Abstract

This paper presents fast first-order methods for solving linear programs (LP) approximately. We adapt online linear programming algorithms to offline LPs and obtain algorithms that avoid any matrix multiplication. We also introduce a variable-duplication technique that copies each variable K times and reduces optimality gap and constraint violation by a factor of \sqrt{K} . Furthermore, we show how online algorithms can be effectively integrated into sifting, a column generation scheme for large-scale LPs. Numerical experiments demonstrate that our methods can serve as either an approximate direct solver, or an initialization subroutine for exact LP solving.

1 Introduction

First-order methods for large-scale linear programs are receiving increasing attention as problem sizes grow beyond the capacity of traditional simplex [12] and interior point methods [38]. When a low or moderate-accuracy solution is required, first-order methods often outperform simplex and interior point solvers as they only involve matrix-vector multiplication and are free of matrix decomposition. A recent practice [3] demonstrates that fine-tuned first-order methods are also capable of solving LPs of millions of variables to high accuracy. However, as [32] suggests, when the problem size further reaches trillions of variables or more, even storing the problem data in memory becomes prohibitive, not to mention performing matrix-vector multiplications. As a result, most first-order methods either resort to distributed architecture [7, 17] or rely on sparsity [32].

In contrast to the LPs discussed above, which we call “offline” LPs, there is another type of LPs called “online” LPs [1, 25]. They come from revenue management [37] and model the situation of making sequential decisions on the customer orders that are described by LP columns. Due to online nature of the problem, generally an algorithm

*Email: gwz@163.shufe.edu.cn

†Email: ge.dongdong@mail.shufe.edu.cn

§Email: yyeye@stanford.edu

for online LPs **1**). only accesses one column at a time; **2**). makes decisions instantly. Through making decisions, the behavior of online algorithms gets refined and improved, which is why they are also known as “online learning”.

In the line of online LP literature, state-of-the-art online LP algorithms build on offline LPs as a subroutine [22, 25, 29], and it seems that *online LP unilaterally benefits from offline LP*. It is therefore natural to ask:

Does online LP benefit offline LP?

In this paper, we answer this question positively by exploiting a recent research direction on fast online algorithms [26, 6]. Unlike the offline LP-based online algorithms, these methods build on stochastic first-order oracles, make decisions and refinements in linear time, and simultaneously estimate primal and dual solutions in a single pass through problem data. Also, they achieve provable optimality guarantees under minimal assumptions on the problem data. All these motivate us to study if these cheap methods help offline LP solving. In particular, we investigate two popular online algorithms: explicit subgradient [26] and implicit proximal point [23].

First-order Methods for Linear Programming First-order methods for LP are recently developed and presented as optimization softwares. Some successful attempts include ABIP [27, 14], COSMO [18], ECLIPSE [7], PDLP [3] and SCS [34]. The above listed algorithms target large-scale LPs, and the major computation bottleneck lies in matrix-vector multiplication (and sometimes one-time matrix factorization). Compared to the aforementioned works, our work is more in line with (block) subgradient-based or coordinate descent-based approaches [32, 33]. What differentiates our method is that these two methods have to update primal and dual variables sequentially, while our proposed method simultaneously updates both solutions.

Simple and Fast Online LP Simple and fast online LP algorithm is recently proposed and analyzed by [26]. It exploits the finite-sum structure of the LP dual problem and runs stochastic subgradient in the dual space, while simultaneously estimating the primal solution by optimality condition. Under mild assumptions, given an LP of m constraints and n variables, the authors show that their algorithm achieves $\mathcal{O}(\sqrt{n} \log n + m\sqrt{n})$ constraint violation and $\mathcal{O}(m\sqrt{n})$ regret (optimality gap) under the random permutation model that we exploit in this paper. Concurrent works [5, 6] further generalize the results to nonlinear objective using a mirror descent framework and achieve $\mathcal{O}(m + \sqrt{mn})$ regret with no constraint violation. We also note that [6] covers an adversarial setting that is more general than random permutation. However, the regret bound is too pessimistic to be applied to LP, and therefore we exploit the setting of [26].

Contributions In this paper, we show that online LP algorithms can benefit offline LP both theoretically and practically. More specifically,

- We investigate how two online learning algorithms perform when they are used to solve offline LPs. These two methods, known as explicit subgradient and implicit proximal point in the online learning literature, are free of any matrix-vector multiplication through sequential online access to LP columns. We provide theoretical analyses of the regret (optimality gap) and constraint violation leveraging the analysis from online LP literature. For both algorithms, we obtain $\mathcal{O}(m \log n + \sqrt{n} \log n + \sqrt{mn})$ optimality gap and $\mathcal{O}(m + \sqrt{mn})$ constraint violation, which improves the results from [26]. Moreover, to enhance the practical performance of the online algorithms and to make them usable for offline LPs, we take advantage of the offline LP setting and propose a variable duplication scheme which further reduce the gap and violation by a factor of \sqrt{K} , where K is the number of copies of each variable.

- For exact LP solving, we identify sifting, an LP column generation framework, where our algorithms perfectly fit in to provide both an initial basis guess and an approximate dual solution. Numerical experiments show that our online algorithm can accelerate sifting by providing a good initialization and stabilizing the dual solution.

Table 1: Previous regret and constraint violation bounds. Ex: explicit update; Im: implicit (proximal point) update; Duplicate: **Algorithm 2**; ρ : regret (optimality gap); v : constraint violation. We note that the Duplicate setting is only available for offline LPs.

Work	Algorithm	Stochastic input (v & ρ)	Random permutation (v & ρ)
[26]	Ex. Subgrad	$\mathcal{O}(m + m\sqrt{n})$ & $\mathcal{O}(m\sqrt{n})$	$\mathcal{O}(m\sqrt{n})$ & $\mathcal{O}(\sqrt{n} \log n + m\sqrt{n})$
[6]	Ex. Mirror	$\mathcal{O}(m + \sqrt{mn})$ & 0	—
This work	Ex. Subgrad	$\mathcal{O}(m + \sqrt{mn})$ & $\mathcal{O}(\sqrt{mn})$	$\mathcal{O}(m + \sqrt{mn})$ & $\mathcal{O}(m \log n + \sqrt{n} \log n + \sqrt{mn})$
	Im. Proximal	$\mathcal{O}(m + \sqrt{mn})$ & $\mathcal{O}(\sqrt{mn})$	$\mathcal{O}(m + \sqrt{mn})$ & $\mathcal{O}(m \log n + \sqrt{n} \log n + \sqrt{mn})$
	Ex/Im. Duplicate	$\mathcal{O}(\frac{m}{K} + \sqrt{\frac{mn}{K}})$ & $\mathcal{O}(\sqrt{\frac{mn}{K}})$	$\mathcal{O}(\frac{m}{K} + \sqrt{\frac{mn}{K}})$ & $\mathcal{O}(\frac{m \log n}{K} + \sqrt{\frac{n}{K}} \log n + \sqrt{\frac{mn}{K}})$

Other Related Work Disregarding the complexity of solving subproblems, offline LP-based algorithms achieve state-of-the-art theoretical guarantees for online LPs. For example, [22, 29, 9] all achieve $\mathcal{O}(\log n)$ regret (up to a $\log \log$ term) under different non-degeneracy assumptions on the problem.

Going beyond the online LP problem, which is classified as online convex optimization with constraint (OCOwC), there is substantial research on general online convex optimization [21]. While most online algorithms are subgradient-based, there is also research on implicit update [23, 10], which is based on proximal point update. In this paper, we choose implicit update as one of the fast algorithms.

Outline of the Paper This paper is organized as follows. In **Section 2**, we introduce the basic problem setup and assumptions; In **Section 3**, we provide theoretical analysis on the performance of our algorithms using language from online LP literature; **Section 4** briefly discusses the sifting procedure for large-scale LPs and how online algorithms can be potentially combined with this framework. Last we conduct numerical experiments in **Section 5** to verify our theory and to show the practical efficiency of our proposed methods. In the appendix we further elaborate on some practical aspects of our methods.

2 Problem Setup and Assumptions

Notations Throughout the paper, we use $\|\cdot\|$ to denote the Euclidean norm and $\langle \cdot, \cdot \rangle$ to denote the Euclidean inner product. Bold letters \mathbf{A}, \mathbf{a} are used to denote matrices and vectors; the subdifferential of a convex function f is denoted by $\partial f(x)$ and $f'(x) \in \partial f(x)$ is called a subgradient; we use $[\cdot]_+ := \max\{\cdot, 0\}$ to denote the element-wise positive part function; $\mathbb{I}\{\cdot\}$ denotes the 0-1 indicator function and δ_S is the indicator function of set S . Unless specified, we use $\mathbb{E}[\cdot]$ to denote expectation taken over a certain permutation of LP columns. We use $\mathbf{a}_{[i:j]}$ to denote indexing of vector \mathbf{a} from the i -th to j -th coordinate, or indexing of a matrix from the i -th to j -th column.

2.1 Linear Programming and Duality

Given a linear program of m constraints and n variables

$$\max_{\mathbf{x} \in \mathcal{F}_p} \langle \mathbf{c}, \mathbf{x} \rangle,$$

its dual problem is given by

$$\min_{(\mathbf{y}, \mathbf{s}) \in \mathcal{F}_d} \langle \mathbf{b}, \mathbf{y} \rangle + \langle \mathbf{1}, \mathbf{s} \rangle$$

where the primal and dual feasible sets are denoted by

$$\begin{aligned} \mathcal{F}_p &:= \{\mathbf{x} : \mathbf{A}\mathbf{x} \leq \mathbf{b}, \mathbf{0} \leq \mathbf{x} \leq \mathbf{1}\} \\ \mathcal{F}_d &:= \{(\mathbf{y}, \mathbf{s}) \geq \mathbf{0} : \mathbf{A}^\top \mathbf{y} + \mathbf{s} \geq \mathbf{c}, \mathbf{s} \geq \mathbf{0}\}, \end{aligned}$$

with $\mathbf{A} \in \mathbb{R}^{m \times n}$, $\mathbf{b} \in \mathbb{R}^m$, $\mathbf{c} \in \mathbb{R}^n$ and $\mathbf{1} = (1, \dots, 1)^\top$ denotes the column vector of all ones. By the same argument as in [26], we remove the dual variable \mathbf{s} and rewrite the dual problem with a finite-sum formulation.

$$\min_{\mathbf{y} \geq \mathbf{0}} \frac{1}{n} \sum_{j=1}^n \langle \mathbf{d}, \mathbf{y} \rangle + [c_j - \langle \mathbf{a}_j, \mathbf{y} \rangle]_+ =: \frac{1}{n} \sum_{j=1}^n f(\mathbf{y}, j) \quad (1)$$

where $\mathbf{d} = \mathbf{b}/n$ and \mathbf{a}_j denotes the j -th column of \mathbf{A} . We also note that each column j is associated with a stochastic function $f(\mathbf{y}, j)$. Given the optimal dual solution \mathbf{y}^* , the optimality conditions of LP tell that

$$x_j^* \in \begin{cases} \{0\}, & c_j < \langle \mathbf{a}_j, \mathbf{y}^* \rangle \\ [0, 1], & c_j = \langle \mathbf{a}_j, \mathbf{y}^* \rangle \\ \{1\}, & c_j > \langle \mathbf{a}_j, \mathbf{y}^* \rangle \end{cases} \quad (2)$$

Taking into account this finite-sum structure of the dual problem, together with the close relevance between primal and dual, it is appealing to apply first-order stochastic algorithms to the dual problem and simultaneously estimate primal solution using the relation (2). This is indeed what “simple and fast online algorithms” do.

2.2 Simple and Fast Online Algorithms

Now we are ready to introduce online algorithms of our interest in **Algorithm 1**.

Algorithm 1: Fast online algorithms for LP

Input: $\mathbf{y}^0, \{f(\mathbf{y}, j)\}$ from LP data $\mathbf{A}, \mathbf{b}, \mathbf{c}$

for $k = 1$ to n **do**

 Choose $i_k \in [n]$

$$\mathbf{y}^{k+1} = \arg \min_{\mathbf{y} \geq \mathbf{0}} \{f_{\mathbf{y}^k}(\mathbf{y}, k) + \frac{1}{2\gamma_k} \|\mathbf{y} - \mathbf{y}^k\|^2\} \quad (3)$$

 Estimate \hat{x}^{i_k} based on (3).

end

Output: $\hat{\mathbf{x}}$

In each iteration, we choose one column $f(\mathbf{y}, i_k)$, approximate it by some $f_{\mathbf{y}^k}(\mathbf{y}, i_k)$ and perform stochastic proximal updates on the dual variable \mathbf{y} . At the end of iteration, we use the current dual information, combined with (2) to estimate the primal solution \hat{x}^{i_k} . Since in each iteration only one column participates in the update, the cost of each iteration is very low, thereby making the methods “simple and fast”.

2.3 Assumptions

We make the following assumptions across the paper.

A1: $\max_i d_i = \bar{d} \geq \min_i d_i = \underline{d} > 0 \quad (\mathbf{d} = \mathbf{b}/n)$

A2: $\|\mathbf{a}_j\|_\infty \leq \bar{a}$ and $|c_j| \leq \bar{c}$ for any $j \in [n]$

A3: For any dual solution $\mathbf{y} \geq \mathbf{0}$, no more than m columns satisfy $c_j = \langle \mathbf{a}_j, \mathbf{y} \rangle$

Remark 1. The above assumptions are standard in the literature of online LP [26, 6, 25]. **A1** is satisfied by a wide range of LPs such as multi-knapsack, set-covering, and online resource allocation. Even if $b_i = 0$, we can perturb it to make the assumption hold; Bounds in **A2** are only used for analysis and \bar{a}, \bar{c} can be computed by a single pass through data. **A3** could be satisfied by an arbitrarily small perturbation of \mathbf{b} [1].

2.4 Performance Measure

We use optimality gap and constraint violation to measure the quality of a given primal solution $\hat{\mathbf{x}}$.

$$\rho(\hat{\mathbf{x}}) := \max_{\mathbf{x} \in \mathcal{F}_p} \langle \mathbf{c}, \mathbf{x} \rangle - \langle \mathbf{c}, \hat{\mathbf{x}} \rangle \tag{4}$$

$$v(\hat{\mathbf{x}}) := \|\mathbf{A}\hat{\mathbf{x}} - \mathbf{b}\|_+ \tag{5}$$

With all the tools in hand, we are ready to present several realizations of **Algorithm 1** and to analyze their performance for offline LPs.

3 Fast Online Algorithms for Offline LPs

In this section, we provide two realizations of **Algorithm 1** and analyze their expected gap and violation. We start by specifying the choice of i_k . Although stochastic input, namely sampling i_k from $[n]$ randomly with replacement is a feasible option, it is somehow risky since it is very likely that some columns are not estimated in n iterations. Therefore random permutation, or sampling without replacement from $[n]$, is a better choice for offline LP’s context, and we can safely stop after n iterations and ensure that all the columns are associated with an estimated primal value.

To avoid the heavy notations from permutation, without loss of generality we assume instead of sampling i_k from $[n]$, we permute the columns of the offline LP, so that we can simply let $i_k = k$ and get the same theoretical results.

Remark 2. As is shown in [26], once we prove the result for the random permutation setting, the analysis can be directly applied to the stochastic input setting with a slightly better bound for the optimality gap.

3.1 Online Explicit Update

In this section, we analyze the performance of online explicit subgradient update in the offline setting. (Sub)gradient-based update approximates $f(\mathbf{y}, k)$ by a linear function

$$\begin{aligned} f_{\mathbf{y}^k}(\mathbf{y}, k) &= \langle f'(\mathbf{y}^k, k), \mathbf{y} - \mathbf{y}^k \rangle \\ &= \langle \mathbf{d} - \mathbf{a}_k \mathbb{I}\{c_k > \langle \mathbf{a}_k, \mathbf{y}^k \rangle\}, \mathbf{y} - \mathbf{y}^k \rangle, \end{aligned} \quad (6)$$

where we take $\mathbf{d} - \mathbf{a}_k \mathbb{I}\{c_k > \langle \mathbf{a}_k, \mathbf{y}^k \rangle\} \in \partial f(\mathbf{y}^k, k)$ and estimate the primal solution by $x^k = \mathbb{I}\{c_k > \langle \mathbf{a}_k, \mathbf{y}^k \rangle\}$. Specifically, the dual update (3) is given in closed form

$$\mathbf{y}^{k+1} = \mathbf{y}^k - \gamma(\mathbf{d} - \mathbf{a}_k x^k)$$

Compared to [26] which also analyzes the explicit update, we provide a sharper analysis to achieve a better trade-off between the optimality gap and constraint violation.

Lemma 1. *Under assumptions **A1** to **A3**, if we take $\gamma_k \equiv \gamma$, then solution $\hat{\mathbf{x}}$ output by **Algorithm 1** using explicit subgradient update (6) satisfies*

$$\begin{aligned} \mathbb{E}[\rho(\hat{\mathbf{x}})] &\leq \mathcal{O}(m \log n + \sqrt{n} \log n) + \frac{m(\bar{a} + \bar{d})^2 \gamma n}{2} \\ \mathbb{E}[v(\hat{\mathbf{x}})] &\leq \frac{m(\bar{a} + \bar{d})^2}{\underline{d}} + \sqrt{m}(\bar{a} + \bar{d}) + \frac{\bar{c}}{\gamma \underline{d}}, \end{aligned}$$

where expectation is taken over the random permutation.

Remark 3. **Lemma 1** implies a trade-off between ρ and v with respect to the stepsize of subgradient update. Since we know $\bar{a}, \bar{c}, \underline{d}, \bar{d}$ in the offline case, it is therefore possible to find an optimal γ to balance the two criteria.

Theorem 1. *Under the same conditions as **Lemma 1**, if we take $\gamma = \sqrt{\frac{2\bar{c}}{\underline{d}(\bar{a} + \bar{d})^2 mn}}$, then **Algorithm 1** using explicit subgradient update (6) outputs a solution $\hat{\mathbf{x}}$ satisfying*

$$\begin{aligned} \mathbb{E}[\rho(\hat{\mathbf{x}})] &\leq \mathcal{O}(m \log n + \sqrt{n} \log n) + \left(\frac{(\bar{a} + \bar{d})^2 \bar{c}}{2\underline{d}} \right)^{1/2} \sqrt{mn} \\ \mathbb{E}[v(\hat{\mathbf{x}})] &\leq \frac{m(\bar{a} + \bar{d})^2}{\underline{d}} + \sqrt{m}(\bar{a} + \bar{d}) + \left(\frac{(\bar{a} + \bar{d})^2 \bar{c}}{2\underline{d}} \right)^{1/2} \sqrt{mn}, \end{aligned}$$

where expectation is taken over the random permutation.

Remark 4. We see the online algorithm gives $\mathcal{O}(m \log n + \sqrt{n} \log n + \sqrt{mn})$ gap and $\mathcal{O}(m + \sqrt{mn})$ violation even if we take γ to be suboptimal value of $\mathcal{O}(\sqrt{mn})$. Compared with the $\mathcal{O}(\sqrt{n} \log n + m\sqrt{n})$ gap and $\mathcal{O}(m\sqrt{n})$ violation of [26], the result is improved with respect to m . The main reason why [26] gets a suboptimal bound is that they choose $\gamma = 1/\sqrt{n}$, which gives an unbalanced trade-off between gap and violation.

Remark 5. The online explicit updates can be implemented in $\mathcal{O}(\text{nnz}(\mathbf{A}))$ time and is free of any matrix-vector operations. See **Section B.1** for more details.

3.2 Online Implicit Update

In this section, we analyze the performance of online implicit update applied to offline LPs. Instead of approximating $f(\mathbf{y}, k)$, we keep all the information using

$$f_{\mathbf{y}^k}(\mathbf{y}, k) = f(\mathbf{y}, k) = \langle \mathbf{d}, \mathbf{y} \rangle + [c_k - \langle \mathbf{a}_k, \mathbf{y} \rangle]_+ \quad (7)$$

and the primal solution is estimated through proximal point

$$\begin{aligned} \min_{\mathbf{y}, s} \quad & \langle \mathbf{d}, \mathbf{y} \rangle + s + \frac{1}{2\gamma_k} \|\mathbf{y} - \mathbf{y}^k\|^2 \\ \text{subject to} \quad & \mathbf{y} \geq \mathbf{0}, s \geq c_k - \langle \mathbf{a}_k, \mathbf{y} \rangle, s \geq 0 \end{aligned}$$

and we let $x^k = \lambda(s \geq c_k - \langle \mathbf{a}_k, \mathbf{y} \rangle)$ be the Lagrangian multiplier of $s \geq c_k - \langle \mathbf{a}_k, \mathbf{y} \rangle$ in the optimal solution.

Remark 6. In the literature of online algorithms, the proximal point update is known as “implicit” update, where “implicit” comes from the optimality condition

$$\mathbf{0} \in \partial f(\mathbf{y}^{k+1}, k) + \gamma_k^{-1}(\mathbf{y}^{k+1} - \mathbf{y}^k) + \mathcal{N}_{\mathbb{R}_+^n}(\mathbf{y}^{k+1})$$

and \mathbf{y}^{k+1} can be expressed implicitly as

$$\mathbf{y}^{k+1} \in \mathbf{y}^k - \gamma_k(\partial f(\mathbf{y}^{k+1}, k) + \mathcal{N}_{\mathbb{R}_+^n}(\mathbf{y}^{k+1})),$$

where $\mathcal{N}_{\mathbb{R}_+^n}(\mathbf{y}^{k+1})$ is the normal cone of the nonnegative orthant at \mathbf{y}^{k+1} . Unlike online update which linearizes $f(\mathbf{y}, k)$, implicit proximal point update preserves all the information and it is shown to be more robust to stepsize selection than subgradient [4, 13].

The analysis of implicit update is similar, and we still have a trade-off between gap and violation

Lemma 2. *Under assumptions **A1** to **A3**, if we take $\gamma_k \equiv \gamma$, then solution $\hat{\mathbf{x}}$ output by **Algorithm 1** using implicit proximal point update (7) satisfies*

$$\begin{aligned} \mathbb{E}[\rho(\hat{\mathbf{x}})] &\leq \mathcal{O}(m \log n + \sqrt{n} \log n) + \frac{5m(\bar{a} + \bar{d})^2 \gamma n}{2} \\ \mathbb{E}[v(\hat{\mathbf{x}})] &\leq \frac{3m(\bar{a} + \bar{d})^2}{\underline{d}} + \sqrt{m}(\bar{a} + \bar{d}) + \frac{\bar{c}}{\gamma \underline{d}}, \end{aligned}$$

where expectation is taken over the random permutation.

Choosing γ properly, we get bounds on gap and violation.

Theorem 2. *Under the same condition as **Lemma 2**, if we take $\gamma = \sqrt{\frac{2\bar{c}}{5\bar{d}(\bar{a} + \bar{d})^2 mn}}$, then **Algorithm 1** using implicit proximal point update (7) outputs a solution $\hat{\mathbf{x}}$ satisfying*

$$\begin{aligned} \mathbb{E}[\rho(\hat{\mathbf{x}})] &\leq \mathcal{O}(m \log n + \sqrt{n} \log n) + \left(\frac{5(\bar{a} + \bar{d})^2 \bar{c}}{2\underline{d}}\right)^{1/2} \sqrt{mn} \\ \mathbb{E}[v(\hat{\mathbf{x}})] &\leq \frac{3m(\bar{a} + \bar{d})^2}{\underline{d}} + \sqrt{m}(\bar{a} + \bar{d}) + \left(\frac{5(\bar{a} + \bar{d})^2 \bar{c}}{2\underline{d}}\right)^{1/2} \sqrt{mn}, \end{aligned}$$

where expectation is taken over the random permutation.

Remark 7. Although we do not see improvement of bounds using implicit update, as will be shown by our numerical experiments, the implicit update often behaves better empirically. One intuitive explanation is that, unlike explicit update which only outputs binary values, an implicit model is capable of dealing with fractional values. To illustrate this consider the following LP

$$\max_{0 \leq x_1, x_2 \leq 1} x_1 + x_2 \quad \text{subject to} \quad x_1 + x_2 \leq 0.5$$

whose optimal value is 0.5. If we do not allow constraint violation greater than 0.1, then subgradient update will never take $x = 1$ from an arbitrary start. However, for implicit update we recover the optimal solution if $\gamma < 0.01$.

3.3 Improvement by Variable Duplication

Despite the efficiency of online algorithms, current gap and violation guarantees are far from enough to solve offline LPs, even approximately. To address this issue, we take advantage of the offline setting and propose to make a trade-off between time and accuracy, more specifically, by **1**). duplicating each column K times **2**). running online algorithm on the augmented problem with nK variables **3**). taking the average of primal estimates. This scheme ends up giving an intuitive \sqrt{K} reduction in the final bound.

Algorithm 2: Online algorithm with duplication

Input: $\mathbf{y}^0, K, \{f(\mathbf{y}, j)\}$ from LP data $\mathbf{A}, \mathbf{b}, \mathbf{c}$

- Duplicate each of $f(\mathbf{y}, j)$ K times and generate permutation for nK columns

$$\underbrace{\{x_{1,1}, \dots, x_{1,n}\}}_{\text{Duplication 1}} \quad \underbrace{\{x_{2,1}, \dots, x_{2,n}\}}_{\text{Duplication 2}} \quad \dots \quad \underbrace{\{x_{K,1}, \dots, x_{K,n}\}}_{\text{Duplication } K}$$

- Run **Algorithm 1** and get $\hat{\mathbf{x}}_{\text{Dup}} = (\hat{\mathbf{x}}_1, \dots, \hat{\mathbf{x}}_K)$
- Aggregate solution $\hat{\mathbf{x}} = \frac{1}{K} \sum_{k=1}^K \hat{\mathbf{x}}_k$.

Output: $\hat{\mathbf{x}}$

Theorem 3. Under assumptions **A1** to **A3**, if we apply **Algorithm 2** with K duplications and take $\gamma = \mathcal{O}(1/\sqrt{Kmn})$, then both implicit and explicit updates output solution $\hat{\mathbf{x}}$ satisfying

$$\begin{aligned} \mathbb{E}[\rho(\hat{\mathbf{x}})] &\leq \mathcal{O}\left(\frac{m \log n}{K} + \sqrt{\frac{n}{K}} \log n + \sqrt{\frac{mn}{K}}\right) \\ \mathbb{E}[v(\hat{\mathbf{x}})] &\leq \mathcal{O}\left(\frac{m}{K} + \sqrt{\frac{mn}{K}}\right). \end{aligned}$$

Remark 8. There is an extra $\mathcal{O}(\frac{\log K}{\sqrt{K}})$ term in the bound for ρ , but note that we generally take $K = \mathcal{O}(n)$ and we drop this term when presenting our results.

Remark 9. We provide an intuitive explanation of the improvement. Taking explicit update as an example: when each variable is duplicated $K > 1$ times, the final output \hat{x}^k would be allowed to take i/K for $i \leq K$, while $K = 1$ only allows $\hat{x}^k \in \{0, 1\}$. In other words, larger K offers higher granularity to approximate fractional solutions.

Till now we have presented the theoretical results on the online algorithms applied to offline LPs. In the following sections, we would focus on how the online algorithms help exact LP solving through sifting.

4 Application: Sifting for Linear Programs

In the previous sections we have discussed the use of online algorithms to approximately solve offline LPs. However, unlike the simplex method, first-order based methods rarely give accurate basis status and generally cannot be applied for exact LP solving. In this section we try to alleviate this issue by identifying the use of our method in sifting, a ‘‘column generation’’ framework for LP. For ease of exposition, we temporarily switch to standard-form LPs

$$\max_{\mathbf{x}} \langle \mathbf{c}, \mathbf{x} \rangle \quad \text{subject to} \quad \mathbf{Ax} = \mathbf{b}, \mathbf{x} \geq \mathbf{0}.$$

Sifting for LP Sifting initially appeared in [16] and was formally presented in [8] to solve LPs with $n \gg m$. Mature LP solvers often use sifting as a candidate solver [35, 30, 19]. Using the idea that the set of basic columns $\mathcal{B} = \{j : x_j^* > 0\}$ is small relative to $[n]$, sifting solves a sequence of working problems which restrict the problem to a more tractable subset of columns $\mathcal{W} \subseteq [n]$, $|\mathcal{W}| \ll n$

$$\max_{\mathbf{x}_{\mathcal{W}}} \langle \mathbf{c}, \mathbf{x}_{\mathcal{W}} \rangle \quad \text{subject to} \quad \mathbf{A} \mathbf{x}_{\mathcal{W}} = \mathbf{b}, \mathbf{x}_{\mathcal{W}} \geq \mathbf{0}.$$

Let $\mathbf{x}_{\mathcal{W}}^*$ and $\mathbf{y}_{\mathcal{W}}^*$ respectively denote the optimal primal and dual solutions to the working problem. If $\mathbf{y}_{\mathcal{W}}^*$ is dual feasible for the original LP, say, $\mathbf{A}^\top \mathbf{y}_{\mathcal{W}}^* \geq \mathbf{c}$, then $\mathcal{B} \subseteq \mathcal{W}$ (assuming the optimal solution is unique) and the original problem is solved. Otherwise we price out the dual infeasible columns $\mathcal{I} = \{j : \langle \mathbf{a}_j, \mathbf{y}_{\mathcal{W}}^* \rangle < c_j\}$ and add them to \mathcal{W} .

Algorithm 3: Sifting procedure for LPs

Input: Initial working set \mathcal{W}

while \mathcal{I} is nonempty **do**

 Solve working problem $\max_{\mathbf{A}_{\mathcal{W}} \mathbf{x}_{\mathcal{W}} = \mathbf{b}, \mathbf{x}_{\mathcal{W}} \geq \mathbf{0}} \langle \mathbf{c}_{\mathcal{W}}, \mathbf{x}_{\mathcal{W}} \rangle$ and get $\mathbf{y}_{\mathcal{W}}^*$

 Update $\mathcal{I} = \{j : \langle \mathbf{a}_j, \mathbf{y}_{\mathcal{W}}^* \rangle < c_j\}$

$\mathcal{W} = \mathcal{W} \cup \mathcal{I}$

end

Output: Optimal solution to LP

As a special case of column generation, sifting faces challenges that are similar to column generation [28]

- (heading-in) a good initialization of \mathcal{W} is often hard
- (dual-oscillation) solution $\mathbf{y}_{\mathcal{W}}^*$ is unstable at the end

Dual Stabilization Among the techniques for sifting, dual stabilization [15, 2, 36] has been one of the most successful attempts. In a word, most of the dual stabilization techniques work by finding some “anchor point” $\hat{\mathbf{y}}$ that lies at the center of dual feasible region [24, 20] and then by stabilizing the dual iterations by taking convex combination

$$\hat{\mathbf{y}}_{\mathcal{W}} = \alpha \mathbf{y}_{\mathcal{W}} + (1 - \alpha) \hat{\mathbf{y}}. \tag{8}$$

However, computing an interior point or some center of the dual feasible region is often too costly for huge LPs.

Accelerate Sifting by Online Algorithm Generally speaking, to accelerate sifting one needs

- a good estimate of $\{j : x_j^* > 0\}$.
- some approximate $\hat{\mathbf{y}} \approx \mathbf{y}^*$
- a cheap algorithm that obtains them

To this point it’s not hard to see that our online algorithm is a perfect candidate to fulfill all three requirements above. First, we can use $\hat{\mathbf{x}}$ as a score function to build initial \mathcal{W} . For example, we can choose some threshold value τ and initialize $\mathcal{W} = \{j : \hat{x}^j \geq \tau\}$. During the sifting procedure, we can use the approximate dual solution from online algorithm to stabilize the dual iterations. Most importantly, online algorithm is cheap enough and

its running time is negligible compared to the whole sifting procedure.

In practice, we can efficiently embed sifting into the LP pre-solver by going through the problem data several times before sifting starts. As our experiments suggest, online algorithm manages to identify the basis status for a wide range of real-life LPs.

Remark 10. Though the online algorithms work for problems with inequality constraints and upper-bounded variables, as the experiments suggest, it often suffices to use the online algorithm as a heuristic in practice.

Due to space limit we leave a more detailed discussion of sifting to **Section B.4**.

5 Experiments

In this section, we conduct numerical experiments to validate the efficiency of our proposed methods. The experiment is divided into two parts. In the first part we verify our theoretical results on multi-knapsack benchmark dataset and its variants. In the second part, we turn to exact LP solving and test large-scale LP benchmark datasets to see how online algorithms benefit sifting solvers.

5.1 Approximate Solver

In this part we test online algorithms in approximate LP solving. We also compare the performance of implicit and explicit updates in practice.

Data Description We use synthetic data from multi-knapsack benchmark. More detailedly, we generate benchmark multi-knapsack problems $\max_{\mathbf{A}\mathbf{x}\leq\mathbf{b},\mathbf{0}\leq\mathbf{x}\leq\mathbf{1}} \langle \mathbf{c}, \mathbf{x} \rangle$ as discussed in [11]: we generate each element of a_{ij} uniformly from $\{1, \dots, 1000\}$. After generating \mathbf{A} , we zero out each element of \mathbf{A} with probability $(1 - \sigma)$, where $\sigma \in (0, 1]$ controls the sparsity of \mathbf{A} . \mathbf{b} is generated by $b_i = \frac{\tau}{n} \sum_j a_{ij}$, where τ is called tightness coefficient. Each element of \mathbf{c} is generated by $c_i = \frac{1}{m} \sum_i a_{ij} + \delta_i$, where δ_i is sampled uniformly from $\{1, \dots, 500\}$.

Performance Metric In the first part of our experiment, given a feasible approximate solution $\hat{\mathbf{x}}$, we use relative optimality to measure its quality

$$r(\hat{\mathbf{x}}) := \left| \frac{\langle \mathbf{c}, \hat{\mathbf{x}} \rangle}{\langle \mathbf{c}, \mathbf{x}^* \rangle} \right|.$$

Testing Configuration and Setup

- 1). **Dataset.** We test $(m, n) \in \{(5, 10^2), (8, 10^3), (16, 2 \times 10^3), (32, 4 \times 10^3)\}$, $\tau \in [10^{-2}, 1]$, $\sigma = 1$.
- 2). **Initial Point.** We let online algorithms start from $\mathbf{0}$.
- 3). **Feasibility.** We force the algorithms to respect constraints (take $\hat{x}^k = 1$ only if $\mathbf{b} - \sum_{j=1}^k \mathbf{a}_j x_j \geq \mathbf{0}$).
- 4). **Duplication.** We allow $K \in \{1, 2, 4, 8, 16, 32\}$
- 5). **Stepsize.** We take $\gamma = 1/\sqrt{Kmn}$.
- 6). **Subproblem.** We discuss the way to efficiently compute implicit update in the appendix **Section B.2**.

First we compare the performance of the two algorithms through their relative optimality under different data settings. For LPs of the same size, we fix (m, n, K) and test $\tau \in [10^{-2}, 1]$ for ten values evenly distributed on the log-scale. Figure 1 illustrates the performance of both implicit and explicit updates. It can be clearly seen that implicit update, in most cases, outperforms the explicit update. Especially when the constraint is tight (τ close to 0) and $K = 1$, we see that the performance of implicit updates are dominant. Besides, we observe that with K increasing, explicit update starts to catch up.

Next we examine the efficiency of the variable duplication scheme by fixing (m, n, τ) and increasing $K \in \{1, 2, 4, 8, 16, 32\}$. Figure 2 illustrates how variable duplication improves performance of the online algorithms and shows its potential in approximate LP solving. It can be seen that as K increases, relative optimality is gradually improved and we can achieve higher than 90% relative optimality given moderate K . Therefore, it suffices to adopt the online algorithm with variable duplication in the applications where an approximately optimal solution is acceptable. In the appendix **Section B.3** we further investigate the performance of online algorithms for direct LP solving.

Another observation from Figure 2 is that when τ is close to 0, as we just mentioned, explicit update is dominated by the implicit update due to the restriction of constraint violation. However, as we increase K , this gap is soon filled. This suggests in practice we can alternatively combine variable duplication with explicit update to achieve comparable performance to the implicit update. Especially when the constraint matrix is sparse, an $\mathcal{O}(\text{nnz}(\mathbf{A}))$ implementation would be fairly competitive.

Figure 1: First row from left to right $(m, n, K) \in \{(5, 10^2, 1), (5, 10^2, 8), (8, 10^3, 1), (8, 10^3, 8)\}$. Second row from left to right $(m, n, K) \in \{(16, 2 \times 10^3, 1), (16, 2 \times 10^3, 8), (32, 4 \times 10^3, 1), (32, 4 \times 10^3, 8)\}$. The x-axis represents τ parameter ranging from 10^{-2} to 1; The y-axis represents the relative optimality.

5.2 Sifting and Large LPs

In this part, we turn to sifting in exact LP solving and see how much online algorithms can help.

Figure 2: From left to right $(m, n) \in \{(5, 10^2), (8, 10^3), (16, 2 \times 10^3), (32, 4 \times 10^3)\}$. The x-axis represents K parameter ranging in $\{1, 2, 4, 8, 16, 32\}$. The y-axis represents the relative optimality.

Data Description We test both synthetic data and real-life large-scale LPs. For the synthetic data, we generate LP instances in the same way as in **Section 5.1**. Besides, we collect 13 instances from [31].

Table 2: Datasets collected from large-scale LP benchmark

Dataset	Row	Column	Dataset	Row	Column
rail507	507	6.4e+04	rail1516	516	4.8e+04
rail582	582	5.6e+04	rail2586	2586	9.2e+05
rail4284	4284	1.0e+06	scpm1	5000	5.0e+05
scpn2	5000	1.0e+06	scpl4	2000	2.0e+05
scpj4scip	1000	1.0e+05	scpk4	2000	1.0e+05
s82	87878	1.7e+06	s100	14733	3.6e+05
s250r10	10962	2.7e+05	-	-	-

Performance Metric We mention in **Section 4** that online algorithm helps sifting in **1**). working problem initialization **2**). dual stabilization, and we test these two aspects using different criteria. For working problem initialization, assume that we get an initial working problem estimate \mathcal{W} from the online algorithm and denote by \mathcal{B} the set of basic columns, then we use

$$\text{acc}(\hat{\mathbf{x}}) := \frac{|\mathcal{B} \cap \mathcal{W}|}{|\mathcal{B}|} \quad \text{and} \quad \text{rdc}(\hat{\mathbf{x}}) := \frac{|\mathcal{W}|}{n}$$

to respectively evaluate **1**). how many basic columns are found out. **2**). size of the initialized working problem relative to the original LP. On the other hand, we also need to evaluate how much, overall, online algorithm can accelerate a sifting solver. To this end we directly use CPU seconds $T(\hat{\mathbf{x}})$ as the metric.

Testing Configuration and Setup

- 1). **Dataset.** We use $(m, n) \in \{(10^2, 10^5), (10^2, 10^6)\}$, $\tau \in \{(0.05, 0.1)\}$ and $\sigma \in \{(0.01, 0.1, 0.15, 0.2)\}$
- 2). **Algorithm Selection.** Since the problems are all sparse, only explicit update is used.
- 3). **Initial Point.** We let online algorithm start from **1**.
- 4). **Duplication.** We take $K = 2$ for all the datasets.

- 5). **Stepsize.** We take $\gamma = 1/\sqrt{Kmn}$.
- 6). **Basis Prediction.** Given the output of online algorithm $\hat{\mathbf{x}}$, we use $\mathcal{W} = \{j : \hat{x}^j \geq 1/K\}$ to initialize the working problem.
- 7). **Dual Stabilization.** We implement a basic dual stabilization procedure which takes $\alpha = 0.4$ in (8).
- 8). **Sifting Solver.** We adopt the sifting solver in CPLEX 12.10 as our benchmark solver.

Table 3: Performance of initializing working problem and CPU solution time of the large-scale LPs

Dataset	acc($\hat{\mathbf{x}}$)	rdc($\hat{\mathbf{x}}$)	T_{CPLEX}	$T(\hat{\mathbf{x}})$

Table 3 describes the practical performance of the the online algorithm applied to practical large-scale LPs. We can see that on the collected benchmark datasets, online algorithm successfully identifies more than 90% of the basic columns in most cases while restricting the size of initialization less than 20% of the original LP size. Especially for the `scp` instances, online algorithm identifies all the basic columns with fewer than 5% of columns. In this case, the original LP is solved after the first sifting iteration and we only need to solve a much smaller LP. For the overall LP solving time, we observe a clear speedup on 6 out of the 13 instances, neutral performance on 3 instances and slow down on 4 of the instances. We interpret this slow-down as the effect of our preliminary implementation of the sifting solver compared to CPLEX.

Finally, we experiment on synthetic datasets that satisfy the assumptions **A1** to **A3**. As **Table 4** shows, sifting solver, combined with our online algorithm, often outperforms the commercial sifting solvers by more than 50%. This further illustrates the practical efficiency of our proposed method.

6 Conclusions

We adapt two fast online algorithms for offline LPs and obtain algorithms that are free of any matrix multiplication or access to the full LP data matrix. We theoretically analyze the optimality gap and constraint violation of the two algorithms and propose a variable-duplication scheme to improve their practical performance. Particularly, we identify the potential of online algorithms in exact LP solving when combined with sifting, an LP column

generation procedure. Our numerical experiments demonstrate the efficiency of online algorithms, both as an approximate direct solver and as an auxiliary routine in sifting. We believe that it is an interesting direction to introduce online algorithms to the context of offline LP solving.

7 Acknowledgement

We thank Yuyang Ye, Xiaocheng Li and the seminar participants at Shanghai University of Finance and Economics for their fruitful discussions and comments. Specially we thank Dr. Qi Huangfu for proposing an $\mathcal{O}(\text{nnz}(\mathbf{A}))$ implementation of the explicit update method and testing it in the state-of-the-art commercial solver COPT [19]. Finally we sincerely appreciate the efforts the Area Chairs and all the reviewers put into the review process.

Structure of the Appendix

The appendix is organized as follows. **Section A** introduces auxiliary results and proves our main results from **Section 3**. As a complement to our main results from **Section 5**, **Section B** gives a more comprehensive treatment of online linear programming applied **1)**. Direct LP solving. **2)**. LP sifting and column generation. **3)**. Mixed integer programming. Particularly we address some practical implementation aspects of both implicit and explicit update in **B.2** and **B.1**.

A Theoretical Aspects of Online Linear Programming

A.1 Auxiliary Results

In this section, we present some auxiliary results from [26] that will help in the proof. Recall that given an index set $\mathcal{S} \subseteq [n]$, we use $\mathbf{A}_{\mathcal{S}}$ to denote the sub-matrix indexed from columns of \mathbf{A} and use $\mathbf{c}_{\mathcal{S}}$ to denote a sub-vector indexed from \mathbf{c} . Then we introduce two auxiliary LPs as follows.

Auxiliary LPs from Proposition 1 of [26]

$$\begin{aligned}
 F_s^* &:= \max_{\mathbf{x}_{[1:s]}} \langle \mathbf{c}_{[1:s]}, \mathbf{x}_{[1:s]} \rangle \\
 &\text{subject to } \mathbf{A}_{[1:s]} \mathbf{x}_{[1:s]} \leq \frac{s\mathbf{b}}{n} \\
 &\quad \mathbf{0} \leq \mathbf{x}_{[1:s]} \leq \mathbf{1} \\
 \\
 \hat{F}_k^* &:= \max_{\mathbf{x}_{[k:n]}} \langle \mathbf{c}_{[k:n]}, \mathbf{x}_{[k:n]} \rangle \\
 &\text{subject to } \mathbf{A}_{[k:n]} \mathbf{x}_{[k:n]} \leq \left(1 - \frac{k-1}{n}\right) \mathbf{b} \\
 &\quad \mathbf{0} \leq \mathbf{x}_{[k:n]} \leq \mathbf{1},
 \end{aligned}$$

The optimal values of the two LPs are denoted by F_s^* and \hat{F}_k^* respectively. The following lemma provides a lens to deal with random permutation.

Lemma 3 (Optimality gap [26]). *We have the following bound on the optimality gap of the online algorithm*

$$\begin{aligned}
 F_n^* - \sum_{k=1}^n \mathbb{E}[c_k x^k] &\leq m\bar{c} + \frac{\bar{c}\sqrt{n} \log n}{d} + m\bar{c} \log n + \frac{\alpha\bar{c}}{n} + \sum_{k=1}^n \mathbb{E} \left[\frac{\hat{F}_{n-k+1}^*}{n-k+1} - c_k x^k \right] \\
 &= \mathcal{O}(m \log n + \sqrt{n} \log n) + \sum_{k=1}^n \mathbb{E} \left[\frac{\hat{F}_{n-k+1}^*}{n-k+1} - c_k x^k \right],
 \end{aligned}$$

where $\alpha = \max\{e, e^{16\bar{a}^2}, 16\bar{a}^2\}$ and the expectation is taken over the random permutation.

Remark 11. Given **Lemma 3**, it remains to analyze the quantity $\sum_{k=1}^n \mathbb{E} \left[\frac{\hat{F}_{n-k+1}^*}{n-k+1} - c_k x^k \right]$ to bound the optimality gap, and in our proof we analyze it under explicit and implicit updates respectively.

We also need a well-known three-point lemma in the analysis of implicit updates.

Lemma 4 (Three-point lemma [1]). *Let f be a convex function and*

$$\mathbf{y}^+ = \arg \min_{\mathbf{y}} \left\{ f(\mathbf{y}) + \frac{1}{2\gamma} \|\mathbf{y} - \mathbf{z}\|^2 \right\},$$

where $\gamma > 0$. Then we have

$$f(\mathbf{y}^+) + \frac{1}{2\gamma} \|\mathbf{y}^+ - \mathbf{z}\|^2 \leq f(\mathbf{y}) + \frac{1}{2\gamma} \|\mathbf{y} - \mathbf{z}\|^2 - \frac{1}{2\gamma} \|\mathbf{y} - \mathbf{y}^+\|^2.$$

Clue of proof With the tools in hand, now we get down to the analysis of different algorithms. Our proof basically follows three steps as follows:

- Tracking the dual iteration $\{\mathbf{y}^k\}$
- Tracking constraint violation and optimality gap
- Taking trade-off between optimality gap and constraint violation by properly choosing γ .

A.2 Proof of Results in Section 3.1

In this section, we present the proof for subgradient-based explicit online algorithm. The following lemma tracks the dual iterations of **Algorithm 1** with explicit update.

Lemma 5 (Tracking the dual iteration). *Under **A1** and **A2**, if we let $\{\mathbf{y}^k\}$ be the sequence of dual iterates generated by **Algorithm 1** with explicit update and $\gamma_k \equiv \gamma$, then*

$$\|\mathbf{y}^k\| \leq \frac{m(\bar{a} + \bar{d})^2\gamma}{\underline{d}} + \sqrt{m}(\bar{a} + \bar{d})\gamma + \frac{\bar{c}}{\underline{d}}.$$

Boundedness of dual iterations turns out to be important for limiting the constraint violation. Now we state the detailed proof of the theoretical results.

A.2.1 Proof of Lemma 5

The proof is adapted from [26] and is improved via a sharper analysis. First recall that we update the dual iterations by

$$\mathbf{y}^{k+1} = [\mathbf{y}^k + \gamma(\mathbf{a}_k \mathbb{I}\{c_k > \langle \mathbf{a}_k, \mathbf{y}^k \rangle\} - \mathbf{d})]_+ = [\mathbf{y}^k + \gamma(\mathbf{a}_k x^k - \mathbf{d})]_+$$

and we successively deduce that

$$\begin{aligned} & \|\mathbf{y}^{k+1}\|^2 - \|\mathbf{y}^k\|^2 \\ & \leq \|\mathbf{y}^k + \gamma(\mathbf{a}_k x^k - \mathbf{d})\|^2 - \|\mathbf{y}^k\|^2 & (9) \\ & \leq -2\gamma \langle \mathbf{d} - \mathbf{a}_k x^k, \mathbf{y}^k \rangle + m(\bar{a} + \bar{d})^2 \gamma^2 & (10) \\ & \leq m(\bar{a} + \bar{d})^2 \gamma^2 + 2\gamma \bar{c} - 2\gamma \underline{d} \|\mathbf{y}^k\|, & (11) \end{aligned}$$

where (9) is due to $\|[\mathbf{x}]_+\| \leq \|\mathbf{x}\|$; (10) uses **A1**, **A2** to get $\gamma^2 \|\mathbf{a}_k x^k - \mathbf{d}\|^2 \leq m(\bar{a} + \bar{d})^2 \gamma^2$ since $\|\mathbf{a}_k\|_\infty \leq \bar{a}$, $\mathbf{0} < \mathbf{d} \leq \bar{d} \cdot \mathbf{1}$ and $|x^k| \leq 1$; (11) uses the relation

$$-2\gamma \langle \mathbf{d}, \mathbf{y}^k \rangle \leq -2\gamma \underline{d} \|\mathbf{y}^k\|_1 \leq -2\gamma \underline{d} \|\mathbf{y}^k\|_2$$

and $\langle \mathbf{a}_k x^k, \mathbf{y}^k \rangle \leq c_k \leq \bar{c}$.

On the other hand, we have, by triangle inequality that

$$\|\mathbf{y}^{k+1}\| \leq \|\mathbf{y}^k + \gamma(\mathbf{a}_k x^k - \mathbf{d})\| \leq \|\mathbf{y}^k\| + \gamma \|\mathbf{a}_k x^k - \mathbf{d}\| \leq \|\mathbf{y}^k\| + \gamma \sqrt{m}(\bar{a} + \bar{d})$$

and if $\|\mathbf{y}^k\| \geq \frac{m(\bar{a} + \bar{d})^2 \gamma + 2\bar{c}}{2\underline{d}}$, by (11) we know that

$$\|\mathbf{y}^{k+1}\|^2 - \|\mathbf{y}^k\|^2 \leq m(\bar{a} + \bar{d})^2 \gamma^2 + 2\gamma \bar{c} - 2\gamma \underline{d} \|\mathbf{y}^k\| \leq 0.$$

Therefore, if $\|\mathbf{y}^1\| \leq \frac{m(\bar{a} + \bar{d})^2 \gamma + 2\bar{c}}{2\underline{d}}$, then $\|\mathbf{y}^k\|$ never exceeds $\frac{m(\bar{a} + \bar{d})^2 \gamma + 2\bar{c}}{2\underline{d}} + \gamma \sqrt{m}(\bar{a} + \bar{d})$ and this completes the proof.

A.2.2 Proof of Lemma 1

By the updating formula of subgradient,

$$\mathbf{y}^{k+1} = [\mathbf{y}^k + \gamma(\mathbf{a} x^k - \mathbf{d})]_+ \geq \mathbf{y}^k + \gamma(\mathbf{a}_k x^k - \mathbf{d})$$

and telescoping over $k = 1, \dots, n$ gives

$$\mathbf{A}\hat{\mathbf{x}} = \sum_{k=1}^n \mathbf{a}_k x^k \leq \mathbf{b} + \gamma^{-1} \sum_{k=1}^n (\mathbf{y}^{k+1} - \mathbf{y}^k) \leq \mathbf{b} + \gamma^{-1} \mathbf{y}^{n+1}.$$

Re-arranging the term, taking positive part and taking expectation with respect to the random permutation, we have

$$\begin{aligned} \mathbb{E}[\|[\mathbf{A}\hat{\mathbf{x}} - \mathbf{b}]_+\|] &\leq \gamma^{-1} \mathbb{E}[\|\mathbf{y}^{k+1}\|] \\ &\leq \gamma^{-1} \left[\frac{m(\bar{a} + \bar{d})^2 \gamma}{\underline{d}} + \gamma \sqrt{m}(\bar{a} + \bar{d}) + \frac{\bar{c}}{\underline{d}} \right] \\ &= \frac{m(\bar{a} + \bar{d})^2}{\underline{d}} + \sqrt{m}(\bar{a} + \bar{d}) + \frac{\bar{c}}{\gamma \underline{d}}, \end{aligned} \tag{12}$$

where (12) invokes **Lemma 5** to bound the constraint violation.

Next we bound $\sum_{k=1}^n \mathbb{E} \left[\frac{\hat{F}_{n-k+1}^*}{n-k+1} - c_k x^k \right]$ and deduce that

$$\begin{aligned} &\|\mathbf{y}^{k+1}\|^2 - \|\mathbf{y}^k\|^2 \\ &= \|[\mathbf{y}^k + \gamma(\mathbf{a}_k x^k - \mathbf{d})]_+\|^2 - \|\mathbf{y}^k\|^2 \\ &\leq \|\mathbf{y}^k + \gamma(\mathbf{a}_k x^k - \mathbf{d})\|^2 - \|\mathbf{y}^k\|^2 \\ &= -2\gamma \langle \mathbf{d} - \mathbf{a}_k x^k, \mathbf{y}^k \rangle + \gamma^2 \|\mathbf{a}_k x^k - \mathbf{d}\|^2 \\ &\leq -2\gamma \langle \mathbf{d} - \mathbf{a}_k x^k, \mathbf{y}^k \rangle + m(\bar{a} + \bar{d})^2 \gamma^2, \end{aligned}$$

where the last inequality again uses the relation $\gamma^2 \|\mathbf{a}_k x^k - \mathbf{d}\|^2 \leq m(\bar{a} + \bar{d})^2 \gamma^2$. Then we take expectation and telescope over $k = 1, \dots, n$ to obtain

$$\begin{aligned} \sum_{k=1}^n \mathbb{E}[\|\mathbf{y}^{k+1}\|^2 - \|\mathbf{y}^k\|^2] &= \mathbb{E}[\|\mathbf{y}^{n+1}\|^2] - \|\mathbf{y}^1\|^2 \\ &\leq \sum_{k=1}^n \mathbb{E}[-2\gamma \langle \mathbf{d} - \mathbf{a}_k x^k, \mathbf{y}^k \rangle + m(\bar{a} + \bar{d})^2 \gamma^2]. \end{aligned}$$

Re-arranging the terms, we have

$$\mathbb{E} \left[\sum_{k=1}^n 2\gamma \langle \mathbf{d} - \mathbf{a}_k x^k, \mathbf{y}^k \rangle \right] \leq \sum_{k=1}^n m(\bar{a} + \bar{d})^2 \gamma^2 - \mathbb{E}[\|\mathbf{y}^{n+1}\|^2] \leq mn(\bar{a} + \bar{d})^2 \gamma^2,$$

Last we observe that [26]

$$\sum_{k=1}^n \mathbb{E} \left[\frac{\hat{F}_{n-k+1}^*}{n-k+1} - c_k x^k \right] \leq \sum_{k=1}^n \mathbb{E}[\langle \mathbf{d} - \mathbf{a}_k x^k, \mathbf{y}^k \rangle] \leq \frac{m(\bar{a} + \bar{d})^2 \gamma n}{2}$$

and plugging the bound back completes the proof.

A.2.3 Proof of Theorem 1

We have, for some Δ independent of γ , that

$$\begin{aligned} \mathbb{E}[\rho(\hat{\mathbf{x}}) + v(\hat{\mathbf{x}})] &\leq \Delta + \frac{m(\bar{a} + \bar{d})^2 \gamma n}{2} + \frac{\bar{c}}{\gamma \underline{d}} \\ (\text{Taking } \gamma &= \sqrt{\frac{2\bar{c}}{\underline{d}(\bar{a} + \bar{d})^2 mn}}) = \Delta + 2 \left(\frac{(\bar{a} + \bar{d})^2 \bar{c}}{2\underline{d}} \right)^{1/2} \sqrt{mn}, \end{aligned}$$

where $\frac{m(\bar{a}+\bar{d})^2\gamma n}{2} = \frac{\bar{c}}{\gamma\bar{d}}$ minimizes the right hand side and this completes the proof.

A.3 Proof of Results in Section 3.2

In this section, we prove the results for implicit update. First we recall the update of **Algorithm 1** under the implicit update.

Update of Online Implicit Update

$$\begin{aligned}\mathbf{y}^{k+1} &= \arg \min_{\mathbf{y} \geq \mathbf{0}} \left\{ \langle \mathbf{d}, \mathbf{y} \rangle + [c_k - \langle \mathbf{a}_k, \mathbf{y} \rangle]_+ + \frac{1}{2\gamma} \|\mathbf{y} - \mathbf{y}^k\|^2 \right\} \\ &= \arg \min_{\mathbf{y} \geq \mathbf{0}} \left\{ \langle \mathbf{d}, \mathbf{y} \rangle + s + \frac{1}{2\gamma} \|\mathbf{y} - \mathbf{y}^k\|^2 : s \geq c_k - \langle \mathbf{a}_k, \mathbf{y} \rangle, s \geq 0 \right\} \\ x^k &= \lambda(s \geq c_k - \langle \mathbf{a}_k, \mathbf{y} \rangle),\end{aligned}$$

where $\lambda(s \geq c_k - \langle \mathbf{a}_k, \mathbf{y} \rangle)$ denotes the Lagrangian multiplier of the constraint $s \geq c_k - \langle \mathbf{a}_k, \mathbf{y} \rangle$. As in the explicit case, we track the dual solution.

Lemma 6 (Tracking the dual iteration). *Under **A1** and **A2**, letting $\{\mathbf{y}^k\}$ be the sequence of dual iterates generated by **Algorithm 1** with implicit update and $\gamma_k \equiv \gamma$, then*

$$\begin{aligned}\|\mathbf{y}^{k+1} - \mathbf{y}^k\| &\leq \sqrt{m}(\bar{a} + \bar{d})\gamma \\ \|\mathbf{y}^k\| &\leq \frac{m(\bar{a} + \bar{d})^2\gamma}{\bar{d}} + \sqrt{m}(\bar{a} + \bar{d})\gamma + \frac{\bar{c}}{\bar{d}}.\end{aligned}$$

After bounding the dual iterations, we can move on to tracking constraint violation and establish a bound of optimality gap, thus giving **Lemma 2** and **Theorem 2**.

A.3.1 Proof of Lemma 6

First we prove that $\|\mathbf{y}^{k+1} - \mathbf{y}^k\| \leq \gamma\sqrt{m}(\bar{a} + \bar{d})$. Note that

$$g(\mathbf{y}) = \langle \mathbf{d}, \mathbf{y} \rangle + [c_k - \langle \mathbf{a}_k, \mathbf{y} \rangle]_+ + \delta_{\mathbf{y} \geq \mathbf{0}}$$

is convex, where $\delta_{\mathbf{y} \geq \mathbf{0}}$ denotes the indicator function of \mathbb{R}_+^m . Then we invoke three-point lemma and

$$\langle \mathbf{d}, \mathbf{y}^{k+1} \rangle + [c_k - \langle \mathbf{a}_k, \mathbf{y}^{k+1} \rangle]_+ + \frac{1}{2\gamma} \|\mathbf{y}^{k+1} - \mathbf{y}^k\|^2 \leq \langle \mathbf{d}, \mathbf{y}^k \rangle + [c_k - \langle \mathbf{a}_k, \mathbf{y}^k \rangle]_+ - \frac{1}{2\gamma} \|\mathbf{y}^{k+1} - \mathbf{y}^k\|^2.$$

Re-arranging the terms, we successively deduce that

$$\begin{aligned}\gamma^{-1} \|\mathbf{y}^{k+1} - \mathbf{y}^k\|^2 &\leq \langle \mathbf{d}, \mathbf{y}^k - \mathbf{y}^{k+1} \rangle + [c_k - \langle \mathbf{a}_k, \mathbf{y}^k \rangle]_+ - [c_k - \langle \mathbf{a}_k, \mathbf{y}^{k+1} \rangle]_+ \\ &\leq \|\mathbf{d}\| \cdot \|\mathbf{y}^k - \mathbf{y}^{k+1}\| + |\langle \mathbf{a}_k, \mathbf{y}^k - \mathbf{y}^{k+1} \rangle| \tag{13}\end{aligned}$$

$$\begin{aligned}&\leq \sqrt{m\bar{d}}\|\mathbf{y}^k - \mathbf{y}^{k+1}\| + \sqrt{m\bar{a}}\|\mathbf{y}^k - \mathbf{y}^{k+1}\| \tag{14} \\ &= \sqrt{m}(\bar{a} + \bar{d})\|\mathbf{y}^k - \mathbf{y}^{k+1}\|,\end{aligned}$$

where (13) uses Cauchy's inequality $\langle \mathbf{a}, \mathbf{b} \rangle \leq \|\mathbf{a}\| \cdot \|\mathbf{b}\|$ and the relation $[x]_+ - [y]_+ \leq |x - y|_+$; (14) again applies Cauchy's inequality together with **A1**, **A2**. Dividing both sides of the inequality by $\|\mathbf{y}^k - \mathbf{y}^{k+1}\|$ shows $\|\mathbf{y}^{k+1} - \mathbf{y}^k\| \leq \gamma\sqrt{m}(\bar{a} + \bar{d})$.

Next we bound $\|\mathbf{y}^k\|$. Due to the complication of implicit update, we resort to a constrained smooth formulation of the proximal subproblem

$$\begin{aligned} \min_{\mathbf{y}} \quad & \langle \mathbf{d}, \mathbf{y} \rangle + s + \frac{1}{2\gamma} \|\mathbf{y} - \mathbf{y}^k\|^2 \quad \text{Dual} \\ \text{subject to} \quad & s \geq c_k - \langle \mathbf{a}_k, \mathbf{y} \rangle \quad x \\ & s \geq 0, \mathbf{y} \geq \mathbf{0} \quad v, \mathbf{w}, \end{aligned}$$

which is a convex quadratic programming problem. Now we check the Lagrangian function

$$L(\mathbf{y}, x, \mathbf{s}, v) = \langle \mathbf{d}, \mathbf{y} \rangle + s + \frac{1}{2\gamma} \|\mathbf{y} - \mathbf{y}^k\|^2 + x(c_k - \langle \mathbf{a}_k, \mathbf{y} \rangle - s) - vs - \langle \mathbf{y}, \mathbf{w} \rangle,$$

where \mathbf{w} is the multiplier of \mathbf{y} and v is the multiplier of s . Writing the KKT conditions, we have

$$\begin{aligned} s &\geq c_k - \langle \mathbf{a}_k, \mathbf{y}^{k+1} \rangle \\ s &\geq 0 \\ \mathbf{d} + \gamma^{-1}(\mathbf{y}^{k+1} - \mathbf{y}^k) - \mathbf{a}_k x^k - \mathbf{w} &= \mathbf{0} \\ v + x^k &= 1 \end{aligned} \tag{15}$$

$$\begin{aligned} \langle \mathbf{y}^{k+1}, \mathbf{w} \rangle &= 0 \\ x^k(c_k - \langle \mathbf{a}_k, \mathbf{y}^{k+1} \rangle - s) &= 0 \\ vs &= 0 \\ (x^k, v, \mathbf{y}^{k+1}, \mathbf{w}) &\geq \mathbf{0} \end{aligned} \tag{16}$$

and from (15) we know that

$$\mathbf{y}^{k+1} = \mathbf{y}^k - \gamma(\mathbf{d} - \mathbf{a}_k x^k) + \gamma \mathbf{w} \tag{17}$$

for some $\mathbf{w} \geq \mathbf{0}$. Also we notice that since $\langle \mathbf{y}^{k+1}, \mathbf{w} \rangle = 0$, $w_i = 0$ whenever $y_i^{k+1} > 0$, which implies

$$\begin{aligned} \|\mathbf{y}^{k+1}\|^2 &= \|\mathbf{y}^k - \gamma(\mathbf{d} - \mathbf{a}_k x^k) + \gamma \mathbf{w}\|^2 \\ &\leq \|\mathbf{y}^k - \gamma(\mathbf{d} - \mathbf{a}_k x^k)\|^2 \\ &= \|\mathbf{y}^k\|^2 - 2\gamma \langle \mathbf{d} - \mathbf{a}_k x^k, \mathbf{y}^k \rangle + \gamma^2 \|\mathbf{d} - \mathbf{a}_k x^k\|^2 \end{aligned} \tag{18}$$

$$\leq \|\mathbf{y}^k\|^2 + 3m(\bar{a} + \bar{d})^2 \gamma^2 + 2\gamma \bar{c} - 2\gamma d \|\mathbf{y}^k\|. \tag{19}$$

where (19) is again by Cauchy's inequality and **A1**, **A2**, $-2\gamma \langle \mathbf{d}, \mathbf{y}^k \rangle \leq 2\gamma d \|\mathbf{y}^k\|_1 \leq -2\gamma d \|\mathbf{y}^k\|$, and that

$$\begin{aligned} \langle \mathbf{a}_k x^k, \mathbf{y}^k \rangle &= \langle \mathbf{a}_k x^k, \mathbf{y}^{k+1} \rangle - \langle \mathbf{a}_k x^k, \mathbf{y}^{k+1} - \mathbf{y}^k \rangle \\ &\leq \langle \mathbf{a}_k x^k, \mathbf{y}^{k+1} \rangle + \|\mathbf{a}_k\| \cdot \|\mathbf{y}^{k+1} - \mathbf{y}^k\| \cdot |x^k| \\ &\leq \bar{c} + \gamma m \bar{a} (\bar{a} + \bar{d}) \\ &\leq \bar{c} + \gamma m (\bar{a} + \bar{d})^2, \end{aligned} \tag{20}$$

where (20) uses $\langle \mathbf{a}_k x^k, \mathbf{y}^{k+1} \rangle \leq \bar{c}$ from (16) and we invoke the bound $\|\mathbf{y}^{k+1} - \mathbf{y}^k\| \leq \gamma \sqrt{m}(\bar{a} + \bar{d})$.

On the other hand, we know that

$$\begin{aligned} \|\mathbf{y}^{k+1}\| &= \|\mathbf{y}^{k+1} - \mathbf{y}^k + \mathbf{y}^k\| \\ &\leq \|\mathbf{y}^{k+1} - \mathbf{y}^k\| + \|\mathbf{y}^k\| \\ &\leq \|\mathbf{y}^k\| + \gamma \sqrt{m}(\bar{a} + \bar{d}), \end{aligned} \tag{21}$$

where (21) again uses $\|\mathbf{y}^{k+1} - \mathbf{y}^k\| \leq \gamma\sqrt{m}(\bar{a} + \bar{d})$. By exactly the same argument as in **Lemma 5**, we know that

$$\|\mathbf{y}^k\| \leq \frac{3m(\bar{a} + \bar{d})^2\gamma}{\underline{d}} + \sqrt{m}(\bar{a} + \bar{d})\gamma + \frac{\bar{c}}{\underline{d}}$$

and this completes the proof.

A.3.2 Proof of Lemma 2

First we consider constraint violation and recall that we run implicit update (17)

$$\mathbf{y}^{k+1} = \mathbf{y}^k - \gamma(\mathbf{d} - \mathbf{a}_k x^k) + \gamma \mathbf{w} \geq \mathbf{y}^k - \gamma(\mathbf{d} - \mathbf{a}_k x^k).$$

Hence telescoping gives

$$\mathbb{E}[\|\mathbf{A}\hat{\mathbf{x}} - \mathbf{b}\|_+] \leq \gamma^{-1}\mathbb{E}[\|\mathbf{y}^{k+1}\|] \leq \frac{3m(\bar{a} + \bar{d})^2}{\underline{d}} + \sqrt{m}(\bar{a} + \bar{d}) + \frac{\bar{c}}{\underline{d}}.$$

As for the optimality gap, we have, similar to [26], that

$$\sum_{k=1}^n \mathbb{E}\left[\frac{\hat{F}_{n-k+1}^*}{n-k+1} - c_k x^k\right] \leq \sum_{k=1}^n \mathbb{E}[\langle \mathbf{d}, \mathbf{y}^k \rangle + [c_k - \langle \mathbf{a}_k, \mathbf{y}^k \rangle]_+ - c_k x^k]$$

Now we look again into the KKT conditions, which, after simplification, gives

$$s \geq [c_k - \langle \mathbf{a}_k, \mathbf{y}^{k+1} \rangle]_+ \tag{22}$$

$$x^k (c_k - \langle \mathbf{a}_k, \mathbf{y}^{k+1} \rangle - s) = 0 \tag{23}$$

$$(1 - x^k)s = 0. \tag{24}$$

Combining the above relations, we successively deduce that

$$c_k x^k = (\langle \mathbf{a}_k, \mathbf{y}^{k+1} \rangle + s)x^k \tag{25}$$

$$= \langle \mathbf{a}_k, \mathbf{y}^{k+1} \rangle x^k + s x^k \tag{26}$$

$$= \langle \mathbf{a}_k, \mathbf{y}^{k+1} \rangle x^k + s \tag{27}$$

$$\geq \langle \mathbf{a}_k, \mathbf{y}^{k+1} \rangle x^k + [c_k - \langle \mathbf{a}_k, \mathbf{y}^{k+1} \rangle]_+,$$

where (25) re-arranges (23) and (27) uses (24). Plugging it back, we can derive the following bound.

$$\begin{aligned} & \sum_{k=1}^n \mathbb{E}[\langle \mathbf{d}, \mathbf{y}^k \rangle + [c_k - \langle \mathbf{a}_k, \mathbf{y}^k \rangle]_+ - c_k x^k] \\ & \leq \sum_{k=1}^n \mathbb{E}[\langle \mathbf{d}, \mathbf{y}^k \rangle + [c_k - \langle \mathbf{a}_k, \mathbf{y}^k \rangle]_+ - \langle \mathbf{a}_k, \mathbf{y}^{k+1} \rangle x^k - [c_k - \langle \mathbf{a}_k, \mathbf{y}^{k+1} \rangle]_+] \\ & = \sum_{k=1}^n \mathbb{E}[\langle \mathbf{d} - \mathbf{a}_k x^k, \mathbf{y}^k \rangle] + \sum_{k=1}^n \mathbb{E}[\langle \mathbf{a}_k x^k, \mathbf{y}^k - \mathbf{y}^{k+1} \rangle] + \sum_{k=1}^n \mathbb{E}\{[c_k - \langle \mathbf{a}_k, \mathbf{y}^k \rangle]_+ - [c_k - \langle \mathbf{a}_k, \mathbf{y}^{k+1} \rangle]_+\} \end{aligned}$$

Next we bound the last two summations by

$$\sum_{k=1}^n \mathbb{E}[\langle \mathbf{a}_k x^k, \mathbf{y}^k - \mathbf{y}^{k+1} \rangle] \leq \sum_{k=1}^n \mathbb{E}[\|\mathbf{a}_k\| \cdot \|\mathbf{y}^k - \mathbf{y}^{k+1}\|] \leq mn\gamma\bar{a}(\bar{a} + \bar{d})$$

$$\begin{aligned}
\sum_{k=1}^n \mathbb{E}\{[c_k - \langle \mathbf{a}_k, \mathbf{y}^k \rangle]_+ - [c_k - \langle \mathbf{a}_k, \mathbf{y}^{k+1} \rangle]_+\} &\leq \sum_{k=1}^n \mathbb{E}[|\langle \mathbf{a}_k, \mathbf{y}^k - \mathbf{y}^{k+1} \rangle|] \\
&\leq \sum_{k=1}^n \mathbb{E}[\|\mathbf{a}_k\| \cdot \|\mathbf{y}^k - \mathbf{y}^{k+1}\|] \\
&\leq mn\gamma\bar{a}(\bar{a} + \bar{d})
\end{aligned}$$

with Cauchy's inequality, **Lemma 6** and **A2**. Then we re-arrange (18) and obtain

$$\begin{aligned}
&2\gamma\langle \mathbf{d} - \mathbf{a}_k x^k, \mathbf{y}^k \rangle \\
&\leq \|\mathbf{y}^k\|^2 - \|\mathbf{y}^{k+1}\|^2 + \gamma^2\|\mathbf{d} - \mathbf{a}_k x^k\|^2 \\
&\leq \|\mathbf{y}^k\|^2 - \|\mathbf{y}^{k+1}\|^2 + \gamma^2 m(\bar{a} + \bar{d})^2
\end{aligned} \tag{28}$$

and (28) uses **A1** and **A2** and the fact that $|x^k| \leq 1$. Finally, we telescope

$$2\gamma\langle \mathbf{d} - \mathbf{a}_k x^k, \mathbf{y}^k \rangle \leq \|\mathbf{y}^k\|^2 - \|\mathbf{y}^{k+1}\|^2 + \gamma^2 m(\bar{a} + \bar{d})^2,$$

as in the previous analysis to get

$$\sum_{k=1}^n \mathbb{E}[\langle \mathbf{d} - \mathbf{a}_k x^k, \mathbf{y}^k \rangle] \leq \frac{m(\bar{a} + \bar{d})^2 n \gamma}{2}.$$

Putting all the bounds together, we have

$$\mathbb{E}[\rho(\hat{\mathbf{x}})] \leq \frac{mn(\bar{a} + \bar{d})^2}{2} \gamma + 2mn\gamma\bar{a}(\bar{a} + \bar{d}) \leq \frac{5m(\bar{a} + \bar{d})^2 n \gamma}{2}$$

and this completes the proof.

A.3.3 Proof of Theorem 2

The proof works exactly in the same way as **Theorem 1** by observing that

$$\mathbb{E}[\rho(\hat{\mathbf{x}}) + v(\hat{\mathbf{x}})] \leq \Delta + \frac{5mn(\bar{a} + \bar{d})^2}{2} \gamma + \frac{\bar{c}}{\gamma \bar{d}}$$

and taking optimal $\gamma^* = \sqrt{\frac{2\bar{c}}{5\bar{d}(\bar{a} + \bar{d})^2 mn}}$ to minimize the right hand side.

A.4 Proof of Results in Section 3.3

A.5 Proof of Theorem 3

In this section we consider the variable duplication scheme. Given an LP

$$\begin{aligned}
&\max_{\mathbf{x}} && \langle \mathbf{c}, \mathbf{x} \rangle \\
&\text{subject to} && \mathbf{A}\mathbf{x} \leq \mathbf{b} \\
&&& \mathbf{0} \leq \mathbf{x} \leq \mathbf{1}
\end{aligned}$$

and its duplicated version

$$\begin{aligned} & \max_{\{\mathbf{x}_j\}} \quad \sum_{j=1}^K \langle \mathbf{c}, \mathbf{x}_j \rangle \\ & \text{subject to} \quad \sum_{j=1}^K \mathbf{A} \mathbf{x}_j \leq K \mathbf{b} \\ & \quad \quad \quad \mathbf{0} \leq \mathbf{x}_j \leq \mathbf{1}, \end{aligned}$$

It's clear that the duplicated LP also satisfies **A1**, **A2**. Also we know that **A3** can be satisfied by an arbitrarily small perturbation of the objective coefficients. Then we immediately have $\sum_{j=1}^K \langle \mathbf{c}, \mathbf{x}_j^* \rangle = K \langle \mathbf{c}, \mathbf{x}^* \rangle$ up to some arbitrarily small perturbation. Suppose that we apply **Theorem 1** or **Theorem 2** to get $\{\mathbf{x}'_j\}$ such that

$$\begin{aligned} \mathbb{E} \left[K \langle \mathbf{c}, \mathbf{x}^* \rangle - \sum_{j=1}^K \langle \mathbf{c}, \mathbf{x}'_j \rangle \right] &= \mathcal{O}(m \log n + \sqrt{nK} \log n + \sqrt{mnK} + \sqrt{nK} \log K) \\ \mathbb{E} \left[\left\| \left[\sum_{j=1}^K \mathbf{A} \mathbf{x}'_j - K \mathbf{b} \right]_+ \right\| \right] &= \mathcal{O}(m + \sqrt{mnK}). \end{aligned}$$

Then in view of $\hat{\mathbf{x}} = \frac{1}{K} \sum_{j=1}^K \mathbf{x}'_j$ we have

$$\begin{aligned} \mathbb{E}[\rho(\hat{\mathbf{x}})] &= \langle \mathbf{c}, \mathbf{x}^* \rangle - \langle \mathbf{c}, \frac{1}{K} \sum_{k=1}^K \mathbf{x}'_k \rangle = \mathcal{O} \left(\frac{m \log n}{K} + \sqrt{\frac{n}{K}} \log n + \sqrt{\frac{mn}{K}} + \sqrt{\frac{n}{K}} \log K \right) \\ \mathbb{E}[v(\hat{\mathbf{x}})] &= \left\| \left[\mathbf{A} \left(\frac{1}{K} \sum_{j=1}^K \mathbf{x}'_j \right) - \mathbf{b} \right]_+ \right\| = \mathcal{O} \left(\frac{m}{K} + \sqrt{\frac{mn}{K}} \right) \end{aligned}$$

assuming that $K = \mathcal{O}(n)$, and this completes the proof.

A.6 Additional Experiment on Violated Assumption

In this section, we carry out additional experiment to see what happens when some of our assumptions are (nearly) violated. Specifically we consider the MKP problem with $\mathbf{b} = \mathbf{1}$.

$$\begin{aligned} & \max_{\mathbf{x}} \quad \langle \mathbf{c}, \mathbf{x} \rangle \\ & \text{subject to} \quad \mathbf{A} \mathbf{x} \leq \mathbf{1} \\ & \quad \quad \quad \mathbf{0} \leq \mathbf{x} \leq \mathbf{1}, \end{aligned}$$

Note that when n is large, **A1** becomes asymptotically violated since $\underline{d} = \frac{1}{n}$ becomes closer to one.

Testing Configuration and Setup We configure the algorithm as follows (**Section 5** gives a more detailed description).

- 1). **Dataset.** We take $(m, n) \in \{(5, 100), (8, 1000), (16, 2000), (32, 4000)\}, \sigma = 1$.
- 2). **Initial Point.** We let online algorithms start from $\mathbf{0}$.
- 3). **Feasibility.** We force the algorithm to respect constraint violation.

Figure 3: From left to right: $(m, n) \in \{(5, 100), (8, 1000), (16, 2000), (32, 4000)\}$ The axis represents K parameter ranging from 1 to 128. y-axis, relative optimality gap

4). **Duplication.** We allow $K \in \{1, 2, 4, 8, 16, 32, 64, 128\}$

5). **Stepsize.** We take $\gamma = (Kmn)^{-1/2}$.

We see that as suggested by our theory, as $d = \frac{1}{n}$ gets smaller, online algorithms perform poorly when $K = 1$, but when we increase K , both implicit and explicit update gradually retrieve low optimality gap.

B Practical Aspects of Online Linear Programming

In this section, we discuss practical aspects of online linear programming in more details. In **B.1** and **B.2**, we show when and how online updates can be carried out efficiently; In **B.2**, we apply online explicit update to more LP problem types and compare its performance with other LP solvers; In **B.4**, we formalize the contents of LP sifting and present more implementation details. Finally we show in **B.5** that online LP is applicable to speedup solution of mixed integer programming.

B.1 Fast $\mathcal{O}(\text{nnz}(\mathbf{A}))$ Implementation For the Explicit Update

In this section, we discuss the practical aspects of implementing the explicit update. The computation of explicit update comes from the following two steps

$$\begin{aligned} x^k &\leftarrow \mathbb{I}\{c_k > \langle \mathbf{a}_k, \mathbf{y} \rangle\} \\ \mathbf{y}^{k+1} &\leftarrow [\mathbf{y}^k + \mathbf{a}_k x^k - \mathbf{d}]_+, \end{aligned}$$

where we take $\gamma = 1$ without loss of generality. Due to the `axpy` operation $\mathbf{y} + \gamma(\mathbf{a}_k x^k - \mathbf{d})$ and the full density of \mathbf{d} , a raw implementation of `axpy` and $[\mathbf{x}]_+$ will immediately result in $\mathcal{O}(mn)$ flops and is undesirable. To address this, we define $p_j(k) := \max_l \{l < k : a_{l,j} \neq 0\}$, the latest iteration l where $a_{l,j}$ is nonzero. Then we observe that

$$\begin{aligned} y_j^{k+1} &= [y_j^k - a_{k,j} x^k - d]_+ \\ &= [[y_j^{k-1} - a_{k-1,j} x^{k-1} - d]_+ - a_{k,j} x^k - d]_+ \\ &= \dots \\ &= [[y_j^{p(k)} - a_{p(k),j} x^{p(k)} - d]_+ - (k - p(k))d]_+, \end{aligned}$$

where we use the relation $[[a - b]_+ - b]_+ = [a - 2b]_+, b \geq 0$ recursively. Further we observe that

$$a_j^{k+1} y_j^{k+1} = a_j^{k+1} [[y_j^{p(k)} - a_{p(k),j} x^{p(k)} - d]_+ - (k - p(k))d]_+,$$

which implies that we only need to evaluate $[[y_j^{p(k)} - a_{p(k),j} x^{p(k)} - d]_+ - (k - p(k))d]_+$ if $a_j^{k+1} \neq 0$ and the operation takes $\mathcal{O}(1)$. Hence we have overall complexity of $\mathcal{O}(\text{nnz}(\mathbf{A}))$ to compute all the primal estimates $\{x^k\}$ and $\mathcal{O}(m)$ to recover \mathbf{y}^{n+1} . In practice we can maintain an \mathbb{N}^m array `lastUpdate[m]` to record and to update $p_j(k)$ for each $j \in [m]$.

B.2 Cases of Simple Implicit Update

In this section we focus on practical implementation of the online implicit update and discuss the case where the implicit is easier to compute. Here we consider

$$\begin{aligned} \min_{\mathbf{y}} \quad & \langle \mathbf{d}, \mathbf{y} \rangle + [c - \langle \mathbf{a}, \mathbf{y} \rangle]_+ + \frac{1}{2\gamma} \|\mathbf{y} - \mathbf{z}\|^2 \\ \text{subject to} \quad & \mathbf{y} \geq \mathbf{0}. \end{aligned}$$

where $\mathbf{a} \geq \mathbf{0}$. Let \mathbf{y}^+ be the optimal solution to the problem and we do case analysis.

Case 1. $c - \langle \mathbf{a}, \mathbf{y}^+ \rangle > 0$. Then $\mathbf{y}^+ = \mathbf{z} - \gamma^{-1}(\mathbf{a} - \mathbf{d})$.

Case 2. $c - \langle \mathbf{a}, \mathbf{y}^+ \rangle < 0$. Then $\mathbf{y}^+ = \mathbf{z} - \gamma^{-1}\mathbf{d}$.

Case 3. $c - \langle \mathbf{a}, \mathbf{y}^+ \rangle = 0$. Then we have, equivalently, that \mathbf{y}^+ is the optimal solution to the following problem.

$$\begin{aligned} \min_{\mathbf{y}} \quad & \langle \mathbf{d}, \mathbf{y} \rangle + \frac{1}{2\gamma} \|\mathbf{y} - \mathbf{z}\|^2 \\ \text{subject to} \quad & \langle \mathbf{a}, \mathbf{y} \rangle = c \\ & \mathbf{y} \geq \mathbf{0}. \end{aligned}$$

Since $\mathbf{a} \geq \mathbf{0}$, letting (A, \bar{A}) be the partition of $[m]$ such that $\mathbf{a}_A > \mathbf{0}$ and we can separate the problem into

$$\begin{aligned} \min_{\mathbf{y}_{\bar{A}}} \quad & \langle \mathbf{d}_{\bar{A}}, \mathbf{y}_{\bar{A}} \rangle + \frac{1}{2\gamma} \|\mathbf{y}_{\bar{A}} - \mathbf{z}_{\bar{A}}\|^2 \\ \text{subject to} \quad & \mathbf{y}_{\bar{A}} \geq \mathbf{0} \end{aligned}$$

and

$$\begin{aligned} \min_{\mathbf{y}_A} \quad & \langle \mathbf{d}_A, \mathbf{y}_A \rangle + \frac{1}{2\gamma} \|\mathbf{y}_A - \mathbf{z}_A\|^2 \\ \text{subject to} \quad & \langle \mathbf{a}_A, \mathbf{y}_A \rangle = c \\ & \mathbf{y}_A \geq \mathbf{0}, \end{aligned}$$

where $\mathbf{y}_{\bar{A}}$ can be efficiently updated and \mathbf{y}_A can be written as

$$\mathbf{y}_A = \text{Proj}_{\Delta_{\mathbf{a}_A/c}}(\mathbf{z}_A - \gamma^{-1}\mathbf{d}_A),$$

where $\text{Proj}_{\Delta_{\mathbf{a}_A/c}}$ denotes orthogonal projection onto the weighted simplex

$$\Delta_{c^{-1}\mathbf{a}_A} := \{\mathbf{y}_A : \langle c^{-1}\mathbf{a}_A, \mathbf{y}_A \rangle = 1, \mathbf{y}_A \geq \mathbf{0}\}$$

and can be efficiently solved using sorting-based method proposed in [16].

Remark 12. In practice, we can try the solutions from the first two cases and verify if they satisfy the conditions. If in both cases the condition is violated, we invoke the above subroutine and compute the projection.

B.3 Direct Approximate LP Solving

In this section, we evaluate of performance of online LP solver for direct LP solving. The experiments in this section consist of two parts. First we focus on the CPU running time of our proposed method and then we turn to more LP instances as an extension of the experiments in the **Section 5**.

CPU Time Evaluation First we evaluate the CPU running time of our methods. As we already discussed, we can implement the online LP algorithm in $\mathcal{O}(\text{nnz}(\mathbf{A}))$ time, which implies our method is high scalable. The following table summarizes the total CPU time **Algorithm 2** with $K = 100$ requires under different settings of m, n and $\text{nnz}(\mathbf{A})$. Now that explicit update is independent of specific numerical values of the matrices, we use the same way of data generation as in **Section 5**.

Table 5 suggests, for the same n , CPU time our method increases almost linearly with respect to $\text{nnz}(\mathbf{A})$, which verifies that the implementation from **Section B.1** is highly scalable to huge linear programs.

Table 5: CPU Time evaluation of explicit update. Time given in CPU seconds.

m	n	nnz	Time	m	n	nnz	Time	m	n	nnz	Time
10^2	10^2	10^3	0.00	10^3	10^2	10^4	0.00	10^4	10^2	10^4	0.01
10^2	10^3	10^4	0.00	10^3	10^3	10^4	0.00	10^4	10^3	10^5	0.04
10^2	10^4	10^4	0.02	10^3	10^4	10^5	0.05	10^4	10^4	10^6	0.38
10^2	10^5	10^5	0.26	10^3	10^5	10^6	0.51	10^4	10^5	10^5	0.28

Real and synthetic LPs Now we switch to a more practical setting where we employ online algorithms to solve real-life instances and compare performance of online algorithm with LP solvers. Our setup is given as follows.

Testing configuration and setup

- 1). **Dataset.** Our dataset comes from three sources. **1).** 7 instances that are LP relaxations from MIPLIB. **2).** 4 MKP instances generated according to the statistics in **Table 5.** **3).** Modified `Netlib` instances.
- 2). **Initial point.** We let online algorithm start from $\mathbf{0}$
- 3). **Feasibility.** We do not enforce feasibility of constraints
- 4). **Duplication.** We allow a maximum of $K = 5000$ variable duplications
- 5). **Stopping criterion.** We let the algorithm stop if

$$\max \left\{ \frac{\|[\mathbf{Ax} - \mathbf{b}]_+\|}{\|\mathbf{b}\|_1 + 1}, \frac{\langle \mathbf{b}^\top \mathbf{y} \rangle + \langle \mathbf{u}, [\mathbf{c} - \mathbf{A}^\top \mathbf{y}]_+ \rangle - \langle \mathbf{c}, \mathbf{x} \rangle}{|\langle \mathbf{b}^\top \mathbf{y} \rangle + \langle \mathbf{u}, [\mathbf{c} - \mathbf{A}^\top \mathbf{y}]_+ \rangle| + |\langle \mathbf{c}, \mathbf{x} \rangle| + 1} \right\} \leq \varepsilon = 5 \times 10^{-3}$$

- 6). **Modification of `Netlib` instances.** Many `Netlib` instances do not meet assumptions for the online algorithm and thus prohibits direct solving. Thus we modify `Netlib` instances by **1).** Taking $\hat{b}_i = \max\{b_i, 10^{-3}\}$. **2).** Enforcing upperbound $u_i = \min\{u_i, 10^2\}$. **3).** Changing constraint senses into \leq .

Remark 13. Since our modification of `Netlib` instances destroys the original bound and coefficients, our experiment on `Netlib` is presented only for reference.

Table 6: Time of solving MIPLIB instances to an $1e-03$ relative accuracy solution and comparison with Gurobi v9.5. Synthetic MKP instance `mkp- $\{i\}$ - $\{j\}$` stands for MKP instance of i rows and j columns. GTime: Gurobi solution time.

B.4 Sifting and Column Generation

In this section, we provide a deeper discussion of online LP in the context of sifting, and more broadly, column generation. We organize this section as follows. First, we introduce the basic setup and intuition of the sifting algorithm and track its history of development. Then we describe several difficulties sifting solvers face in practice and some popular solutions. Last we show that our method perfectly aligns with sifting and how we can make use of outputs of online algorithms to speed up sifting.

B.4.1 Sifting: Column Generation for Linear Programming

Assume we are solving a standard-form LP

$$\begin{aligned} \max_{\mathbf{x}} \quad & \langle \mathbf{c}, \mathbf{x} \rangle \\ \text{subject to} \quad & \mathbf{A}\mathbf{x} = \mathbf{b} \\ & \mathbf{x} \geq \mathbf{0} \end{aligned}$$

where $\mathbf{A} \in \mathbb{R}^{m \times n}$ and suppose $n \gg m$. By the theory of LP, we know that given an optimal basis \mathcal{B}^* and the corresponding solution \mathbf{x}^* , $\|\mathbf{x}^*\|_0 := |\{i | x_i^* > 0\}| \leq m \ll n$. This property tells us one important fact that most columns are redundant for optimality. One illustration of this property is that if we somehow manage to find a subset $\mathcal{B}^* \subseteq \mathcal{W} \subseteq [n]$ and solve a smaller LP

$$\begin{aligned} \max_{\mathbf{x}_{\mathcal{W}}} \quad & \langle \mathbf{c}_{\mathcal{W}}, \mathbf{x}_{\mathcal{W}} \rangle \\ \text{subject to} \quad & \mathbf{A}_{\mathcal{W}}\mathbf{x}_{\mathcal{W}} = \mathbf{b} \\ & \mathbf{x}_{\mathcal{W}} \geq \mathbf{0}, \end{aligned}$$

then $\langle \mathbf{c}_{\mathcal{W}}, \mathbf{x}_{\mathcal{W}}^* \rangle = \langle \mathbf{c}_{\mathcal{W}}, \mathbf{x}_{\mathcal{W}}^* \rangle + \langle \mathbf{c}_{\bar{\mathcal{W}}}, \mathbf{x}_{\bar{\mathcal{W}}}^* \rangle = \langle \mathbf{c}, \mathbf{x}^* \rangle$ and we solve the original LP at lower cost by concatenating $\mathbf{x}^* = (\mathbf{x}_{\mathcal{W}}^*, \mathbf{x}_{\bar{\mathcal{W}}}^* = \mathbf{0})$. The very intuition behind sifting is to iteratively update \mathcal{W} till $\mathcal{B}^* \subseteq \mathcal{W}$ in hope of $|\mathcal{W}| \ll [n]$.

Although we solve for the optimal primal solution \mathbf{x}^* , one of the most important components of sifting instead lies in the dual solution \mathbf{y}^* , as dual solutions tell us how to update \mathcal{W} if $\mathcal{B}^* \not\subseteq \mathcal{W}$. Given optimal $(\mathbf{x}_{\mathcal{W}}^*, \mathbf{y}_{\mathcal{W}}^*)$ to the aforementioned LP but \mathcal{W} does not contain any optimal bases, we know that $\mathbf{c} - \mathbf{A}^{\top} \mathbf{y}_{\mathcal{W}}^* \not\leq \mathbf{0}$, or $\mathbf{x}^* =$

$(\mathbf{x}_{\mathcal{W}}^*; \mathbf{x}_{\bar{\mathcal{W}}}^* = \mathbf{0})$ is certificated as optimal. In other words, we know some dual infeasibility hides in $\bar{\mathcal{W}}$:

$$c_j - \langle \mathbf{a}_j, \mathbf{y}_{\mathcal{W}}^* \rangle > 0, \quad \text{for some } j \in \mathcal{I} \subseteq \bar{\mathcal{W}}.$$

and this information guides us to eliminate such dual infeasibility by updating $\mathcal{W} \leftarrow \mathcal{W} \cup \mathcal{I}$. Now that $(\mathbf{x}_{\mathcal{W}}^*, \mathbf{x}_{\mathcal{I}} = \mathbf{0})$ is feasible for the updated LP, sifting subproblems can be efficiently warm-started from the previous iterations.

Now we are ready to formalize the LP sifting procedure. Given $\mathcal{W} \subseteq [n]$, the smaller LP is called a *working problem* and the procedure finding $\mathcal{I} \subseteq \bar{\mathcal{W}}$ is called *pricing*. Sifting iteratively updates the working problem, by pricing out dual infeasible columns till $\mathcal{I} = \emptyset$.

Development of LP Sifting The idea of sifting was initially proposed in [16] and formalized in a case study [8] to solve the LP relaxation of a huge airline crew scheduling problem. One advantage of sifting is the freedom to choose solvers for the working problems, such as simplex and the interior point method. Since then, sifting has been adopted as a common framework for huge LPs and applied in different fields [8, 14, 17]. State-of-the-art mathematical programming softwares [3, 35, 19, 30] these days implement their own sifting solvers and trigger it when the ratio n/m is large. In a word, sifting has evolved into a mature engineering technique for huge LPs.

Connection with Column Generation It’s not hard to see sifting bears great resemblance to column generation [11] from early LP/MIP literature. To some extent sifting is a special case of column generation and one major difference lies in the treatment in the pricing problem. In sifting we can enumerate all the columns to find $\mathcal{I} = \{j \in \bar{\mathcal{W}} : c_j - \langle \mathbf{a}_j, \mathbf{y}_{\mathcal{W}}^* \rangle > 0\}$, while in the traditional setting of column generation (for example, cutting stock [2]) we often resort to heuristics or combinatorial approaches to identify “the most infeasible column”

$$\max_{j \in \bar{\mathcal{W}}} c_j - \langle \mathbf{a}_j, \mathbf{y}_{\mathcal{W}}^* \rangle.$$

Due to the deep connection between sifting and column generation, most techniques developed for column generation can be smoothly applied to sifting. In the next section, we discuss the difficulties of implementing a sifting solver and some widely known solutions from column generation literature.

B.4.2 Difficulties and Solutions

In this section, we discuss the difficulties when implementing a sifting solver. There are three major difficulties well-known as **1).** heading-in **2).** tailing-off and **3).** dual oscillation. And we would like to further ascribe these difficulties [11] to a lack of *prior knowledge*.

Lack of Prior Primal Knowledge We refer to prior primal knowledge as a measure of *likelihood* that each column participates in the optimal, or simply a feasible basis. We believe a lack of this knowledge is partially responsible for the heading-in and tailing-off effect.

Heading-in effect appears in the initialization of sifting, where we have to start from some initial working problem \mathcal{W} and move on. However, if we are given no prior knowledge, how to pick \mathcal{W} becomes a problem: it’s unlikely that arbitrarily initialized \mathcal{W} would produce a feasible, not to mention an approximately optimal solution to the

original problem. Therefore most sifting implementation resorts to big- M method, where the original problem is augmented by two blocks of artificial variables associated with big- M penalties.

$$\begin{aligned} & \max_{\mathbf{x}, \mathbf{s}_l, \mathbf{s}_u} \quad \langle \mathbf{c}_{\mathcal{W}}, \mathbf{x}_{\mathcal{W}} \rangle - M \langle \mathbf{e}, \mathbf{s}_l \rangle - M \langle \mathbf{e}, \mathbf{s}_u \rangle \\ \text{subject to} \quad & \mathbf{A}_{\mathcal{W}} \mathbf{x}_{\mathcal{W}} - \mathbf{s}_l + \mathbf{s}_u = \mathbf{b} \\ & \mathbf{x}_{\mathcal{W}}, \mathbf{s}_l, \mathbf{s}_u \geq \mathbf{0} \end{aligned}$$

The augmented problem is equivalent to the original problem if M is sufficiently large and is always feasible. However, whenever \mathbf{s}_l or \mathbf{s}_u has an entry in the basis, $M \langle \mathbf{e}, \mathbf{s}_l \rangle + M \langle \mathbf{e}, \mathbf{s}_u \rangle$ would make the objective value from sifting far from the true approximate objective, and thus the initial sifting iterations provide little information about the original problem: we get no information until we kick \mathbf{s}_l and \mathbf{s}_u out of basis. This effect is known as heading-in and can be addressed by the prior knowledge about an approximate feasible primal solution.

Tailing-off refers to the phenomenon where consecutive sifting iterations bring little progress when sifting converges. In other words, at the end of sifting we keep pricing out “useless” columns that bring no actual improvement, and the true optimal basic columns stay in \mathcal{W} . While several factors may contribute to tailing-off, prior knowledge about some approximate optimal solution can efficiently alleviate this effect. Namely given some approximate optimal solution $\hat{\mathbf{x}}$, we could either incorporate $\hat{\mathbf{x}}$ in the pricing rule, or simply keep all the basic columns in $\hat{\mathbf{x}}$ in the working problem.

Lack of Prior Dual Knowledge We refer to dual prior knowledge as an approximate dual optimal solution. A lack of this knowledge directly results in the notorious dual oscillation effect in sifting. For a more rigorous definition and analysis of dual oscillation we refer the interested readers to [11, 5], and in a word dual oscillation refers to the dual sequence $\{\mathbf{y}_{\mathcal{W}}^*\}$ performs unstably, which is also one important reason why tailing-off happens. There is vast literature attacking the issue of dual oscillation, and a systematic approach, known as dual stabilization, has been proposed and successfully applied to many applications. An important aspect of dual stabilization is to make $\{\mathbf{y}_{\mathcal{W}}^*\}$ go more smoothly by taking average

$$\mathbf{y}_{\mathcal{W}}^* \leftarrow \alpha \mathbf{y}_{\mathcal{W}}^* + (1 - \alpha) \hat{\mathbf{y}}, \alpha \in (0, 1]$$

where $\hat{\mathbf{y}}$ is an “anchor point” in the dual space obtained either before or during sifting. Some common choices of $\hat{\mathbf{y}}$ are geometric centers of the primal polytope $\{\mathbf{x} : \mathbf{A}\mathbf{x} = \mathbf{b}, \mathbf{x} \geq \mathbf{0}\}$, such as analytic center [12] and Chebyshev center [9]. But these centers are generally too costly to be computed and less practical for really huge-scale problems.

So far we have discussed several issues sifting faces and their solutions. Overall we should find some approximate primal/dual optimal solution at low cost, and our online algorithms has a role to play here.

B.4.3 Accelerated Sifting via Online Algorithms

Finally, we are ready to present our accelerated sifting procedure using online algorithms. Recall that our method **1).** outputs an approximate primal estimate $\hat{\mathbf{x}}$. **2).** outputs a dual approximate. **3).** runs in $\mathcal{O}(\text{nnz}(\mathbf{A}))$ time. Therefore our method can provide both primal and dual estimate at very low cost.

Figure 4: Convergence of the dual solution \mathbf{y}^k to the optimal \mathbf{y}^*

Remark 14. Generally online algorithm does not address heading-in since the problem structure we target admits a trivial primal feasible solution $\mathbf{x} = \mathbf{0}$. But providing an initial good guess of optimal basis can often speed up sifting.

B.5 Integer Programming

Finally, we remark that our method can be naturally extended to binary (and integer) programming. Let $\mathbf{x}_{\text{Bin}}^*$ denote the optimal solution to the binary problem and let $\mathbf{x}_{\text{LP}}^*, \mathbf{y}_{\text{LP}}^*$ be the optimal solution to the LP relaxation. Also let $\hat{\mathbf{x}}_{\text{Bin}}$ be some integer feasible solution and $\hat{\mathbf{y}}_{\text{LP}}$ be some dual feasible solution, then the following chain of inequalities hold

$$\langle \mathbf{c}, \hat{\mathbf{x}}_{\text{Bin}} \rangle \leq \langle \mathbf{c}, \mathbf{x}_{\text{Bin}}^* \rangle \leq \langle \mathbf{c}, \mathbf{x}_{\text{LP}}^* \rangle \leq \langle \mathbf{b}, \mathbf{y}_{\text{LP}}^* \rangle + \langle \mathbf{1}, [\mathbf{c} - \mathbf{A}^\top \mathbf{y}_{\text{LP}}^*]_+ \rangle \leq \langle \mathbf{b}, \hat{\mathbf{y}}_{\text{LP}} \rangle + \langle \mathbf{1}, [\mathbf{c} - \mathbf{A}^\top \hat{\mathbf{y}}_{\text{LP}}]_+ \rangle$$

and

$$\langle \mathbf{c}, \mathbf{x}_{\text{LP}}^* \rangle - \langle \mathbf{c}, \hat{\mathbf{x}}_{\text{Bin}} \rangle \leq \langle \mathbf{b}, \hat{\mathbf{y}}_{\text{LP}} \rangle + \langle \mathbf{1}, [\mathbf{c} - \mathbf{A}^\top \hat{\mathbf{y}}_{\text{LP}}]_+ \rangle - \langle \mathbf{c}, \hat{\mathbf{x}}_{\text{Bin}} \rangle,$$

which implies $\hat{\mathbf{y}}$ provides a valid dual bound for the binary programming problem. Combined with $\hat{\mathbf{x}}$ obtained by rounding solution from online algorithm $\hat{\mathbf{x}}_{\text{LP}}$, we can expect solving a binary programming problem without resorting to branch and bound. As with general integer problems, we can split $x_j \in \{0, \dots, U\}$ into $x_j = \sum_{k=1}^U x_{jk}$ and re-apply the algorithm for binary problems.
