ABSTRACT. We use symplectic self-dual additive codes over \mathbb{F}_4 obtained from metacirculant graphs to construct, for the first time, $[\![\ell, 0, d]\!]$ qubit codes with parameters $(\ell, d) \in \{(78, 20), (90, 21), (91, 22), (93, 21), (96, 21)\}$. Secondary constructions applied to the qubit codes result in many qubit codes that perform better than the previous best-known.

1. Introduction. We work on three closely connected objects, namely, a metacirculant graph G, a symplectic self-dual additive code C over \mathbb{F}_4 , and its corresponding quantum stabilizer code Q. The route is straightforward. Let I be the identity matrix of a suitable dimension and ω be a root of $x^2 + x + 1 \in \mathbb{F}_2[x]$. We search for a G whose adjacency matrix A(G) leads to C, which is generated by the row span of $A(G) + \omega I$. This code C, in turn, yields Q via the stabilizer method.

For lengths $\ell \in \{27, 36\}$ exhaustive searches are feasible, allowing us to construct some families of additive codes that contain some code C with an improved minimum distance when compared with the best that circulant graphs can lead to. For lengths $\ell \in \{78, 90, 91, 93, 96\}$ we run randomized non-exhausted searches to come up with the improved additive codes. We exhibit numerous instances when the resulting qubit codes Q have better parameters than the best-known comparable quantum codes.

The general construction of quantum stabilizer codes, wherein classical codes are used to describe the quantum error operators, is well-established. Our main reference for the qubit case is the seminal work of Calderbank, Rains, Shor, and Sloane in [4]. Two recent introductory expositions can be found in [9] and [7].

To get to metacirculant graphs, we recall *circulant graphs*, which have been more extensively studied. A recent survey on the subject can be found in [15]. The following definition of circulant graphs is given in [2].

²⁰²⁰ Mathematics Subject Classification. Primary: 94B25, 81P73; Secondary: 05C75.

Key words and phrases. additive codes, graph codes, metacirculant graph, quantum codes, self-dual codes.

Definition 1.1. Let \mathbb{Z}_n denote the ring of integers modulo *n* and let

$$\mathbb{Z}_n^* := \{ x \in \mathbb{Z}_n : 0 < x \le n/2 \}.$$

The circulant graph $\Gamma_n(S)$ is the graph with the vertex set \mathbb{Z}_n where any two vertices x and y are adjacent if and only if $|x - y|_n \in S$, with $S \subseteq \mathbb{Z}_n^*$ and

$$\begin{cases} |a|_n := |a| & \text{if } 0 \le a \le n/2, \\ |a|_n := n - a & \text{if } n/2 < a < n. \end{cases}$$

The adjacency matrix of a circulant graph is a circulant matrix. An $n \times n$ matrix A is called a *circulant matrix* if it has the form

$$A = \begin{pmatrix} a_1 & a_2 & \cdots & a_{n-1} & a_n \\ a_n & a_1 & \cdots & a_{n-2} & a_{n-1} \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ a_3 & a_4 & \cdots & a_1 & a_2 \\ a_2 & a_3 & \cdots & a_n & a_1 \end{pmatrix}.$$
 (1)

If the adjacency matrix A := A(G) of G is circulant, then $a_1 = 0$ and $a_i =$ a_{n+2-i} for $i \in \{2, \ldots, \lfloor n/2 \rfloor\}$. Circulant matrices are used as building blocks in the constructions of many different classes of codes. Examples include self-dual codes, cyclic codes, and quadratic residue codes.

Circulant graphs are vertex transitive [2]. They are the Cayley graphs of \mathbb{Z}_n . In 1982, Alspach and Parsons [1] constructed a family of vertex transitive graphs. Each graph in the family has a transitive permutation group as a subgroup of its automorphism group. They named the family *metacirculant graphs* as it contains the class of circulant graphs.

Li et al. in [13, Definition 1.1], following D. Marušič in [14], call a graph $\Gamma =$ (V, E) an (m, n)-metacirculant if |V| = mn and Γ has two automorphisms ρ and σ that satisfy some conditions. First, $\langle \rho \rangle$ is semiregular and has m orbits on V. Second, σ cyclically permutes the *m* orbits of $\langle \rho \rangle$ and normalizes $\langle \rho \rangle$. Third, σ^m fixes at least one vertex of Γ . In this work, we follow an equivalent combinatorial definition.

Definition 1.2. ([1]) Let m, n be two fixed positive integers and $\alpha \in \mathbb{Z}_n$ be a unit. Let $S_0, S_1, \ldots, S_{\lfloor m/2 \rfloor} \subseteq \mathbb{Z}_n$ satisfy the four properties

- 1. $S_0 = -S_0$.
- 2. $0 \notin S_0$.
- 3. $\alpha^{m}S_{k} = S_{k}$ for $1 \le k \le \lfloor m/2 \rfloor$. 4. If *m* is even then $\alpha^{m/2}S_{m/2} = -S_{m/2}$.

The meta-circulant graph $\Gamma := \Gamma(m, n, \alpha, S_0, S_1, \dots, S_{\lfloor m/2 \rfloor})$ has the vertex set $V(\Gamma) = \mathbb{Z}_m \times \mathbb{Z}_n$. Let V_0, V_1, \dots, V_{m-1} , where $V_i := \{(i, j) : 0 \le j \le n-1\}$ is a partition of $V(\Gamma)$. Let $1 \le k \le \lfloor m/2 \rfloor$. Vertices (i, j) and (i + k, h) are adjacent if and only if $(h-j) \in \alpha^i S_k$.

Henceforth, we assume m > 1, since a metacirculant graph with m = 1 is a circulant graph.

Example 1. The Petersen graph is $\Gamma(2, 5, 2, \{1, 4\}, \{0\})$. The vertices are partitioned into

 $V_0 := \{(0,0), (0,1), (0,2), (0,3), (0,4)\}$ and $V_1 := \{(1,0), (1,1), (1,2), (1,3), (1,4)\}, \{(1,0), (1,1), (1,2), (1,3), (1,4)\}, (1,1), (1,2), (1,3), (1,4)\}$

with adjacent vertices (0, j) and (1, j), for $0 \le j \le 4$. Figure 1 relabels the vertices lexicographically, that is, the upper layer contains the vertices in V_0 as $1, \ldots, 5$ while the lower layer presents the vertices in V_1 as $6, \ldots, 10$.

FIGURE 1. The Petersen Graph as $\Gamma(2, 5, 2, \{1, 4\}, \{0\})$.

The following fact is well-known.

Theorem 1.3. ([1]) Let $\phi(\cdot)$ denote the Euler totient function. If gcd(m,n) = 1 and $gcd(m,\phi(n)) = 1$, then the metacirculant $\Gamma(m,n,\alpha,S_0,S_1,\ldots,S_{\lfloor m/2 \rfloor})$ is isomorphic to a circulant graph.

The next lemma determines the valence.

Lemma 1.4. Any $G := \Gamma(m > 1, n, \alpha, S_0, S_1, \dots, S_{\lfloor m/2 \rfloor})$ is regular with valence

$$\begin{cases} |S_0| + |S_1| & \text{if } m = 2, \\ |S_0| + |S_{\lfloor m/2 \rfloor}| + 2\left(\sum_{r=1}^{\lfloor m/2 \rfloor - 1} |S_r|\right) & \text{if } m \ge 4 \text{ is even}, \\ |S_0| + 2\left(\sum_{r=1}^{\lfloor m/2 \rfloor} |S_r|\right) & \text{if } m \ge 3 \text{ is odd}. \end{cases}$$
(2)

Proof. Since the automorphism group of G acts transitively on its vertices, G is a regular graph. Hence, it suffices to determine the degree of vertex $(0,0) \in V_0$. The vertex is adjacent to a vertex $(0,h) \in V_0$ if and only if $h \in S_0$. This implies that (0,0) is adjacent to $|S_0|$ vertices in V_0 .

Next, (0,0) is adjacent to a vertex $(k,h) \in V_k$ if and only if $h \in S_k$. Hence, (0,0) is adjacent to $|S_k|$ vertices in V_k . The set S_k determines the edges between layers V_0 and V_k whose indices differ by k for $1 \leq k \leq \lfloor m/2 \rfloor$. When m is odd, the index 0 of V_0 differs by k from both the indices k and m - k of V_k and V_{m-k} for all $1 \leq k \leq \lfloor m/2 \rfloor$. When m is even, $V_{m/2} = -V_{m/2}$, which implies that the index 0 of V_0 differs by k from both the indices k and m - k of V_k and V_{m-k} for all $1 \leq k \leq \lfloor m/2 \rfloor - 1$. Thus, the degree of vertex (0,0) is as given in Equation 2.

Theorem 1.5. Let $S := \{S_0, S_1, \ldots, S_{\lfloor m/2 \rfloor}\}$. Let the graph $G := \Gamma(m, n, \alpha, S)$ be given. Let $\{V_i : i \in \{0, 1, \ldots, m-1\}\}$, with $V_i := \{(i, j) : 0 \le j < n\}$, be the partition of the vertex set into m layers, each containing n vertices. Then G is a multi-partite metacirculant graph with m partitions if and only if S_0 is the empty set.

Proof. By Definition 1.2, two vertices (i, j) and (i+k, h) are adjacent in $\Gamma(m, n, \alpha, S)$ if and only if $h - j \in \alpha^i S_k$. Both vertices are in the same layer V_i whenever k = 0.

Hence, the two vertices (i, j) and (i, h) in V_i are adjacent if and only if $h - j \in \alpha^i S_0$. The set S_0 being empty implies $h - j \notin \alpha^i S_0$. Thus, there is no edge between any pair of vertices within the same layer V_i .

2. Self-dual additive codes from metacirculant graphs. A code over $\mathbb{F}_4 := \{0, 1, \omega, \overline{\omega} = \omega^2 = 1 + \omega\}$ is said to be *additive* if it is \mathbb{F}_2 -linear, *i.e.*, the code is closed under addition but closure under multiplication by the elements in $\mathbb{F}_4 \setminus \mathbb{F}_2$ is not required. An \mathbb{F}_4 -linear code is additive. An element **c** of *C* is called a codeword of *C*. The *weight* of **c** is the number of nonzero entries that it has. The *minimum distance* of *C* is the least non-zero weight of all codewords in *C*. If *C* is an additive code of length ℓ over \mathbb{F}_4 , of size 2^k and minimum distance *d*, then we denote *C* by $(\ell, 2^k, d)_4$.

The trace Hermitian inner product of $\mathbf{x} = (x_1, \ldots, x_n)$ and $\mathbf{y} = (y_1, \ldots, y_n)$ in \mathbb{F}_4^n is given by

$$\mathbf{x} * \mathbf{y} = \sum_{j=1}^{n} \left(x_j y_j^2 + x_j^2 y_j \right).$$
(3)

Given an additive code C, its symplectic dual C^* is

 $C^* = \{ \mathbf{x} \in \mathbb{F}_4^n : \mathbf{x} * \mathbf{c} = 0 \text{ for all } \mathbf{c} \in C \}$

and C is said to be (symplectic) self-dual if $C = C^*$.

An additive \mathbb{F}_4 self-dual code is called *Type II* if all of its codewords have even weights. A code which is not Type II is called *Type I*. It is well-known that Type II codes must have even lengths.

Self-dual codes, under various inner products and possible alphabet sets, have been extensively studied due to their rich algebraic, combinatorial, and geometric structures. A major reference on this topic is the book [16] authored by Nebe, Rains, and Sloane. Of particular relevance to our family of additive self-dual codes here, labeled as family 4^{H+} in [16], is the treatment in Section 6 of Chapter 7 and in Chapter 11.

Let $A(\Gamma)$ be the adjacency matrix of the graph Γ and I be the identity matrix. The following nice result was first shown by Schlingemann in [18] and subsequently discussed in [5, Section 3]. Every graph represents a self-dual additive code over \mathbb{F}_4 and every self-dual additive code over \mathbb{F}_4 can be represented by a graph. In particular, the additive \mathbb{F}_4 -code $C := C(\Gamma)$ generated by the row span of the matrix $A(\Gamma) + \omega I$ is symplectic self-dual.

Danielsen and Parker gave a complete classification of *all* self-dual additive codes over \mathbb{F}_4 for $n \leq 12$ in [5]. Follow-up works, covering $n \leq 50$, were contributed by Gulliver and Kim in [11], by Varbanov in [19], by Grassl and Harada in [10], and by Saito in [17]. Their collective efforts focused on codes derived from graphs whose adjacency matrices are either *circulant* or *bordered circulant*.

The following result classifies Type I and Type II additive \mathbb{F}_4 self-dual codes generated by metacirculant graphs.

Theorem 2.1. Let C be an additive \mathbb{F}_4 self-dual code generated by

$$\Gamma(m, n, \alpha, S_0, S_1, \dots, S_{\lfloor m/2 \rfloor})$$
, with $2 \mid (mn)$.

Let

$$\Delta_S := \begin{cases} |S_0| & \text{if } m \text{ is odd,} \\ |S_0| + |S_{\lfloor m/2 \rfloor}| & \text{if } m \text{ is even.} \end{cases}$$
(4)

Then C is Type II if and only if Δ_S is odd.

Proof. Let mn be even. An additive self-dual \mathbb{F}_4 code $C = C(\Gamma)$ is Type II if and only if all vertices of Γ have odd degree [5]. Lemma 1.4 gives the valence of $\Gamma(m, n, \alpha, S_0, S_1, \ldots, S_{\lfloor m/2 \rfloor})$. By Equation 2, the valence is odd if and only if Δ_S is odd.

The three parameters of a qubit code $Q \subseteq \mathbb{C}^{2^{\ell}}$ are its *length* ℓ , *dimension* K over \mathbb{C} , and *minimum distance* d = d(Q). The notation

$$((\ell, K, d))$$
 or $\llbracket \ell, k, d \rrbracket$ with $k = \log_2 K$

signifies that Q encodes K logical qubits as ℓ physical qubits, with d being the smallest number of simultaneous quantum error operators that can send a valid codeword into another.

A symplectic self-dual additive code C over \mathbb{F}_4 of length ℓ and minimum distance d gives an $\llbracket \ell, 0, d \rrbracket_2$ qubit code Q. Since k = 0, that is the code Q consists of a single quantum state, one needs to carefully interpret the meaning of minimum distance. As explained in [4, Sect. III], an $\llbracket \ell, 0, d \rrbracket$ code Q has the property that, when subjected to a decoherence of $\lfloor (d-1)/2 \rfloor$ coordinates, it is possible to determine exactly which coordinates were decohered. This code can be used, for example, to test if certain storage locations for qubits are decohering faster than they should.

Such a code Q can be of interest in their own right. A famous example is the unique $[\![2,0,2]\!]$ code that corresponds to the maximally entangled quantum state known as the EPR pair in the famed paper [6] of Einstein, Podolsky, and Rosen. More commonly, a zero-dimensional code is used as a seed in some secondary constructions of quantum codes to produce qubit codes with k > 0.

Theorem 2.2. [4, Theorem 6] Assume that a qubit $((\ell, K, d > 1))_2$ code Q exists. Then the following qubit codes exist. An $((\ell, K', d))_2$ code for all $1 < K' \leq K$ by subcode construction. A $((\lambda, K, d))_2$ code for all K > 1 and $\lambda \geq \ell$ by lengthening. An $((\ell - 1, K, d - 1))_2$ code by puncturing.

There is also a quantum analogue of the *shortening* construction on classical code, although the former is less straightforward to perform. Interested reader can consult [9, Section 4.3] for the procedure.

Example 2. The $[12, 6, 6]_4$ dodecacode \mathcal{D} yields the unique [12, 0, 6] qubit code. It can be generated by the metacirculant graph $G_{12} := \Gamma(2, 6, 5, \{3\}, \{0, 3, 4, 5\})$. Figure 2 shows G_{12} with the vertices relabeled for convenience. The dodecacode is Type II, with weight distribution

wt	$\#\mathbf{c}$								
0	1	6	396	8	1,485	10	1,980	12	234 ·

Many known optimal or currently best-performing qubit codes of length ℓ with K = 1 in the literature, *i.e.*, $[\![\ell, 0, d]\!]_2$ with best-known or optimal d, are constructed based on circulant graphs [5, 10, 17]. We will soon show that strict improvements can be gained when one starts with metacirculant graphs. We use MAGMA [3] for all computations.

3. Higher best-known minimum distances of additive symplectic selfdual codes. This section presents additive symplectic self-dual codes of length $\ell \in \{27, 36\}$ with stricly higher minimum distances than any that can be derived from circulant graphs. The strict improvements, however, do not extend to the quantum setup. There are $[\![\ell, 0, d]\!]$ qubit codes, constructed from other approaches

FIGURE 2. $G_{12} := \Gamma(2, 6, 5, \{3\}, \{0, 3, 4, 5\})$ of the dodecacode \mathcal{D} . \Box

as recorded in the corresponding entries in [8], whose minimum distances are equal to the ones that we derive here.

For length $\ell = 27$, Varbanov in [19] concluded after an exhaustive search that the circulant graph construction only yields additive self-dual codes $(27, 2^{27}, \hat{d})_4$ of highest minimum distance $d = 8 \ge \hat{d}$. Using the metacirculant graph construction, we obtain additive self-dual codes with parameters $(27, 2^{27}, 9)_4$. They yield [[27, 0, 9]] qubit codes, which meet the best-known parameters in [8].

Proposition 1. There are two inequivalent families of $(27, 2^{27}, 9)_4$ additive selfdual codes, each consisting of 108 equivalent codes. They yield $[\![27, 0, 9]\!]$ qubit stabilizer codes.

Proof. An exhaustive search found 216 metacirculant graphs $\{\Gamma(3, 9, \alpha, S_0, S_1)\}$ in two non-isomorphic families, corresponding to two inequivalent codes. Tables 2 and 3 give the complete list of α, S_0, S_1 .

The families $\mathcal{F}_{27,1}$ and $\mathcal{F}_{27,2}$ are represented by the graphs

$$G_{27,1} := \Gamma(3, 9, 4, \{2, 7\}, \{0, 1, 2, 3, 4, 5, 8\}) \text{ and}$$

$$G_{27,2} := \Gamma(3, 9, 7, \{1, 3, 6, 8\}, \{0, 5, 8\}).$$
(5)

Figure 3 visualizes $G_{27,2}$ according to the vertex relabeling done in Table 1 to highlight its metacirculant structure. One can do similarly for the more complicated looking $G_{27,1}$. The even weights in both families of codes have the same number of codewords. The weight distributions are in Table 4.

A self-dual additive $(36, 2^{36}, 12)_4$ code from circulant graphs does not exist, since the best minimum distance is confirmed to be 11 in [10, 17]. The metacirculant graph construction increases the known minimum distance of length 36 additive self-dual codes to 12.

Proposition 2. There are 72 metacirculant graphs with (m,n) = (2,18), producing two inequivalent additive symplectic self-dual $(36,2^{36},12)_4$ Type II codes. We can separate the 72 graphs into two families, each containing 36 isomorphic graphs.

FIGURE 3. $G_{27,2} := \Gamma(3,9,4,[\{2,7\},\{0,1,2,3,4,5,8\}])$ from the family $\mathcal{F}_{27,2}$. Edges between \mathcal{L}_1 and \mathcal{L}_2 are in red, between \mathcal{L}_1 and \mathcal{L}_3 are in black, between \mathcal{L}_2 and \mathcal{L}_3 are in blue.

They yield $[\![36,0,12]\!]_2$ qubit codes. The respective families $\mathcal{F}_{36,1}$ and $\mathcal{F}_{36,2}$ are represented by the graphs

$$G_{36,1} := \Gamma(2, 18, 1, \{4, 6, 12, 14\}, \{3, 4, 6, 7, 9, 11, 12, 14, 15\}),$$

$$G_{36,2} := \Gamma(2, 18, 1, \{4, 6, 12, 14\}, \{1, 4, 7, 8, 9, 10, 11, 14, 17\}).$$
(6)

Proof. The weight distributions of the self-dual codes $C_{36,1}$ and $C_{36,2}$ derived, respectively, from $G_{36,1}$ and $G_{36,2}$ are in Table 5. The list of $\{\alpha, S_0, S_1\}$ for the metacirculant graphs $\Gamma(2, 18, \alpha, S_0, S_1)$ that splits into two families is given in Table 6. The two graphs $G_{36,1}$ and $G_{36,2}$ are presented in Table 7. They share common structures within each of the two layers and differ only on the edges connecting distinct layers.

PADMAPANI SENEVIRATNE AND MARTIANUS FREDERIC EZERMAN

TABLE 1. List of edges of $G_{27,1}$ and in $G_{27,2}$. Vertices 1 to 9 are in \mathcal{L}_1 . Vertices 10 to 18 are in \mathcal{L}_2 . Vertices 19 to 27 are in \mathcal{L}_3 . Edges $\{(i, j)\}$ are listed as $(i, \{j \in J\})$ with $i \in \mathcal{L}_r$ and $J \subset \mathcal{L}_s$

4. Improved qubit codes. Here we present improved qubit codes $[\![\ell, 0, d]\!]_2$ for lengths $\ell \in \{78, 90, 91, 93, 96\}$. Due to the large sizes of the relevant graphs, their presentation will be given in the appendix.

Applying secondary constructions yields more qubit codes with strictly better parameters that previously known. There are computational routines used by M. Grassl to perform the propagation rules on the improved codes submitted for inclusion to his online table [8]. We highlight the process only for $\ell = 78$, for brevity.

8

TABLE 2. List of α and S_0, S_1 for $\Gamma(3, 9, \alpha, S_0, S_1)$ corresponding to $\mathcal{F}_{27,1}$ in Proposition 1.

	Family $\mathcal{F}_{27,1}$

	$\{2, 4, 5, 7\}$	$\{\{0, 1, 4, 5, 6, 7\}, \{2, 3, 5, 6, 7, 8\}, \{0, 2, 3, 4, 5, 8\},\$				
	$\{1, 4, 5, 8\}$	$ \{1, 2, 3, 4, 6, 7\}, \{0, 1, 2, 5, 6, 8\}, \{0, 1, 3, 4, 7, 8\}\}. $ $ \{\{0, 1, 2, 3, 5, 8\}, \{0, 1, 4, 6, 7, 8\}, \{1, 3, 4, 5, 6, 7\}, $ $ \{0, 2, 5, 6, 7, 8\}, \{2, 3, 4, 5, 6, 8\}, \{0, 1, 2, 3, 4, 7\}\}. $				

Proposition 3. The metacirculant graph

 $G_{78} := \Gamma(6, 13, 12, \{1, 4, 6, 7, 9, 12\}, \{1, 2, 3, 5, 7, 8, 9, 11\},$

 $\{1, 2, 4, 5, 8, 10\}, \{1, 2, 3, 6, 7, 8, 12\})$ (7)

yields a new $(78, 2^{78}, 20)_4$ Type II additive self-dual code. The corresponding Q_{78} is a $[78, 0, 20]_2$ qubit code. Prior to our discovery, the best-known was $[78, 0, 19]_2$ and the first known occurence of d = 20 was at $\ell = 80$. Our improved qubit code has

Family $\mathcal{F}_{27,2}$

been listed as the current best-known since October 13, 2020 in Grassl's Table [8] based on a private communication.

Proof. A randomized search in MAGMA found G_{78} . The graph yields the self-dual additive code C_{78} of distance d = 20. By Theorem 2.1, $\Delta_S = |S_0| + |S_3| = 13$, which implies that C_{78} is Type II. The qubit code Q_{78} can then be certified to have the claimed parameters. For an easier inspection, since G_{78} is too complex to visualize, we list the edges in Table 10.

By propagation rules, strict improvements were also achieved by puncturing, shortening, lengthening, and taking a subcode of Q_{78} . Table 9 provides the details.

Proposition 4. The metacirculant graph

 $G_{90} := \Gamma(10, 9, 8, \{1, 8\}, \{0, 1, 2, 4, 5, 8\}, \{5, 6\},$ $\{2, 4, 5, 6, 8\}, \{0, 1, 2, 4, 7\}, \{0, 5, 7, 8\})$ (8)

generates a new $(90, 2^{90}, 21)_4$ additive self-dual code C_{90} . The resulting $[\![90, 0, 21]\!]$ qubit code Q_{90} has better minimum distance than the best-known $[\![90, 0, 20]\!]$ in $[\![8]$.

Proof. The graph G_{90} and the resulting codes C_{90} and Q_{90} as well as their parameters were found by MAGMA searches. The code C_{90} is Type I by Theorem 2.1, since $\Delta_S = |S_0| + |S_5| = 6$. For verification, G_{90} is described by its list of edges in Table 11.

Proposition 5. The multi-partite metacirculant graph

 $G_{91} := \Gamma(7, 13, 3, \{\}, \{4, 7, 8, 10, 11, 12\},$ $\{1, 3, 4, 7, 8, 9, 10, 11, 12\}, \{0, 4, 7, 8, 10, 11, 12\}) \quad (9)$

generates a new $(91, 2^{91}, 22)_4$ additive self-dual Type I code C_{91} . The corresponding $[\![91, 0, 22]\!]_2$ qubit code Q_{91} improves the minimum distance of the $[\![91, 0, 21]\!]$ code in $[\![8]$.

Proof. By Theorem 1.5, G_{91} is a multi-partite graph. The vertices are partitioned into 7 layers, each containing 13 vertices. We used MAGMA to verify that the minimum distance d of the generated $[91, 45.5, d]_4$ self-dual additive code C_{91} is indeed 22. This code is clearly Type I since its length is odd. The corresponding $[91, 0, 22]_2$

qubit code Q_{91} improves on the $[\![91, 0, 21]\!]$ code currently listed as best-known in [8]. The list of the neighbours of each vertex in G_{91} is in Table 12.

Proposition 6. The metacirculant graph

 $G_{93} := \Gamma(3, 31, 1, \{10, 12, 14, 15, 16, 17, 19, 21\},$ $\{2, 7, 8, 10, 11, 13, 15, 16, 17, 19\}) \quad (10)$

Graph ${\cal G}$	$d_{\min}(G)$	$\nu(G)$	$\gamma(G)$	$ {\rm Aut}(G) $
G_{12}	6	5	4	24
$G_{27,1}$	9	16	6	27
$G_{27,2}$	9	10	4	27
$G_{36,1}$	12	13	6	72
$G_{36,2}$	12	13	4	72
G_{78}	20	41	7	78
G_{90}	21	42	7	90
G_{91}	22	44	7	546
G_{93}	22	28	4	186
G_{96}	22	35	6	96

TABLE 8. Properties of the Graphs

generates a new $(93, 2^{93}, 22)_4$ additive self-dual code C_{93} . The code is Type I due to its odd length. The resulting $[\![93, 0, 21]\!]_2$ qubit code Q_{93} has an improved minimum distance compared with the prior best known $[\![93, 0, 20]\!]_2$ code in $[\![8]\!]$.

Proof. We used MAGMA to verify that the generated $(93, 2^{93}, d)_4$ additive self-dual code C_{93} has minimum distance d = 21. This Type I code corresponds to a $[93, 0, 21]_2$ qubit code Q_{93} . For verification, Table 13 lists the edges of G_{93} .

Proposition 7. The metacirculant graph

$$G_{96} := \Gamma(6, 16, 7, \{2, 4, 6, 7, 9, 10, 12, 14\}, \{1, 3, 4, 5, 7, 9, 10\}, \{3, 5, 11, 14\}, \{0, 2, 7, 10, 15\})$$
(11)

generates a new $(96, 2^{96}, 22)_4$ additive self-dual Type II code C_{96} . The resulting $[\![96, 0, 22]\!]_2$ qubit code Q_{96} improves the minimum distance of the prior best-known $[\![96, 0, 20]\!]_2$ quantum code in $[\![8]\!]$.

Proof. Table 14 lists the neighbours of each vertex of G_{96} , for verification. We confirmed that the minimum distance of C_{96} is 22 by using MAGMA. Since $\Delta_S = |S_0| + |S_3| = 13$, the code is Type II by Theorem 2.1.

5. Concluding Remarks. There are at least two challenging aspects in finding improved symplectic self-dual additive codes over \mathbb{F}_4 or strictly better qubit codes. First, the search space quickly widens as the length ℓ grows. Second, determining the minimum distances of the codes is computationally expensive.

We have shown that focusing on metacirculant graphs which are not isomorphic to the circulant ones is a fruitful approach.

Bringing this work to its end, Table 8 summarizes the properties of the graphs that we have used above. All of them have diameter 2 and girth 3. Included in the table, for each graph G, are the minimum distance $d_{\min}(G)$ of the generated additive code C := C(G), the valency $\nu(G)$, the size $\gamma(G)$ of the maximum clique, and the size $|\operatorname{Aut}(G)|$ of the automorphism group of G.

Appendix. The metacirculant graphs defined in Section 4 are described here in details for reconstruction and verification, should the need arise. For a cleaner presentation, we relabel the vertices as positive integers instead of as tuples (i, j) with $0 \le i < m$ and $0 \le j < n$. Given m and n, vertices in partition V_0 , now called

layer \mathcal{L}_1 , are labeled 1 to n. Vertices n + 1 to 2n are in partition V_1 , now called layer \mathcal{L}_2 . We repeat the assignment until all vertices are accounted for.

For G_{ℓ} with $\ell \in \{78, 93, 96\}$, the edges in G_{ℓ} are listed according to their layer(s) to highlight the partitioning of the vertices and how different layers are connected. The numbers of layers for $\ell \in \{90, 91\}$ are > 6. To keep the description for each graph within a page, we simply list their edges.

The 1 599 Edges of G_{78} in Proposition 3: Vertices are partitioned into 6 layers $\mathcal{L}_1, \ldots, \mathcal{L}_6$, with 13 vertices in each layer. Vertices $z, z+1, \ldots, z+12$ are in \mathcal{L}_{k+1} for $0 \le k \le 5$ and z = 13k+1.

PADMAPANI SENEVIRATNE AND MARTIANUS FREDERIC EZERMAN

TABLE 13. The 1302 edges of G_{93} in Proposition6. Vertices are partitioned into 3 layers of 31 vertices each. Vertices 1 to 31 are in \mathcal{L}_1 . Vertices 32 to 62 are in \mathcal{L}_2 . Vertices 63 to 93 are in \mathcal{L}_3 . Edges $\{(i, j)\}$ are listed as $(i, \{j \in J\})$ with $i \in \mathcal{L}_r$ and $J \subset \mathcal{L}_s$

TABLE 14. The 1680 edges of G_{96} in Proposition7. Vertices are partitioned into 6 layers $\mathcal{L}_1, \ldots, \mathcal{L}_{10}$, with 16 vertices in each layer. Vertices $z, z+1, \ldots, z+15$ are in \mathcal{L}_{k+1} for $0 \le k \le 5$ and z = 16k+1.
