

A 1-Separation Formula for the Graph Kemeny Constant and Braess Edges

Nolan Faught*, Mark Kempton†, Adam Knudson‡

Abstract

Kemeny’s constant of a simple connected graph G is the expected length of a random walk from i to any given vertex $j \neq i$. We provide a simple method for computing Kemeny’s constant for 1-separable via effective resistance methods from electrical network theory. Using this formula, we furnish a simple proof that the path graph on n vertices maximizes Kemeny’s constant for the class of undirected trees on n vertices. Applying this method again, we simplify existing expressions for the Kemeny’s constant of barbell graphs and demonstrate which barbell maximizes Kemeny’s constant. This 1-separation identity further allows us to create sufficient conditions for the existence of Braess edges in 1-separable graphs. We generalize the notion of the Braess edge to Braess sets, collections of non-edges in a graph such that their addition to the base graph increases the Kemeny constant. We characterize Braess sets in graphs with any number of twin pendant vertices, generalizing work of Kirkland et. al. [9] and Ciardo [7].

1 Introduction

Kemeny’s constant is an invariant of a Markov chain that represents the expectation of the hitting times. Kemeny’s constant of a Markov chain P is computed with the sum

$$\mathcal{K}(P) = \sum_j \pi_j m_{ij},$$

where π_j is the j -th entry of the stationary distribution of the Markov chain and m_{ij} is the hitting time of j for a random walk with initial state i . Although this sum is not well-defined for all Markov chains, it is well-defined for random walks on simple connected graphs. In this context, Kemeny’s constant measures the expected length of a random walk between two randomly chosen vertices, and serves as a measure of how well-connected a graph is. For a more comprehensive discussion of Kemeny’s constant, we refer the reader to [6]. This has mathematical applications to graph theory, and real-world applications in robotics [15], web navigation [11], and mathematical chemistry [12].

Intuitively, adding edges to a graph increases connectivity and generates shortcuts for random walks, so we would expect Kemeny’s constant to decrease when we add connections to a graph. Typically this is true, but the authors of [9] demonstrate that most trees contain a pair of vertices such that adding an edge between them increases Kemeny’s constant. This phenomenon is an

instance of Braess' traffic-planning paradox, presented in [3] (see [4] for an English translation), in which the deletion of an edge from a network improves some properties of connectivity. A non-edge e of a graph G that results in an increase of $\mathcal{K}(G)$ when inserted is a *Braess edge*.

The authors of [9] go on to prove that *twin pendants* (degree one vertices adjacent to the same vertex) in trees are always Braess. Building on this, [7] proves that twin pendants are always Braess on any nontrivial connected graph.

In the work of [9] and [7], the graphs in which Braess edges are observed to occur all have a *1-separation*, that is, a single vertex whose removal disconnects the graph. This gives rise to the question if Braess edges occur in other graphs with 1-separations. From this perspective, Kemeny's constant in a graph with a 1-separation is naturally approached using the *effective resistance* (also called *resistance distance*) from electrical network theory. Kemeny's constant can be expressed using a formula involving effective resistances in a graph (see Lemma 1.1 below). In addition, effective resistance is easily computed in graphs with a 1-separation (see Proposition 1.4 below). This provides the motivation for the present paper, in which we study Kemeny's constant in graphs with a 1-separation.

In this paper, we give a 1-separation formula for Kemeny's constant, that is, a formula for Kemeny's constant of a graph with a 1-separation given Kemeny's constant of simpler subgraphs. See Theorem 2.1 below. The proof of this Theorem makes use of the effective resistance and its nice behavior in graphs with a 1-separation. Furthermore, we demonstrate several uses of this 1-separation formula. First, we give simple expressions for Kemeny's constant of barbell graphs, which were studied in [5]. Barbell graphs are of interest in the study of Kemeny's constant, as they are believed, based on empirical computation, to maximize Kemeny's constant among graphs on a given number of vertices. From [5], it is known that certain barbells on n vertices have Kemeny's constant on the order of n^3 , and that order n^3 is the largest Kemeny's constant can be. Our 1-separation formula allows us to give an exact expression for Kemeny's constant in barbell graphs that is much simpler than that found in [5], and we are able to determine what barbell has the largest Kemeny's constant among all barbell graphs on n vertices. Second, we use our formula to prove that, among all trees on n vertices, the path graph has the largest Kemeny's constant. Finally, we will return our focus to Braess' paradox and use our formula to find conditions under which a graph with a 1-separation has a Braess edge or a Braess set of edges. We generalize work of [9] and [7] to include any number of twin pendants.

1.1 Notation and Preliminaries

We introduce a few definitions and results that we will use. We denote by $r_G(i, j)$ the *effective resistance* between vertex i and j , considering the graph as an electric circuit with each edge representing a unit resistor. This quantity is given by $r_G(i, j) = (e_i - e_j)^T L^\dagger (e_i - e_j)$ where e_i is the vector with a 1 in the i -th position and zeros elsewhere and L^\dagger is the Moore-Penrose pseudoinverse of the graph Laplacian matrix (see [1]).

Lemma 1.1 (Corollary 1 of [13]). *Suppose that $G = (V, E)$ is a simple connected graph, where R denotes the matrix whose (i, j) -th entry is the effective resistance between i and j , d the vector whose i -th entry is the degree of vertex i , and $m = |E|$. Kemeny's constant of the graph is related to the effective resistance by the identity*

$$\mathcal{K}(G) = \frac{d^T R d}{4m} = \frac{1}{4m} \sum_{i, j \in G} d_i d_j r_G(i, j).$$

The notion of the moment is proposed for rooted trees in [8]. We extend this concept to the more general class of simple connected graphs.

Definition 1.2. Let $G = (V, E)$ be a simple connected graph. Let e_v denote the vector with a 1 in the v -th position and zeros elsewhere. The *moment* of $v \in V$ is

$$\mu(G, v) = d^T R e_v = \sum_{i \in V(G)} d_i r_G(i, v).$$

Definition 1.3. Let G_1, G_2 be simple connected graphs and with labelled vertices $v_1 \in V(G_1)$, and $v_2 \in V(G_2)$. The *1-sum* $G = G_1 \oplus_{v_1, v_2} G_2$ is the graph created by taking a copy of G_1, G_2 , removing v_1 , and replacing every edge of the form $\{i, v_1\} \in E(G_1)$ with $\{i, v_2\}$. We often omit the subscript when the choice and/or labelling of vertices is clear. We say $G_1 \oplus_v G_2$ has a *1-separation*, and that v is a *1-separator* or *cut vertex*.

Figure 1: The graph $G = G_1 \oplus_v G_2$ created from G_1 and G_2

Proposition 1.4 (Theorem 2.5 of [2], Cut Vertex Theorem). *Let G be the 1-sum of G_1, G_2 with labelled vertex v . For $i \in V(G_1), j \in V(G_2)$,*

$$r_G(i, j) = r_{G_1}(i, v) + r_{G_2}(v, j).$$

2 The 1-Separation Formula

In this section we will derive various useful expressions for Kemeny's constant of graphs with 1-separations. These will make it easier to compute Kemeny's constant for 1-connected graphs, lead to a result about trees with maximal Kemeny's constant, and help us determine a sufficient condition on graph structures that may allow for Braess edges.

Theorem 2.1 below is a special case of Theorem 2.3 and used as a base cases in its proof. However, it is useful enough in its own right that we have included it as a theorem of its own.

Theorem 2.1. *Let G be a graph with a 1-separator v . Let G_1, G_2 be the two graphs of the 1-separation so $G = G_1 \oplus_v G_2$ and $m = |E(G)| = |E(G_1)| + |E(G_2)| = m_1 + m_2$. Then we have*

$$\mathcal{K}(G) = \frac{m_1 (\mathcal{K}(G_1) + \mu(G_2, v)) + m_2 (\mathcal{K}(G_2) + \mu(G_1, v))}{m_1 + m_2}.$$

Proof. We simplify the expression for Kemeny's constant in Lemma 1.1 via application of Proposition 1.4. Throughout the proof, we denote r_{G_1} and r_{G_2} with the shorthand r_1 and r_2 and d_{v_1} refers to the degree of v as a vertex of G_1 , while d_{v_2} its degree as a vertex of G_2 . Partition the vertex set V into $V_1 = V(G_1) \setminus \{v\}$, $V_2 = V(G_2) \setminus v$, and $\{v\}$, so that we now consider the sum over each part. Due to the symmetricity of effective resistance, each case $i \in V_k, j \in V_\ell, k \neq \ell$ is similar to $i \in V_\ell, j \in V_k$.

Let $i \in V_1$ and $j \in V_2$, then the sum over the parts is

$$\begin{aligned}
\frac{1}{4m} \sum_{i \in V_1, j \in V_2} d_i d_j r_G(i, j) &= \frac{1}{4m} \sum_{i \in V_1} d_i \sum_{j \in V_2} d_j (r_1(i, v) + r_2(v, j)) \\
&= \frac{1}{4m} \sum_{i \in V_1} d_i \left[\sum_{j \in V_2} d_j r_2(j, v) + \sum_{j \in V_2} d_j r_1(i, v) \right] \\
&= \frac{1}{4m} \left(\sum_{i \in V_1} d_i \mu(G_2, v) + \sum_{j \in V_2} d_j \left[\sum_{i \in V_1} d_i r_1(i, v) \right] \right) \\
&= \frac{1}{4m} ((2m_1 - d_{v_1})\mu(G_2, v) + (2m_2 - d_{v_2})\mu(G_1, v)) \\
&= \frac{m_1 \mu(G_2, v) + m_2 \mu(G_1, v)}{2m} - \frac{d_{v_1} \mu(G_2, v) + d_{v_2} \mu(G_1, v)}{4m}.
\end{aligned}$$

Taking the sum over $i, j \in V_1$,

$$\begin{aligned}
\frac{1}{4m} \sum_{i, j \in V_1} d_i d_j r_G(i, j) &= \frac{1}{4m} \sum_{i, j \in V(G_1)} d_i d_j r_1(i, j) - \frac{2}{4m} \sum_{i \in V_1} d_{v_1} d_i r_1(i, v) \\
&= \frac{m_1 \mathcal{K}(G_1)}{m} - \frac{d_{v_1} \mu(G_1, v)}{2m}.
\end{aligned}$$

The case for $i, j \in V_2$ is similar, with the sum evaluating to

$$\frac{1}{4m} \sum_{i, j \in V_2} d_i d_j r_G(i, j) = \frac{m_2 \mathcal{K}(G_2)}{m} - \frac{d_{v_2} \mu(G_2, v)}{2m}.$$

Finally, the sum over $i \in V_1$ with $j = v$ is

$$\frac{1}{4m} \sum_{i \in V_1} d_i d_v r_G(i, v) = \frac{d_v}{4m} \sum_{i \in V_1} d_i r_1(i, v) = \frac{(d_{v_1} + d_{v_2})\mu(G_1, v)}{4m},$$

which is similar to the sum over $i \in V_2$ with $j = v$,

$$\frac{1}{4m} \sum_{i \in V_1} d_i d_v r_2(i, v) = \frac{(d_{v_1} + d_{v_2})\mu(G_2, v)}{4m}.$$

Combining and doubling the appropriate terms,

$$\begin{aligned}
\frac{1}{4m} \sum_{i, j} d_i d_j r_G(i, j) &= 2 \left(\frac{m_1 \mu(G_2, v) + m_2 \mu(G_1, v)}{2m} - \frac{d_{v_1} \mu(G_2, v) + d_{v_2} \mu(G_1, v)}{4m} \right) \\
&\quad + \frac{m_1 \mathcal{K}(G_1)}{m} - \frac{d_{v_1} \mu(G_1, v)}{2m} + \frac{m_2 \mathcal{K}(G_2)}{m} - \frac{d_{v_2} \mu(G_2, v)}{2m} \\
&\quad + 2 \left(\frac{(d_{v_1} + d_{v_2})\mu(G_1, v)}{4m} \right) + 2 \left(\frac{(d_{v_1} + d_{v_2})\mu(G_2, v)}{4m} \right) \\
&= \frac{m_1 (\mathcal{K}(G_1) + \mu(G_2, v)) + m_2 (\mathcal{K}(G_2) + \mu(G_1, v))}{m}.
\end{aligned}$$

□

We will also consider graphs which have multiple 1-separations and get an expression for Kemeny's constant for such graphs. Before that we prove a useful Lemma.

Lemma 2.2. *Let $G = G_1 \oplus_{v_{1,2}} G_2 \oplus_{v_{2,3}} \dots \oplus_{v_{n-1,n}} G_n$. Then for some $v_{0,1} = v_0 \in G_1$ we have*

$$\mu(G, v_0) = \sum_{i=1}^n \mu(G_i, v_{i-1,i}) + 2 \sum_{i=2}^n r(v_{i-2,i-1}, v_{i-1,i}) \sum_{j=i}^n m_j.$$

Proof. We proceed by induction on n . For $n = 1$ this is immediate.

Suppose $n = 2$. In this case let $d_G(i)$ denote the degree of vertex i in $V(G)$. Then we have

$$\begin{aligned} \mu(G, v_0) &= \sum_{i \in G} d_G(i) r(i, v_0) \\ &= \sum_{\substack{i \in G_1 \\ i \neq v_{1,2}}} d_{G_1}(i) r_1(i, v_0) + (d_{G_1}(v_{1,2}) + d_{G_2}(v_{1,2})) r(v_{1,2}, v_0) \\ &\quad + \sum_{\substack{i \in G_2 \\ i \neq v_{1,2}}} d_{G_2}(i) (r_2(i, v_{1,2}) + r(v_{1,2}, v_0)) \\ &= \mu(G_1, v_0) + \mu(G_2, v_{1,2}) + 2m_2 r(v_{1,2}, v_0). \end{aligned}$$

Now suppose for some $k \geq 2$ the expression is true. Let $G = G_1 \oplus_{v_{1,2}} \dots \oplus_{v_{k-1,k}} (G_k \oplus_{v_{k,k+1}} G_{k+1})$. Note that $|E(G_k \oplus_{v_{k,k+1}} G_{k+1})| = m_k + m_{k+1}$. By the inductive hypothesis we have

$$\begin{aligned} \mu(G, v_0) &= \sum_{i=1}^{k-1} \mu(G_i, v_{i-1,i}) + 2 \sum_{i=2}^{k-1} r(v_{i-2,i-1}, v_{i-1,i}) \sum_{j=i}^{k-1} m_j + \mu((G_k \oplus_{v_{k,k+1}} G_{k+1}), v_{k-1,k}) \\ &\quad + 2 \sum_{i=2}^k r(v_{i-2,i-1}, v_{i-1,i}) (m_k + m_{k+1}) \end{aligned}$$

But $\mu((G_k \oplus_{v_{k,k+1}} G_{k+1}), v_{k-1,k}) = \mu(G_k, v_{k-1,k}) + \mu(G_{k+1}, v_{k,k+1}) + 2m_{k+1} r(v_{k-1,k}, v_{k,k+1})$. Substituting this into the above expression we will get the result. \square

Now we are ready to find Kemeny's constant for a graph with multiple 1-separations.

Theorem 2.3. *Let $G = G_1 \oplus_{v_{1,2}} G_2 \oplus_{v_{2,3}} \dots \oplus_{v_{n-1,n}} G_n$. Let $q_{i,j}$ be as follows.*

$$q_{i,j} = \begin{cases} (j-1, j) & j > i \\ (j, j+1) & j < i \end{cases}$$

Then Kemeny's constant of G is given by the following.

$$\mathcal{K}(G) = \frac{\sum_{i=1}^n m_i \left(\mathcal{K}(G_i) + \sum_{j \neq i} \mu(G_j, v_{q_{i,j}}) \right) + 2 \sum_{\substack{1 \leq i < j \leq n \\ j-i \geq 2}} m_i m_j r(v_{i,i+1}, v_{j-1,j})}{\sum_{i=1}^n m_i}.$$

Proof. For $n = 1$ this is true. For $n = 2$ this is true by Theorem 2.1.

Suppose this expression is true for some $n = k \geq 2$. Let

$$G = G_1 \oplus_{v_{1,2}} G_2 \oplus_{v_{2,3}} \cdots \oplus_{v_{k-1,k}} (G_k \oplus_{v_{k,k+1}} G_{k+1}).$$

Let $H_i = G_i$ for $i < k$ and let $H_k = (G_k \oplus_{v_{k,k+1}} G_{k+1})$. Then we can express G as

$$G = H_1 \oplus_{v_{1,2}} H_2 \oplus_{v_{2,3}} \cdots \oplus_{v_{k-1,k}} H_k.$$

If $m_i = |E(G_i)|$ and $\tilde{m}_i = |E(H_i)|$ then $m_i = \tilde{m}_i$ for $i < k$ and $\tilde{m}_k = m_k + m_{k+1}$. Notice by Theorem 2.1 and Theorem 2.2 we have the following.

$$\mathcal{K}(H_k) = \frac{m_k (\mathcal{K}(G_k) + \mu(G_{k+1}, v_{k,k+1})) + m_{k+1} (\mathcal{K}(G_{k+1}) + \mu(G_k, v_{k,k+1}))}{m_k + m_{k+1}} \quad (1)$$

$$\mu(H_k, v_{k-1,k}) = \mu(G_k, v_{k-1,k}) + \mu(G_{k+1}, v_{k,k+1}) + 2m_{k+1}r(v_{k-1,k}, v_{k,k+1}). \quad (2)$$

By the inductive hypothesis we have the following.

$$\mathcal{K}(G) = \frac{\sum_{i=1}^k \tilde{m}_i \left(\mathcal{K}(H_i) + \sum_{j \neq i} \mu(H_j, v_{q_i,j}) \right) + 2 \sum_{\substack{1 \leq i < j \leq k \\ j-i \geq 2}} \tilde{m}_i \tilde{m}_j r(v_{i,i+1}, v_{j-1,j})}{\sum_{i=1}^k \tilde{m}_i} \quad (3)$$

Now we will examine the numerator terms of (3). Using (2), for $i < k$ a term in the first term in the numerator looks like the following.

$$m_i \left(\mathcal{K}(G_i) + \sum_{\substack{j \neq i \\ j < k}} \mu(G_j, v_{q_i,j}) + \mu(G_k, v_{k-1,k}) + \mu(G_{k+1}, v_{k,k+1}) + 2m_{k+1}r(v_{k-1,k}, v_{k,k+1}) \right) \quad (4)$$

This gives the i -th term in the first sum of (3) and a resistance term.

Now, for $i = k$, (1) gives that a term in the first sum of (3) looks like the following.

$$m_k \left(\mathcal{K}(G_k) + \sum_{i \neq k} \mu(G_i, v_{q_i,k}) \right) + m_{k+1} \left(\mathcal{K}(G_{k+1}) + \sum_{i \neq k+1} \mu(G_i, v_{q_i,k}) \right) \quad (5)$$

Now consider the second term of (3). Terms in that sum that involve H_k will look like the following.

$$2m_i m_k r(v_{i,i+1}, v_{k-1,k}) + 2m_i m_{k+1} r(v_{i,i+1}, v_{k-1,k}) \quad (6)$$

But by combining (6) with the resistance term from (4) and using Proposition 1.4 we get

$$\begin{aligned} & 2m_i m_k r(v_{i,i+1}, v_{k-1,k}) + 2m_i m_{k+1} r(v_{i,i+1}, v_{k-1,k}) + 2m_i m_{k+1} r(v_{k-1,k}, v_{k,k+1}) \\ &= 2m_i m_k r(v_{i,i+1}, v_{k-1,k}) + 2m_i m_{k+1} r(v_{i,i+1}, v_{k,k+1}). \end{aligned} \quad (7)$$

Thus combining (4), (5), and (7) we get that

$$\mathcal{K}(G) = \frac{\sum_{i=1}^{k+1} m_i \left(\mathcal{K}(G_i) + \sum_{j \neq i} \mu(G_j, v_{q_i,j}) \right) + 2 \sum_{\substack{1 \leq i < j \leq k+1 \\ j-i \geq 2}} m_i m_j r(v_{i,i+1}, v_{j-1,j})}{\sum_{i=1}^{k+1} m_i}$$

and the result is proven. \square

Using the previous Theorem to consider a graph with multiple components all 1-summed at the same vertex gives the following result.

Corollary 2.4. *Let $G = G_1 \oplus_v G_2 \oplus_v \dots \oplus_v G_n$ and $m_i = |E(G_i)|$. Then Kemeny's constant of G is*

$$\mathcal{K}(G) = \frac{\sum_{i=1}^n m_i \left(\mathcal{K}(G_i) + \sum_{j \neq i} \mu(G_j, v) \right)}{\sum_{i=1}^n m_i}.$$

Proof. If $v_{i,i+1} = v_{j-1,j} = v$ then $r(v_{i,i+1}, v_{j-1,j}) = 0$. The result then follows directly from Theorem 2.3. \square

3 Applications of the 1-Separation Formula

In this section we will demonstrate how these results can simplify the computation of Kemeny's constant for graphs with a 1-separation. We will obtain an expression for Kemeny's constant of barbell graphs. We also provide a result about trees with maximal Kemeny's constant. Now, we state without proof the resistance, Kemeny's constant, and moment of some graphs that are both easy to compute and will prove useful. See [1] for details about how to compute effective resistance.

Proposition 3.1. *Let K_n and P_n be, respectively, the complete graph and path graph on n vertices $\{1, 2, \dots, n\}$. Then*

$$\begin{aligned} r_{K_n}(i, j) &= \frac{2}{n} \\ r_{P_n}(i, j) &= d(i, j) \end{aligned}$$

where $d(i, j)$ is the distance from i to j .

Proposition 3.2. *Let K_n , P_n , and S_n be, respectively, the complete graph, path graph, and star graph on n vertices $\{1, 2, \dots, n\}$. Let 1 be the central vertex of S_n . Then*

$$\begin{aligned} \mathcal{K}(K_n) &= \frac{(n-1)^2}{n} & \mathcal{K}(P_n) &= \frac{2n^2 - 4n + 3}{6} & \mathcal{K}(S_n) &= n - \frac{3}{2} \\ \mu(K_n, j) &= \frac{2(n-1)^2}{n} & \mu(P_n, j) &= (n-j)^2 + (j-1)^2 & \mu(S_n, 1) &= n - 1. \end{aligned}$$

3.1 Barbell Graphs

In [5] barbell graphs are studied because of their large Kemeny's constants by using tools of spectral graph theory. They give the following definition for these barbell graphs.

Definition 3.3. (Definition 1.3 of [5]) The graph $B(k, a, b, c)$ on $ka + b + c$ vertices is formed by taking k copies of P_a (path on a vertices) and putting a clique at both ends to "glue" the paths together; we then connect all vertices of a K_b to one set of neighbors in the graph with degree k and a K_c to the other set of neighbors in the graph with degree k .

Figure 2: The graph $B(1, 6, 4, 5)$

We will concern ourselves only with barbells with $k = 1$. Using Theorem 2.3 makes it much easier to get an expression for Kemeny's constant of 1-connected barbell graphs, and the resulting expression is much simpler than that found in [5].

Theorem 3.4. *Kemeny's Constant of a Barbell graph $G = B(1, a, b, c)$ is given by*

$$\begin{aligned} \mathcal{K}(G) = \frac{1}{m} & \left[\binom{b+1}{2} \left(\frac{b^2}{b+1} + (a-1)^2 + \frac{2c^2}{c+1} \right) + (a-1) \left(\frac{2a^2 - 4a + 3}{6} + \frac{2b^2}{b+1} + \frac{2c^2}{c+1} \right) \right. \\ & \left. + \binom{c+1}{2} \left(\frac{c^2}{c+1} + (a-1)^2 + \frac{2b^2}{b+1} \right) + 2 \binom{b+1}{2} \binom{c+1}{2} (a-1) \right] \end{aligned}$$

where $m = \binom{b+1}{2} + \binom{c+1}{2} + a - 1$.

Proof. The graph $B(1, a, b, c)$ is the one sum of K_{b+1} , K_{c+1} , and P_a . Notice that $r_{P_a}(1, a) = a - 1$. With this fact and with Proposition 3.2 the result is an immediate consequence of Theorem 2.3 with $n = 3$. \square

As shown in [5], the barbell with maximum Kemeny constant (among all barbells on n vertices) will occur when a, b, c are all close to $\frac{n}{3}$. A more careful analysis of the expression in Theorem 3.4 shows that $B(1, \frac{n}{3} + 2, \frac{n}{3} - 1, \frac{n}{3} - 1)$ will be the actual barbell with largest Kemeny constant. In the next two corollaries one can see that Kemeny's constant of these two barbells have the same order of magnitude and differ only in the lower terms.

Corollary 3.5. *Kemeny's Constant of a Barbell graph $B(1, \frac{n}{3}, \frac{n}{3}, \frac{n}{3})$ is given by*

$$\mathcal{K} \left(B \left(1, \frac{n}{3}, \frac{n}{3}, \frac{n}{3} \right) \right) = \frac{1}{54} \left[n^3 + 3n^2 + 24n - 36 + \frac{-513n^2 + 1782n - 1701}{n^3 + 9n^2 + 9n - 27} \right].$$

Corollary 3.6. *Kemeny's Constant of a Barbell graph $B(1, \frac{n}{3} + 2, \frac{n}{3} - 1, \frac{n}{3} - 1)$ is given by*

$$\mathcal{K} \left(B \left(1, \frac{n}{3} + 2, \frac{n}{3} - 1, \frac{n}{3} - 1 \right) \right) = \frac{1}{54} \left[n^3 + 3n^2 + 60n - 270 + \frac{297n^2 - 729n + 5832}{n^3 + 9n} \right].$$

3.2 Trees

In this section we use Theorem 2.1 to show that the path graph has the largest Kemeny's constant among trees of order n . We first show that the path graph also has the largest moment among trees of order n . While this was shown by Proposition 5.2 of [8], for the sake of completeness we give a different proof using results from this paper. We note that in trees the effective resistance between vertices i, j is the graph distance between i, j (see [1]).

Lemma 3.7. *Let T_n denote a tree on n vertices and let $v \in V(T_n)$. Then $\mu(T_n, v) \leq \mu(P_n, 1)$.*

Proof. This is trivial to check for $n = 1, 2, 3$.

Suppose for some $k \geq 3$ that $\mu(T_k, v) \leq \mu(P_k, 1)$. Let $l \leq k$, $n = k + l - 1$, and $T_n = T_k \oplus_w T_l$. Then without loss of generality, by Theorem 2.2 we have

$$\begin{aligned} \mu(T_n, v) &= \mu(T_k, v) + \mu(T_l, w) + 2(l-1)r(w, v) \\ &\leq \mu(P_k, 1) + \mu(P_l, 1) + 2(l-1)(k-1) \\ &= \mu(P_n, 1). \end{aligned}$$

Thus for all n , $\mu(T_n, v) \leq \mu(P_n, 1)$. □

Theorem 3.8. *Among all trees on n vertices, the path P_n maximizes Kemeny's constant.*

Proof. Let T_n be a tree of order n . The result is trivial for $n = 1, 2, 3$.

We proceed with the inductive step. Suppose for some $k \geq 3$ the path graph P_k has maximal Kemeny's constant among trees of order k . Let $n = k + l - 1$ for some $l \leq k$. Consider the tree T_n obtained by 1-summing T_k and T_l together at some vertex v . Then by Theorem 2.1 and Lemma 3.7 we have

$$\begin{aligned} \mathcal{K}(T_n) &= \frac{(k-1)[\mathcal{K}(T_k) + \mu(T_l, v)] + (l-1)[\mathcal{K}(T_l) + \mu(T_k, v)]}{k+l-2} \\ &\leq \frac{(k-1)[\mathcal{K}(P_k) + \mu(P_l, 1)] + (l-1)[\mathcal{K}(P_l) + \mu(P_k, 1)]}{k+l-2} \\ &= \mathcal{K}(P_{k+l-1}) \\ &= \mathcal{K}(P_n). \end{aligned}$$

Thus among all trees of order n , the path graph has maximal Kemeny's constant. □

4 Braess Edges

In this section we will consider the notion of Braess edges introduced in [9]. We expand the idea of a Braess edge to a Braess set. We first provide an expression for the difference in Kemeny's constant after edges are added in one component of a graph with a 1-separation. Then, we provide a sufficient condition for such edges to be Braess. Finally, we consider a particular family of graphs as an example.

Definition 4.1 (Braess Edges).

- A *Braess edge* is a non-edge e of G such that when e is added to G , Kemeny's constant increases.
- A *Braess set* is a set of non-edges of G such that when the set is added to G , Kemeny's constant increases.

Let $G = G_1 \oplus_v G_2$ and m_1 and m_2 denote the number of edges in G_1 and G_2 , respectively. We let \mathcal{L} denote a set of pairs $\{u, v\}$ of G_2 that are not edges in G and let $\widehat{G} = (V, \widehat{E})$ denote the graph given by adding \mathcal{L} to G and note $|\widehat{E}| = m + l$. Note that the choice of G_2 is arbitrary, and the following result applies to a set of edges \mathcal{L} in either part of the separation.

Theorem 4.2. *Let G and \widehat{G} be as defined above. Then we have the following.*

$$\mathcal{K}(\widehat{G}) - \mathcal{K}(G) = \frac{lm_1(\mu(G_1, v) - \mathcal{K}(G_1))}{m(m+l)} + \frac{Am_1^2 + ((A+C)m_2 + Bl)m_1 + C(m_2^2 + lm_2)}{m(m+l)}$$

Where $A = \mu(\widehat{G}_2, v) - \mu(G_2, v)$, $B = \mathcal{K}(\widehat{G}_2) - \mu(G_2, v)$, and $C = \mathcal{K}(\widehat{G}_2) - \mathcal{K}(G_2)$.

Proof. Theorem 2.1 gives $\mathcal{K}(G)$ and $\mathcal{K}(\widehat{G})$ so all we must do is subtract one from the other. For convenience let $\mu(G) = \mu(G, v)$.

$$\begin{aligned} \mathcal{K}(\widehat{G}) - \mathcal{K}(G) &= \frac{m_1[\mathcal{K}(G_1) + \mu(\widehat{G}_2)] + (m_2 + l)[\mathcal{K}(\widehat{G}_2) + \mu(G_1)]}{m+l} \\ &\quad - \frac{m_1[\mathcal{K}(G_1) + \mu(G_2)] + m_2[\mathcal{K}(G_2) + \mu(G_1)]}{m} \\ &= \frac{m \left[m_1[\mathcal{K}(G_1) + \mu(\widehat{G}_2)] + (m_2 + l)[\mathcal{K}(\widehat{G}_2) + \mu(G_1)] \right]}{m(m+l)} \\ &\quad - \frac{(m+l)[m_1[\mathcal{K}(G_1) + \mu(G_2)] + m_2[\mathcal{K}(G_2) + \mu(G_1)]]}{m(m+l)} \\ &= \frac{lm_1(\mu(G_1) - \mathcal{K}(G_1))}{m(m+l)} \\ &\quad + \frac{m(m_2 + l)\mathcal{K}(\widehat{G}_2) - (m+l)m_2\mathcal{K}(G_2) + mm_1\mu(\widehat{G}_2) - (m+l)m_1\mu(G_2)}{m(m+l)} \\ &= \frac{lm_1(\mu(G_1) - \mathcal{K}(G_1))}{m(m+l)} \\ &\quad + \frac{mm_1(\mu(\widehat{G}_2) - \mu(G_2)) + lm_1(\mathcal{K}(\widehat{G}_2) - \mu(G_2))}{m(m+l)} \\ &\quad + \frac{mm_2(\mathcal{K}(\widehat{G}_2) - \mathcal{K}(G_2)) + lm_2(\mathcal{K}(\widehat{G}_2) - \mathcal{K}(G_2))}{m(m+l)} \\ &= \frac{lm_1(\mu(G_1, v) - \mathcal{K}(G_1))}{m(m+l)} + \frac{Am_1^2 + ((A+C)m_2 + Bl)m_1 + C(m_2^2 + lm_2)}{m(m+l)}. \end{aligned}$$

Thus we have arrived at the result, taking $A = \mu(\widehat{G}_2, v) - \mu(G_2, v)$, $B = \mathcal{K}(\widehat{G}_2) - \mu(G_2, v)$, and $C = \mathcal{K}(\widehat{G}_2) - \mathcal{K}(G_2)$. \square

Corollary 4.3. *If $Am_1^2 + ((A+C)m_2 + Bl)m_1 + C(m_2^2 + lm_2) > 0$ then \mathcal{L} , the set of edges added, is a Braess set.*

Proof. It was shown in Proposition 3.2 of [7] that the first term in Theorem 4.2 is non negative, so if the second term is positive then \mathcal{L} is a Braess set of edges. \square

Notably, the Braess set is not closed under union nor intersection; for example, the path on 7 vertices with the natural labelling $\{1, 2, \dots, 7\}$ admits the Braess set $\{(1, 3), (5, 7)\}$, but neither of the singleton sets $\{(1, 3)\}$ nor $\{(5, 7)\}$ are Braess themselves. Braess sets are an isolated occurrence, it seems.

It is also worth noting that if $A = \mu(\widehat{G}_2) - \mu(G_2) > 0$ then for a sufficiently large m_1 , the expression in Corollary 4.3 will be positive. That is, if the set of edges added to G_2 cause an increase in the moment of $v \in G_2$, then that is a Braess set provided G_1 has enough edges. Thus it appears that in graphs with a 1-separation, the moment of the individual graph components plays a more significant role in the existence of Braess sets than Kemeny's constant of the individual components.

We began studying Kemeny's constant in 1-connected graphs because intuition lead to believe that the presence of 1-separations caused Braess edges. This next result seems to support that intuition.

Corollary 4.4. *Set $G_1 = K_n \oplus P_n$. Then for any graph G_2 and any non-edge e of G_2 , e is Braess in $G = G_1 \oplus G_2$ for sufficiently large n . In particular, for any G_2 , there is a G_1 such that any pair in G_2 is Braess.*

Proof. Let $G_1 = K_n \oplus P_n$ be the 1-sum of a complete graph to the end of a path graph. Using Lemma 2.2, Theorem 2.1, and Proposition 3.2 we can show that

$$\begin{aligned}\mathcal{K}(G_1) &= \frac{3n^4 - n^3 + 5n^2 - 18n + 12}{3n(n+2)} \\ \mu(G_1, v) &= (n-1)^2 \left(n + 1 + \frac{2}{n} \right) \\ \mu(G_1, v) - \mathcal{K}(G_1) &= \frac{3n^4 - 2n^2 - 8n + 6}{3(n+2)}\end{aligned}$$

where v is the degree 1 vertex of G_1 . Notice that $|E(G_1)| = \binom{n}{2} + n - 1$.

Now fix G_2 and choose an edge to add. Note that in terms of Corollary 4.3, A, B, C, l are all constants. Now plugging all this information into Theorem 4.2 and looking only at the numerator we get the following.

$$\begin{aligned}m(m+1) \left(\mathcal{K}(\hat{G}) - \mathcal{K}(G) \right) &= \frac{(n+2)(n-1)}{2} \left(\frac{3n^4 - 2n^2 - 8n + 6}{3(n+2)} \right) + \frac{A(n+2)^2(n-1)^2}{4} \\ &\quad + ((A+C)m_2 + B) \frac{(n+2)(n-1)}{2} + C(m_2^2 + m_2)\end{aligned}$$

Notice the first term is $O(n^5)$ and positive, while the other terms are in $O(n^4)$. Therefore, even if all of $A, B, C < 0$, we would still see an increase in Kemeny's constant, provided n is large enough.

Thus for any G_2 and any non-edge e in G_2 , there exists a G_1 such that if $G = G_1 \oplus G_2$, e is a Braess edge. \square

We do not claim that G_1 as described in the above proof is the only graph to have this property, but it was used to show that there always exists a graph that has this property. Depending on choice of G_2 and the edge added one could potentially have G_1 be any graph at all, as was shown in [7] where $G_2 = P_3$ and P_3 was vertex summed to G_1 at the center node of P_3 .

4.1 A graph with k pendant vertices attached

Let G, \widehat{G} be as above. This section looks at the case where G_2 is a star graph S_{k+1} and v is the central vertex. This can also be viewed as attaching k pendant vertices at a point $v \in G_1$. The main result in this section is that any set of edges added to G_2 in this set up will be a Braess set of edges so long as G_1 is sufficiently large. This generalizes work of [7]. We first find Kemeny's constant of a graph with k pendant vertices attached.

Theorem 4.5. *Let $G = G_1 \oplus_v S_{k+1}$ where v is the central vertex of S_{k+1} . Then*

$$\mathcal{K}(G) = \frac{m_1 \mathcal{K}(G_1) + k \mu(G_1, v) + k(m_1 + k - \frac{1}{2})}{m_1 + k}.$$

Proof. Using Proposition 3.2 and Theorem 2.1 we get

$$\begin{aligned} \mathcal{K}(G) &= \frac{m_1 (\mathcal{K}(G_1) + \mu(S_{k+1}, v)) + k (\mathcal{K}(S_{k+1}) + \mu(G_1, v))}{m_1 + k} \\ &= \frac{m_1 (\mathcal{K}(G_1) + k) + k(k + 1 - \frac{3}{2} + \mu(G_1, v))}{m_1 + k} \\ &= \frac{m_1 \mathcal{K}(G_1) + k \mu(G_1, v) + k(m_1 + k - \frac{1}{2})}{m_1 + k}. \end{aligned}$$

□

Now we state a result from electrical network theory that will be instrumental in the main proof of this section.

Proposition 4.6 (Mesh-Star Transform). *A complete graph K_n with unit resistance on each edge is equivalent to a star graph S_{n+1} with resistance $\frac{1}{n}$ on each edge.*

Theorem 4.7. *Let $G = G_1 \oplus_v S_{k+1}$ where v is the central vertex of S_{k+1} . Then any set of l edges added in S_{k+1} is a Braess set given*

$$|E(G_1)| > \begin{cases} \frac{1}{8} [\sqrt{33l^2 + 50l + 17} - l - 1] & \text{if } l < k \\ \frac{1}{8} [\sqrt{33k^2 - 30k + 1} - k - 1] & \text{if } l \geq k \end{cases}.$$

Proof. Using Corollary 4.3 we can determine whether or not \mathcal{L} , the l added edges, is a Braess set. For convenience let f denote the expression in Corollary 4.3. Note that $m_2 = k$ so we have $f = Am_1^2 + ((A + C)k + Bl)m_1 + C(k^2 + lk)$. As can be seen by Corollary 4.3, if $A > 0$ then $f > 0$ so long as m_1 is sufficiently large. For convenience, let $S_{k+1} = G_2$.

To be sure that \mathcal{L} is a Braess set we will find lower bounds for the terms A, B, C . By Proposition 3.2 we know that $\mu(G_2, v) = k$ and $\mathcal{K}(G_2) = k - \frac{1}{2}$. Now we look at A .

To find a suitable lower bound on $\mu(\widehat{G}_2, v)$ we will find the smallest possible resistance distance from one of the k pendants, i , to v given we know the degree of i , d_i . By Rayleigh's monotonicity law ([10], Lemma D), adding an edge in a graph can only either decrease or have no effect on resistance distance between two points. It follows then that the resistance $\hat{r}_2(i, v)$ when $d_i = d$ is smallest when enough edges are added between v and the $k - 1$ pendant vertices that are not i to make a complete graph K_k and then adding edges connected to i until $d_i = d$.

Figure 3: A mesh-star transformation of K_5 to S_6 with $d_i = 3$

By Proposition 4.6, this is equivalent to a star graph S_{k+1} with edge weights of $\frac{1}{k}$ and a vertex connected to d of the pendants of the star by edge weights of 1. So $\hat{r}_2(i, v)$ is the same as the resistance from the vertex of degree d to one of the adjacent vertices. If $d = 1$ then $\hat{r}_2(i, v) = 1$. Suppose $d > 1$. Then using the series and parallel rules for circuit reductions we have

$$\hat{r}_2(i, v) = \frac{1}{\frac{1}{1} + \frac{1}{\frac{1}{k} + \frac{1}{\frac{d-1}{1+\frac{1}{k}}}}} = \frac{1}{1 + \frac{1}{\frac{1}{k} + \frac{1+\frac{1}{k}}{d-1}}} = \frac{1}{1 + \frac{k(d-1)}{d+k}} = \frac{k+d}{d(k+1)}.$$

So we have the following.

$$\begin{aligned} \mu(\hat{G}_2, v_2) &= \tilde{d}_2^T \hat{R}_2 e_{v_2} = \sum_{i \in \hat{G}_2 \setminus \{v\}} \hat{d}_i \hat{r}_2(i, v) \\ &\geq \sum_{i \in \hat{G}_2 \setminus \{v\}} \frac{k+d_i}{d_i(k+1)} \\ &= \frac{1}{k+1} \left[\sum_{i \in \hat{G}_2 \setminus \{v\}} k + \sum_{i \in \hat{G}_2 \setminus \{v\}} d_i \right] \\ &= \frac{k^2 + k + 2l}{k+1} \end{aligned}$$

So we have $A = \mu(\hat{G}_2, v) - \mu(G_2, v) \geq \frac{2l}{k+1}$.

For the bounds on B and C we will make use of the fact proven in [14] that for an undirected graph on n vertices, Kemeny's constant is smallest for a complete graph where $\mathcal{K}(K_n) = \frac{(n-1)^2}{n}$. Then $B = \mathcal{K}(\hat{G}_2) - \mu(G_2, v) \geq \frac{-k}{k+1}$ and $C = \mathcal{K}(\hat{G}_2) - \mathcal{K}(G_2) \geq \frac{-k}{k+1} + \frac{1}{2}$. So setting B, C equal to their lower bounds we have $B = \frac{-k}{k+1}$ and $C = B + \frac{1}{2}$.

Now let \tilde{f} be f where A, B, C have been replaced by these lower bounds. Hence if $\tilde{f} > 0$ then $f > 0$. Then treating \tilde{f} as a quadratic of variable m_1 it is seen that $\tilde{f} > 0$ whenever

$$|E(G_1)| = m_1 > \frac{1}{8l} \left[k^2 - 2kl - k + \sqrt{k(k^3 - 16l^2 + 2k^2(6l - 1) + k(20l^2 - 12l + 1))} \right] \quad (8)$$

This bound on m_1 as is has some issues. For example, if $l = 1$ it is known that the edge will be Braess for all nontrivial connected graphs. However, as k increases (8) only guarantees this edge to be Braess for increasingly large graphs. For instance if $k = 10$ and $l = 1$ (8) would suggest we need $m_1 > 26$ which is unnecessarily large.

This behavior can be improved. For fixed l , (8) is monotonically increasing in k for values of k that make sense. Since often times adding l edges won't affect all k pendants we can look to treat such cases as having a smaller value of k . Since any edge added between twin pendant vertices will be Braess and since this function is increasing in k , we look for the largest number of pendants affected (new value of k to work with) by adding an edge while never adding an edge between twin pendants if possible. For $l < k$ this new value of k is $l + 1$. Thus, if $l < k$ then plugging $k = l + 1$ into the bound gives that a Braess set of edges is guaranteed if $m_1 > \frac{1}{8} [\sqrt{33l^2 + 50l + 17} - l - 1]$.

If $l \geq k$ then we can come to a cleaner (though slightly rougher) expression as well. The bound is strictly decreasing in l for fixed k . Then for $l \geq k$, the substitution $l = k$ yields that the added edges form a Braess set whenever $m_1 > \frac{1}{8} [\sqrt{33k^2 - 30k + 1} - k - 1]$. □

4.1.1 Pendant Triplets

While we now have a bound for conditions in which l edges added to a group of k pendants attached at a vertex in a graph are Braess, if we choose a specific k we can work out more specifically how the addition of certain edges affects Kemeny's constant. Here we examine the case of $k = 3$.

While these are the same types of graphs examined in Section 2, to avoid excessive subscripts we redefine these specific graphs in a new way.

Let G be a connected graph, $|V(G)| = n$, and $|E(G)| = m$. Let \bar{G} be the graph obtained from G by attaching 3 pendant vertices at v . We will first provide a formula for Kemeny's constant $\mathcal{K}(\bar{G})$ in terms of the graph G .

Lemma 4.8. *Let \bar{G} be a graph as described above. Then*

$$\mathcal{K}(\bar{G}) = \frac{2m\mathcal{K}(G) + 6\mu(G, v) + 6m + 15}{2m + 6}$$

Proof. Using Theorem 4.5 with $k = 3$ gives the result. □

Now we will define another graph \tilde{G} which is obtained from \bar{G} by adding an edge between two of the vertices in $\{a, b, c\}$. For later comparisons we will derive an expression for the Kemeny's constant of \tilde{G} in terms of the graph G .

Lemma 4.9. *Let \tilde{G} be as above. Then*

$$\mathcal{K}(\tilde{G}) = \frac{6m\mathcal{K}(G) + 24\mu(G, v) + 22m + 61}{6m + 24}$$

Proof. It can be shown that in this case that $\mathcal{K}(G_2) = \frac{61}{24}$ and $\mu(G_2, v) = \frac{11}{3}$. Using this, an easy simplification of Theorem 2.1 gives the result. □

Define the graph \hat{G} from \tilde{G} in the following way. Suppose \tilde{G} has an edge ab . Then adding the edge bc will give \hat{G} .

Lemma 4.10. *Let \hat{G} be as above. Then*

$$\mathcal{K}(\hat{G}) = \frac{4m\mathcal{K}(G) + 20\mu(G, v) + 16m + 47}{4m + 20}$$

Proof. It can be shown that $\mathcal{K}(G_2) = \frac{47}{20}$ and $\mu(G_2, v) = 4$. The result follows from Theorem 2.1. \square

Define G^* from \widehat{G} by adding the edge $\{a, c\}$.

Lemma 4.11. *Let G^* be as above. Then*

$$\mathcal{K}(G^*) = \frac{2m\mathcal{K}(G) + 12\mu(G, v) + 9m + 27}{2m + 12}$$

Proof. In this case we have $G_2 = K_4$. By Proposition 3.2 $\mathcal{K}(K_4) = \frac{9}{4}$ and $\mu(K_4, v) = \frac{9}{2}$. \square

Now that the Kemeny's constant of each graph $\bar{G}, \widetilde{G}, \widehat{G}, G^*$ can be expressed in terms of the graph G , it is easy and interesting to compare these graphs to each other. The next five theorems will do just that.

Theorem 4.12. *Let G, \widetilde{G} , and \widehat{G} be as above. Suppose $|E(G)| \geq 4$. Then*

$$\mathcal{K}(\widehat{G}) > \mathcal{K}(\widetilde{G}).$$

Proof. Using Lemmas 4.9, 4.10 we have

$$\begin{aligned} \mathcal{K}(\widehat{G}) &> \mathcal{K}(\widetilde{G}) \\ \frac{4m\mathcal{K}(G) + 20\mu(G, v) + 16m + 47}{4m + 20} &> \frac{6m\mathcal{K}(G) + 24\mu(G, v) + 22m + 61}{6m + 24} \\ (4m\mathcal{K}(G) + 20\mu(G, v) + 16m + 47)(6m + 24) &> (6m\mathcal{K}(G) + 24\mu(G, v) + 22m + 61)(4m + 20) \\ 24m\mu(G, v) - 24m\mathcal{K}(G) + 8m^2 - 18m - 92 &> 0 \\ 24m(\mu(G, v) - \mathcal{K}(G)) + 2(4m^2 - 9m - 46) &> 0. \end{aligned}$$

The first term is proven to be non-negative in Proposition 3.2 of [7]. Treating the second term as a polynomial of variable m it is seen that it is positive for integers at least 5. Checking all possibilities where $|E(G_1)| = 4$ one can find that this expression is still positive. However, it can be shown that this is negative for $G_1 = S_4$, thus it is not true for all graphs with $|E(G_1)| = 3$. \square

Theorem 4.13. *Let G, \widehat{G} , and G^* be as above. Suppose $|E(G)| \geq 2$. Then*

$$\mathcal{K}(G^*) > \mathcal{K}(\widehat{G}).$$

Proof. Using Lemmas 4.10, 4.11 we have

$$\begin{aligned} \mathcal{K}(G^*) &> \mathcal{K}(\widehat{G}) \\ \frac{2m\mathcal{K}(G) + 12\mu(G, v) + 9m + 27}{2m + 12} &> \frac{4m\mathcal{K}(G) + 20\mu(G, v) + 16m + 47}{4m + 20} \\ (2m\mathcal{K}(G) + 12\mu(G, v) + 9m + 27)(4m + 20) &> (4m\mathcal{K}(G) + 20\mu(G, v) + 16m + 47)(2m + 12) \\ 8m(\mu(G, v) - \mathcal{K}(G)) + 4m^2 + 2m - 24 &> 0 \\ 8m(\mu(G, v) - \mathcal{K}(G)) + 2(2m^2 + m - 12) &> 0. \end{aligned}$$

Once again the first term is known to be non-negative by Proposition 3.2 of [7]. The second term as a polynomial of variable m is positive for integers at least 3.

Now suppose $m = 2$. Then $G = P_3$. Thus $\mathcal{K}(G) = \frac{3}{2}$ and either $\mu(P_3, v) = 4$ or $\mu(P_3, v) = 2$. In both cases the above expression is positive, hence $\mathcal{K}(G^*) > \mathcal{K}(\hat{G})$.

Now suppose $m = 1$. Then $G = P_2$, $\mathcal{K}(G) = \frac{1}{2}$, and $\mu(G, v) = 1$. In this case, the expression is negative so $\mathcal{K}(G^*) < \mathcal{K}(\hat{G})$. \square

Theorem 4.14. *Let G, \tilde{G} , and G^* be as above. Suppose $|E(G)| \geq 4$. Then*

$$\mathcal{K}(G^*) > \mathcal{K}(\tilde{G}).$$

Proof. Using Lemmas 4.9, 4.11 we will show when the following is true.

$$\begin{aligned} \mathcal{K}(G^*) &> \mathcal{K}(\tilde{G}) \\ \frac{2m\mathcal{K}(G) + 12\mu(G, v) + 9m + 27}{2m + 12} &> \frac{6m\mathcal{K}(G) + 24\mu(G, v) + 22m + 61}{6m + 24} \\ (2m\mathcal{K}(G) + 12\mu(G, v) + 9m + 27)(6m + 24) &> (6m\mathcal{K}(G) + 24\mu(G, v) + 22m + 61)(2m + 12) \\ 24m(\mu(G, v) - \mathcal{K}(G)) + 2(5m^2 - 4m - 42) &> 0. \end{aligned}$$

Again, the first term is known to be non-negative by Proposition 3.2 of [7]. The second term as a polynomial of variable m is positive for all integers at least 4. Thus the result is proved. \square

Theorem 4.15. *Let G, \bar{G} , and \hat{G} be as above. Suppose $|E(G)| \geq 1$. Then*

$$\mathcal{K}(\hat{G}) > \mathcal{K}(\bar{G}).$$

Proof. Using Lemmas 4.8, 4.10 we have

$$\begin{aligned} \mathcal{K}(\hat{G}) &> \mathcal{K}(\bar{G}) \\ \frac{4m\mathcal{K}(G) + 20\mu(G, v) + 16m + 47}{4m + 20} &> \frac{2m\mathcal{K}(G) + 6\mu(G, v) + 6m + 15}{2m + 6} \\ (4m\mathcal{K}(G) + 20\mu(G, v) + 16m + 47)(2m + 6) &> (2m\mathcal{K}(G) + 6\mu(G, v) + 6m + 15)(4m + 20) \\ 16m(\mu(G, v) - \mathcal{K}(G)) + 2(4m^2 + 5m - 9) &> 0. \end{aligned}$$

By Proposition 3.2 of [7] the first term is non-negative. Treating the second term as a polynomial of variable m it is seen that it is 0 at $m = 1$ and positive for all values of $m > 1$.

Now suppose $m = 1$. Then $G = P_2$, $\mathcal{K}(G) = \frac{1}{2}$, and $\mu(G, v) = 1$. Then the above expression is positive so $\mathcal{K}(\hat{G}) > \mathcal{K}(\bar{G})$. \square

Theorem 4.16. *Let G, \bar{G} , and G^* be as above. Suppose $|E(G)| \geq 1$. Then*

$$\mathcal{K}(G^*) \geq \mathcal{K}(\bar{G})$$

with equality if and only if $G = P_2$.

Proof. Using Lemmas 4.8, 4.11 we have

$$\begin{aligned} \mathcal{K}(G^*) &\geq \mathcal{K}(\bar{G}) \\ \frac{2m\mathcal{K}(G) + 12\mu(G, v) + 9m + 27}{2m + 12} &\geq \frac{2m\mathcal{K}(G) + 6\mu(G, v) + 6m + 15}{2m + 6} \\ (2m\mathcal{K}(G) + 12\mu(G, v) + 9m + 27)(2m + 6) &\geq (2m\mathcal{K}(G) + 6\mu(G, v) + 6m + 15)(2m + 12) \\ 12m(\mu(G, v) - \mathcal{K}(G)) + 6(m^2 + m - 3) &\geq 0. \end{aligned}$$

By Proposition 3.2 of [7] the first term is non-negative. The second term as a polynomial of variable m is positive for all integers at least 2.

Now suppose $m = 1$. Then $G = P_2$, $\mathcal{K}(G) = \frac{1}{2}$, and $\mu(G, v) = 1$. Then the above inequality is an equality. □

In summary in the $k = 3$ case for graphs of this construction we see that for almost all graphs, the more edges get added in the pendant portion of the graph, the larger Kemeny's constant will be. One of the few graphs where this is not the case is $G = P_2$. In this case we have that $\mathcal{K}(\hat{G}) = \mathcal{K}(G^*) < \mathcal{K}(\widehat{G}) < \mathcal{K}(\bar{G})$, so each additional edge actually decreases the Kemeny constant slightly until it is back to where it started.
