# Formation of coalition structures as a non-cooperative game

Dmitry Levando, \*

#### Abstract

We study coalition structure formation with intra and inter-coalition externalities in the introduced family of nested non-cooperative simultaneous finite games. A non-cooperative game embeds a coalition structure formation mechanism, and has two outcomes: an allocation of players over coalitions and a payoff for every player. Coalition structures of a game are described by Young diagrams. They serve to enumerate coalition structures and allocations of players over them. For every coalition structure a player has a set of finite strategies. A player chooses a coalition structure and a strategy.

A (social) mechanism eliminates conflicts in individual choices and produces final coalition structures. Every final coalition structure is a non-cooperative game. Mixed equilibrium always exists and consists of a mixed strategy profile, payoffs and equilibrium coalition structures. We use a maximum coalition size to parametrize the family

## 1 Introduction

The paper was inspired by John Nash's "Equilibrium Points in n-person games, "(1950). This remarkably short, but highly influential note of only 5 paragraphs established an equilibrium concept and the proof of its existence without explicit specification of a final coalition structure. Prior to the Nash's paper, the generalization of the concept of equilibrium for coalition games provided by von Neumann for the case of two-players zero-sum game was done by portioning the players into two groups and regarding several players as a single player. However up to now, none of these competing approaches revealed expected progress in non-cooperative multiple group formation. ept for this game?

Since those times the game theory landscape is exposed for the notorious dichotomy: the cooperative game theory (CGT) versus the non-cooperative game theory (NGT). CGT deals with coalitions as elementary items with vague individual activity, NGT deals with strategic individual behavior; the theories are compared in Table 1. The research program of the current paper is in the third column: it targets goals of CGT by the tools of NGT. We study a non-cooperative construction of multiple coalitions from a noncooperative setup, with existence of intra and inter coalition externalities, caused by individual actions of players. The paper offers a generalization of the non-cooperative game from Nash (1950) to address the problem of multiple coalition formation absent in Nash (1953). We present a simultaneous, finite strategies, non-cooperative game, which has (mixed) equilibrium coalition structures. The difference of the approach with CGT is, that payoff are not "awarded to each player" (Serrano, 2020), but emerge from actions of all interacting players, even from those in other coalitions.

	CGT	NGT	this paper	
type of a mapping	set to point	vector to vector	tensor to tensor	
individual action	no	always	always	
individual motivation	no	always	always	
explicit allocation of players over coalitions	yes	no	yes	
inter-coalition externalities	sometimes	vague	explicit, from all players in other coalitions	
intra-coalition externalities	no	explicit, but within one implicit coalition	explicit, from players in the coalition	

Table 1: Comparison of game theories and the suggested research program

Importance of studying externalities between coalitions, a case impossible within the Nash Program, was mentioned by Maskin, (2011). Practice of social analysis and social design also requires studying non-cooperative and simultaneous formation of *multiple* coalitions, or coalition structures. This makes Nash program to construct one coalition from individual actions be too restrictive.

We will use the terms "coalition structure," or a "partition,"<sup>1</sup> to denote a collection of non-overlapping subsets from a set of players, which in a union

 $<sup>^1\</sup>mathrm{Existing}$  literature uses both terms.

make the original set. A group, or a coalition, is an element of a coalition structure or of a partition.

A partition induces two types of effects on a player's payoff. First, through actions of players of the same coalition, what producers *intra*-coalition externalities inside the coalition. Second, from the players who are outside the coalition, and produce *inter*-group externalities for other coalitions.

The paper of Nash (1953) suggested that cooperation should be studied using non-cooperative fundamentals with formation of only one group, this conjecture known nowadays as the Nash Program. His approach includes an "umpire"<sup>2</sup> that filters<sup>3</sup> actions of two players to let them reach an equilibrium.<sup>4</sup> Serrano (2004) commented this as: "the vexed issue of enforcement of outcomes cannot be overlooked, and one must assume either an enforcement by the designer or by other vehicles which will typically be left unspecified."Our approach exploits an outside mechanism, which serves to describe "social artifacts" of coalition formation.

The best analogy for a difference between the Nash Program and the current research is the difference between partial and general equilibrium analysis in economics. The former isolates one market ignoring cross-market interactions, the latter explicitly studies cross market interactions, along with activities at every specific market.

Formation and disintegration of every coalition depends on individual expectation of it's members from every feasible alternative to deviate, including iterative reasoning about expectations of all players, including those in other coalitions. In the suggested model a player has alternatives, described in terms of formed coalition structures and allocations of other players over them. And the Young diagrams serve to enumerate the appearing alterna-

<sup>&</sup>lt;sup>2</sup>Nash (1953): "The point of this discussion is that we must assume there is an adequate mechanism for forcing the players to stick to their threats and demands once made, for one to enforce the bargain once agreed. Thus, we need a sort of umpire who will enforce contracts or commitments."

<sup>&</sup>lt;sup>3</sup>i.e. checks that actions satisfy some rules, known as the axioms.

<sup>&</sup>lt;sup>4</sup>The paper has also restriction on construction of payoffs.

tives.

The mechanism of our model is the following. First, we impose a restriction on a maximum coalition size, and using Young diagrams construct all possible coalition partitions and all possible allocation of players. Second, for every possible allocation of players in every possible Young diagram we assign every player a finite strategy set and payoff. Every coalition structure becomes a playable non-cooperative game. Third, we let players choose a coalition partition and a strategy, from individual strategy set for this coalition structure. Fourth, an external social mechanism<sup>5</sup> transforms all individual choices into final coalition structures and individual strategies (they can differ from initial ones). The mechanism has an enforcement role to clear up conflicts of choices between players. Every resulting coalition structure is a playable non-cooperative game with allocation of players over coalitions. By topological reasons an equilibrium in mixed strategies always exists. Increasing the size of a coalition we obtain a family of embedded games, where each has coalition structures and an equilibrium, possibly in mixed strategies.

The model separates, those who make decisions, agents, and social artifacts, which exist beyond agents. The latter include social norms, customs and traditions, brute force and enforcements along with a variety of different transaction costs and imperfect information. Agents adjust individual interactive beliefs to those of other players, and operations of the mechanism. The mechanism is the link to the social design that we do not study here.

The contributions of this paper are: a construction of a non-cooperative simultaneous game with a coalition structure formation mechanism, and stability criteria, including one non-cooperative with self-enforcement for the strong Nash equilibrium (Aumann, 1990).

These results are different from the strong Nash equilibrium, coalitionproof equilibrium, multiple value approaches of the cooperative game theory. Existence of an equilibrium does not depend on a number of deviators or

<sup>&</sup>lt;sup>5</sup>we mean the sociological term "social artifacts."

their threats to deviate, but on individual actions of players. Non-cooperative game of Nash is a partial case of the suggested model.

The paper has the following plan. Section 2 presents an example approach, Section 3 presents the model with another example, Section 4 introduces stability criteria, then follow the Discussion and a Conclusion.

# 2 An example of a game of two players

The example generalizes the Prisoner's Dilemma for the case of explicit coalitions structures formation. It serves to demonstrate, how the model from the next section works. The example argues the popular statement, that Pareto efficient outcome of the Dilemma means cooperation as a membership in one coalition. Cooperation in the example is creation of positive externalities, but not necessarily a belonging to the same coalition or a group. To construct coalition partitions we demonstrate a simple mechanism, where the grand coalition can be formed only from unanimous choices.

### 2.1 Matrix game: generalization of the Prisoners' dilemma

There are 2 players, and they can form two types of coalition structures. Letter K is a size of a maximum coalition for any partition. If K = 1 then there is only one final partition,

$$\mathcal{P}(K=1) \equiv P_{separ} = \Big\{\{1\}, \{2\}\Big\},\$$

with one player in each coalition. For K = 2 there are two final partitions,

$$\mathcal{P}(K=2) = (P_{separ}, P_{joint}) = \left\{\{\{1\}, \{2\}\}, \{1, 2\}\right\},\$$

where  $P_{joint} = \{1, 2\}$  is the grand coalition. The partition structures  $\mathcal{P}(K = 1)$  and  $\mathcal{P}(K = 2)$  are nested,  $\mathcal{P}(K = 1) \subset \mathcal{P}(K = 2)$ .

Figure 1: An increase in available coalition structures with an increase in K.

We describe sizes of coalitions and allocations of players in coalitions with the Young diagrams. This allows us to partition a set of agents by sizes of coalitions.<sup>6</sup> Everywhere in this model a box contains exactly one player. A coalition is a horizontal sequence of boxes, what in terminology of the Young diagrams is a ribbon. Length of a ribbon is a size of the coalition. For K = 1 there are two ribbons length one, located vertically:  $\begin{array}{c} 1\\ 1 \end{array}$ .

For the maximum coalition size K = 2, there are two cases. The case K = 1 is still valid here, but another case is feasible, the grand coalition: a horizontal ribbon length two, see below, Figure 1.

For every coalition structure a player has a set of strategies. For K = 1player i, i = 1, 2, has two strategies: H(igh) and L(ow),  $S_i(K = 1) = (L_{i,K=1,P_{separ}}, H_{i,K=1,P_{separ}})$ . Set of strategies of both players for K = 1 is

$$S(K = 1) = \times_{i=1,2} \left( L_{i,K=1,P_{separ}}, H_{i,K=1,P_{separ}} \right) = \times_{i=1,2} S_i(K = 1).$$

For K = 2 the coalition structure  $P_{separ}$  and the relevant strategies are still feasible. Thus,  $L_{i,K=1,P_{separ}} = L_{i,K=2,P_{separ}}$  and  $H_{i,K=1,P_{separ}} = H_{i,K=2,P_{separ}}$ .

<sup>&</sup>lt;sup>6</sup>This section demonstrates the first property of the Young diagrams, used in the model. The second one is presented later.

But for K = 2 there are additional strategies from  $P_{joint}$ , so

$$S_i(K=2) = \left\{ \underbrace{L_{i,K=2,P_{separ}}, H_{i,K=2,P_{separ}}}_{S_i(K=1) \text{ for } P_{separ}}, \underbrace{L_{i,K=2,P_{joint}}, H_{i,K=2,P_{joint}}}_{+ \text{ strategies for } P_{joint}} \right\},$$

with a general element  $s_i$ .

The Young diagrams are implicit in the above construction of  $S_i(K = 2)$ , and we can write them explicitly:

$$S_i(K=2) = \left(S_i(P_{separ})\right) \cup \left(S_i(P_{joint})\right),$$

where  $S_i(P_k) = (L_{i,K=2,P_k}, H_{i,K=2,P_k}), k \in \{P_{separ}, P_{joint}\}$ . The last notation for  $S_i(K=2)$  will be used for generalization of the model. Then, a set of all strategies of both players for K=2 is

$$S(2) = S_1(K=2) \otimes S_2(K=2),$$

with a general element s. We use the  $\otimes$ -product to combine all cases of individual strategy sets. Similar to partitions, strategy sets are nested for different K,  $S(K = 1) \subset S(K = 2)$ .

Tables 2 collects all 16 outcomes of the game. Payoffs are constructed according to the Prisoner' Dilemma. One can observe the nested structure of the table for K = 1 and K = 2.

Now we compare payoffs and coalitions for two strategy profiles:  $s = (L_{1,K=2,P_{separ}}, L_{2,K=2,P_{separ}})$  and  $s = (L_{1,K=2,P_{joint}}, L_{2,K=2,P_{joint}})$ , which differ only in coalition structures. Both profiles lead to the non-equilibrium Paretoefficient outcomes. Traditional interpretation of such outcome is cooperation, with an assumption of a unanimous agreement to form a coalition. But here, the strategy profiles induce the same payoffs (0,0) for *different* coalition structures:  $\mathbf{P}_{separ} = \{\{1\}, \{2\}\}\}$  and  $\mathbf{P}_{joint} = \{1,2\}$ . Thus we can claim only that players generate positive externalities for each other, but not

Table 2: Payoff and coalition structures for the games: what players expect from a game. If players disagree, then outcomes are written separately. Pareto-efficient outcomes are underlined, equilibria are in the bold font.

necessarily stay in the same coalition.

#### 2.2 An example of a mechanism

There are cases, when players have conflicts in choosing coalition structures. For example, one player chooses to be alone,  $s_i = (L_{i,K=2,P_{separ}})$ , and another chooses to be together  $s_{-i} = (L_{-i,K=2,P_{joint}})$ , and then, the players disagree on final coalition structures, see cells of Table 2.<sup>7</sup> So, non-cooperative coalition structure formation requires a resolution for the conflict.<sup>8</sup>

We describe a mechanism to resolve the conflict as a mapping, and for example, take a unanimous mechanism for coalition structures formation. This means: the players can be together, only if both choose to be together, in other words only if both choose  $P_{joint} = \{1, 2\}$  and are interested in the following Young diagram 2 . In all other cases the players are allocated to different coalitions with the diagram 1.

<sup>&</sup>lt;sup>7</sup>Note, that due to nested property of strategy sets there is  $(L_{i,K=2,P_{separ}}) = (L_{i,K=1,P_{separ}}).$ 

<sup>&</sup>lt;sup>8</sup>a brief discussion of the approach is in Section 3.

Figure 2: The unanimous rule in terms of the Young diagrams

Given the mechanism, the players form the grand coalition, only for the strategy profiles  $\{(Z_{i,K=2,\mathbf{P}_{joint}}, \tilde{Z}_{-i,K=2,\mathbf{P}_{joint}})$ , such that  $Z, \tilde{Z} \in H, L, i = 1, 2\}$ . For all other strategy profiles only partition  $\mathbf{P}_{separ} = \{\{1\}, \{2\}\}\}$  is feasible for them, see Figure 2 and Tables 3, 4.

We can describe a mechanism as a mappings of Young diagrams. see Figure 2, where the first diagram is a choice of the first player, the second choice is one of the second, and at the right-hand part is a resulting coalition structure.

The mechanism for the example is in Table 4. The first column identifies a conflict in chosen coalition structures. The second is a mapping from strategies, chosen by players into strategies, after an application of the mechanism, in bold font. The last column is resulting coalition structure, in bold font. Equilibria strategies profiles are marked with a star, as usual.

A result of the mechanism is a coalition structure: an allocation of players over coalitions, and strategies of players for this coalition structure. A mechanism  $\mathcal{R}$  makes every emerging coalition structure be a playable noncooperative game. Table 4 is an explicit link between Tables 2 and 3 to construct coalition structures.

There are three ways to reach equilibrium in  $P_{separ}$ , but only one for  $P_{joint}$ . We can see, that in an equilibrium we need to assign probability 3/4 to  $\mathbf{H}_{i,K=2,P_{separ}}^*$ , and probability 1/4 to  $\mathbf{H}_{i,K=2,P_{joint}}^*$ . So, the coalition structure  $P_{separ}$  has equilibrium probability 3/4, the coalition structure  $P_{joint}$  has an equilibrium probability 1/4. However, probabilities for the initial strategies are different,  $Prob(S_{i,K=2,P_{separ}}) = Prob(S_{i,K=2,P_{joint}} = 2) = 1/2$ , and we can use them to construct probabilities for the mechanism. The mechanism operates in a predetermined way, it loads strategies of the players, transforms them following some rule, and generates an outcome.

Every equilibrium is inefficient, and players have negative inter- or intracoalition externalities, depending on which coalition structure is formed. One need to note, that for K = 1, there are no changes in construction of the game, and a standard non-cooperative game of Nash is valid. But the difference is that here players have explicit coalitions of size one.

## **3** Formal setup of the model

Nash (1950, 1951) suggested a non-cooperative game that consists of a set of players N, with a general element i, a set of individual finite strategies  $S_i, i \in N$ , and payoffs, defined as a mapping from a set of all strategies (possibly mixed) into a payoff profile of all players,  $S = \times_{i \in N} S_i \mapsto U = (U_i(S))_{i \in N} \subset \mathbb{R}^{\#N}, U_i < \infty, i \in N$ . An equilibrium in the game is a fixed point of the mapping  $S \mapsto S$ , with a relevant payoff profile  $U^* = (U_1^*, \ldots, U_N^*)$ .

For this paper we do not need assumptions of CGT, like a number of players, a number of deviators, threats from a deviating coalition, etc to construct an equilibrium. We construct a model as a non-cooperative game.

Table 4: The rule: the coalition structure  $\{1, 2\}$  can be formed only from unanimous agreement of both agents. The first column in an indicator of a conflict in choices of coalition structures, the second is a mapping of initial strategies of both players to the final strategies, the third is a final coalition. We use different fonts to discriminate strategies chosen from strategies formed by the mechanism. Equilibria strategy profiles are marked with '\*'.

Figure 3: Different Young diagrams with maximum coalition sizes K = 1, 2, 3, and without allocation of players.

#### 3.1 Coalition structures and strategies

Let integer  $N, 2 \leq N$ , be a set of players and a number of players. Let a game has an integer parameter  $K, 1 \leq K \leq N$ , a maximum coalition size. We will construct coalition structures with restrictions on a maximum coalition size using Young diagrams. They describe collections of boxes from N items with a restriction on the largest length K of a horizontal line of boxes (a ribbon in terms of the Young diagram literature). Exactly one player is assigned to one box, a ribbon is a coalition, and a length of a ribbon is a coalition size, all ribbons describe coalition sizes, that partition N. Let  $\mathcal{P}(\mathcal{K})$  be all possible Young diagrams from N elements with the restriction K:

$$\mathcal{P}(K) = \Big\{ P = \{g\} \colon g \subset N, \forall \bar{g}, \tilde{g} \colon \bar{g} \neq \tilde{g}, \cup g = N \colon \#g \leq K \Big\},\$$

where g is a coalition for a subset of players from N;  $\{g\}$  is a partition of N, or a coalition structure; different coalitions do not overlap, but together make the set of all players N. A size of any coalition does not exceed given K. The same in terms of the Young diagrams: g is a ribbon, length of a ribbon is no greater than K, a sum of all ribbons is N; all ribbons in one diagram make a partition of N into coalitions. Examples of Young diagrams  $\mathcal{P}(\mathcal{K})$  for three players and different Ks is in Figure 3:

An increase in K induces an inclusion of a Young diagram with a smaller K by one with a greater K, what forms the Young lattice, a partially ordered

Figure 4: Different allocations of player with the same structure of Young diagrams. Players may have different strategy sets in every case.

1	C		1	A		1	В	1	

 $\operatorname{set}$ :

$$\mathcal{P}(K=1) \subset \ldots \subset \mathcal{P}(K) \subset \ldots \subset \mathcal{P}(K=N).$$

The bigger is K, the more coalition structures are involved into activity. We have seen this in the example above. A power of  $\mathcal{P}(K)$  is a Bell number  $B_K$  with a recurrence relation:  $B_{K+1} = \sum_{k=0}^{K} \binom{K}{k} B_k$ . Number of all possible allocations of players for all coalition structures is  $A_N^{B_K}$ .

Allocations of players over boxes is the way to study externalities: a change in allocations is able to change externalities. Thus we will discriminate Young diagrams at Figure 4: they differ only by allocation of players over boxes, although they have similarities: one coalition size one, and one coalition size two. For each of these cases a player may have different strategy sets.

Let P(K) be a diagram from  $\mathcal{P}(K)$ , with fixed sizes of coalitions. Let  $\{P(K)\}$  be all possible allocations of players in P(K). A player has a finite<sup>9</sup> strategy set  $S_i(P, K)$  for every coalition structure P in  $\{P(K)\}$ . Strategies may differ for different allocations of players, although a Young diagram is the same, see Figure 4. A set of all strategies of i is

$$S_i(K) = \Big\{ S_i(P, K) \colon i \in N, P \subset \{P(K)\}, P(K) \subset \mathcal{P}(K) \Big\},\$$

<sup>&</sup>lt;sup>9</sup>Finite strategies are chosen as they used in Nash (1950).

or

$$S_i(K) = \bigcup_{P(K) \in \mathcal{P}(K)} \Big( \bigcup_{P \in \{P(K)\}} S_i(P, K) \Big),$$

where  $S_i(P, K)$  is a set of finite strategies of i with the maximum coalition size K in the Young diagram P;  $\{P(K)\}$  is a set of all allocations of players for a coalition partition P(K) with fixed sizes of coalitions,  $P(K) \subset \mathcal{P}(K)$ . If possible, we will write  $S_i(P)$  for a particular P, omitting maximum coalition size K.

Let a set of all strategies of all players be  $S(K) = \bigotimes_{i \in N} S_i(K)$ , a tensor product of individual strategy sets of all players, where K is a maximum coalition size. Individual strategy sets for different K are nested:

$$S_i(K=1) \subset \ldots \subset S_i(K) \subset \ldots \subset S_i(K=N),$$

what we have observed in the example above.

A strategy set of all players is constructed as it was in the example of the previous section:

$$S(K) = \bigcup_{P(K) \in \mathcal{P}(K)} \Big( \bigcup_{P \in \{P(K)\}} \Big( \otimes_{i \in N} S_i(P, K) \Big) \Big).$$

So far we have expanded the strategies setup of a standard non-cooperative game to a case, with coalition structures. ction.

## 3.2 Mechanism

Coalition structures chosen by different players can be incompatible, we have seen this above. In practice, such conflicts are resolved by social norms, customs and traditions, brute force and enforcements along with a variety of different transaction costs and imperfect information. These social artifacts we will address as a social mechanism. Individual impact of a mechanism is that an individual choice of a coalition structure may not come true.

A mechanism determines final alternatives for each player, where one

can deviate. This makes an individual choice be bounded, bounded by the environment. The alternatives are enumerated by final coalition structures and allocations of players over them.

A social mechanism joins a strategy profile from N players and transforms it into one final coalition structure, and a relevant strategy profile for this coalition structure. Let  $\mathcal{R}(K)$  be a mechanism, which transforms every strategy profile  $(s_1, \ldots, s_i, \ldots, s_N), s_i \in S_i(K), i \in N$ , into some strategy set of a mechanism:

$$\mathbf{S}(K) = \bigcup_{\mathbf{P}(K)} \Big( \bigcup_{\mathbf{P} \in \{\mathbf{P}(K)\}} \otimes_{i \in N} S_i(\mathbf{P}) \Big),$$

where a final coalition structure  $\mathbf{P}$  serves as an index.<sup>10</sup> Let  $\mathbf{P}(K)$  be all coalition structures, supported by  $\mathcal{R}(K)$ , and let  $\{\mathbf{P}(K)\}$  be the implementable by the mechanism coalition structures, which differ by allocation of players, and  $S_i(P)$  is a set of strategies of *i* for a coalition structure *P*. In the example below, from three diagrams in Figure 4, a mechanism supports formation of only one.

We assume, that a strategy profile in S(K) is transformed in a strategy profile of  $\mathbf{S}(K)$ , but not vice verse. We continue the example of three players, let K = 2, and final coalition structures are:  $\begin{array}{c|c} 1 & A \\ 1 & B \\ 1 & C \end{array}$  and  $\begin{array}{c|c} 2 & C & A \\ 1 & B \\ 1 & C \end{array}$ , see

Table 5, where  $\mathbf{S}_i(\mathbf{P}, K = 2)$  is a strategy set of *i* after application of the

<sup>&</sup>lt;sup>10</sup>This means, a Young diagram fixes sizes of coalitions, and we need to list allocations of all players over relevant coalitions.

mechanism. Note, that even  $\begin{pmatrix} 2 & A \\ 1 & B \end{pmatrix}$  is formed, there is  $S_i \begin{pmatrix} 2 & A \\ 1 & B \end{pmatrix}, K = 2 \neq \mathbf{S}_i \begin{pmatrix} 2 & A \\ 1 & B \end{pmatrix}, K = 2 \end{pmatrix}$ .

For this example we do not need details, how to construct  $\mathbf{S}_i(P)$ .

**Definition 1.** A coalition structure formation mechanism  $\mathcal{R}(K)$  is a mapping such that:

- 1. Domain of  $\mathcal{R}(K)$  is a set of all strategy profiles, S(K).
- 2. A range of  $\mathcal{R}(K)$  is
  - a set of final (implementable) coalition partitions P(K) ⊂ P(K), with a general element P,
  - a set of strategies S(P(K), K) with a general element  $s = (s_1, \ldots, s_N)$ ,  $S(K) \subset S(K)$ .

The mechanism  $\mathcal{R}(K)$  reframes S(K) into implementable, and non-implementable coalition structures, along with relevant sets of strategies for implementable:  $\mathbf{S}(K) = \bigcup_{\mathbf{P}(K)} \left( \bigcup_{\mathbf{P} \in \{\mathbf{P}(K)\}} \mathbf{S}(\mathbf{P}, K) \right)$ , where  $\mathbf{S}(\mathbf{P}, K) = \times_{i \in N} S_i(\mathbf{P}, K)$  is set of strategies of all players for a coalition structure P. Two different final coalition structures,  $\mathbf{\bar{P}}$  and  $\mathbf{\tilde{P}}, \mathbf{\bar{P}} \neq \mathbf{\tilde{P}}$ , have different coalition structure strategy sets  $\mathbf{S}(\mathbf{\bar{P}}, K) \cap \mathbf{S}(\mathbf{\tilde{P}}, K) = \emptyset$ .

Formally the same:

Table 5: Example of a mechanism to form two coalition structures from three agents A, B, C and K = 2. Strategy set of i in a final coalition structure **P** is  $\mathbf{S}_i(\mathbf{P}, K = 2)$ . The mechanism of the example supports formation of only two coalition structures. Note, that there are three coalition structures of the same type , but we do not rank them; this will complicate the exposition, but will not change the idea. There are mixed strategies, which will be used for expected utility construction further. Every time only one coalition structure can be realized.

Initial Young diagrams $\mathcal{P}(K=2)$	1 1 1	2 1		
Possible allocations of players $P \in$ $\{P(K = 2)\}$	$ \begin{array}{c c} 1 & A \\ 1 & B \\ 1 & C \end{array} $	$ \begin{array}{c c} 2 & A & B \\ 1 & C \\ \end{array} $	$ \begin{array}{c c} 2 & C & A \\ 1 & B \\ \end{array} $	$ \begin{array}{c cc} 2 & B & C \\ 1 & A \\ \end{array} $
Coalition structures implementable by $\mathcal{R}(K = 2)$ , $\mathbf{P} \in \{\mathbf{P}(K)\}.$	$\mathbf{P} = \begin{array}{ccc} 1 & A \\ 1 & B \\ 1 & C \end{array}$	-	$\mathbf{P} = \begin{array}{c} 2 & \overline{C} & A \\ 1 & B \end{array}$	-
Coalition structure strategies set $\mathbf{S}(K=2)$ $= \cup_{\mathbf{P}} \mathbf{S}_{\mathbf{P}}$	$\begin{array}{c} \mathbf{S}_{\mathbf{P}} = \\ \times_{i \in \\ \{A,B,C\}} \\ \mathbf{S}_{i}(\mathbf{P},K=2) \end{array}$	-	$\mathbf{S}_{\mathbf{P}} = \\ \times_{i \in \\ \{A,B,C\}} \\ \mathbf{S}_{i}(\mathbf{P}, K = 2)$	-
Individual mixed strategies for a coalition structure, $\sum_{\mathbf{P}} \Sigma_i(\mathbf{P}, K) = 1$	$\left(\Sigma_i(\mathbf{P})\right)_{i\in A,B,C}$	-	$\left(\Sigma_i(\mathbf{P})\right)_{i\in A,B,C}$	-
Individual payoffs	$\left(U_i(\mathbf{P},\mathbf{S}_i)\right)_{i\in\{A,B,C\}}$	-	$\left(U_i(\mathbf{P},\mathbf{S}_i)\right)_{i\in\{A,B,C\}}$	-

$$\mathcal{R}(K) \colon S(K) = \bigotimes_{i \in N} S_i(K) \mapsto : \begin{cases} \mathbf{S}(K) \subseteq S(K), \\ \mathbf{S}(K) = \bigcup_{\mathbf{P}(K)} \left( \bigcup_{\mathbf{P} \in \{\mathbf{P}(K)\}} \mathbf{S}(\mathbf{P}, K) \right), \\ \forall \bar{\mathbf{P}}, \tilde{\mathbf{P}} \in \{\mathbf{P}(K)\} \subseteq \mathbf{P}(K), \bar{\mathbf{P}} \neq \tilde{\mathbf{P}} \Rightarrow \mathbf{S}(\bar{P}, K) \cap \mathbf{S}(\tilde{P}, K) = \{\emptyset \\ \forall s = (s_1, \dots, s_N) \in S(K) \\ \exists \mathbf{s} = (\mathbf{s}_1, \dots, \mathbf{s}_N) \in \mathbf{S}(K) \\ \text{such that } \exists \mathbf{P} \colon \mathbf{s} \in \mathbf{S}(\mathbf{P}, K), \end{cases}$$

We assume, that even if resulting  $\mathbf{S}(\bar{\mathbf{P}}, K)$  and  $\mathbf{S}(\tilde{\mathbf{P}}, K)$  are numerically identical, but correspond to different coalition structures,  $\bar{\mathbf{P}} \neq \tilde{\mathbf{P}}$ , we consider them as different,  $\mathbf{S}(\bar{\mathbf{P}}, K) \neq \mathbf{S}(\tilde{\mathbf{P}}, K)$ . We also assume that  $\mathcal{R}(K)$ is a predetermined mechanism, it does not randomize, and it is known for everybody.

**Definition 2.** The family of mechanisms with

$$\mathscr{R} = \mathcal{R}(K = 1) \subset \ldots \subset \mathcal{R}(K) \subset \ldots \subset \mathcal{R}(K = N),$$

is a nested family of rules.

This means just consistency in formation of coalition structures, if maximum coalition size increases. It is not a necessary restriction, but in many cases it may be desirable.

One may think about the game as a two-stage game: first players move, then a mechanism. But as far a mechanism is known for the players, this is a non-necessary complication.

## 3.3 Payoffs

The next step is to construct coalition partition specific payoffs. For every final coalition structure  $\mathbf{P}$  player *i* has a payoff function

$$U_i(\mathbf{P}, K) \colon \mathbf{S}(\mathbf{P}, K) \to \mathbb{R}_+,$$

such that every  $U_i(\mathbf{P}, K)$  is bounded,  $U_i(\mathbf{P}, K) < \infty$ , and  $\mathbf{S}(\mathbf{P}, K)$  is a set of feasible strategies of all players for  $\mathbf{P}$ . We construct payoffs only on coalition structures implementable by a mechanism.

Every coalition structure has an allocation of players, every player has a set of strategies for this coalition structure and a payoff. Thus every coalition structure is a non-cooperative game, and it is a playable game. Each time only one such game is played. If a game, or a realization of a coalition structure, is played, all players are exposed for intra and inter-coalition externalities, which depend on allocation of players and strategies of the players in this coalition structure.

Let

$$\mathcal{U}_i(K) = \left\{ U_i(\mathbf{P}, K) \colon \mathbf{S}(\mathbf{P}, K) \subset \mathbf{S}(K), \mathbf{P} \in \{\mathbf{P}(K)\} \subset \mathbf{P}(K) \subseteq \mathcal{P}(K) \mid \mathcal{R}(K) \right\}$$

be a set of all payoffs of i for all implementable coalition structures with all possible allocations of the players.

An increase in K increases the number of possible partitions and the set of strategies. Hence we obtain a nested family of individual payoff functions:

$$\mathcal{U}_i(K=1) \subset \ldots \subset \mathcal{U}_i(K) \subset \ldots \subset \mathcal{U}_i(K=N).$$

We have observed the nested property of payoffs in the matrix game above.

#### 3.3.1 A game

**Definition 3** (a simultaneous non-cooperative coalition structure formation game). A non-cooperative game for coalition structure formation consists of two parts, an environment and properties of agents:

$$\Gamma(K) = \left\langle \underbrace{\left\{ K, \mathcal{P}(K), \mathcal{R}(K) \right\}}_{environment}, \underbrace{\left( N, S_i(K), \mathcal{U}_i(K) \right)_{i \in N}}_{properties \ of \ agents} \right\rangle,$$

#### where

- K is a maximum coalition size,
- $\mathcal{P}(K)$  is a set of Young diagrams for N players,
- $\mathcal{R}(K)$  is a coalition structure formation mechanism,
- N is a set of agents with a general element  $i, N \ge K$ ,
- $S_i(K)$  is a set of individual strategies of i,
- \$\mathcal{U}\_i(\mathbf{P}, K)\$ is a set of payoffs, defined over coalition partitions, supplied by the mechanism \$\mathcal{R}\$,

such that:

$$\left(\mathcal{P}(K), S(K)\right) \stackrel{\mathcal{R}(K)}{\to} \left\{ \left(\boldsymbol{P}, \boldsymbol{S}(\boldsymbol{P}, K)\right) \colon \boldsymbol{P} \in \{\boldsymbol{P}(\boldsymbol{K})\} \subset \mathbf{P}(K) \right\} \to \left\{ \left(\boldsymbol{P}, \mathcal{U}_{i}(\boldsymbol{P}, K)\right)_{\substack{i \in N \\ \boldsymbol{P} \in \{\boldsymbol{P}(\boldsymbol{K})\} \subset \mathbf{P}(K)}} \right\}.$$

For K = 1 we obtain the traditional non-cooperative game of Nash:  $S = \times_{i \in N} S_i \rightarrow \left( U_i(S, K = 1) \right)_{i \in N}$ , but with explicit allocations of players in coalitions size 1.

Varying K, a maximum coalition size, we obtain a family of the nested games with the trivially proved proposition.

**Proposition 1** (family of games). A family of the games:

$$\mathcal{G} = \Gamma(K = 1) \subset \ldots \subset \Gamma(K) \subset \ldots \subset \Gamma(K = N).$$

is nested for a nested family of mechanisms,

$$\mathscr{R} = \mathcal{R}(K = 1) \subset \ldots \subset \mathcal{R}(K) \subset \ldots \subset \mathcal{R}(K = N).$$

A game of finite strategies may have no pure strategies equilibrium. Further we assume that the mechanism  $\mathcal{R}(K)$  does not randomize.

#### 3.4 Mixed strategies

We can define mixed strategies over initial strategy set  $(S_1, \ldots, S_N)$  of all players, or a strategy set  $(\mathbf{S}_1, \ldots, \mathbf{S}_N)$  implementable by the mechanism. We follow the second way, see Table 5. Let  $\Sigma_i(K)$  be a set of all mixed strategies of *i*, defined over  $\mathbf{S}_i(K)$ :

$$\Sigma_i(K) = \Big\{ \sigma_i(K) \colon \int_{\substack{\mathbf{s}_i(\mathbf{P},K)\\\forall \mathbf{P}}} d\sigma_i(K) = 1 \Big\},$$

with a general element  $\sigma_i(K)$ , where,  $\mathbf{S}_i(\mathbf{P}, K)$  is a strategy set of *i* implementable by  $\mathcal{R}(K)$  for a coalition structure  $\mathbf{P}$ . Normalizing integral is the Lebegue integral defined over all implementable coalition structures  $\mathbf{P}$ . The set  $\Sigma_i(K)$  is convex by properties of probability spaces. For simplicity, we do not use bold font for mixed strategies, although they are defined over strategy sets after application of the mechanism  $\mathcal{R}(K)$ .

We have observed mixed strategies in the example in Table 3, where in equilibrium the mechanism randomizes between  $\mathbf{H}_i(K = 2, P_{separ})$  and  $\mathbf{H}_i(K = 2, P_{joint})$ , or players equally randomizing between  $H_i(K = 2, P_{separ})$ and  $H_i(K = 2, P_{joint})$ .

Expected utility of i is defined as usual:

$$EU_i^{\Gamma(K)}\Big(\sigma_i(K), \sigma_{-i}(K)\Big) = \int_{\mathbf{S}(K) = \bigcup \mathbf{S}(\mathbf{P}, K)} U_i(\mathbf{s}_i, \mathbf{s}_{-i}) d\sigma_i(K) d\sigma_{-i}(K).$$

Expected utility is constructed in the standard way: a weighted payoff for every possible outcome of the game, while an outcome includes a coalition structure.

At the moment we have all components to define an equilibrium in mixed strategies with formation of coalition partitions.

**Definition 4** (an equilibrium). A mixed strategies profile  $\sigma^*(K) = (\sigma_i^*(K))_{i \in N}$ is an equilibrium strategy profile for a game  $\Gamma(K)$  if for every  $\sigma_i(K) \neq \sigma_i^*(K)$  the following inequality for every player i from N holds true:

$$EU_i^{\Gamma(K)}\Big(\sigma_i^*(K), \sigma_{-i}^*(K)\Big) \ge EU_i^{\Gamma(K)}\Big(\sigma_i(K), \sigma_{-i}^*(K)\Big).$$

**Proposition 2.** An equilibrium in mixed strategies always exists.

A proof follows from topological considerations of convexity of probability spaces defined over finite tensors spaces.

Equilibrium in the game  $\Gamma(K)$  is defined in the standard way, it is just an expansion of Nash theorem. The existence result is different from those of CGT approach, where an equilibrium may not exist. There is no bargaining, and there is complete information about fundamentals of the game. Another outcome of the model is that there is no need to introduce additional properties of games, like axioms on a system of payoffs, super-additivity, weights, etc. The goal of cooperative game theory is achieved within a noncooperative framework. Equilibrium existence result can be generalized for the whole family of games.

**Theorem 1.** The family of games  $\mathcal{G} = \{\Gamma(K), K = 1, 2, ..., N\}$  has an equilibrium in mixed strategies,

$$\sigma^*(\mathcal{G}) = \left(\sigma^*(K=1), \dots, \sigma^*(K=N)\right)$$

This result is obvious, and it expands the classical Nash theorem. Actually it says nothing about inheritance of properties in the set of mechanisms  $\mathcal{R}(K), K = 1, N$ . An equilibrium in the game can also be characterized by equilibrium partitions.

**Definition 5** (equilibrium coalition structures or partitions). A set of partitions  $\{\mathbf{P}^*\}(K), \{\mathbf{P}^*\}(K) \subset \mathbf{P}(K), \text{ of a game } \Gamma(K), \text{ is a set of equi$ librium (mixed) partitions, if it is induced by an equilibrium strategy profile $<math>\sigma^*(K) = (\sigma_i^*(K))_{i \in N}$ . We need to note, that even if a coalition structure is implementable by  $\mathcal{R}(K)$ , that does not imply, that every implementable coalition structure is in an equilibrium. We also assume that a mechanism is free, and there are no costs to form coalition structures. These complications require introduction of resources into the game.

## 4 Stability

A desirability of an individual deviation depends on individual expectation from every feasible alternative to deviate. Here, a player has alternatives, described in terms of formed coalition structures and allocations of other players over them. And the Young diagrams serve to enumerate the appearing alternatives. This resolves the problem of recurrent formation of coalitions of deviators themselves implicitly hidden in approaches based on threats and inside/outside deviators.

There are many ways to think about alternatives and induced stability within the framework of the model. We limit the scope only to stability in terms of a maximum coalition size K, what means that we are working with a framework of the whole family of games  $\mathcal{G}$ . Every criterion induces corresponding stable partition structures, which are omitted here. Stability is understood in terms of mixed strategies. We introduce local, global stability criteria, and a criterion for the strong Nash equilibrium.

**Definition 6** (local non-cooperative coalition structure stability criterion). The family of games  $\mathcal{G} = \{\Gamma(K), K = 1, 2, ..., N\}$  has a mixed strategies profile  $\sigma^*(K) = (\sigma_i^*(K))_{i \in N}$  as a locally stable profile if for every game  $\Gamma(K) \in \mathcal{G}$  and  $\sigma_i(K) \neq \sigma_i^*(K)$ ,  $i \in N$ , there is

$$EU_i^{\Gamma(K)}\left(\sigma_i^*(K), \sigma_{-i}^*(K)\right) \ge EU_i^{\Gamma(K_1)}\left(\sigma_i(K_1), \sigma_{-i}^*(K_1)\right),$$

and  $K_1 \in \{\max 0, K - 1, \min\{K + 1, N\}\}.$ 

This means that one unit deviation in coalition size can not deteriorate expected payoffs. A locally stable mixed strategy equilibrium profile induces corresponding locally stable coalition structures.

The global criterion is constructed in the natural way: there is only one K, when a family of games induces maximum expected payoffs for each player.

**Definition 7** (global non-cooperative coalition structure stability criterion). The family of games  $\mathcal{G} = \{\Gamma(K), K = 1, 2, ..., N\}$  has a mixed strategies profile  $\sigma^*(K) = (\sigma_i^*(K))_{i \in N}$  as a globally stable profile if for every game  $\Gamma(K) \in \mathcal{G}$ , for every  $\sigma_i(K) \neq \sigma_i^*(K)$ , and every maximum coalition size  $K_1$ different from  $K, K_1 \neq K$  there is:

$$EU_i^{\Gamma(K)}\left(\sigma_i^*(K), \sigma_{-i}^*(K)\right) \ge EU_i^{\Gamma(K_1)}\left(\sigma_i(K_1), \sigma_{-i}^*(K_1)\right),$$

 $i \in N$ .

And finally we can reconsider the strong Nash equilibrium in terms of stability of the suggested non-cooperative game. The strong Nash equilibrium has a restriction on the coalition size, it must have the maximum size. This means the same, as "all agents in one coalition," but allows to make more.

**Definition 8** (non-cooperative strong Nash equilibrium criterion). The family of games  $\mathcal{G} = \{\Gamma(K), K = 1, 2, ..., N\}$  has a mixed strategies profile  $\sigma^*(K) = (\sigma_i^*(K))_{i \in N}$  as a strong mixed strategy profile if for every game  $\Gamma(K) \in \mathcal{G}$ , for every  $\sigma_i(K) \neq \sigma_i^*(K)$ ,  $i \in N$ , there is:

- $EU_i^{\Gamma(K)} \Big( \sigma_i^*(K), \sigma_{-i}^*(K) \Big) \ge EU_i^{\Gamma(K_1)} \Big( \sigma_i(K_1), \sigma_{-i}^*(K_1) \Big),$
- $\forall K_1 \neq K, K = N,$
- and only the grand coalition is in an equilibrium,  $\{P(K = N)\} = \{N\}$ .

This criterion supports a non-cooperative criterion for the strong Nash equilibrium. Aumann (1990) claimed in the title that "Nash equilibria are

not self-enforcing." We provide a non-cooperative criterion, when the grand coalition is self-enforcing.

One can take this criterion as "the noncooperative implementation of the ... cooperative solution" (Serrano, 2021), in the meaning of a cooperation for everybody. The criterion induces the same result, as the strong Nash equilibrium, but it explicitly deals with individual actions, not with inside or outside deviators.

## 5 Discussion

The justification of a non-cooperative game approach applied to studying coalition formation, comes from Maskin (2011) and a remark of Serrano (2014), that for studying coalition formation "it may be worth to use strategic-form games, as proposed in the Nash program."

The recent survey of advances in solutions for the Nash Program is Serrano (2021), but it has a limited attention to non-cooperative toolkit for the problem.

Insufficiency of cooperative game theory to study coalitions and coalition structures was earlier reported by many authors. Maskin (2011) wrote that "features of cooperative theory are problematic because most applications of game theory to economics involve settings in which externalities are important, Pareto inefficiency arises, and the grand coalition does not form." Myerson (p.370, 1991) noted that "we need some model of cooperative behavior that does not abandon the individual decision-theoretic foundations of game theory." Thus there is a demand for a specially designed non-cooperative game to study coalition structures formation along with an adequate equilibrium concept for this game.<sup>11</sup> The research program in Table

<sup>&</sup>lt;sup>11</sup>Serrano (2021), describes the challenge of the Nash Program in the following way: "The initial interpretation of the Nash program, as formulated in Nash (1953), was to describe the strategic rules of negotiation underlying an axiomatic solution. According to this view, the primitive is a given axiomatic solution and the goal is to enhance its

1 satisfies these requirements.

There is a voluminous literature on the topic, the short list of authors is far from complete: Aumann, Hart, Holt, Maschler, Maskin, Myerson, Peleg, Roth, Serrano, Shapley, Schmeidler, Trockel, Weber, Winter, Wooders and many others. Serrano (2021) presents statistics of papers on the topic.

Much work has been done, taking a "threat" as a basic concept for coalition formation analysis, as it was initially suggested by Nash (1953). Consider a strategy profile from a subset of players. Let this profile be a threat to someone, beyond this subset. Threatening and deviating players may produce externalities for each other (and negative externalities not excluding!). Literature studies credibility of the threat based on the dilemma "to join or not." In this paper players have much wider menu of actions.

Also, the deviators may produce gains for someone in other coalitions, or they can join other coalitions, and produce other externalities for the coalition of an origin, and induce a chain of further deviations. And finally the problem becomes recurrent and intricate.

Blocking approach is another form of a threat, for example Aumann, Dreze, (1974), who studied cooperative approach to coalition structures. The weak point here is the same as with a threat. Those who block, can form many blocking coalitions, which can even neutralize mutual threat to the original coalition, and the story of a non-cooperative coalition structure construction repeats. Actually, further investigation of these kind of reasonings has led to this paper.

Demange (2017) provides a survey on group formation from coalition deviation. All decisions in the current model are made individually, before a coalition structure is formed. Mobility between groups, individually based and rational, may happen in the presented model in mixed strategies cases. Possibilities for new groups to emerge depend on strategies and intra and

understanding, by obtaining it as a result of a completely different approach." The model demonstrates, that coalitions can be formed as a non-cooperative one stage game with complete information. One can extend the game in time in the usual way.

inter coalition externalities.

Serrano (2021) provides a survey for "bargaining design," what intrinsically deals with imperfect information and games in extended form. Our model can be developed as a game in extended form too, with multiple coalitions in an equilibrium at every stage. We expect that all the existing machinery of non-cooperative games can be applied for the presented toolkit.

The difference of the research agenda of this paper with the Nash program (Serrano 2004, 2021) is the attention to non-cooperative formation of complex coalition structures, different from one grand coalition. The best analogy for the difference is the difference between partial equilibrium at one market and general equilibrium for many markets. The former isolates a market ignoring cross-market interactions, the latter explicitly studies cross market interactions. This analogy is similar to intra and inter coalition externalities.

The constructed model satisfies the goals setup in Table 1. The finite non-cooperative game allows to study what can be a cooperative behavior, when the individuals "rationally further their individual interests" (Olson, 2009).

This paper has two contributions in comparison to the original paper of Nash: a construction of a family of non-cooperative games with an embedding coalition structure formation mechanism, and stability criteria. The noncooperative game suggested by Nash is a partial case for these games.

Every game in a family has an equilibrium, may be in mixed strategies. This differs from results of cooperative game theory, where games may have no equilibrium, like games with empty cores, etc.

The introduced equilibrium concept differs from the strong Nash, coalitionproof (Bernheim, Peleg, Whinston, 1987) and k-equilibrium concepts. The differences are: non-cooperative approach to coalition formation, an explicit allocation of payoffs and a combined presence of intra- and inter- coalition (or group) externalities. The list of differences is not complete and can be specified for any relevant paper.

Differences from the core approach of Aumann (1960) and from voluminous cooperative games literature are obvious: a presence of externalities, no restrictions that only one group deviates, no restrictions on the direction of a deviation (inside or outside), a construction of individual payoffs from a strategy profile of all players, an equilibrium always exists. The approach allows to study coalition structures, which differ from the grand coalition as in Shapley value. Finally the introduced concepts enables to offer a set of non-cooperative stability criteria, what is not done in other literature.

The suggested approach is different in a role for a central planner offered by Nash, who "argued that cooperative actions are the result of some process of bargaining" Myerson (p.370, 1991). There are two possible understanding for "cooperation" in this paper. First, allocation in one coalition. second. creating positive externalities, even being in different coalitions.

Guido, Robbett and Romaniuc (2019) survey cooperation for group formation for social dilemma games. They claim that a cooperation more likely to emerge endogenously for "like-minded partners," than in "exogenously formed groups." The presented model can be used to respond for this kind of empirical research.

## 6 Conclusion

The paper suggests a new family of simultaneous, non-cooperative, finite games with the properties: in an equilibrium players can stay in different coalitions and be exposed for intra- and inter- coalition externalities. The model separates, agents, and a social mechanism to construct coalition structures. The setup of the research program in Table 1 is fulfilled: the constructed game satisfies the required features, Using the model one can study coalition structure stability in terms of non-cooperative games, with the developed machinery of non-cooperative games. The approach can be applied and further developed for many areas of social sciences.
