BERRY-ESSÉEN BOUNDS AND ALMOST SURE CLT FOR THE QUADRATIC VARIATION OF A GENERAL GAUSSIAN PROCESS

YONG CHEN, ZHEN DING, AND YING LI

Abstract. In this paper, we consider the explicit bound for the second-order approximation of the quadratic variation of a general fractional Gaussian process $(G_t)_{t>0}$. The second order mixed partial derivative of the covariance function $R(t, s) = \mathbb{E}[G_t G_s]$ can be decomposed into two parts, one of which coincides with that of fractional Brownian motion and the other of which is bounded by $(ts)^{H-1}$ up to a constant factor. This condition is valid for a class of continuous Gaussian processes that fails to be self-similar or have stationary increments. Under this assumption, we obtain the optimal Berry-Esséen bounds when $H \in (0, \frac{2}{3}]$ and the upper Berry-Esséen bounds when $H \in (\frac{2}{3}, \frac{3}{4}]$. As a by-product, we also show the almost sure central limit theorem (ASCLT) for the quadratic variation when $H \in (0, \frac{3}{4}]$. The results extend that of [10] to the case of general Gaussian processes, improve the Berry-Esséen bounds and unify the proofs in [14], [1] and [7] for respectively the sub-fractional Brownian motion, the bi-fractional Brownian motion and the sub-bifractional Brownian motion.

Keywords: Malliavin calculus; Optimal Fourth Moment theorem; Berry-Esséen bounds; Gaussian process.

1. INTRODUCTION

We are interested in the explicit bound for the second-order approximation of the quadratic variation of a general fractional Gaussian process $G = \{G_t : t \geq 0\}$ on $[0, T]$, defined as

$$
Z_n := \sum_{k=0}^{n-1} \left[(G_{k+1} - G_k)^2 - \mathbb{E}[(G_{k+1} - G_k)^2] \right].
$$

Let the renormalization of Z_n be

$$
V_n := \frac{1}{\sigma_n} Z_n,\tag{1.1}
$$

where $\sigma_n > 0$ is so that $\mathbb{E}[V_n^2] = 1$, i.e., $\sigma_n^2 := \mathbb{E}[Z_n^2]$.

When G is the fractional Brownian motion B^H , by using Stein method and Malliavin calculus, Nourdin and Peccati [9, 10] derived explicit bounds for the total variation distance between the law of V_n and the standard normal law N. From then on, the same problem was extended to some other fractional Gaussian processes such as the sub-fractional Brownian motion, the bi-fractional Brownian motion and the sub-bifractional Brownian motion in [14], [1] and [7] respectively.

We find that the above four types of fractional Gaussian processes are all special examples of the following general Gaussian process G. Let

$$
R^{B}(s,t) = \frac{1}{2}(|s|^{2H} + |t|^{2H} - |t - s|^{2H}),
$$
\n(1.2)

be the covariance function of the fractional Brownian motion ${B^H(t), t > 0}$.

HYPOTHESIS 1.1. For $H \in (0, 1)$, the covariance function $R(t, s) = \mathbb{E}[G_tG_s]$ satisfies that

- (1) for any $s \geq 0$, $R(0, s) = 0$.
- (2) for any fixed $s \in (0,T)$, $R(t,s)$ is continuous on $[0,T]$ and differentiable function with respect to t on $(0, s) \cup (s, T)$, such that $\frac{\partial}{\partial t} R(t, s)$ is absolutely integrable.
- (3) for any fixed $t \in (0,T)$, the difference

$$
\frac{\partial R(t,s)}{\partial t} - \frac{\partial R^{B}(t,s)}{\partial t}
$$

is continuous on $[0, T]$, and it is differentiable with respect to s on $(0, T)$ such that $\Psi(t, s)$, the partial derivative with respect to s of the difference, satisfies

$$
|\Psi(t,s)| \le C_H' |ts|^{H-1},\tag{1.3}
$$

where the constants $H, C'_H \geq 0$ do not depend on T, and $R^B(t, s)$ is the covariance function of the fractional Brownian motion as in [\(1.2\)](#page-1-0).

Example 1.2. The subfractional Brownian motion $\{S^H(t), t \ge 0\}$ with parameter $H \in (0, 1)$ has the covariance function

$$
R(t,s) = s^{2H} + t^{2H} - \frac{1}{2} \left((s+t)^{2H} + |t-s|^{2H} \right),
$$

which satisfies Hypothesis [1.1.](#page-1-1)

Example 1.3. The bi-fractional Brownian motion ${B^{H,K}(t), t \ge 0}$ with parameters $H', K \in (0, 1)$ has the covariance function

$$
R(t,s) = \frac{1}{2} \left((s^{2H'} + t^{2H'})^K - |t - s|^{2H'K} \right),
$$

which satisfies Hypothesis [1.1](#page-1-1) when $H := H'K$.

Example 1.4. The generalized sub-fractional Brownian motion $S^{H',K}(t)$ with parameters $H' \in (0,1)$, $K \in [1,2)$ and $H'K \in (0,1)$ satisfies Hypothesis [1.1](#page-1-1) when $H := H'K$. The covariance function is

$$
R(t, s) = (s^{2H'} + t^{2H'})^K - \frac{1}{2} \left[(t+s)^{2H'K} + |t-s|^{2H'K} \right].
$$

Notation 1. Given two deterministic numeric sequences $(a_n)_{n\geq 0}, (b_n)_{n\geq 0}$, we use the following notations and definitions for respectively commensurability, equivalence:

$$
a_n \approx b_n \iff \exists c, C > 0 : cb_n \ge a_n \le Cb_n
$$
, for *n* large enough,
 $a_n \sim b_n \iff \exists c_n, C_n > 0 : \lim_{n \to \infty} c_n = \lim_{n \to \infty} C_n = 1$, $c_n b_n \le a_n \le C_n b_n$, for *n* large enough.

Now we list our main results as follows:

Theorem 1.5. Let $N \sim N(0, 1)$ and V_n be given as in [\(1.1\)](#page-0-0) and suppose Hypoth-esis [1.1](#page-1-1) holds. When $H \in (0, \frac{2}{3})$ $\frac{2}{3}$),

$$
d_{TV}(V_n, N) \asymp n^{-\frac{1}{2}};\tag{1.4}
$$

when $H=\frac{2}{3}$ $\frac{2}{3}$,

$$
d_{TV}(V_n, N) \simeq n^{-\frac{1}{2}} \log^2 n; \tag{1.5}
$$

when $H \in \left(\frac{2}{3}\right)$ $\frac{2}{3}$, $\frac{3}{4}$ $\frac{3}{4}$), there exists a positive contant c_H depending on H such that for any $n \geq 1$,

$$
d_{TV}(V_n, N) \le c_H \times n^{\frac{1}{2}(4H-3)};
$$
\n(1.6)

when $H=\frac{3}{4}$ $\frac{3}{4}$, there exsits a positive contant c such that for any $n \geq 1$,

$$
d_{TV}(V_n, N) \le \frac{c}{(\log n)^{\frac{3}{2}}};\tag{1.7}
$$

- Remark 1.6. (1) The above Berry-Esséen types bounds are more sharp than those obtained in [14], [1] and [7] for respectively the sub-fractional Brownian motion, the bi-fractional Brownian motion and the sub-bifractional Brownian motion.
	- (2) We do not know how to obtain the optimal bound in the case of $H \in (\frac{2}{3})$ $\frac{2}{3}$, $\frac{3}{4}$ $\frac{3}{4}$.

(3) In the same vein, we can also extend Theorem [1.5](#page-2-0) to the pth Hermite variation with $p > 2$.

As a by-product of Theorem [1.5,](#page-2-0) we have the ASCLT of the sequence $(V_n)_{n>1}$.

Theorem 1.7. If $H \in (0, \frac{3}{4})$ $\frac{3}{4}$ then the sequence $(V_n)_{n\geq 1}$ satisfies the ASCLT. In other words, for any bounded and continuous function $\varphi : \mathbb{R} \to \mathbb{R}$, we have almost surely,

$$
\frac{1}{\log n} \sum_{k=1}^{n} \frac{1}{k} \varphi(V_k) \xrightarrow{a.s.} \mathbb{E}\varphi(N)
$$
\n(1.8)

as $n\rightarrow\infty$, where $N \sim N(0, 1)$.

2. Preliminary

In this section, we describe some basic facts on stochastic calculus with respect to the Gaussian process, for more complete presentation on the subject can be found in $[6]$.

Denote $G = \{G_t, t \in [0, T]\}$ as a continuous centered Gaussian process with $G_0 = 0$ and the covariance function

$$
\mathbb{E}(G_t G_s) = R(s, t), \ s, t \in [0, T], \tag{2.1}
$$

defined on a complete probability space(Ω , F, P), where the F is generated by the Gaussian family G . Suppose in addition that the covariance function R is continuous. Let $\mathcal E$ denote the space of all real valued step functions on $[0, T]$. The Hilbert space $\mathfrak H$ is defined as the closure of $\mathcal E$ endowed with the inner product

$$
\langle \mathbb{1}_{[a,b)}, \mathbb{1}_{[c,d]} \rangle_{\mathfrak{H}} = \mathbb{E}((G_b - G_a)(G_d - G_c)),\tag{2.2}
$$

where $\mathbb{1}_{[a,b)}$ is the indicator function of the interval $[a,b)$. With abuse of notation, we also denote $G = \{G(h), h \in \mathfrak{H}\}\$ as the isonormal Gaussian process on the probability space, indexed by the elements in the Hilbert space \mathfrak{H} . Then G is a Gaussian family of random variables such that

$$
\mathbb{E}(G) = \mathbb{E}(G(h)) = 0, \ \mathbb{E}(G(g)G(h)) = \langle g, h \rangle_{\mathfrak{H}}, \quad \forall g, h \in \mathfrak{H}.
$$
 (2.3)

Notation 2. Let $R^B(t, s)$ be the covariance function of the fractional Brownian motion as in [\(1.2\)](#page-1-0). $\mathcal{V}_{[0,T]}$ denote the set of bounded variation functions on [0, T]. For functions $f, g \in \mathcal{V}_{[0,T]}$, we define two products as

$$
\langle f, g \rangle_{\mathfrak{H}_1} = -\int_{[0,T]^2} f(t) \frac{\partial R^B(t,s)}{\partial t} dt \nu_g(ds),
$$

$$
\langle f, g \rangle_{\mathfrak{H}_2} = C_H' \int_{[0,T]^2} |f(t)g(s)| (ts)^{H-1} dt ds.
$$
 (2.4)

The following proposition is an extension of [\[6,](#page-19-0) Theorem 2.3] and [5, Proposition 2.2, which gives the inner products representation of the Hilbert space \mathfrak{H} :

Proposition 2.1. $\mathcal{V}_{[0,T]}$ is dense in \mathfrak{H} and we have

$$
\langle f, g \rangle_{\mathfrak{H}} = \int_{[0,T]^2} R(t,s) \nu_f(\mathrm{d}t) \nu_g(\mathrm{d}s), \qquad \forall f, g \in \mathcal{V}_{[0,T]}, \tag{2.5}
$$

where ν_g is the restriction to $([0, T], \mathcal{B}([0, T]))$ of the Lebesgue-Stieljes signed measure associated with g^0 defined as

$$
g^{0}(x) = \begin{cases} g(x), & \text{if } x \in [0, T). \\ 0, & \text{otherwise.} \end{cases}
$$

Furthermore, if the covariance function $R(t, s)$ satisfies Hypothesis [1.1,](#page-1-1) then

$$
\langle f, g \rangle_{\mathfrak{H}} = -\int_{[0,T]^2} f(t) \frac{\partial R(t,s)}{\partial t} dt \nu_g(ds), \qquad \forall f, g \in \mathcal{V}_{[0,T]}.
$$
 (2.6)

In particular, we have

$$
|\langle f, g \rangle_{\mathfrak{H}} - \langle f, g \rangle_{\mathfrak{H}_1}| \le \langle f, g \rangle_{\mathfrak{H}_2}, \qquad \forall f, g \in \mathcal{V}_{[0,T]}.
$$
 (2.7)

Remark 2.2. When $H \in \left(\frac{1}{2}\right)$ $\frac{1}{2}$, 1), Hypothesis [1.1](#page-1-1) (3) and Lemma [3.1](#page-7-0) imply that the identity (2.6) can be rewritten as

$$
\langle f, g \rangle_{\mathfrak{H}} = \int_{[0,T]^2} f(t)g(s) \frac{\partial^2 R(t,s)}{\partial t \partial s} dt ds, \quad \forall f, g \in \mathcal{V}_{[0,T]}.
$$
 (2.8)

In this case, the inequality [\(2.7\)](#page-4-1) has obtained from [\(2.8\)](#page-4-2) in [4]. When $H \in (0, \frac{1}{2})$ $(\frac{1}{2}),$ it is well known that both $\frac{\partial^2}{\partial t \partial s} R(t, s)$ and $\frac{\partial^2}{\partial t \partial s} R^B(t, s)$ are not absolutely integrable. But the absolute integrability of their difference makes the key inequality [\(2.7\)](#page-4-1) still valid.

Proof. The first claim and the identity [\(2.5\)](#page-4-3) are rephrased from Theorem 2.3 of [\[6\]](#page-19-0). Hypothesis [1.1](#page-1-1) (2) and Lemma [3.1](#page-7-0) imply the inner products representation $(2.6).$ $(2.6).$

Finally, it follows from the identity [\(2.6\)](#page-4-0) and Notation [2](#page-3-0) that

$$
\langle f, g \rangle_{\mathfrak{H}_1} - \langle f, g \rangle_{\mathfrak{H}} = \int_{[0,T]^2} f(t) \left[\frac{\partial R(t,s)}{\partial t} - \frac{\partial R^B(t,s)}{\partial t} \right] dt \nu_g(ds).
$$

By the fundamental theorem of calculus (see Proposition 1.6.41 of [13]), Hypoth-esis [1.1](#page-1-1) (1) and (3) imply that when $s \neq t$,

$$
\frac{\partial R(t,s)}{\partial t} - \frac{\partial R^{B}(t,s)}{\partial t} = \int_{0}^{s} \Psi(t,r) dr.
$$
 (2.9)

Hence, Lemma [3.1](#page-7-0) implies that

$$
\langle f, g \rangle_{\mathfrak{H}} - \langle f, g \rangle_{\mathfrak{H}_1} = - \int_{[0,T]} f(t) dt \int_{[0,T]} \left[\frac{\partial R(t,s)}{\partial t} - \frac{\partial R^B(t,s)}{\partial t} \right] \nu_g(ds)
$$

$$
= \int_{[0,T]} f(t) dt \int_{[0,T]} g(s) \Psi(t,s) ds,
$$

which implies the inequality [\(2.7\)](#page-4-1) since $\Psi(t, s)$ satisfies the inequality [\(1.3\)](#page-1-2). \square

Denote $\mathfrak{H}^{\otimes p}$ and $\mathfrak{H}^{\odot p}$ as the pth tensor product and the pth symmetric tensor product of the Hilbert space \mathfrak{H} . Let \mathcal{H}_p be the pth Wiener chaos with respect to G. It is defined as the closed linear subspace of $L^2(\Omega)$ generated by the random variables $\{H_p(G(h)) : h \in \mathfrak{H}, \|h\|_{\mathfrak{H}} = 1\}$, where H_p is the pth Hermite polynomial defined by

$$
H_p(x) = (-1)^p e^{\frac{x^2}{2}} \frac{d^p}{dx^p} e^{-\frac{x^2}{2}}, \quad p \ge 1,
$$

and $H_0(x) = 1$. We have the identity $I_p(h^{\otimes p}) = H_p(G(h))$ for any $h \in \mathfrak{H}$ with $||h||_{\mathfrak{H}} = 1$ where $I_p(\cdot)$ is the pth multiple Wiener-Itô integral. Then the map I_p provides a linear isometry between $\mathfrak{H}^{\odot p}$ (equipped with the norm $\sqrt{p!} \| \cdot \|_{\mathfrak{H}^{\otimes p}}$) and \mathcal{H}_p . Here $\mathcal{H}_0 = \mathbb{R}$ and $I_0(x) = x$ by convention.

The following Theorem [2.3,](#page-5-0) known as the optimal fourth moment theorem, provides exact rates of convergence in total variation distance between a multiple Wiener-Itô integral and a normal distribution (see [12, 3]).

Theorem 2.3. Let $N \sim N(0, 1)$ be a standard Gaussian random variable. Let ${F_n : n \geq 1}$ be a sequence of random variables living in the pth multiple Wiener-Itô integral with unit variance. If $\lim_{n\to\infty} \mathbb{E}[F_n^4] = 3$, then there exist two finite constants $0 < c < C$ (possibly depending on p and on the sequence ${F_n}$, but not on n) such that the following estimate in total variation holds for every n:

$$
c\mathbf{M}(F_n) \le d_{TV}(F_n, N) \le C\mathbf{M}(F_n),
$$

where

$$
\mathbf{M}(F_n) := \max \left\{ \left| \mathbb{E}[F_n^3] \right|, \mathbb{E}[F_n^4 - 3] \right\}.
$$

The quantities $\kappa_3(F_n) := \mathbb{E}(F_n^3)$ and $\kappa_4(F_n) := \mathbb{E}[F_n^4] - 3$ are called the 3rd and 4th cumulants of F_n . That $\kappa_3(F_n)$ coincides with the third moment is because F_n is centered. Moreover, $\kappa_4(F_n)$ is strictly positive (see [11, 8]).

The following theorem is used to show the ASCLT.

Theorem 2.4 ([2]). Let $p \ge 2$ be an integer, and let $F_n = I_q(f_n)$, with $f_n \in \mathfrak{H}^{\odot p}$. Assume that for all n, and that $F_n \stackrel{law}{\rightarrow} \mathcal{N}(0,1)$ as $n \to \infty$. If the two following conditions are satisfied

$$
(1). \sum_{n=2}^{\infty} \frac{1}{n \log^2 n} \sum_{k=1}^n \frac{1}{k} \|f_k \otimes_r f_k\|_{\mathfrak{H}^{\otimes 2(q-r)}} < \infty, \text{ for every } 1 \le r \le p-1,
$$
\n
$$
(2). \sum_{n=2}^{\infty} \frac{1}{n \log^3 n} \sum_{k,l=1}^n \frac{|\langle f_k, f_l \rangle_{\mathfrak{H}^{\otimes p}}|}{kl} < \infty.
$$
\n
$$
(2.10)
$$

Then $\{F_n : n \geq 1\}$ satisfies an ASCLT.

Denote

$$
\rho(r) := \frac{1}{2} (|r+1|^{2H} + |r-1|^{2H} - 2|r|^{2H}), \quad r \in \mathbb{Z}.
$$

It is well-known that for any $r \neq 0$, $\rho(r)$ is positive when $H \in (\frac{1}{2})$ $(\frac{1}{2}, 1)$ and is negative when $H \in (0, \frac{1}{2})$ $\frac{1}{2}$). It behaves asymptotically as $|r| \to \infty$,

$$
\rho(r) \sim H(2H - 1) |r|^{2H - 2}.
$$

In particular, when $H > \frac{1}{2}$, for $|r|$ large enough,

$$
\rho(r) \ge H(H - \frac{1}{2})(1 + |r|)^{2H - 2}.
$$

The following proposition is cited from [9, p.74].

Proposition 2.5. If $H\in(0,\frac{3}{4})$ $rac{3}{4}$) then

$$
\lim_{n \to \infty} \frac{2}{n} \sum_{i,j=0}^{n-1} \rho^2(i-j) = 2 \sum_{r \in \mathbb{Z}} \rho^2(r) := \sigma^2; \tag{2.11}
$$

and if $H=\frac{3}{4}$ $rac{3}{4}$ then

$$
\lim_{n \to \infty} \frac{2}{n \log n} \sum_{i,j=0}^{n-1} \rho^2(i-j) = \frac{9}{16}.
$$

The following propositions are cited from Proposition 6.6 and Proposition 6.7 of [3] respectively. For the case of $H=\frac{3}{4}$ $\frac{3}{4}$, please refer to [8].

Proposition 2.6. We have

$$
\sum_{j,k,l=0}^{n-1} \rho(j-k)\rho(k-l)\rho(j-l) \asymp \begin{cases} n, & \text{if } H \in (0\frac{2}{3}),\\ n\log^2 n, & \text{if } H = \frac{2}{3},\\ n^{6H-3}, & \text{if } H \in (\frac{2}{3},\frac{3}{4}]. \end{cases}
$$

and

$$
\sum_{i,j,k,l=0}^{n-1} \rho(i-j)\rho(i-k)\rho(k-l)\rho(j-l) \asymp \begin{cases} n, & if H \in (0, \frac{5}{8}), \\ n(\log n)^3, & if H = \frac{5}{8}, \\ n^{8H-4}, & if H \in (\frac{5}{8}, \frac{3}{4}]. \end{cases}
$$

3. proof of Theorems [1.5](#page-2-0) and [1.7.](#page-3-1)

We will discuss exclusively the case $H \neq \frac{1}{2}$ $\frac{1}{2}$ since the case $H = \frac{1}{2}$ $\frac{1}{2}$ is easy. First, we need two technical lemmas. The first one is a variant of the classical integration by parts formula. It is well known that when $f, \phi : \mathbb{R} \to \mathbb{R}$ are monotone nondecreasing and continuous functions, then

$$
-\int_{[a,b]} f d\phi = \int_{[a,b]} \phi df + f(a)\phi(a) - f(b)\phi(b)
$$
\n(3.1)

for any compact interval [a, b] $\vert 13$, p.160]. If f are continuously differentiable on [a, b], we formally have the following expression (see (10) of [5]):

$$
d(f \cdot \mathbf{1}_{[a,b]}(\cdot)) = \Big[f'(t) \mathbf{1}_{[a,b]}(t) + f(t) \big(\delta_a(t) - \delta_b(t) \big) \Big] dt,
$$

This expression suggests that we can take the terms $f(a)\phi(a) - f(b)\phi(b)$ in the right hand side of (3.1) as parts of the measure ν_f for conveniences. This is what the following lemma to do.

Lemma 3.1. (Integration by parts formula) Let $[a, b]$ be a compact interval of positive length, let $\phi : [a, b] \to \mathbb{R}$ be continuous on $[a, b]$ and differentiable in (a, b) , such that ϕ' is absolutely integrable. For any $f \in \mathcal{V}_{[a,b]}$, we have

$$
-\int_{[a,b]} f(t)\phi'(t)dt = \int_{[a,b]} \phi(t)\nu_f(dt),
$$
\n(3.2)

where ν_f is given as in Proposition [2.1,](#page-4-4) i.e., ν_f is the restriction to $([a, b], \mathcal{B}([a, b]))$ of the Lebesgue-Stieljes signed measure associated with f^0 defined as

$$
f^{0}(x) = \begin{cases} f(x), & \text{if } x \in [a, b). \\ 0, & \text{otherwise.} \end{cases}
$$

Proof. The proof is similar to that of [5, Proposition 2.2]. We establish this in stages. We first deal with the case when f is a step functions on $[a, b)$ of the form

$$
f = \sum_{j=0}^{N-1} f_j \mathbf{1}_{[t_j, t_{j+1})},
$$

where $\{a = t_0 < t_1 < \cdots < t_N = b\}$ is a partition of $[a, b)$ and $f_j \in \mathbb{R}$. The corresponding signed measure is [\[6,](#page-19-0) p.1123]

$$
\nu_f = \sum_{j=1}^{N-1} (f_j - f_{j-1})\delta_{t_j} + f(a+) \delta_0 - f(b-) \delta_T.
$$

By the fundamental theorem of calculus again, the assumption of ϕ implies that

$$
\int_{[t_j, t_{j+1})} \phi'(t) dt = \phi(t_{j+1}) - \phi(t_j).
$$

Hence, the following formula of integration by parts hold:

$$
-\int_{[a,b]} f(t)\phi'(t)dt = \sum_{j=0}^{N-1} f_j [\phi(t_j) - \phi(t_{j+1})]
$$

=
$$
\sum_{j=1}^{N-1} (f_j - f_{j-1})\phi(t_j) + f_0\phi(t_0) - f_{N-1}\phi(t_N)
$$

=
$$
\int_{[a,b]} \phi(t)\nu_f(dt).
$$
 (3.3)

Now we assume that f is a right continuous monotone non-decreasing function on [a, b). For any sequence partitions $\pi_n = \{a = t_0^n < t_1^n < \cdots < t_{k_n}^n = b\}$ such that $\pi_n \subset \pi_{n+1}$ and $|\pi_n| \to 0$ as $n \to \infty$, consider

$$
f_n = \sum_{j=0}^{k_n-1} f(t_j^n) \mathbf{1}_{[t_j^n, t_{j+1}^n)},
$$

which is uniform bounded since f is bounded. It is clear that the sequence of signed measures ν_{f_n} converges weakly to ν_f [\[6\]](#page-19-0). Hence, we have

$$
\int_{[a,b]} \phi(t)\nu_f(\mathrm{d}t) = \lim_{n \to \infty} \int_{[a,b]} \phi(t)\nu_{f_n}(\mathrm{d}t)
$$
\n
$$
= -\lim_{n \to \infty} \int_{[a,b]} f_n(t)\phi'(t)\mathrm{d}t \qquad \text{(by (3.3))}
$$
\n
$$
= -\int_{[a,b]} f(t)\phi'(t)\mathrm{d}t,
$$

where the last line is from Lebesgue's dominated theorem since f_n is uniform bounded and ϕ' are absolutely integrable.

Finally, it is well known that every function of bounded variation is the difference of two bounded monotone non-decreasing function and that the value of f at its points of discontinuity are irrelevant for the purposes of determining the Lebesgue-Stieltjes measure ν_f [13]. Hence, [\(3.2\)](#page-7-2) is valid for any $f \in \mathcal{V}_{[a,b]}$. . — Первый профессиональный стандарт и профессиональный стандарт и профессиональный стандарт и профессиональны

Lemma 3.2. Let v_1, \dots, v_l be positive. There is a positive constant c depending on v_1, \dots, v_l such that when $r \in \mathbb{N} := \{1, 2, \dots\}$ is large enough,

$$
\sum_{r_i \in \mathbb{N}, \sum_{i=1}^l r_i < r} r_1^{v_1 - 1} r_2^{v_2 - 1} \cdots r_l^{v_l - 1} \le c \times r^{\sum_{i=1}^l v_i}.\tag{3.4}
$$

Remark 3.3. When v_1, \dots, v_l are negative, the following inequality is trivial: there is a positive constant c depending on v_1, \dots, v_l such that when $r \in \mathbb{N}$ is large enough,

$$
\sum_{r_i \in \mathbb{N}, \sum_{i=1}^l r_i < r} r_1^{v_1 - 1} r_2^{v_2 - 1} \cdots r_l^{v_l - 1} \le c < \infty. \tag{3.5}
$$

Proof. Let $v_0 > 0$. It is well-known that on the standard simplex in \mathbb{R}^l :

$$
T^l := \left\{ (x_1, \cdots, x_l) : \, x_i \geq 0, \, \sum_{i=1}^l x_i \leq 1 \right\},\,
$$

the following integral converges:

$$
\int_{T^l} x_1^{v_1-1} x_2^{v_2-1} \cdots x_l^{v_l-1} (1 - x_1 - \cdots - x_l)^{v_0-1} dx = \frac{\Pi_{i=0}^l \Gamma(v_i)}{\Gamma(\sum_{i=0}^l v_i)}
$$

where $\Gamma(\cdot)$ the Gamma function. The change of variables implies that there is a positive constant c depending on v_0, v_1, \dots, v_l such that when $r \in \mathbb{N}$ is large

enough,

$$
\sum_{r_i \in \mathbb{N}, \sum_{i=1}^l r_i < r} r_1^{v_1 - 1} r_2^{v_2 - 1} \cdots r_l^{v_l - 1} (r - r_1 - \cdots - r_l)^{v_0 - 1} \leq c \times r^{-1 + \sum_{i=0}^l v_i}.
$$

Especially, when $v_0 = 1$, the above inequality collapses to [\(3.4\)](#page-9-0).

Without any loss of generality, we suppose for simplicity that $C_H' = 1$ in this section. Denote

$$
\theta(i,j) := \mathbb{E}\Big[\big(G_{i+1} - G_i\big)\big(G_{j+1} - G_j\big)\Big],
$$

$$
\gamma(i,j) := \theta(i,j) - \rho(i-j).
$$
 (3.6)

Proposition 3.4. Under Hypothesis [1.1,](#page-1-1) there exists a positive constant c such that for any $n \geq 1$,

$$
\frac{1}{n} \sum_{i,j=0}^{n-1} \gamma(i,j)^2 \le c \times n^{(4H-3)\vee(-1)}.
$$
\n(3.7)

Hence, we have that as $n \to \infty$, when $H \in (0, \frac{3}{4})$ $\frac{3}{4}$,

$$
\frac{1}{n}\sum_{i,j=0}^{n-1}\gamma(i,j)^2 \to 0;
$$

and when $H=\frac{3}{4}$ $\frac{3}{4}$,

$$
\frac{1}{n \log n} \sum_{i,j=0}^{n-1} \gamma(i,j)^2 \to 0.
$$

Proof. It is clear that we need only show the inequality [\(3.7\)](#page-10-0) holds. It follows [\(2.2\)](#page-3-2), the definition of the inner product, that

$$
\theta(i,j) = \mathbb{E}\Big[\big(G_{i+1} - G_i \big) \big(G_{j+1} - G_j \big) \Big] = \langle \mathbb{1}_{[i,i+1)}, \mathbb{1}_{[j,j+1)} \rangle_{\mathfrak{H}},
$$

and

$$
\rho(i-j) = \mathbb{E}\Big[\Big(B_{i+1}^H - B_i^H\Big)\Big(B_{j+1}^H - B_j^H\Big)\Big] = \langle \mathbb{1}_{[i,i+1)}, \mathbb{1}_{[j,j+1)} \rangle_{\mathfrak{H}_1},
$$

where B^H is the fractional Brownian motion with Hurst index H. The inequality [\(2.7\)](#page-4-1) implies that

$$
|\gamma(i,j)| = |\theta(i,j) - \rho(i-j)| \le \int_{[0,T]^2} \mathbb{1}_{[i,i+1)}(r_1) \mathbb{1}_{[j,j+1)}(r_2) (r_1 r_2)^{H-1} dr_1 dr_2
$$

$$
= \frac{1}{H^2} [(i+1)^H - i^H] [(j+1)^H - j^H]. \tag{3.8}
$$

Hence, as $n \to \infty$,

$$
\frac{1}{n} \sum_{i,j=0}^{n-1} \gamma(i,j)^2 \le \frac{1}{nH^4} \sum_{i,j=0}^{n-1} \left[(i+1)^H - i^H \right]^2 \left[(j+1)^H - j^H \right]^2
$$

$$
= \frac{1}{n} \left(\frac{1}{H^2} \sum_{i=0}^{n-1} \left[(i+1)^H - i^H \right]^2 \right)^2.
$$
(3.9)

It is clear that the function $f(u) = (1+u)^H$ in $u \in [0, \infty)$ is concave, i.e., $f''(u) \leq 0$, which implies that for any $u \geq 0$, $(1+u)^H \leq 1 + Hu$. Hence, for any $i \geq 1$,

$$
(i+1)^{H} - i^{H} = i^{H} \left[(1 + \frac{1}{i})^{H} - 1 \right] \leq H \times i^{H-1}.
$$
 (3.10)

We have that there exists a positive constant c independent on n such that

$$
\frac{1}{H^2} \sum_{i=0}^{n-1} \left[(i+1)^H - i^H \right]^2 \le \frac{1}{H^2} + \sum_{i=1}^{n-1} i^{2(H-1)} \le c \times n^{(2H-1)\vee 0},\tag{3.11}
$$

please refer to Lemma 6.3 of [9].

By plugging the above inequality into [\(3.9\)](#page-11-0), we obtain the desired inequality (3.7) .

Proposition 3.5. Recall that $\sigma_n^2 := \mathbb{E}[Z_n^2]$ and σ^2 is given as in [\(2.11\)](#page-6-0). Under Hypothesis [1.1,](#page-1-1) we have (i) when $H \in (0, \frac{3}{4})$ $\frac{3}{4}$, as $n \to \infty$,

$$
\frac{\sigma_n^2}{n} \to \sigma^2. \tag{3.12}
$$

(*ii*) when $H = \frac{3}{4}$ $\frac{3}{4}$, as $n \to \infty$,

$$
\frac{\sigma_n^2}{n \log n} \to \frac{9}{16}.\tag{3.13}
$$

Proof. By the definition of multiple Wiener-Itô integrals, we rewrite Z_n as follows:

$$
Z_n = I_2(g_n),\tag{3.14}
$$

where

$$
g_n = \sum_{i=0}^{n-1} \mathbb{1}_{[i,i+1)}^{\otimes 2}.
$$
 (3.15)

By Itô's isometry, we have

$$
\sigma_n^2 = \mathbb{E}[Z_n^2] = 2 \|g_n\|_{\mathfrak{H}}^2 = 2 \sum_{i,j=0}^{n-1} \langle \mathbb{1}_{[i,i+1)}, \mathbb{1}_{[j,j+1)} \rangle_{\mathfrak{H}}^2 = 2 \sum_{i,j=0}^{n-1} \theta(i,j)^2.
$$
 (3.16)

B-E BOUNDS AND ASCLT FOR QUADRATIC VARIATION OF GAUSSIAN PROCESSES 13

It is clear that the identity [\(3.6\)](#page-10-1) implies that

$$
\frac{1}{n}\sum_{i,j=0}^{n-1}\theta(i,j)^2 = \frac{1}{n}\sum_{i,j=0}^{n-1}\rho^2(i-j) + \frac{1}{n}\sum_{i,j=0}^{n-1}\gamma^2(i,j) + \frac{2}{n}\sum_{i,j=0}^{n-1}\rho(i-j)\gamma(i,j). \quad (3.17)
$$

The Cauchy-Schwarz inequality implies that the third term satisfies that as $n \rightarrow$ ∞,

$$
\left|\frac{2}{n}\sum_{i,j=0}^{n-1}\rho(i-j)\gamma(i,j)\right|\leq 2\Big(\frac{1}{n}\sum_{i,j=0}^{n-1}\rho^2(i-j)\times\frac{1}{n}\sum_{i,j=0}^{n-1}\gamma(i,j)^2\Big)^{\frac{1}{2}}\to 0,
$$

where in the last line we have used Propositions [2.5](#page-6-1) and [3.4.](#page-10-2) By plugging this limit into the identity [\(3.17\)](#page-12-0) and using Propositions [2.5](#page-6-1) and [3.4](#page-10-2) again, we obtain the desired limit [\(3.12\)](#page-11-1).

In the similar vein, the desired limit (3.13) holds.

Proposition 3.6. Let $\theta(i, j)$, $\gamma(i, j)$, $\rho(r)$ be given as in [\(3.6\)](#page-10-1). When $H \in (0, 1)$, there exists a positive constant c such that for all $n \geq 1$

$$
\left| \sum_{j,k,l=0}^{n-1} \gamma(j,k)\gamma(k,l)\gamma(j,l) \right| \le c \times n^{(6H-3)\vee 0},
$$

$$
\left| \sum_{j,k,l=0}^{n-1} \gamma(j,k)\gamma(k,l)\rho(j-l) \right| \le c \times n^{(6H-3)\vee 0},
$$
 (3.18)

$$
\left| \sum_{j,k,l=0}^{n-1} \gamma(j,k)\rho(k-l)\rho(j-l) \right| \le c \times n^{(6H-3)\vee 0}.
$$
 (3.19)

Proof. It follows from the inequalites [\(3.8\)](#page-10-3) and [\(3.11\)](#page-11-3) that

$$
\left| \sum_{j,k,l=0}^{n-1} \gamma(j,k)\gamma(k,l)\gamma(j,l) \right| \leq \sum_{j,k,l=0}^{n-1} |\gamma(j,k)\gamma(k,l)\gamma(j,l)|
$$

$$
\leq \left(\frac{1}{H^2} \sum_{j=0}^{n-1} \left[(j+1)^H - j^H \right]^2 \right)^3
$$

$$
\leq c \times n^{(6H-3)\vee 0}.
$$

Similarly, we have

$$
\left| \sum_{j,k,l=0}^{n-1} \gamma(j,k)\gamma(k,l)\rho(j-l) \right|
$$

$$
\leq \sum_{j,k,l=0}^{n-1} |\gamma(j,k)\gamma(k,l)\rho(j-l)|
$$

\n
$$
\leq cn^{(2H-1)\vee 0} \sum_{j,l=0}^{n-1} [(j+1)^{H} - j^{H}] [(l+1)^{H} - l^{H}] |\rho(j-l)|.
$$
 (3.20)

In the above summation, when $j = l$, it is clear that

$$
\sum_{j=l} \left[(j+1)^{H} - j^{H} \right] \left[(l+1)^{H} - l^{H} \right] |\rho(j-l)| = \sum_{j=0}^{n-1} \left[(j+1)^{H} - j^{H} \right]^{2} \le cn^{(2H-1)\vee 0}.
$$

When $j = 0 < l$, we have

$$
\sum_{j=0

$$
\leq c \times \sum_{l=1}^{n-1} l^{H-1} l^{2H-2}
$$

$$
\leq c \times n^{(3H-2)\vee 0},
$$
$$

where in the last line we use Lemma 6.3 of [9]. The symmetry, the inequality (3.10) , the monotonicity of the power function $f(x) = x^{\nu}$ with $x > 0$, $\nu < 0$, and the change of variable $k = l - j$ imply that the other terms are less than:

$$
2 \times \sum_{0 < j < l \le n-1} \left[(j+1)^H - j^H \right] \left[(l+1)^H - l^H \right] |\rho(j-l)|
$$
\n
$$
\le c \times \sum_{0 < j < l \le n-1} j^{H-1} l^{H-1} (l-j)^{2H-2}
$$
\n
$$
\le c \times \sum_{j,k \in \mathbb{N}, j+k < n} j^{2H-2} k^{2H-2} \le c \times n^{(4H-2)\vee 0}.
$$

where the last line is from Lemma [3.2.](#page-9-1) Plugging the above three estimates into [\(3.20\)](#page-13-0), we obtain the inequality [\(3.18\)](#page-12-1).

Finally, we have

$$
\left| \sum_{j,k,l=0}^{n-1} \gamma(j,k)\rho(k-l)\rho(j-l) \right|
$$

$$
\leq \sum_{j,k,l=0}^{n-1} |\gamma(j,k)\rho(k-l)\rho(j-l)|
$$

B-E BOUNDS AND ASCLT FOR QUADRATIC VARIATION OF GAUSSIAN PROCESSES 15

$$
\leq \frac{1}{H^2} \sum_{j,k,l=0}^{n-1} \left[(j+1)^H - j^H \right] \left[(k+1)^H - k^H \right] |\rho(k-l)\rho(j-l)|. \tag{3.21}
$$

In the similar vein, we have that in the summation the contribution of all the terms such that $j = k$ or $k = l$ or $j = l$ or $j = 0$ or $k = 0$ or $l = 0$ are negligible to compare with $n^{(6H-3)\vee 0}$. The symmetry implies that other terms are less than:

$$
2 \times \sum_{0 < j < k < n, l \neq j, k} |\gamma(j, k)\rho(k - l)\rho(j - l)|
$$
\n
$$
\leq c \times \sum_{0 < j < k < n, l \neq j, k} j^{H-1} k^{H-1} |k - l|^{2H-2} |j - l|^{2H-2}.
$$

According to the distinct orders of j, k, l, we do the change of variables $a =$ j, $k - j = b, l - k = c$ when $0 < j < k < l$, or $a = j, l - j = b, k - l = c$ when $0 < j < l < k$, or $a = l$, $j - l = b$, $k - j = c$ when $0 < l < j < k$, and then by the monotonicity of the power function again, we have

$$
\sum_{0 < j < k < n, l \neq j, k} j^{H-1} k^{H-1} |k - l|^{2H-2} |j - l|^{2H-2}
$$
\n
$$
\leq 3 \times \sum_{a, b, c \in \mathbb{N}, a+b+c < n} a^{2H-2} b^{2H-2} c^{2H-2}
$$
\n
$$
\leq c \times n^{(6H-3)\vee 0},
$$

where the last line is from Lemma [3.2.](#page-9-1) Taking the above three inequalities together, we obtain the desired (3.19) .

In the same way, we can show the following proposition.

Proposition 3.7. Let $\theta(i, j)$, $\gamma(i, j)$, $\rho(r)$ be given as in [\(3.6\)](#page-10-1). When $H \in (0, 1)$, there exists a positive constant c such that for all $n \geq 1$

$$
\left| \sum_{i,j,k,l=0}^{n-1} \gamma(i,j)\gamma(i,k)\gamma(k,l)\gamma(j,l) \right| \le c \times n^{(8H-4)\vee 0},
$$

$$
\left| \sum_{i,j,k,l=0}^{n-1} \gamma(i,j)\gamma(i,k)\gamma(k,l)\rho(j-l) \right| \le c \times n^{(8H-4)\vee 0},
$$
 (3.22)

$$
\left| \sum_{i,j,k,l=0}^{n-1} \gamma(i,j)\gamma(i,k)\rho(k-l)\rho(j-l) \right| \le c \times n^{(8H-4)\vee 0},\tag{3.23}
$$

$$
\left| \sum_{i,j,k,l=0}^{n-1} \gamma(i,j)\rho(i-k)\rho(k-l)\rho(j-l) \right| \le c \times n^{(8H-4)\vee 0}.\tag{3.24}
$$

Proof. Similarly, we have

$$
\left| \sum_{i,j,k,l=0}^{n-1} \gamma(i,j) \gamma(i,k) \gamma(k,l) \gamma(j,l) \right| \leq \sum_{i,j,k,l=0}^{n-1} |\gamma(j,k) \gamma(i,k) \gamma(k,l) \gamma(j,l)|
$$

$$
\leq \left(\frac{1}{H^2} \sum_{j=0}^{n-1} \left[(j+1)^H - j^H \right]^2 \right)^4
$$

$$
\leq c \times n^{(8H-4)\vee 0},
$$

and

$$
\left| \sum_{i,j,k,l=0}^{n-1} \gamma(i,j)\gamma(i,k)\gamma(k,l)\rho(j-l) \right|
$$

\n
$$
\leq \sum_{i,j,k,l=0}^{n-1} |\gamma(i,j)\gamma(i,k)\gamma(k,l)\rho(j-l)|
$$

\n
$$
\leq c \times n^{(4H-2)\vee 0} \sum_{j,l=0}^{n-1} [(j+1)^H - j^H] [(l+1)^H - l^H] |\rho(j-l)|.
$$

\n
$$
\leq c \times n^{(8H-4)\vee 0},
$$

where in the last line we have used the proof of the inequality (3.18) , please refer to [\(3.20\)](#page-13-0). Next, we have

$$
\left| \sum_{i,j,k,l=0}^{n-1} \gamma(i,j)\gamma(i,k)\rho(k-l)\rho(j-l) \right|
$$

\n
$$
\leq \sum_{i,j,k,l=0}^{n-1} |\gamma(i,j)\gamma(i,k)\rho(k-l)\rho(j-l)|
$$

\n
$$
\leq c \times n^{(2H-1)\vee 0} \sum_{j,k,l=0}^{n-1} [(j+1)^H - j^H] [(l+1)^H - l^H] |\rho(k-l)\rho(j-l)|
$$

\n
$$
\leq c \times n^{(8H-4)\vee 0}
$$

where in the last line we have used the proof of the inequality (3.19) , please refer to [\(3.21\)](#page-14-0).

Finally, we have

$$
\left| \sum_{i,j,k,l=0}^{n-1} \gamma(i,j)\rho(i-k)\rho(k-l)\rho(j-l) \right|
$$

\n
$$
\leq \sum_{i,j,k,l=0}^{n-1} |\gamma(i,j)\rho(i-k)\rho(k-l)\rho(j-l)|
$$

\n
$$
\leq \frac{1}{H^2} \sum_{i,j,k,l=0}^{n-1} [(i+1)^H - i^H] [(j+1)^H - j^H] |\rho(i-k)\rho(k-l)\rho(j-l)|.
$$

It is easy to show that when any two index of i, j, k, l are equal or any index vanishes, the contribution to the sum are negligible to compare with $n^{(8H-4)\vee 0}$. The symmetry implies that other terms is less than

$$
4 \times \sum_{0 < i < j < n, 0 < k < l < n, i, j \neq k, l} i^{H-1} j^{H-1} |i - k|^{2H-2} |k - l|^{2H-2} |j - l|^{2H-2}.
$$

According to the distinct orders of i, j, k, l, we do the change of variables $a =$ i, $j - i = b, k - j = c, l - k = d$ when $0 < i < j < k < l$, or $a = i, k - i = b, j - k =$ $c, l - j = d$ when $0 < i < k < j < l$, or $a = j$, $k - i = b$, $l - k = c$, $j - l = d$ when $0 < i < k < j < l$, or $a = k$, $i - k = b$, $j - i = c$, $l - j = d$ when $0 < k < i < j < l$, or or $a = k$, $i - k = b$, $l - i = c$, $j - l = d$ when $0 < k < i < j < l$, or $a = k, l - k = b, i - l = c, j - i = d$ when $0 < k < i < j < l$, and then by the monotonicity of the power function again, we have

$$
\sum_{0 < i < j < n, 0 < k < l < n, i, j \neq k, l} j^{H-1} k^{H-1} |k - l|^{2H-2} |j - l|^{2H-2}
$$
\n
$$
\leq 6 \sum_{a, b, c, d \in \mathbb{N}, a+b+c+d < n} a^{2H-2} b^{2H-2} c^{2H-2} d^{2H-2}
$$
\n
$$
\leq c \times n^{(8H-4)\vee 0},
$$

where the last line is from Lemma [3.2.](#page-9-1) \square

Proof of Theorem [1.5.](#page-2-0) We will discuss exclusively the case $H \in (0, \frac{3}{4})$ $\frac{3}{4}$) since the case $H = \frac{3}{4}$ $\frac{3}{4}$ is similar. Recall [\(3.14\)](#page-11-5) and [\(3.15\)](#page-11-6), the expressions of Z_n and g_n . Denote

$$
F_n := \frac{Z_n}{\sqrt{n}} = \frac{I_2(g_n)}{\sqrt{n}}.
$$

First, the identities (6.2-6.3) of [3] imply that

$$
\kappa_3(F_n) = \mathbb{E}[F_n^3] = \frac{8}{n^{\frac{3}{2}}} \sum_{j,k,l=0}^{n-1} \theta(j,k)\theta(k,l)\theta(j,l)
$$
\n(3.25)

$$
\kappa_4(F_n) = \mathbb{E}[F_n^4] - 3\mathbb{E}[F_n^2]^2 = \frac{48}{n^2} \|g_n \otimes_1 g_n\|_{\mathfrak{H}^{\otimes 2}}^2 = \frac{48}{n^2} \sum_{j,k,l=0}^{n-1} \theta(i,j)\theta(j,k)\theta(k,l)\theta(j,l)
$$
\n(3.26)

The symmetry and [\(3.6\)](#page-10-1) imply that

$$
\sum_{j,k,l=0}^{n-1} \theta(j,k)\theta(k,l)\theta(j,l) = \sum_{j,k,l=0}^{n-1} \rho(j-k)\rho(k-l)\rho(j-l) + \sum_{j,k,l=0}^{n-1} \gamma(j,k)\gamma(k,l)\gamma(j,l) + 3\sum_{j,k,l=0}^{n-1} \gamma(j,k)\gamma(k,l)\rho(j-l) + 3\sum_{j,k,l=0}^{n-1} \gamma(j,k)\rho(k-l)\rho(j-l)
$$

Rearranging, and using Proposition [3.6](#page-12-3) we have that there exists a positive constant c such that

$$
\left| \kappa_3(F_n) - \frac{8}{n^{\frac{3}{2}}} \sum_{j,k,l=0}^{n-1} \rho(j,k)\rho(k,l)\rho(j,l) \right| \le c \times n^{(6H-3)\vee 0 - \frac{3}{2}},
$$

which together with Proposotion [2.6,](#page-7-3) implies that when $H \in (0, \frac{2}{3})$ $(\frac{2}{3}),$

$$
\kappa_3(F_n) \asymp n^{-\frac{1}{2}};\tag{3.27}
$$

and when $H=\frac{2}{3}$ $\frac{2}{3}$,

$$
\kappa_3(F_n) \asymp n^{-\frac{1}{2}} \log^2 n; \tag{3.28}
$$

and when $H \in \left(\frac{2}{3}\right)$ $\frac{2}{3}, \frac{3}{4}$ $\frac{3}{4}),$

$$
|\kappa_3(F_n)| \le n^{\frac{1}{2}(4H-3)};\tag{3.29}
$$

In the same vein, Proposition 3.7 implies that there exists a positive constant c such that

$$
\left|\kappa_4(F_n) - \frac{48}{n^2} \sum_{i,j,k,l=0}^{n-1} \rho(i-j)\rho(i-k)\rho(k-l)\rho(j-l)\right| \le c \times n^{(8H-6)\vee 0},
$$

which together with Proposotion [2.6,](#page-7-3) implies that when $H \in (0, \frac{5}{8})$ $(\frac{5}{8}),$

$$
\kappa_4(F_n) \asymp n^{-1};\tag{3.30}
$$

B-E BOUNDS AND ASCLT FOR QUADRATIC VARIATION OF GAUSSIAN PROCESSES 19 and when $H=\frac{5}{8}$ $\frac{5}{8}$,

$$
\kappa_4(F_n) \asymp n^{-1} \log^3 n; \tag{3.31}
$$

and when $H \in (\frac{5}{8})$ $\frac{5}{8}, \frac{3}{4}$ $\frac{3}{4}),$

$$
|\kappa_4(F_n)| \le n^{8H-6};\tag{3.32}
$$

Combing [\(3.27\)](#page-17-0)-[\(3.32\)](#page-18-0) with Theorem [2.3](#page-5-0) and Propositions [2.6,](#page-7-3) [3.5,](#page-11-7) we obtain the desired result since

$$
\kappa_4(V_n) = \frac{n^{\frac{3}{2}}}{\sigma_n^3} \kappa_3(F_n), \qquad \kappa_4(V_n) = \frac{n^2}{\sigma_n^4} \kappa_4(F_n).
$$

Proof of Theorem [1.7.](#page-3-1) From Theorem [1.5,](#page-2-0) V_n satisfies the CLT. Hence, we need only to check the conditions (1) and (2) of Theorem [2.4](#page-6-2) are valid. We will discuss exclusively the case $H \in (0, \frac{3}{4})$ $\frac{3}{4}$) since the case $H = \frac{3}{4}$ $\frac{3}{4}$ is similar.

Recall $V_n = I_2(f_n)$ where

$$
f_n = \frac{1}{\sigma_n} g_n = \frac{\sqrt{n}}{\sigma_n} \frac{g_n}{\sqrt{n}},
$$
\n(3.33)

which together with (3.26) and Proposition [3.5](#page-11-7) implies that

$$
||f_n \otimes_1 f_n||_{\mathfrak{H}^{\otimes 2}}^2 \le c \times \frac{1}{n^2} ||g_n \otimes_1 g_n||_{\mathfrak{H}^{\otimes 2}}^2
$$

$$
\le c \times \begin{cases} \frac{1}{n}, & \text{if } H \in (0, \frac{5}{8}), \\ \frac{(\log n)^3}{n}, & \text{if } H = \frac{5}{8}, \\ n^{8H-6}, & \text{if } H \in (\frac{5}{8}, \frac{3}{4}). \end{cases}
$$

Hence, the condition (1) of Theorem [2.4](#page-6-2) is valid.

To check the condition (2) of Theorem [2.4,](#page-6-2) first noting that $\mathbb{E}[V_n^2] = 2 ||f_n||_{\mathfrak{H}^{\otimes 2}}^2 =$ 1, we need only to show that when $0 < k < l$, the following inequality holds:

$$
|\langle f_k, f_l \rangle_{\mathfrak{H}^{\otimes 2}}| \le c \times \left[\sqrt{\frac{k}{l}} + (kl)^{(2H-1)\vee 0 - \frac{1}{2}} \right]. \tag{3.34}
$$

In fact, we have

$$
|\langle f_k, f_l \rangle_{\mathfrak{H}^{\otimes 2}}| \leq c \times \frac{1}{\sqrt{kl}} |\langle g_k, g_l \rangle_{\mathfrak{H}^{\otimes 2}}|
$$

$$
= c \times \frac{1}{\sqrt{kl}} \sum_{i=0}^{k-1} \sum_{j=0}^{l-1} \theta^2(i, j)
$$

$$
\leq c \times \frac{2}{\sqrt{kl}} \sum_{i=0}^{k-1} \sum_{j=0}^{l-1} \left[\gamma^2(i,j) + \rho^2(i-j) \right]. \tag{3.35}
$$

[2, Theorem 5.1] implies that

$$
\frac{1}{\sqrt{kl}}\sum_{i=0}^{k-1}\sum_{j=0}^{l-1}\rho^2(i-j) \le c \times \sqrt{\frac{k}{l}}.
$$

It follows from the inequality [\(3.8\)](#page-10-3) that

$$
\frac{1}{\sqrt{kl}}\sum_{i=0}^{k-1}\sum_{j=0}^{l-1}\gamma^2(i,j) \le c \times \frac{1}{\sqrt{kl}}\sum_{i=0}^{k-1}[(i+1)^H - i^H]^2 \times \sum_{j=0}^{l-1}[(j+1)^H - j^H]^2
$$

$$
\le c \times (kl)^{(2H-1)\vee 0-\frac{1}{2}},
$$

where in the last line we have used the inequality (3.11) . Plugging the above two inequalities into (3.35) , we obtain the desired (3.34) . Hence, the ASCLT holds when $H \in (0, \frac{3}{4})$ 4). \Box

ACKNOWLEDGEMENTS

Many thanks to Prof. X. Huang for valuable comments on Lemma [3.1.](#page-7-0) The work of Yong Chen is supported by National Natural Science Foundation of China (No.11961033)
