#### Abstract

Boolean functions can be represented in many ways including logical forms, truth tables, and polynomials. Additionally, Boolean functions have different canonical representations such as minimal disjunctive normal forms. Other canonical representation is based on the polynomial representation of Boolean functions where they can be written as a nested product of canalizing layers and a polynomial that contains the noncanalizing variables. In this paper we study the problem of identifying the canalizing layers format of Boolean functions. First, we show that the problem of finding the canalizing layers is NP-hard. Second, we present several algorithms for finding the canalizing layers of a Boolean function, discuss their complexities, and compare their performances. Third, we show applications where the computation of canalizing layers can be used for finding a disjunctive normal form of a nested canalizing function. Another application deals with the reverse engineering of Boolean networks with a prescribed layering format. Finally, implementations of our algorithms in Python and in the computer algebra system Macaulay2 are available at <a href="https://github.com/ckadelka/BooleanCanalization">https://github.com/ckadelka/BooleanCanalization</a>.

Keywords: Boolean functions, Canalizing layers, NP-hard, Disjunctive normal forms, Reverse engineering

#### 1. Introduction

Boolean canalization was first introduced by S. Kauffman [1]. This concept was inspired by the concept of canalization in evolutionary biology [2] which is a measure of the ability to produce the same phenotype regardless of the variability in genotype [3]. Boolean canalization has been extensively studied in the context of dynamics of the Boolean networks [4, 5, 6, 7]. Boolean nested canalizing functions have been shown to be equivalent to unate cascade functions [4] – a class of functions that show up in the computer science literature [8, 9]. Boolean nested canalizing functions have been extended to the multistate case where variables can take on more than two variables and the dynamics of networks with these kinds of functions have been studied [10, 11, 12, 13].

The concept of canalizing layers was introduced in [6] in the context of nested canalizing functions. Later, a full stratification of the variables of any Boolean function was provided in [14]. The layers format provides a unique way (up to permutations within the layers) of representing Boolean functions. The canalizing layers are related to the symmetry groups of the variables in a nested canalizing function [15]. The canalizing layers format have been used for quantifying the total effect of network perturbations and control [7, 13].

In this paper we present algorithms for finding the canalizing layers of a Boolean function. We also provide implementations of the algorithms in Python and in the computer algebra system Macaulay2 [16]. Although, our implementations can handle the functions of most published models, the problem of finding the canalizing layers in NP-hard (see Section 3).

The canalizing layers format can be used to obtain useful information about the Boolean functions in a model. In this paper, we show two practical applications. First, we show how to obtain a disjunctive normal form for a nested canalizing function from the canalizing layers format. Second,

<sup>\*</sup>Corresponding author

we provide an application for how to do reverse engineering with a prescribed layering format that takes advantage of canalizing layers format of the candidate functions.

This paper is structured in the following way: in Section 2 we provide the theoretical background of Boolean canalization and the canalizing layers format. In Section 3 we show that the problem of finding the canalizing layers is NP-hard. In Section 4 we describe multiple algorithms and compare their performance. In Section 5.1 we describe how to obtain disjunctive normal forms from the canalizing layers format. In Section 5.2 we provide an application for using the layers format for reverse engineering. In Section 6 we provide discussions and conclusions.

## 2. Background

In this section, we review some concepts and definitions and introduce the concept of canalization as well as layers of canalization.

Definition 2.1. A Boolean function  $f(x_1,\ldots,x_n)$  is canalizing if there exists a variable  $x_i, a, b \in$  $\{0, 1\}$  and a Boolean function  $g(x_1, \ldots, x_{i-1}, x_{i+1}, \ldots, x_n) \not\equiv b$  such that

$$f(x_1, x_2, ..., x_n) = \begin{cases} b, & \text{if } x_i = a \\ g(x_1, x_2, ..., x_{i-1}, x_{i+1}, ..., x_n), & \text{if } x_i \neq a \end{cases}$$

Definition 2.2. [14] A Boolean function  $f(x_1, \ldots, x_n)$  is k-canalizing, where  $1 \le k \le n$ , with respect to the permutation  $\sigma \in \mathcal{S}_n$ , inputs  $a_1, \ldots, a_k$  and outputs  $b_1, \ldots, b_k$ , if

$$f(x_1,\dots,x_n) = \begin{cases} b_1 & x_{\sigma(1)} = a_1, \\ b_2 & x_{\sigma(1)} \neq a_1, x_{\sigma(2)} = a_2, \\ b_3 & x_{\sigma(1)} \neq a_1, x_{\sigma(2)} \neq a_2, x_{\sigma(3)} = a_3, \\ \vdots & \vdots & \vdots \\ b_k & x_{\sigma(1)} \neq a_1, \dots, x_{\sigma(k-1)} \neq a_{k-1}, x_{\sigma(k)} = a_k, \\ g \not\equiv b_k & x_{\sigma(1)} \neq a_1, \dots, x_{\sigma(k-1)} \neq a_{k-1}, x_{\sigma(k)} \neq a_k, \end{cases}$$

where  $g = g(x_{\sigma(k+1)}, \dots, x_{\sigma(n)})$  is a Boolean function on n-k variables. When g is not canalizing, the integer k is the canalizing depth of f [5]. An n-canalizing function is also called nested canalizing function (NCF), and, by definition, all Boolean functions are 0-canalizing.

Authors He and Macauley provided the following powerful stratification theorem.

**Theorem 2.3** ([14]). Every Boolean function  $f(x_1, ..., x_n) \not\equiv 0$  can be uniquely written as

$$f(x_1, \dots, x_n) = M_1(M_2(\dots(M_{r-1}(M_r p_C + 1) + 1) \dots) + 1) + b, \tag{1}$$

where each  $M_i = \prod_{j=1}^{k_i} (x_{i_j} + a_{i_j})$  is a nonconstant extended monomial,  $p_C$  is the core polynomial of f, and  $k = \sum_{i=1}^{r} k_i$  is the canalizing depth. Each  $x_i$  appears in exactly one of  $\{M_1, \ldots, M_r, p_C\}$ ,

and the only restrictions are the following "exceptional cases":

- 1. If  $p_C \equiv 1$  and  $r \neq 1$ , then  $k_r \geq 2$ ;
- 2. If  $p_C \equiv 1$  and r = 1 and  $k_1 = 1$ , then b = 0.

When f is a non-canalizing functions (i.e., when k = 0), we simply have  $p_C = f$ .

Theorem 2.3 shows that any Boolean function has a unique standard extended monomial form, in which the variables are partitioned into different layers based on their dominance. Any variable that is canalizing (independent of the values of other variables) is in the first layer. Any variable that "becomes" canalizing when excluding all variables from the first layer is in the second layer, etc. All remaining variables that never become canalizing are part of the core polynomial. The number of variables that eventually become canalizing is the canalizing depth, and NCFs are exactly those functions where all variables eventually become canalizing.

Definition 2.4. [17] The layer structure of a Boolean function  $f(x_1, \ldots, x_n)$  with canalizing depth k is defined as the vector  $(k_1, \ldots, k_r)$ , where r is the number of layers and  $k_i$  is the size of the ith layer,  $i = 1, \ldots, r$ . The layer structure follows directly from the unique standard monomial form of f (Theorem 2.3).

Example 2.5. The function  $f = (x_1 + 1)x_2[(x_3 + 1)x_4(x_5x_6 + x_7 + 1) + 1]$  has layer structure  $(k_1 = k_2 = 2)$ . The unique standard extended monomial form is  $f = M_1[M_2(p_C + 1) + 1]$ , where  $M_1 = (x_1 + 1)x_2$ ,  $M_2 = (x_3 + 1)x_4$ , and  $p_C = x_5x_6 + x_7$ .

Remark 2.6. Two variables that appear in the same layer canalize a function to the same output value. That implies that the number of layers of a canalizing function expressed as in Definition 2.2 is simply the number of changes in the vector of canalized outputs,  $(b_1, b_2, \ldots, b_k)$ .

## 3. Finding Canalizing Layers is NP-hard

In this section we show that the problem of determining the specific layer structure of a Boolean function is **NP**-hard, thus requiring efficient algorithms.

**Theorem 3.1.** (adapted version of Theorem 2.5 in [15]) Unless  $\mathbf{P} = \mathbf{NP}$ , there is no polynomial time algorithm for determining the symmetry level of a Boolean function f specified as a Boolean expression, even if f is a CNF expression.

This theorem was proved by showing that determining the symmetry level of a Boolean function is equivalent to solving the CNF Satisfiability Problem (SAT), which is known to be **NP**-hard. We will now show that a polynomial time algorithm for the identification of layers and core polynomial of a Boolean function would also yield the symmetry level in polynomial time.

**Theorem 3.2.** Unless P = NP, there is no polynomial time algorithm for determining the standard monomial form (Theorem 2.3; i.e., the layers and the core polynomial) of a Boolean function f specified as a Boolean expression, even if f is a CNF expression.

The following proof was adapted from [15].

*Proof.* Assume there is a polynomial time algorithm  $\mathcal{A}$  that yields the canonical monomial form, as stated in Theorem 2.3, for any Boolean function. We will show that  $\mathcal{A}$  can be used to efficiently solve the CNF Satisfiability problem (SAT) which is known to be NP-hard [18].

Let g be a CNF formula representing an instance of SAT. Let  $X = \{x_1, x_2, \ldots, x_n\}$  denote the set of Boolean variables used in g. Let  $y_1 \notin \{x_1, x_2, \ldots, x_n\}$  be a new variable and h be the Boolean function with 1 layer:  $h = y_1$ . Now, we create another CNF formula f as  $f = g \wedge h$ . Note that f is a function of n+1 variables, namely  $x_1, x_2, \ldots, x_n, y_1$ . Since g is a CNF formula, so is f. We have the following claims.

Claim 1: If g is not satisfiable, the number of layers of f is 0.

**Proof of Claim 1:** If g is not satisfiable, f is also not satisfiable; that is, for all inputs, the value of f is 0. Thus, the canonical monomial form for f is  $f = P_C = 0$ . Thus, the number of layers of f is 0.

Claim 2: If g is satisfiable, the number of layers of f is at least 1.

**Proof of Claim 2:** Suppose g is satisfiable. Since h has 1 layer, f has at least 1 layer.

Suppose we execute the polynomial algorithm  $\mathcal{A}$  on the function f defined above. If g is not satisfiable, then from Claim 1, the number of layers of f is 0. Thus,  $\mathcal{A}$  will produce 0 layers. On the other hand, if g is satisfiable, by Claim 2, the number of layers of f is at least 1; so,  $\mathcal{A}$  will produce at least 1 layer. In other words, g is not satisfiable iff the number of layers produced by  $\mathcal{A}$  is 0. Since  $\mathcal{A}$  runs in polynomial time, we have an efficient algorithm for SAT, contradicting the assumption that  $P \neq NP$ .

## 4. Algorithms for Layers of Canalization

In this section we present algorithms for finding the layers of canalization of a Boolean function in three different cases:

- i. The function is presented as a polynomial  $f: \{0,1\}^n \to \{0,1\}$  (Section 4.1).
- ii. The function is given as a vector (Section 4.2).
- iii. The function is nested canalizing with a known order of canalizing variables (Section 4.3).

The layer structure produced by Algorithms 1 and 2 is a modification of the presentation in Equation 1. In particular the output is an ordered pair (layers, core polynomial) where

• layers is a list of ordered pairs of canalizing inputs (as a list) and canalized outputs (as an integer) of the form

```
\{(\text{layer } 1, \text{ output } 1), \dots, (\text{layer } k, \text{ output } k)\}
```

and each layer is a list of variables and their canalizing inputs of the form

```
\{(\text{var } 1, \text{ input } 1), (\text{var } 2, \text{ input } 2), \dots, (\text{var } r, \text{ input } r)\}
```

• core polynomial is a polynomial, denoted  $p_C$  in Theorem 2.3.

# 4.1. Algorithm for Boolean functions represented as polynomials

The first algorithm, implemented in Macaulay2, takes as input *any* Boolean function and returns its canalizing layers. The algorithm is based on successive evaluations of the inputs of the functions to check for canalizing inputs and subsequent removal of these from the search. It was implemented in Macaulay2.

```
Algorithm 1 Polynomial Form
```

```
Input: A Boolean function f: \{0,1\}^n \to \{0,1\} as a polynomial.
Output: Layer structure of f.
 1: Layers = \{\}
2: Set NewVar = support(f)
                                                                                  \triangleright get variables of f
   while NewVar \neq \emptyset do
     NewLayer = \{\} and NegNewLayer = \{\}
     foreach x_i \in NewVar do
       foreach a \in \{0, 1\} do
6:
         \hat{X} = (x_1, \dots, x_{i-1}, x_i = a, x_{i+1}, \dots, x_n)
 7:
                                                                                 \triangleright evaluate at x_i = a
         g = f(\hat{X})
                                                                             ▶ polynomial evaluation
8:
       if support(g) == \emptyset then
9:
10:
         Append (x_i, a) to NewLayer.
                                                               Append (x_i, a+1) to NegNewLayer
                                                          > store non-canalizing input in each layer
11:
     Append (NewLayer, f(\{variables in NewLayer\})) to Layers
12:
     Set NewVar = NewVar \setminus \{variables in NewLayer\}
13:
     Set f = f(\{\text{variables in } NegNewLayer\})
14:
     if NewLayer == \emptyset then
15:
       Break:
16:
                                                                                  ⊳ end of while loop
17: return Layers, f(NewVar)
                                                                ▶ return layers and core polynomial.
```

# 4.2. Algorithm for Boolean functions represented as truth tables

The second algorithm, implemented in Python, uses elementary linear algebra and recursion to compute the layer structure of any Boolean function  $f(x_1, \ldots, x_n)$  in n variables. Consider a binary truth table represented as a  $2^n \times (n+1)$ -matrix over  $\{0,1\}$  where the left-hand side of dimension  $2^n \times n$  corresponds to the inputs of a function  $f: \{0,1\}^n \to \{0,1\}$  and the  $(2^n \times 1)$ -dimensional right-hand side corresponds to the outputs of f when evaluated on the inputs. Let  $\mathbf{T}_n = (\mathbf{t}_1, \ldots, \mathbf{t}_n) \in \{0,1\}^{2^n \times n}$  be the left-hand side of a binary truth table. That is,  $\mathbf{t}_i$  is a binary vector of length  $2^n$ , which has 1 in the rows of  $\mathbf{T}_n$  where  $x_i = 1$ , and 0 otherwise. We will think of the right-hand side of a binary truth table as f, written as a row vector. With  $\langle \cdot, \cdot \rangle$  denoting the dot product, we have the following:

- $x_i = 0$  canalizes f to the value 0 if and only if  $\langle 1 f, 1 \mathbf{t}_i \rangle = 2^{n-1}$
- $x_i = 1$  canalizes f to the value 0 if and only if  $\langle 1 f, \mathbf{t}_i \rangle = 2^{n-1}$
- $x_i = 0$  canalizes f to the value 1 if and only if  $\langle f, 1 \mathbf{t}_i \rangle = 2^{n-1}$
- $x_i = 1$  canalizes f to the value 1 if and only if  $\langle f, \mathbf{t}_i \rangle = 2^{n-1}$

With this we can define four sets

$$I_{0\to 0}(f) := \left\{ i \in \{1, \dots, n\} \mid \langle 1 - f, 1 - \mathbf{t}_i \rangle = 2^{n-1} \right\}$$

$$I_{1\to 0}(f) := \left\{ i \in \{1, \dots, n\} \mid \langle 1 - f, \mathbf{t}_i \rangle = 2^{n-1} \right\}$$

$$I_{0\to 1}(f) := \left\{ i \in \{1, \dots, n\} \mid \langle f, 1 - \mathbf{t}_i \rangle = 2^{n-1} \right\}$$

$$I_{1\to 1}(f) := \left\{ i \in \{1, \dots, n\} \mid \langle f, \mathbf{t}_i \rangle = 2^{n-1} \right\}$$

Then  $I_{a\to b}(f)$  contains all the indices of canalizing variables that canalize f to the canalized output value b if they take on the canalizing input value a, for  $a, b \in \{0, 1\}$ . For brevity, let  $I_b(f) = I_{0\to b}(f) \cup I_{1\to b}(f)$ . By Definition 2.1, constant functions are not canalizing. Therefore, we have

- $|I_0(f)| + |I_1(f)|$  is the number of canalizing variables
- $I_0(f) = I_1(f) = \emptyset \iff f$  is not canalizing.

By Remark 2.6, all canalizing variables can lize f to the same output value. Thus,

- $I_0(f) \neq \emptyset \Longrightarrow I_1(f) = \emptyset$
- $I_1(f) \neq \emptyset \Longrightarrow I_0(f) = \emptyset$

This allows us to use these dot products to define an iterative process that finds all layers of a Boolean function, recording layer by layer the canalizing inputs, canalized outputs and canalizing variables (see Algorithm 2).

Example 4.1. Let n=3 and consider the left-hand side of the  $(2^3\times 3)$ -truth table

$$\mathbf{T}_3 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \\ 0 & 1 & 1 \\ 1 & 0 & 0 \\ 1 & 0 & 1 \\ 1 & 1 & 0 \\ 1 & 1 & 1 \end{pmatrix}.$$

Let  $f(x_1, x_2, x_3) = x_1 \wedge (x_2 \vee x_3)$ . As a row vector (with variable order  $x_1, x_2, x_3$ ), we can express f as f = (0, 0, 0, 0, 0, 1, 1, 1). Then, we have

$$f \cdot \mathbf{T}_3 = (3, 2, 2), \ f \cdot (\mathbf{1} - \mathbf{T}_3) = (0, 1, 1),$$

where  $\mathbf{1} - \mathbf{T}_3$  is the difference of the  $(8 \times 3)$ -matrix of ones and  $\mathbf{T}_3$  modulo 2. None of these entries equal  $2^{3-1} = 4$ ; hence  $I_1(f) = \emptyset$ .

On the other hand,

$$(1-f) \cdot \mathbf{T}_3 = (1,2,2), (1-f) \cdot (\mathbf{1} - \mathbf{T}_3) = (4,3,3).$$

Thus,  $I_0(f) = \{1\}$  and  $x_1$  is therefore the only canalizing variable of f with  $x_1 = 0$  canalizing f to 0. Removing the first layer  $\{x_1\}$  from f yields the subfunction  $g = f(1, x_2, x_3) = x_2 \vee x_3$  or (0, 1, 1, 1) as a row vector.

Now we repeat the process and find that  $I_0(g) = \emptyset$  since  $(1-g) \cdot \mathbf{T}_2 = (0,0)$  and  $(1-g) \cdot (\mathbf{1} - \mathbf{T}_2) = (1,1)$ . Likewise  $I_1(g) = \{2,3\}$  since  $g \cdot \mathbf{T}_2 = (2,2)$  and  $g \cdot (\mathbf{1} - \mathbf{T}_2) = (1,1)$ . Therefore,  $\{x_2, x_3\}$  forms the second layer of canalizing variables of f with canalizing output 1. The process is completed because the new subfunction h = g(1,1) = 1 contains no more variables. Note that for non-NCFs, the process completes when no new canalizing variables are found, *i.e.* when both  $I_0$  and  $I_1$  are empty.

# Algorithm 2 Truth Table Form

```
Input: A Boolean function f: \{0,1\}^n \to \{0,1\} as a (1 \times n)-row vector.
Output: Layer structure of f.
 1: Layers = \{\}
                                                                                        2: Set n = \log_2(\text{length } f)
                                                      \triangleright number of variables of f; n and f will change
 3: if support(f) == \emptyset then
                                                                                           \triangleright f is constant
      return (Layers, f)
                                                      ▷ constant functions are not canalizing - Def 2.1
 5: Initialize \mathbf{T}_n
 6: Set v = (1, ..., 1)
                                                                                 \triangleright row vector of 2^n ones
 7: Set M = [v', \dots, v']
                                                          \triangleright matrix of 2^n \times n ones; \mathbf{v}' = \text{transpose of } \mathbf{v}
 8: NewLayer = \{\}
                                                                               ⊳ stores the current layer
 9: NegNewLayer = \{\}
                                                         ▶ stores non-canalizing input of current layer
10: Compute (v-f) \cdot \mathbf{T}_n, (v-f) \cdot (M-\mathbf{T}_n), and derive I_{0\to 0}(f), I_{1\to 0}(f), and I_0(f)
   if I_0(f) \neq \emptyset then

# 4.3. Algorithm for nested canalizing functions

The authors of [4] developed a parametrization of NCFs corresponding to points in the affine space  $\mathbb{F}_2^{2^n}$  that satisfy a certain collection of polynomial equations. Since the terms of a Boolean polynomial consist of square-free monomials, we can uniquely index monomials by the subsets of  $[n] = \{1, 2, \ldots, n\}$  corresponding to the variables appearing in the monomial, so that the set of all Boolean polynomials can be expressed as

$$\left\{ \sum_{S \subseteq [n]} c_s \prod_{i \in S} x_i \, \middle| \, c_s \in \mathbb{F}_2 \right\}.$$

We use this parametrization, and in particular Corollary 3.6 in [4], to suggest a linear time algorithm for finding the canalizing layers of a given NCF. The algorithm is based on the following theorem which is a straightforward consequence of Corollary 3.6 in [4].

**Theorem 4.2.** Let f be an NCF in variable order  $x_1, x_2, \ldots, x_n$ , with canalizing input values  $a_i$  and corresponding canalizing output values  $b_i$ ,  $1 \le i \le n$ . If

$$c_{\{1,2,...,j\}} = c_{\{1,2,...,j,j+1\}} c_{[n] \backslash \{1,2,...,j,j+1\}} \quad \text{for all} \quad j=1,\dots,n-1,$$

then  $x_j$  and  $x_{j+1}$  are in the same layer.

Therefore, if the canalizing order of the n variables of an NCF is known, one needs to check at most n-1 equalities; that is, the algorithm suggested by Theorem 4.2 will take linear time in the number of variables.

## 4.4. Time complexity of the algorithms

As an indication for the time complexity, we recorded the average run time of both algorithms for random Boolean functions in 4 to 16 variables. We tested two extremes: the run time for random non-canalizing functions and for random nested canalizing (i.e., most canalizing) functions. For each even number of variables  $n \in [4, 16]$  and for both types of functions, we randomly generated five Boolean functions of that type as a row vector of length  $2^n$ , which served as the input for Algorithm 2. To use the same sets of random functions in Algorithm 1, we transformed the row vectors into polynomials in disjunctive normal form, which were then reduced by Macaulay2 prior to recording run time.

At small numbers of variables ( $n \le 10$ ), both algorithms were on average faster at determining that there were no canalizing variables than at finding all layers of an NCF (Figure 1A). Interestingly for functions in many variables, this switched for Algorithm 1; its run time increased only marginally for NCFs, much slower than for non-canalizing functions. This is likely because Algorithm 1 benefits from a high amount of structure in nested canalizing polynomials, highlighting the advantage of the use of the polynomial representation over truth tables (i.e., vectors). Note that the algorithms are implemented in two different programming languages, which prohibits a direct comparison of the run time.

Algorithm 2 can be sped up by pre-computing the left-hand side of the truth table  $\mathbf{T}_m$  for all m with  $1 \le m \le n$ . In our limited experiment this reduced the run time by 66.7% (n=4) to 90.2% (n=10) for non-canalizing functions and by 35.8% (n=4) and 83% (n=14) for NCFs (Figure 1B).

Figure 1: Comparison of the run time of the algorithms. (A) For both algorithms (color), we compared the average computation time of the layers for non-canalizing (solid lines with circles) and nested canalizing (dotted lines with x) Boolean functions in 4-16 variables (x-axis). (B) Comparison of the basic version of Algorithm 2 (blue) and a modified version of the algorithm where the left-hand side of the truth table  $\mathbf{T}_m$  has been pre-computed for all m with  $1 \le m \le n$ .

# 5. Applications

In this section, we present two applications that utilize the canalizing structure of an NCF: converting the function into disjunctive normal form (Sec. 5.1), and reverse-engineering an unknown function from (partial) knowledge of its layers (Sec. 5.2).

## 5.1. Finding disjunctive normal forms using canalizing layers

A disjunctive normal form (DNF) is a canonical representation of Boolean functions which consists of a disjunction of conjunctions (or sum of products). A disjunctive normal form is a useful representation of Boolean functions that has been used for many applications. For instance, a minimal DNF is needed for the identification of stable motifs [19, 20]. In this section we will use the canalizing layers format to obtain a disjunctive normal form expression for a nested canalizing function. In general, the Quine-McCluskey algorithm [21] can be used to find a disjunctive normal formal for any Boolean function.

The following proposition is a special case of Theorem 2.3 where we assume that the Boolean function is nested canalizing.

**Proposition 5.1.** Every nested canalizing function  $f(x_1, \ldots, x_n)$  can be uniquely written as

$$f(x_1, \dots, x_n) = M_1(M_2(\dots(M_{r-1}(M_r+1)+1)\dots)+1)+b,$$
(2)

where  $M_i = \prod_{j=1}^{k_i} (y_{i_j} + 1)$ ,  $y_{i_j} \in \{x_i, \overline{x}_{i_j}\}$ , and  $n = k_1 + \dots + k_r$ . Each variable  $y_i$  appears in exactly one of the  $M_1, M_2, \dots, M_r$ .

Remark 5.2.

1. Note that the extended monomials in Proposition 5.1 can be written as

$$M_i = \prod_{j=1}^{k_i} (y_{i_j} + 1) = \overline{y}_{i_1} \wedge \dots \wedge \overline{y}_{i_{k_i}}.$$

2. The negated form of f is f+1. Thus, to obtain the canalizing layers description of  $\overline{f}$  we add 1 to Equation 2:

$$\overline{f}(x_1, \dots, x_n) = M_1(M_2(\dots(M_{r-1}(M_r+1)+1)\dots)+1)+b+1.$$
(3)

Now using the first part of Remark 5.2, we introduce the following notation

$$\overline{M}_i = y_{i_1} \vee \cdots \vee y_{i_{k_i}}.$$

Given a nested canalizing function that is written as in Equation 2, one can obtain a disjunctive normal form (DNF) for f from the layers format given in Equation 2.

**Theorem 5.3.** Let f be a nested canalizing function that is written as in Equation 2. Then the following formulas provide a disjunctive normal form (DNF) for f depending of the value of b in Equation 2.

1. If b = 0, then a DNF of f is given by

$$f = \bigvee_{i=0}^{\lfloor r/2 \rfloor} \left( M_{2i+1} \wedge \bigwedge_{j=1}^{i} \overline{M}_{2j} \right). \tag{4}$$

2. If b = 1, then a DNF of f is given by

$$f = \bigvee_{i=0}^{\lfloor r/2 \rfloor} \left( \overline{M}_{2i+1} \wedge \bigwedge_{j=1}^{i} M_{2j} \right). \tag{5}$$

*Proof.* We consider two cases for the value of b.

1. If b = 0, then

$$M_{2i+1} \wedge \overline{M}_{2j} = M_{2i+1} \wedge (y_{i_1} \vee \dots \vee y_{i_{k_i}}) = \bigvee_{k=1}^{k_i} M_{2i+1} \wedge y_{i_j}$$

Thus, Equation 4 is in disjunctive normal form.

2. If b = 1, then

$$\overline{M}_{2i+1} \wedge M_{2j} = (y_{i_1} \vee \dots \vee y_{i_{k_i}}) \wedge M_{2j} = \bigvee_{k=1}^{k_i} y_{i_j} \wedge M_{2j}$$

Thus, Equation 5 is in disjunctive normal form.

Remark 5.4. We make the following observations on Theorem 5.3.

- 1. When i = 0, the term inside the parentheses of Equation 4 (Equation 5) reduces to  $M_1$  ( $\overline{M}_1$ ).
- 2. When r is even and i = r/2, the term  $\overline{M}_{r+1}$  inside the parentheses of Equations 4-5 should be set to 1.

Example 5.5. Let  $f = x_1x_2x_3x_4 + x_1x_2x_3 + x_1x_2x_4 + x_2x_3x_4 + x_1x_2 + x_1x_3 + x_2x_3 + x_2x_4 + x_1 + x_2 + x_3 + 1$ . The layers format of this function is  $f = M_1(M_2 + 1)$  where  $M_1 = (x_1 + 1)(x_3 + 1)$  and  $M_2 = x_2(x_4 + 1)$ . Thus, the value of b in Equation 2 is b = 0. Then, from Equation 4, the disjunctive normal form is  $f = M_1 \wedge \overline{M}_2 = (M_1 \wedge \overline{x}_2) \vee (M_1 \wedge x_4) = (\overline{x}_1 \wedge \overline{x}_3 \wedge \overline{x}_2) \vee (\overline{x}_1 \wedge \overline{x}_3 \wedge x_4)$ .

Example 5.6. Let  $f = x_1x_2x_3x_4 + x_1x_2x_3 + x_2x_3x_4 + x_2x_3 + x_4$ . The layers format of this function is  $f = M_1(M_2 + 1) + 1$  where  $M_1 = x_4 + 1$  and  $M_2 = (x_1 + 1)x_2x_3$ . Thus, the value of b in Equation 2 is b = 1. Then, from Equation 5, the disjunctive normal form is  $f = \overline{M}_1 \vee M_2 = x_4 \vee (\overline{x}_1 \wedge x_2 \wedge x_3)$ .

5.2. Reverse engineering nested canalizing functions

When part of the canalizing structure of an NCF is known, one can generate all NCFs with that structure using the parametrization of NCFs corresponding to points in the affine space  $\mathbb{F}_2^{2^n}$  provided in [4], together with the following corollary to Theorem 2.3.

Corollary 5.7. Let  $f(x_1, ..., x_n)$  be a polynomial over  $\mathbb{F}_2$ .

- 1. A variable  $x_i$  is canalizing in the first layer of f with canalizing input 0 if and only if  $f(x_1, \ldots, x_n) f(0, \ldots, 0) = x_i \cdot g$  for some function g.
- 2. A variable  $x_i$  is canalizing in the first layer of f with canalizing input 1 if and only if  $f(x_1, \ldots, x_i + 1, \ldots, x_n) f(0, \ldots, 1, \ldots, 0) = x_i \cdot g$  for some function g, where 1 is at the ith coordinate in  $(0, \ldots, 1, \ldots, 0)$ .

*Proof.* Part 1 follows directly from Theorem 2.3. Part 2 also follows from Theorem 2.3 by noticing that the constant term of  $f(x_1, \ldots, x_i + 1, \ldots, x_n)$  is obtained by setting  $x_i = 1$  and  $x_j = 0$  for  $j \neq i$ , so it is given by  $f(0, \ldots, 1, \ldots, 0)$ .

Example 5.8. Let  $f = x_1x_2 + x_1 + 1 \in \mathbb{F}_2[x_1, x_2]$ . Then  $f(x_1, x_2) - f(0, 0) = x_1x_2 + x_1 + 1 - 1 = x_1x_2 + x_1$  and since it can be factored as  $x_1(x_2 + 1)$ , we see that  $x_1$  is a canalizing variable in the first layer of f with canalizing input 0. Now,  $f(x_1 + 1, x_2 + 1) - f(1, 1) = x_1x_2 + x_2$  and since we can factor it as  $x_2(x_1 + 1)$ , we have that  $x_2$  is canalizing in the first layer of f with canalizing input 1.

Corollary 5.7 allows for quick identification of the canalizing variables in the outermost layer of a function and we will use it as we "reverse engineer" an NCF from partial information on its canalizing structure. To illustrate the process we will consider the regulation of the mammalian cell cycle and specifically how the members of the E2F family of transcription factors are regulated by other elements. This example is based on the work in [22] in which the mammalian cell cycle is modeled using logical framework.

Example 5.9. Mammalian cell division is tightly controlled and coordinated with the overall growth of the organism. The protein Rb forms a complex with members of the E2F family of transcription factors, turning them from transcriptional activators to repressors. As a result, Rb is considered an inhibitor of E2F and so is CycB. The role CycA plays in the regulation of E2F is more complicated. While generally an inhibitor for E2F, CycA's effect on E2F is known to be altered by p27 but we will assume we do not know how. Thus the layering structure of the polynomial that models the dynamics of E2F will be an NCF in variables  $x_1 = \text{CycB}$ ,  $x_2 = \text{Rb}$ ,  $x_3 = \text{p27}$ , and  $x_4 = \text{CycA}$  distributed across two layers as follows:

Layer 1 has canalizing output 1 and contains  $x_1$  with canalizing input 1 and  $x_2$  also with canalizing input 1; Layer 2 has unknown canalizing output and contains  $x_3$  with unknown canalizing input and  $x_4$  with canalizing input 0.

The goal is to find all NCFs with this prescribed canalizing structure.

First, we will use Theorem 3.3 in [4] which provides relationships among the coefficients in the NCF. (For ease of reading, we write below, for example,  $c_{123}$  instead of  $c_{\{1,2,3\}}$ .) Notice that not all the equations that follow from the theorem carry useful information. Here, we present only those that are not trivially true.

$$c_{1234} = 1 (6)$$

$$c_2 = c_{12}c_{234} \tag{7}$$

$$c_3 = c_{123}c_{234}c_{134} \tag{8}$$

$$c_4 = c_{234}c_{134}c_{124} (9)$$

$$c_{13} = c_{123}c_{134} (10)$$

$$c_{14} = c_{134}c_{124} (11)$$

$$c_{23} = c_{123}c_{234} (12)$$

$$c_{24} = c_{234}c_{124} (13)$$

$$c_{34} = c_{234}c_{134} (14)$$

Second, we use Corollary 3.6 in [4] and the fact that variables in the same layer have the same canalizing output, while those in adjacent layers have different canalizing output to ensure that  $x_1$  and  $x_2$  are in one layer and  $x_3$  and  $x_4$  and in a different layer. The corollary produces the following nontrivial equations:

$$c_1 = c_{12}c_{134} (15)$$

$$c_{12} = c_{123}c_{124} + 1 (16)$$

We solve the system of eleven equations (3)-(12) using Gröbner bases with lexicographic order to find that the system has five free parameters,  $c_{134} = a$ ,  $c_{234} = b$ ,  $c_{124} = c$ ,  $c_{123} = d$ , and  $c_{\emptyset} = e$ . The rest of the coefficients can be expressed in terms of these free parameters as  $c_1 = acd + a$ ,  $c_2 = bcd + b$ ,  $c_3 = abd$ ,  $c_4 = abc$ ,  $c_{12} = cd + 1$ ,  $c_{13} = ad$ ,  $c_{14} = ac$ ,  $c_{23} = bd$ ,  $c_{24} = bc$ , and  $c_{34} = ab$ . Thus the family of functions that satisfy the prescribed canalizing structure is of the form

$$f = x_1 x_2 x_3 x_4 + (acd + a)x_1 + (bcd + b)x_2 + abdx_3 + abcx_4 + (cd + 1)x_1 x_2 + adx_1 x_3 + acx_1 x_4 + bdx_2 x_3 + abcx_4 + (cd + 1)x_1 x_2 + adx_1 x_3 + acx_1 x_4 + bdx_2 x_3 + abcx_4 + abc$$

$$bcx_2x_4 + abx_3x_4 + ax_1x_3x_4 + bx_2x_3x_4 + cx_1x_2x_4 + dx_1x_2x_3 + e$$
.

So far, we have ensured that the above family of functions are nested canalizing in canalizing order  $x_1, x_2, x_3, x_4$  and that  $x_1$  and  $x_2$  are in one layer and  $x_3$  and  $x_4$  are in a different layer. We have not guaranteed  $x_1$  and  $x_2$  will be in the first layer or that the variables will have the required canalizing input and output.

To make sure that variables  $x_1$  and  $x_2$  will be in the first layer and both have canalizing input 1, we will use Corollary 5.7 and consider  $f(x_1 + 1, x_2 + 1, x_3, x_4) - f(1, 1, 0, 0)$  which, expanded, is

$$x_1 + ax_1 + cdx_1 + acdx_1 + x_2 + bx_2 + cdx_2 + bcdx_2 + x_1x_2 + cdx_1x_2 + dx_3 + adx_3 + bdx_3 + abdx_3 + dx_1x_3 + bdx_3 + adx_3 + bdx_3 + adx_3 + bdx_3 + adx_3 + bdx_3 + adx_3 + ad$$

$$adx_{1}x_{3} + dx_{2}x_{3} + bdx_{2}x_{3} + dx_{1}x_{2}x_{3} + cx_{4} + acx_{4} + bcx_{4} + abcx_{4} + cx_{1}x_{4} + acx_{1}x_{4} + cx_{2}x_{4} + bcx_{2}x_{4} + bcx_{2}x_{4} + bcx_{2}x_{3} + bdx_{2}x_{3} + dx_{1}x_{2}x_{3} + cx_{2}x_{3} + acx_{1}x_{4} + acx_{1}x_{2}x_{3} + acx_{1}x_{$$

$$cx_{1}x_{2}x_{4} + x_{3}x_{4} + ax_{3}x_{4} + bx_{3}x_{4} + abx_{3}x_{4} + x_{1}x_{3}x_{4} + ax_{1}x_{3}x_{4} + x_{2}x_{3}x_{4} + bx_{2}x_{3}x_{4} + x_{1}x_{2}x_{3}x_{4}.$$

In order to be able to factor out  $x_1$  and  $x_2$  from all nonconstant terms, we need to select zero coefficients for all terms that do not have both  $x_1$  and  $x_2$ , that is, set to zero the coefficients for the terms  $x_1, x_2, x_3, x_4, x_1x_3, x_2x_3$ , etc. This generates a system of 11 nonlinear equations in variables a, b, c, d over  $\mathbb{F}_2$  which has (lexicographic) Gröbner basis  $\{a+1, b+1\}$ , so we set a=b=1 in f to obtain

$$f' = e + x_1 + cdx_1 + x_2 + cdx_2 + x_1x_2 + cdx_1x_2 + dx_3 + dx_1x_3 + dx_2x_3 + dx_1x_2x_3 + cx_4 + cx_1x_4 + cx_2x_4 + cx_1x_2x_4 + x_3x_4 + x_1x_3x_4 + x_2x_3x_4 + x_1x_2x_3x_4 + x_1x_2x_3x_4.$$

Now notice that when we plug  $x_1$ 's or  $x_2$ 's canalizing value into f', we get  $f'(1, x_2, x_3, x_4) = f'(x_1, 1, x_3, x_4) = 1 + cd + e$ . Since we want the output to be 0, we set e = cd + 1. Furthermore, since we have already guaranteed that  $x_1$  and  $x_2$  will be in the first layer with canalizing input 1, we can now set them equal to their noncanalizing input, 1, and proceed with the next layer, working with the much simpler function  $f'(0,0,x_3,x_4) = 1 + cd + dx_3 + cx_4 + x_3x_4$ .

We now want to make sure that  $x_4$  has canalizing input 0. (Recall that we made sure that  $x_3$  and  $x_4$  are in a different layer by using Corollary 3.6 in [4].) Recalling Corollary 5.7, we need to be able to factor out  $x_4$  from all nonconstant terms of  $f'(0,0,x_3,x_4)$  which requires us to set d=0. The resulting function is  $1+cx_4+x_3x_4$ . We can quickly check that, indeed, when  $x_4$  takes on its canalizing input, 0, the output is a constant, 1. Notice that although we did not explicitly prescribe the canalizing output of  $x_4$ , we made sure it is different from the canalizing output of Layer 1 or else  $x_4$  would not be in a different layer from  $x_1$  and  $x_2$ . The function  $1+cx_4+x_3x_4$  depends on a single parameter, c, whose value decides the canalizing input of  $x_3$  (which we kept undetermined). When  $x_3=0$ ,  $1+cx_4+x_3x_4$  evaluates to  $1+cx_4$ , meaning that if the canalizing input of  $x_3$  is 0, then we must set c=0; if  $x_3=1$ , the function evaluates to  $1+(c+1)x_4$ , i.e. if the canalizing input of  $x_3$  is 1, then we must set c=1. Since the canalizing input of  $x_3$  is to be left undetermined, we will keep c as a parameter and conclude that the one-parameter family of functions with the required canalizing structure is the set

$$\{1 + x_1 + x_2 + x_1x_2 + cx_4 + cx_1x_4 + cx_2x_4 + cx_1x_2x_4 + x_3x_4 + x_1x_3x_4 + x_2x_3x_4 + x_1x_2x_3x_4 \mid c \in \mathbb{F}_2\}.$$

## 6. Conclusion

In this paper we develop and implement two algorithms for finding the layer structure of a general Boolean function, and propose a third algorithm for the special case of nested canalizing functions. The implementation in Python requires the truth table format of the function while the Macaulay2 version requires a polynomial version of the function. We showed that the use of the polynomial version is advantageous when the function exhibits canalization; if the function is non-canalizing the run time of both algorithms increases very similarly at an exponential speed. The code is available at the GitHib repository <a href="https://github.com/ckadelka/BooleanCanalization">https://github.com/ckadelka/BooleanCanalization</a>.

We demonstrated two uses of layer structures of Boolean functions. In one application given the layer structure of a nested canalizing function, we showed how to find its disjunctive normal form, an NP-hard problem in the general case. In a second application we showed how to recover the complete family of functions that satisfy given partial layer information.
