_1(g) & \delta_{23}(g) \\ 0 & 0 & \lambda(g) \end{pmatrix}.$$

By Lemma 2.2, T(G) acts trivially on  $\mathbb{F}_p v_0$ , and also on  $W/\mathbb{F}_p v_0$ , hence

$$T(G) \subseteq \left(\begin{array}{ccc} 1 & \mathbb{F}_p & \mathbb{F}_p \\ 0 & 1 & \mathbb{F}_p \\ 0 & 0 & 1 \end{array}\right).$$

So one of the following three cases holds:

- (i) |T(G)| = p,
- (ii)  $|T(G)| = p^2$ ,
- (iii)  $|T(G)| = p^3$ .

**Corollary 7.1.** If case (i) holds. Then  $S(V)^G$  is Gorenstein.

*Proof.* Since  $|T(G)| = p, T(G) := <\sigma > \text{ or } <\tau >$ , where

$$\sigma = \begin{pmatrix} 1 & 0 & a \\ 0 & 1 & b \\ 0 & 0 & 1 \end{pmatrix}, \tau = \begin{pmatrix} 1 & c & d \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, a, b, c, d \in \mathbb{F}_p.$$

Assume firstly that  $T(G) = \langle \sigma \rangle$ . We shall change the basis of V into  $\{w_2, aw_1 - bw_2, v_0\}$ . We have,  $\sigma(aw_1 - bw_2) = a(w_1 + bv_0) - b(w_2 + av_0) = aw_1 - bw_2$ . Suppose  $a \neq 0$ , so  $0 \neq w'_1 := (aw_1 - bw_2) \in S(V)^{T(G)}$ . Therefore  $\sigma$  is represented with respect to  $\{w_2, w'_1, v_0\}$  by the matrix:

$$\sigma = \left( \begin{array}{rrr} 1 & 0 & a \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{array} \right).$$

Consequently, by [3, Lemma 3.13]  $S(V)^{T(G)} = \mathbb{F}_p[x, w'_1, v_0]$  is a polynomial ring, and  $x = w_2^p - (av_0)^{p-1}w_2$ . Let  $m = (x, w'_1, v_0)$  be the graded maximal homogenous ideal of  $S(V)^{T(G)}$ .

Since  $T(G) \triangleleft G$ ,  $\mathbb{F}_p[x, w'_1, v_0]$  is g-stable and since g preserve degrees we get that  $g(\mathbb{F}_p w'_1 + \mathbb{F}_p v_0) \in (\mathbb{F}_p w'_1 + \mathbb{F}_p v_0)$  for every  $g \in G$ . This implies that  $(\mathbb{F}_p w'_1 + \mathbb{F}_p v_0)$  is G-module. Therefore G has a triangular presentation with respect to the new basis  $\{w_2, w'_1, v_0\}$ . Hence we still use the same  $\lambda_2(g), \delta_{12}(g), \delta_{13}(g), \lambda_1(g), \delta_{23}(g)$ , for the new presentation of g, with respect to the basis  $\{w_2, w'_1, v_0\}$ .

We have:

$$(7.a) \begin{cases} g(x) = \lambda_2(g)^p w_2^p + \delta_{12}(g)^p (w_1')^p + \delta_{13}(g)^p v_0^p - (a\lambda(g)v_0)^{p-1} (\lambda_2(g)w_2 + \delta_{12}(g)w_1' + \delta_{13}(g)v_0).\\ g(w_2) = \lambda_2(g)w_2 + \delta_{12}(g)w_1' + \delta_{13}(g)v_0.\\ g(w_1') = \lambda_1(g)w_1' + \delta_{23}(g)v_0.\\ g(v_0) = \lambda(g)v_0. \end{cases}$$

Now since  $gT(G)g^{-1} = T(G)$ ,  $\mathbb{F}_p[x, w'_1, v_0]$  is g-stable and since g preserve degrees we get:

$$(7.b) \begin{cases} g(x) = \alpha_1 (w_2^p - (av_0)^{p-1} w_2) + \alpha_2 (w_1')^p + \alpha_3 v_0^p + \text{mixed terms in} \{w_1', v_0\} \\ \alpha_1, \alpha_2, \alpha_3 \in \mathbb{F}_p. \end{cases}$$

Hence by comparing coefficient of  $w_2^p$  in g(x), we get that  $\alpha_1 = \lambda_2(g)^p$ . So g acts linearly on  $m/m^2$  and is represented by the matrix:

$$\begin{pmatrix} \lambda_2(g)^p & 0 & 0\\ 0 & \lambda_1(g) & \delta_{23}(g)\\ 0 & 0 & \lambda(g) \end{pmatrix} = \begin{pmatrix} \lambda_2(g) & 0 & 0\\ 0 & \lambda_1(g) & \delta_{23}(g)\\ 0 & 0 & \lambda(g) \end{pmatrix}.$$

Hence by [Theorem 1.2]  $S(V)^G$  is Gorenstein. If a = 0, then  $S(V)^{T(G)} = \mathbb{F}_p[w_2, x, v_0]$  where  $x = w_1^p - (bv_0)^{p-1}w_1$ . So we have:

$$(7.c) \begin{cases} g(x) = (\lambda_1(g)w_1 + \delta_{23}(g)v_0)^p - (bv_0)^{p-1}(\lambda_1(g)w_1 + \delta_{23}(g)v_0). \\ g(x) = \gamma_1 x + \gamma_2 w_2^p + \gamma_3 v_0^p + \text{mixed terms in}\{w_2, v_0\}. \quad \gamma_1, \gamma_2, \gamma_3 \in \mathbb{F}_p. \end{cases}$$

Hence by comparing coefficient of  $w_1^p$  in both expressions, we get that  $\gamma_1 = \lambda_1(g)^p = \lambda_1(g)$ . Hence by taking  $m = (w_2, x, v_0)$ , the matrix representing  $g|m/m^2$  with respect to  $\bar{w}_2, \bar{x}, \bar{v}_0$  is

$$\left(\begin{array}{ccc} \lambda_2(g) & \delta_{12}(g) & \delta_{13}(g) \\ 0 & \lambda_1(g)^p & 0 \\ 0 & 0 & \lambda(g) \end{array}\right),\,$$

so its determinant is  $\lambda_2(g) \cdot \lambda_1(g) \cdot \lambda(g) = 1$ , for each  $g \in G$ , and  $S(V)^G$  is Gorenstein.

Assume now that  $T(G) = \langle \tau \rangle$ . If c = 0, then we are exactly in the first case. So we may assume that  $c \neq 0$ . Consider  $w'_1 := cw_1 + dv_0$ , then  $\{w_2, w'_1, v_0\}$  is a basis of V, with  $\{w'_1, v_0\}$  a basis of W. Then the matrix of  $\tau$  with respect to this new basis is

$$\tau = \left( \begin{array}{rrr} 1 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{array} \right).$$

Hence  $S(V)^{<\tau>} = \mathbb{F}_p[z, w'_1, v_0]$ , where  $z = w_2^p - (w'_1)^{p-1}w_2$ .

By the same discussion as above, we have:

$$(7.d) \begin{cases} g(z) = \lambda_2(g)^p w_2^p + \delta_{12}(g)^p (w_1')^p + \delta_{13}(g)^p v_0^p + g(-(w_1')^{p-1})(\lambda_2(g)w_2 + \delta_{12}(g)w_1' + \delta_{13}(g)v_0). \\ g(z) = \beta_1 z + \beta_2(w_1')^p + \beta_3 v_0^p + \text{mixed terms in } \{w_1', v_0\}. \quad \beta_1, \beta_2, \beta_3 \in \mathbb{F}_p. \\ g(w_1') = \lambda_1(g)w_1' + \delta_{23}(g)v_0. \end{cases}$$

Hence by comparing coefficient of  $w_2^p$  in g(z), we get  $\beta_1 = \lambda_2(g)^p$ . Let  $m = (z, w'_1, v_0)$  be the graded maximal homogenous ideal of  $S(V)^{T(G)}$ . So g acts linearly on  $m/m^2$  and is represented by the matrix:

$$\left(\begin{array}{ccc} \lambda_2(g)^p & 0 & 0\\ 0 & \lambda_1(g) & \delta_{23}(g)\\ 0 & 0 & \lambda(g) \end{array}\right) = \left(\begin{array}{ccc} \lambda_2(g) & 0 & 0\\ 0 & \lambda_1(g) & \delta_{23}(g)\\ 0 & 0 & \lambda(g) \end{array}\right).$$

Hence by [Theorem 1.2]  $S(V)^G$  is Gorenstein.

**Corollary 7.2.** If case (ii) holds. Then  $S(V)^G$  is Gorenstein.

*Proof.* Since  $|T(G)| = p^2$ , it is elementary abelian, hence

$$T(G) = \begin{pmatrix} 1 & \mathbb{F}_p & \mathbb{F}_p \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \quad or \quad T(G) = \begin{pmatrix} 1 & 0 & \mathbb{F}_p \\ 0 & 1 & \mathbb{F}_p \\ 0 & 0 & 1 \end{pmatrix}.$$

Assume firstly that,

$$T(G) = \left(\begin{array}{rrr} 1 & \mathbb{F}_p & \mathbb{F}_p \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{array}\right).$$

Hence by **Proposition 4.3**,  $S(V)^{T(G)} = S(V)^{Fix_{T(G)}(W)} = S(W)[t]$  is a polynomial ring where  $t = w_2^{p^2} + q_1w_2^p + q_2w_2$ , and  $q_1, q_2 \in \mathbb{F}_p[w_1, v_0]$  is homogenous of degrees  $p^2 - p, p^2 - 1$  respectively. Let  $m = (t, w_1, v_0)$  be the graded maximal homogenous ideal of  $S(V)^{T(G)}$ . By a similar discussion to the one in (7.d) we get that g acts linearly on  $m/m^2$  and is represented by the matrix:

$$\begin{pmatrix} \lambda_2(g)^{p^2} & 0 & 0\\ 0 & \lambda_1(g) & \delta_{23}(g)\\ 0 & 0 & \lambda(g) \end{pmatrix} = \begin{pmatrix} \lambda_2(g) & 0 & 0\\ 0 & \lambda_1(g) & \delta_{23}(g)\\ 0 & 0 & \lambda(g) \end{pmatrix}.$$

Consequently, by [Theorem 1.2]  $S(V)^G$  is Gorenstein.

Assume now that

$$T(G) = \begin{pmatrix} 1 & 0 & \mathbb{F}_p \\ 0 & 1 & \mathbb{F}_p \\ 0 & 0 & 1 \end{pmatrix}.$$

Hence by the **Corollary 6.5**,  $S(V)^{T(G)} = \mathbb{F}_p[y, x, v_0]$  is a polynomial ring, where  $y = w_2^p - v_0^{p-1}w_2$ and  $x = w_1^p - v_0^{p-1}w_1$ . We have, using  $F = \mathbb{F}_p$  (so  $\lambda(g)^{p-1} = 1$ ):

$$(7.e) \begin{cases} g(y) = (\lambda_2(g)w_2^p + \delta_{12}(g)w_1^p + \delta_{13}(g)v_0^p) - v_0^{p-1}(\lambda_2(g)w_2 + \delta_{12}(g)w_1 + \delta_{13}(g)v_0) = \lambda_2(g)y + \delta_{12}(g)x_1 + \delta_{13}(g)v_0 = \lambda_2(g)y + \delta_{12}(g)y + \delta_{12}(g)y + \delta_{13}(g)y + \delta_{13}(g)$$

Let  $m = (y, x, v_0)$  be the graded maximal homogenous ideal of  $S(V)^{T(G)}$ . So g acts linearly on m (resp.  $m/m^2$ ) and is represented by the matrix:

$$\left(\begin{array}{ccc} \lambda_2(g) & \delta_{12}(g) & 0\\ 0 & \lambda_1(g) & 0\\ 0 & 0 & \lambda(g) \end{array}\right).$$

Consequently, by [Theorem 1.2]  $S(V)^G$  is Gorenstein.

**Corollary 7.3.** If case (iii) holds. Then  $S(V)^G$  is Gorenstein.

*Proof.* Since  $|T(G)| = p^3$ ,

$$T(G) = \begin{pmatrix} 1 & \mathbb{F}_p & \mathbb{F}_p \\ 0 & 1 & \mathbb{F}_p \\ 0 & 0 & 1 \end{pmatrix}.$$

Hence  $T(G) = U_3(\mathbb{F}_p)$ , the group of all upper triangular matrices with 1's along the diagonal and entries from the finite field  $\mathbb{F}_p$ . This group was shown to have a polynomial ring of invariants by Bertin [1].

We shall find explicitly the generators of  $S(V)^{T(G)}$ .  $T(G) = \langle \sigma_1, \sigma_2, \sigma_3 \rangle$ , where

$$\sigma_1 = \begin{pmatrix} 1 & 0 & 1 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \sigma_2 = \begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \sigma_3 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{pmatrix}.$$

Consequently, by [3, Lemma 3.13],  $S(V)^{\langle \sigma_1 \rangle} = \mathbb{F}_p[a, w_1, v_0]$ , is a polynomial ring where  $a = w_2^p - v_0^{p-1}w_2$ . Define  $u = a^p - b^{p-1}a$ , where  $b := w_1^p - v_0^{p-1}w_1$ . Observe that  $\sigma_3(b) = b, \sigma_3(a) = a, \sigma_2(b) = b, \sigma_2(a) = a + b$ , hence  $\sigma_2(u) = u$ . We have, for i = 1, 2, 3:

$$\begin{cases} \sigma_i(u) = u. \\ \sigma_i(b) = b. \\ \sigma_i(v_0) = v_0. \end{cases}$$

The T(G)-invariants  $\{u, b, v_0\}$  are algebraically independent over  $\mathbb{F}_p$ . Since  $deg(u) \cdot deg(b) \cdot deg(v_0) = p^2 \cdot p \cdot 1 = p^3 = |T(G)|$ , we have by [4, Theorem 3.9.4] that  $S(V)^{T(G)} = \mathbb{F}_p[u, b, v_0]$  is a polynomial ring. Let  $m = (u, b, v_0)$  be the graded maximal homogenous ideal of  $S(V)^{T(G)}$ . Since  $g(b) = \lambda_1(g)^p w_1^p + s = \alpha b + \beta v_0^p$ , where  $s \in m^2$ , and  $\alpha, \beta \in \mathbb{F}_p$ , we get that  $\alpha = \lambda_1(g)^p$ . Since  $g(u) = \lambda_2(g)^{p^2}u + r = \gamma u + \delta b^p + \pi v_0^{p^2} + \text{mixed terms in } \{b, v_0\}$ , where  $r \in m^2$ , and  $\gamma, \delta, \pi \in \mathbb{F}_p$ , we get that  $\gamma = \lambda_2(g)^{p^2}$ . Hence,

$$g|m/m^{2} = \begin{pmatrix} \lambda_{2}(g)^{p^{2}} & 0 & 0\\ 0 & \lambda_{1}(g)^{p} & 0\\ 0 & 0 & \lambda(g) \end{pmatrix} = \begin{pmatrix} \lambda_{2}(g) & 0 & 0\\ 0 & \lambda_{1}(g) & 0\\ 0 & 0 & \lambda(g) \end{pmatrix}.$$

Consequently, by [Theorem 1.2]  $S(V)^G$  is Gorenstein.

# 8 Chapter(G): V is indecomposable and contains (at least) two 1-dimensional G- submodules.

Let  $Fw_1, Fw_2$  be the two 1-dimensional G-submodules. Hence  $W = Fw_1 + Fw_2$  is G-submodule of V. Let  $v \in V \setminus W$ , so  $\{v, w_1, w_2\}$  is a basis of V. Each  $g \in G$  is represented with respect to this basis by the matrix :

$$g = \begin{pmatrix} \lambda(g) & \delta_{12}(g) & \delta_{13}(g) \\ 0 & \lambda_2(g) & 0 \\ 0 & 0 & \lambda_1(g) \end{pmatrix}.$$

In particular each transvection  $\sigma \in T(G)$  is represented by the matrix :

$$\sigma = \left(\begin{array}{ccc} \lambda(\sigma) & \delta_{12}(\sigma) & \delta_{13}(\sigma) \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{array}\right).$$

Hence T(G)|W = Id. Hence

$$T(G) \subseteq \left(\begin{array}{rrrr} 1 & F & F \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{array}\right).$$

Therefore by **Proposition 4.3**  $S(V)^{T(G)} = S(W)[z]$ , where  $z = v^{p^t} + q_1 v^{p^{t-1}} + ... + q_t v$ , an homogenous polynomial, where  $q_i \in S(W)^{T(G)|W} = S(W)$  and  $|T(G)| = p^t$ . Let  $m = (z, w_2, w_1)$ . Then  $m/m^2 = F\bar{z} + F\bar{w}_2 + F\bar{w}_1$ . Now for  $g \in G$  we have  $g(z) = \alpha z + x$  where x is in  $m^2$ . Therefore  $\bar{g}(\bar{z}) = \alpha \bar{z}$ , where  $\bar{g} = gT(G)$ . Also  $g(z) = g(v)^{p^t} + g(q_1)g(v)^{p^{t-1}} + ... + g(q_t)g(v) = \lambda(g)^{p^t}v^{p^t} + \text{mixed}$  terms. Hence  $\alpha = \lambda(g)^{p^t}$  and therefore  $\bar{g}$  is represented on  $F\bar{z} + F\bar{w}_2 + F\bar{w}_1$  by the matrix :

$$\left(\begin{array}{cc} \lambda(g)^{p^{t}} & 0 & 0\\ 0 & \lambda_{2}(g) & 0\\ 0 & 0 & \lambda_{1}(g) \end{array}\right)$$

Therefore by [Theorem 1.2]  $S(V)^G$  is Gorenstein iff  $\lambda(g)^{p^t} \cdot \lambda_2(g) \cdot \lambda_1(g) = 1$ , for each  $g \in G$ .

**Corollary 8.1.** Suppose  $V = \mathbb{F}_p^3$ , contains two 1- dimensional G-submodules and  $G \subseteq SL(3, \mathbb{F}_p)$ . Then  $S(V)^G$  is Gorenstein.

*Proof.*  $\lambda(g) \in \mathbb{F}_p$  hence  $\lambda(g)^{p^t} \cdot \lambda_2(g) \cdot \lambda_1(g) = \lambda(g) \cdot \lambda_2(g) \cdot \lambda_1(g) = det(g) = 1$ , where the last equality holds since  $g \in SL(3, \mathbb{F}_p)$ .
