## BIASED MULTILINEAR MAPS OF ABELIAN GROUPS

SEAN EBERHARD

Abstract. We adapt the theory of partition rank and analytic rank to the category of abelian groups. If  $A_1, \ldots, A_k$  are finite abelian groups and  $\varphi$ :  $A_1 \times \cdots \times A_k \to \mathbf{T}$  is a multilinear map, where  $\mathbf{T} = \mathbf{R}/\mathbf{Z}$ , the bias of  $\varphi$  is defined to be the average value of  $\exp(i2\pi\varphi)$ . If the bias of  $\varphi$  is bounded away from zero we show that  $\varphi$  is the sum of boundedly many multilinear maps each of which factors through the standard multiplication map of  $\mathbf{Z}/q\mathbf{Z}$  for some bounded prime power q. Relatedly, if  $F : A_1 \times \cdots \times A_{k-1} \to B$  is a multilinear map such that  $P(F = 0)$  is bounded away from zero, we show that  $F$  is the sum of boundedly many multilinear functions of a particular form. These structure theorems generalize work of several authors in the elementary abelian case to the arbitrary abelian case. The set of all possible biases is also investigated.

#### CONTENTS

#### 1. Introduction

<span id="page-0-0"></span>Suppose  $A_1, \ldots, A_k$  are finite abelian groups and  $\varphi : A_1 \times \cdots \times A_k \to \mathbf{T}$  is a multilinear map, where  $\mathbf{T} = \mathbf{R}/\mathbf{Z}$ . Let  $e(x) = \exp(i2\pi x)$  be the standard character of **T**. The bias of  $\varphi$  is defined by

(1) 
$$
\text{bias}(\varphi) = \mathbf{E}_{x \in A_{[k]}} e(\varphi(x)).
$$

Here and throughout we use the following index notation. The symbol  $[k]$  denotes the index set  $\{1, \ldots, k\}$ . For  $I \subseteq [k]$ ,

<span id="page-0-1"></span>
$$
A_I = \prod_{i \in I} A_i.
$$

For  $x \in A_{[k]},$ 

$$
x_I = (x_i)_{i \in I} \in A_I.
$$

We write  $I^c$  for  $[k] \setminus I$ . Also, we are using the expectation symbol to denote the (finite) average over the set  $A_{[k]}$ .

The concept of bias often comes up in the following way. Suppose  $F: A_{[k-1]} \to B$ is a multilinear map of abelian groups such that  $P(F = 0)$  is bounded away from zero. Letting  $A_k$  be the dual group  $\widehat{B}$ , we can define a multilinear map  $\varphi : A_{[k]} \to \mathbf{T}$ by

$$
\varphi(x) = x_k(F(x_{[k-1]})),
$$

S. Eberhard has received funding from the European Research Council (ERC) under the European Union's Horizon 2020 research and innovation programme (grant agreement No. 803711).

#### 2 SEAN EBERHARD

and for this map we have bias( $\varphi$ ) =  $P(F = 0)$ . Moreover, F is determined by  $\varphi$ , so if we can say something about the structure of  $\varphi$  then we will know something about the structure of F. Thus the study of multilinear kernels is reduced to the study of bias.

If  $A_1, \ldots, A_k$  are vector spaces over a field  $\mathbf{F} = \mathbf{F}_q$  then it is usually more natural to consider a multi-**F**-linear map  $\varphi: A_{[k]} \to \mathbf{F}$  and to define

$$
bias(\varphi) = \mathbf{E}_{x \in A_{[k]}} \chi(\varphi(x))
$$

where  $\chi : \mathbf{F}_q \to \mathbf{T}$  is any standardized character such as  $\chi(x) = e((\text{tr } x)/p)$ , where tr :  $\mathbf{F}_q \to \mathbf{F}_p$  is the absolute trace. Bias in this context was introduced by Gowers and Wolf in [\[GW\]](#page-11-1) and studied extensively by several authors. The term analytic rank is used for the quantity

$$
AR(\varphi) = \log_q(\text{bias}(\varphi)^{-1}).
$$

The partition rank PR( $\varphi$ ) of  $\varphi$  is the minimal number r such that  $\varphi$  is the sum of r multilinear maps of the form

 $\varphi_1(x_I)\varphi_2(x_{I^c}),$ 

where  $I \subseteq [k]$  and  $0 < |I| < k$ . Multilinear maps of bounded partition rank are uniformly biased: in fact,  $AR(\varphi) \le PR(\varphi)$ . This is one of several nice lemmas appearing in a paper by Lovett [\[L\]](#page-11-2). The main theorem in this field is a converse: uniformly biased multilinear maps have bounded partition rank, or in other words partition rank is bounded in terms of analytic rank.

<span id="page-1-0"></span>**Theorem 1.1.** Suppose  $A_1, \ldots, A_k$  are finite  $\mathbf{F}_q$ -vector spaces and  $\varphi : A_{[k]} \to \mathbf{F}_q$ is multilinear over  $\mathbf{F}_q$ . If  $\text{bias}(\varphi) \geq \epsilon > 0$  then  $\varphi$  has partition rank  $O_{\epsilon,k,q}(1)$ . In other words,  $PR(\varphi) \leq F(k, AR(\varphi), q)$  for some function F.

This result was essentially proved by Green and Tao [\[GT\]](#page-11-3). Subsequent research has focused on quantitative aspects (which were initially poor). The dependence on q was removed by Bhowmick and Lovett in [\[BL\]](#page-11-4) (so  $PR(\varphi) \leq F(k, AR(\varphi))$ ). In breakthrough work Janzer [\[J\]](#page-11-5) and Milićević [\[M\]](#page-11-6) independently proved that  $PR(\varphi) \leq$  $C_k(\text{AR}(\varphi)^{D_k} + 1)$  for constants  $C_k, D_k$ . Recently, Cohen and Moshkovitz [\[CM\]](#page-11-7) proved that  $PR(\varphi) \leq (2^{k-1} + 1) AR(\varphi) + 1$  provided that  $q > q_0(k, AR(\varphi))$ .

In this note we consider biased multilinear maps of arbitrary abelian groups. We will use Theorem [1.1](#page-1-0) as a block box (and only the prime field case) and we will deduce an analogous structure theorem for arbitrary abelian groups. To state this structure theorem we need a suitable notion of partition rank. For  $q$  a prime power, let  $m_q : (\mathbf{Z}/q\mathbf{Z})^2 \to \mathbf{T}$  be the bilinear map defined by  $m(x, y) = xy/q \text{ mod } 1$ . We say that  $\varphi: A_{[k]} \to \mathbf{T}$  factors through  $m_q$  if it has the form

$$
\varphi(x) = m_q(\varphi_1(x_I), \varphi_2(x_{I^c}))
$$

<span id="page-1-1"></span>for some  $I \subseteq [k]$  with  $0 < |I| < k$ . Here  $\varphi_1 : A_I \to \mathbf{Z}/q\mathbf{Z}$  and  $\varphi_2 : A_{I^c} \to \mathbf{Z}/q\mathbf{Z}$ must both be multilinear.

**Theorem 1.2.** Suppose  $A_1, \ldots, A_k$  are finite abelian groups and  $\varphi : A_{[k]} \to \mathbf{T}$  is multilinear. If bias $(\varphi) \geq \epsilon > 0$  then  $\varphi$  is the sum of  $O_{\epsilon,k}(1)$  multilinear maps each of which factors through  $m_q$  for some prime power  $q \leq O_{\epsilon,k}(1)$ .

It is easy to see that Theorem [1.1](#page-1-0) and Theorem [1.2](#page-1-1) agree in the case of vector spaces over a prime finite field, but neither result is more general than the other. (A common generalization would consider R-modules for some commutative ring R; Theorem [1.1](#page-1-0) would be the case  $R = \mathbf{F}_q$  and Theorem [1.2](#page-1-1) would be the case  $R = \mathbf{Z}$ .)

The following corollary follows from the connection mentioned already between bias and multilinear kernels. It states that a multilinear function F with  $P(F = 0)$  bounded away from zero must be the sum of boundedly many functions each of which "crushes" a nontrivial subset of the variables before mapping to the range. Here  $\text{cod}(g)$  denotes the codomain of the function g.

<span id="page-2-4"></span>Corollary 1.3. Suppose  $A_1, \ldots, A_{k-1}, B$  are finite abelian groups and  $F: A_{[k-1]} \to$ B is a multilinear map such that  $P(F = 0) \ge \epsilon > 0$ . Then there is an expression

$$
F(x) = \sum_{\emptyset \neq I \subseteq [k-1]} G_I(g_I(x_I), x_{[k-1]\setminus I}),
$$

where for each I the functions  $g_I$  and  $G_I$  are multilinear maps

$$
g_I: A_I \to \text{cod}(g_I),
$$
  
\n $G_I: \text{cod}(g_I) \times A_{[k-1]\setminus I} \to B,$ 

and  $|\text{cod}(g_I)| \leq O_{\epsilon,k}(1)$ .

In the last section we give an application of Theorem [1.2](#page-1-1) to the set all possible biases. Let  $\Phi_k$  be the set of all multilinear maps  $\varphi: A_1 \times \cdots \times A_k \to \mathbf{T}$  (for any finite abelian groups  $A_1, \ldots, A_k$  and let

$$
B_k = \{\text{bias}(\varphi) : \varphi \in \Phi_k\}.
$$

We show that  $B_k$  is a small subset of [0, 1] in various senses; for example, all its limit points are algebraic.

<span id="page-2-0"></span>Elsewhere we will give an application to probabilistically nilpotent finite groups.

### 2. Basic properties of bias

Several nice lemmas about bias over vector spaces were proved by Lovett in [\[L\]](#page-11-2). We need analogues in the category of abelian groups.

In this section we will sometimes consider functions  $\varphi: A_{[k]} \to \mathbf{T}$  which are not multilinear, but we still define bias( $\varphi$ ) by [\(1\)](#page-0-1). If  $\varphi : A_{[k]} \to \mathbf{T}$  is a map we write  $\varphi_{x_I}: A_{I^c} \to \mathbf{T}$  for the map obtained by restriction:

<span id="page-2-1"></span>
$$
\varphi_{x_I}(x_{I^c})=\varphi(x).
$$

Obviously,

(2) 
$$
\text{bias}(\varphi) = \mathbf{E}_{x_I} \text{bias}(\varphi_{x_I}).
$$

In particular, consider [\(2\)](#page-2-1) in the case  $I = \{i\}^c$ . If  $\varphi(x)$  is linear in  $x_i$  then  $bias(\varphi_{x_I})$ is 1 or 0 according to whether  $\varphi_{x_I} \equiv 0$ , so

(3) 
$$
\text{bias}(\varphi) = \mathbf{P}_{x_I}(\varphi_{x_I} \equiv 0).
$$

<span id="page-2-3"></span>This shows that, while in general bias( $\varphi$ ) is complex-valued, bias( $\varphi$ )  $\in [0,1]$  provided that  $\varphi$  is linear in at least one of its arguments.

**Lemma 2.1.** Assume  $\varphi : A_{[k]} \to \mathbf{T}$  is multilinear. For each  $i \in [k]$ ,

<span id="page-2-2"></span>bias
$$
(\varphi) \ge 1 - \prod_{j \ne i} (1 - 1/|A_j|).
$$

If  $\varphi$  is nontrivial then

bias
$$
(\varphi) \le 1 - \prod_{j \neq i} (1 - 1/p_j),
$$

where  $p_i$  is the smallest prime divisor of  $|A_i|$ .

*Proof.* Let  $I = \{i\}^c$ . If  $x_j = 0$  for any  $j \in I$  then  $\varphi_{x_I} \equiv 0$ , so from [\(3\)](#page-2-2) we have

1 - bias(
$$
\varphi
$$
) =  $\mathbf{P}(\varphi_{x_I} \neq 0) \le \prod_{j \in I} \mathbf{P}(x_j \neq 0) = \prod_{j \neq i} (1 - 1/|A_j|).$ 

The second inequality is proved by induction. The case  $k = 1$  is clear, because if  $\varphi$  is linear and nontrivial then bias( $\varphi$ ) = 0, and the right-hand side is also 0. Let  $k > 1$ . By [\(2\)](#page-2-1) with  $I = \{j\}$  we have

$$
1 - \text{bias}(\varphi) = \mathbf{E}_{x_j}(1 - \text{bias}(\varphi_{x_j})).
$$

Let  $B_j = \{x_j \in A_j : \varphi_{x_j} \equiv 0\}$ . By induction if  $x_j \notin B_j$  then

$$
1 - \text{bias}(\varphi_{x_j}) \ge \prod_{j' \ne i, j} (1 - 1/p_{j'}).
$$

Thus

$$
1 - \text{bias}(\varphi) \ge (1 - |B_j|/|A_j|) \prod_{j' \ne i,j} (1 - 1/p_{j'}).
$$

But  $B_j$  is a subgroup of  $A_j$ , and proper since  $\varphi$  is nontrivial, so  $|B_j|/|A_j| \leq 1/p_j$ . This completes the induction.  $\Box$ 

<span id="page-3-0"></span>**Lemma 2.2.** For  $I \subseteq [k]$ , let  $\varphi_I : A_I \to \mathbf{T}$  be  $|I|$ -linear. Let  $\varphi : A_{[k]} \to \mathbf{T}$  be the function

$$
\varphi(x) = \sum_{I \subseteq [k]} \varphi_I(x_I).
$$

Suppose  $J \subseteq [k]$  is any subset such that  $\varphi_I = 0$  for  $I \supsetneq J$ . Then

 $|\text{bias}(\varphi)| \leq \text{bias}(\varphi_J).$ 

*Proof.* Let  $i \in [k]$ . Write

$$
\varphi = \varphi_i + \varphi_{i'},
$$

where

$$
\varphi_i = \sum_{I \subseteq [k], i \in I} \varphi_I,
$$

$$
\varphi_{i'} = \sum_{I \subseteq [k], i \notin I} \varphi_I.
$$

Note that  $\varphi_i$  is linear in  $x_i$  and  $\varphi_{i'}$  is indepenent of  $x_i$ , so

bias
$$
(\varphi)
$$
 =  $\mathbf{E}_{x_{\{i\}^c}}(e(\varphi_{i'})\mathbf{E}_{x_i}e(\varphi_i))$ 

Hence by the triangle inequality

$$
|\operatorname{bias}(\varphi)| \leq \mathbf{E}_{x_{\{i\}^c}} |\mathbf{E}_{x_i} e(\varphi_i)|.
$$

But since  $\varphi_i$  is linear in  $x_i$ ,  $\mathbf{E}_{x_i}e(\varphi_i) \geq 0$ , so we may drop the absolute value signs. Hence

$$
|\operatorname{bias}(\varphi)| \leq \mathbf{E}_{x_{I\setminus i}} \mathbf{E}_{x_i} e(\varphi_i(x)) = \operatorname{bias}(\varphi_i).
$$

<span id="page-3-1"></span>Repeat for every  $i \in J$ .

**Lemma 2.3.** Let  $\varphi, \psi : A_{[k]} \to \mathbf{T}$  be multilinear. Then

 $bias(\varphi + \psi) \geq bias(\varphi) bias(\psi).$ 

*Proof.* Let  $x, y \in A_{[k]}$  be independent. Then

bias
$$
(\varphi)
$$
 bias $(\psi)$  =  $\mathbf{E}_{x,y}e(\varphi(x) + \psi(y)) = \mathbf{E}_{x,y}e(\varphi(x) + \psi(x + y)).$ 

We may expand

$$
\psi(x+y) = \sum_{I \subseteq [k]} \psi_I(x_I, y_{I^c}),
$$

where  $\psi_I: A_I \times A_{I^c} \to \mathbf{T}$  is again k-linear. Note that  $\psi_{[k]} = \psi(x)$ . For each fixed  $y \in A_{[k]}$ , the previous lemma with  $J = [k]$  implies that

$$
|\mathbf{E}_x e(\varphi(x) + \psi(x+y))| \le \mathbf{E}_x e(\varphi(x) + \psi(x)) = \text{bias}(\varphi + \psi).
$$

Hence the lemma follows from the triangle inequality.  $\Box$ 

Suppose  $\varphi: A_{[k]} \to \mathbf{T}$  is k-linear and  $\psi: B_{[l]} \to \mathbf{T}$  is l-linear. We say  $\varphi$  factors through  $\psi$  if there is an *l*-partition

$$
[k] = I_1 \cup \cdots \cup I_l \qquad (I_1, \ldots, I_l \neq \emptyset)
$$

and for each  $j \in [l]$  an  $|I_j|$ -linear map

$$
\varphi_j : A_{I_j} \to B_j
$$

such that  $\varphi$  factors as

$$
\varphi=\psi(\varphi_{I_1},\ldots,\varphi_{I_l}),
$$

i.e.,

$$
\varphi: A_{[k]} \cong \prod_j A_{I_j} \xrightarrow{(\varphi_{I_j})_j} B_{[l]} \xrightarrow{\psi} \mathbf{T}.
$$

<span id="page-4-0"></span>**Lemma 2.4.** Suppose  $\varphi: A_{[k]} \to \mathbf{T}$  and  $\psi: B_{[l]} \to \mathbf{T}$  are multilinear and  $\varphi$  factors through  $\psi$ . Then  $\text{bias}(\varphi) \geq \text{bias}(\psi)$ .

*Proof.* Suppose  $[k] = I_1 \cup \cdots \cup I_l$  and

$$
\varphi=\psi(\varphi_{I_1},\ldots,\varphi_{I_l}).
$$

For  $b \in B_{[l]}$ , let

$$
\varphi_b = \psi(\varphi_{I_1} + b_1, \ldots, \varphi_{I_l} + b_l).
$$

Clearly

$$
\mathbf{E}_b \operatorname{bias}(\varphi_b) = \operatorname{bias}(\psi).
$$

By Lemma [2.2,](#page-3-0) for every  $b \in B_{[l]}$  we have

$$
|\operatorname{bias}(\varphi_b)| \le \operatorname{bias}(\varphi_0) = \operatorname{bias}(\varphi).
$$

Hence  $\text{bias}(\psi) \leq \text{bias}(\varphi)$ .

Corollary 2.5. Suppose  $\varphi : A_{[k]} \to \mathbf{T}$  and  $\psi : B_{[l]} \to \mathbf{T}$  are multilinear and  $\varphi$ factors through  $\psi$ . Then  $\text{bias}(\varphi) \geq 1 - \prod_{j \neq i} (1 - 1/|\tilde{B}_j|)$  for each  $i \in [l]$ .

*Proof.* Combine the previous lemma with Lemma [2.1.](#page-2-3)  $\Box$ 

<span id="page-4-3"></span>Recall that  $m_q$  denotes the map  $\mathbf{Z}/q \times \mathbf{Z}/q\mathbf{Z} \to \mathbf{T}$  defined by  $m(x, y) = xy/q$  mod 1, where  $q$  is a prime power.

**Corollary 2.6.** Suppose  $\varphi : A_{[k]} \to \mathbf{T}$  is the sum of maps  $\varphi_1, \ldots, \varphi_r$  and  $\varphi_i$  factors through  $m_{q_i}$ . Then

$$
bias(\varphi) \ge q_1^{-1} \cdots q_r^{-1}.
$$

*Proof.* Combine the previous corollary with Lemma [2.3.](#page-3-1)  $\Box$ 

<span id="page-4-2"></span>**Corollary 2.7.** Suppose  $A'_i \leq A_i$  for each i. Let  $\varphi : A_{[k]} \to \mathbf{T}$  be multilinear and let  $\varphi'$  be the restriction of  $\varphi$  to  $A'_{[k]}$ . Then  $\text{bias}(\varphi') \geq \text{bias}(\varphi)$ .

*Proof.* Since  $\varphi'$  factors through  $\varphi$ , we may apply Lemma [2.4](#page-4-0) to  $(\varphi', \varphi)$ .

<span id="page-4-1"></span>The following lemma, which gives a little more information than the second part of Lemma [2.1,](#page-2-3) illustrates the utility of the last corollary.

**Lemma 2.8.** Suppose  $\varphi : A_{[k]} \to \mathbf{T}$  is multilinear and suppose the image of  $\varphi$ has an element of order  $q = p^{n'}$  for some prime p. Then  $\text{bias}(\varphi) \leq \text{bias}(\psi)$ , where  $\psi: (\mathbf{Z}/q\mathbf{Z})^k \to \mathbf{T}$  is defined by

$$
\psi(x_1,\ldots,x_k)=x_1\cdots x_k/q \pmod{1}.
$$

In particular, for  $k \geq 2$ ,

$$
bias(\varphi) \le (n+1)^{k-2}/q.
$$

*Proof.* Suppose  $\varphi(a_1, \ldots, a_k)$  has order  $q = p^n$ . Let  $A'_i = \langle a_i \rangle$  for each i. Then

 $\text{bias}(\varphi) \leq \text{bias}(\varphi|_{A'_{[k]}}).$ 

Hence without loss of generality  $A_i$  is generated by  $a_i$  for each i. Note that  $\varphi_{qa_i} = 0$ for each *i*, so  $\varphi$  factors through  $\prod_{i=1}^{k} \langle a_i \rangle / \langle qa_i \rangle$ . Hence we may assume that  $qa_i = 0$ for each *i*. Also note that  $p^{n-1}a_i \neq 0$  for each *i*, since

$$
\varphi(\ldots, a_{i-1}, p^{n-1}a_i, a_{i+1}, \ldots) = p^{n-1}\varphi(a_1, \ldots, a_k) \neq 0.
$$

Hence each  $a_i$  has order q, so  $\varphi$  is equivalent to the map  $\psi$  in the statement of the lemma.

For the second statement we may assume  $\varphi = \psi$ . Let  $v_p$  denote the p-adic valuation. From [\(3\)](#page-2-2),

bias(
$$
\varphi
$$
) =  $\mathbf{P}(x_1 \cdots x_{k-1} = 0)$   
\n=  $\mathbf{P}(v_p(x_1) + \cdots + v_p(x_{k-1}) \ge n)$   
\n $\le \sum_{v_1 + \cdots + v_{k-1} = n} \mathbf{P}(v_p(x_i) \ge v_i \text{ for each } i < k)$   
\n=  $\sum_{v_1 + \cdots + v_{k-1} = n} p^{-v_1 - \cdots - v_{k-1}}$   
\n=  $M/q$ ,

<span id="page-5-0"></span>where M is the number of solutions to  $v_1 + \cdots + v_{k-1} = n$  in nonnegative integers. Clearly  $M \leq (n+1)^{k-2}$ . .

# 3. THE STRUCTURE THEOREM

In this section we prove Theorem [1.2.](#page-1-1) Throughout we consider  $k$  to be fixed and dependence on  $k$  will not be explicit. We start with some simple reductions.

Suppose  $\varphi: A_{[k]} \to \mathbf{T}$  is multilinear and bias $(\varphi) \geq \epsilon$ . We may decompose each  $A_i$  into its p-primary parts:

$$
A_i = \bigoplus_p A_i^{(p)}.
$$

Then  $\varphi$  decomposes as

$$
\varphi=\sum_p \varphi_p,
$$

where  $\varphi_p$  factors as

$$
A_{[k]} \to A_1^{(p)} \times \cdots \times A_k^{(p)} \to \mathbf{T}.
$$

The bias of  $\varphi$  correspondingly decomposes as

$$
bias(\varphi) = \prod_p bias(\varphi_p).
$$

By Lemma [2.1,](#page-2-3)  $bias(\varphi_p) \leq 1 - (1 - 1/p)^{k-1} \leq 1 - 1/2^{k-1}$  whenever  $\varphi_p$  is nontrivial, so since bias $(\varphi) \geq \epsilon$  it follows that there are at most  $\log \epsilon^{-1} / \log(1 - 1/2^{k-1})^{-1}$ primes such that  $\varphi_p \neq 0$ . Hence it suffices to consider the *p*-primary parts separately, so without loss of generality  $A_1, \ldots, A_k$  are *p*-groups.

Let  $K_i = \{a_i \in A_i : \varphi_{a_i} \equiv 0\}$ . By replacing  $A_i$  with  $A_i/K_i$  we may assume  $K_i = 0$ , so  $\varphi$  is nondegenerate in the sense that  $\varphi_{a_i} \not\equiv 0$  for each nonzero  $a_i \in A_i$ . Then if  $A_i$  has an element of order  $q = p^n$ , the image of  $\varphi$  also contains an element of order  $q$ , so by Lemma [2.8,](#page-4-1)

bias
$$
(\varphi_p) \le (n+1)^{k-2}/q \le (\log_2 q + 1)^{k-2}/q
$$
.

This implies that q is bounded in terms of  $\epsilon$  (and k). Hence we may assume that  $A_1, \ldots, A_k$  have bounded exponent (and in particular p is bounded).

We will now deduce Theorem [1.2](#page-1-1) from Theorem [1.1](#page-1-0) using the following elementary lemma about extending multilinear maps. For any abelian  $p$ -group, let  $A[p]$ denote the subgroup  $\{x \in A : px = 0\}$  and let pA denote the subgroup  $\{px : x \in A\}$ .

<span id="page-6-0"></span>**Lemma 3.1.** Let  $A_1, \ldots, A_k$  be finite abelian p-groups and q a power of p.

(1) (domain enlargement) Suppose  $\varphi: pA_1 \times A_{[2,k]} \to \mathbf{Z}/q\mathbf{Z}$  is a multilinear map. Assume  $\varphi(x) = 0$  whenever  $px_i = 0$  for any  $i > 1$ . Then  $\varphi$  factors through  $pA_1 \times \prod_{i \in [2,k]} A_i/A_i[p]$ , and there is a multilinear map  $\psi : A_{[k]} \to$  $\mathbf{Z}/(pq)\mathbf{Z}$  extending  $\varphi$  in the sense that the following diagram commutes:

(2) (range enlargement) Suppose  $\varphi : A_{[k]} \to \mathbf{Z}/q\mathbf{Z}$  is a multilinear map such that  $\varphi(x) = 0$  whenever  $px_i = 0$  for any  $i \in [k]$ . Then  $\varphi$  factors through  $\prod_{i\in[k]}A_i/A_i[p]$ , and there is a multilinear map  $\psi: A_{[k]} \to \mathbf{Z}/(pq)\mathbf{Z}$  such that  $\psi$  mod  $q = \varphi$ , as in the following commutative diagram:

(3) (extension of rank-one maps) Suppose  $\varphi: pA_1 \times A_{2,k} \to \mathbf{T}$  is a multilinear map such that  $\varphi(x) = 0$  whenever  $px_i = 0$  for any  $i > 1$ , and factoring through  $m_q$ . Then  $\varphi$  extends to a multilinear map  $\psi : A_{[k]} \to \mathbf{T}$  factoring through  $m_{pq}$ , as in the following commutative diagram:

Proof. By the structure theorem for finite abelian groups, we may write

 $A_i = \langle e_{i1} \rangle \oplus \cdots \oplus \langle e_{id_i} \rangle \qquad (1 \leq i \leq k),$ 

where each  $e_{ij}$  has order some power of  $p$ . (1) Write

$$
\varphi_{j_1\cdots j_k} = \varphi(pe_{1j_1}, e_{2j_2}, \ldots, e_{kj_k}) \in \mathbf{Z}/q\mathbf{Z}.
$$

We may identify  $\mathbf{Z}/q\mathbf{Z}$  with  $p(\mathbf{Z}/(pq)\mathbf{Z})$ . For each  $j_1, \ldots, j_k$ , let  $\psi_{j_1\cdots j_k} \in \mathbf{Z}/(pq)\mathbf{Z}$ be an arbitrary solution to

$$
p\psi_{j_1\cdots j_k} = \varphi_{j_1\cdots j_k}.
$$

Suppose  $i > 1$  and  $e_{ij_i}$  has order  $p^n$ . By the assumption that  $\varphi$  factors through  $pA_1 \times \prod_{i \in [2,k]} A_i/A_i[p]$ , we must have  $p^{n-1}\varphi_{j_1\cdots j_k} = 0$ . Hence  $p^n\psi_{j_1\cdots j_k} = 0$ . Similarly, if  $e_{1j_1}$  has order  $p^n$ , then

$$
p^{n}\psi_{j_{1}\cdots j_{k}} = p^{n-1}\varphi_{j_{1}\cdots j_{k}} = \varphi(p^{n}e_{1j_{1}}, e_{2j_{2}}, \ldots, e_{kj_{k}}) = 0.
$$

Hence we may define  $\psi : A_{[k]} \to \mathbf{Z}/(pq)\mathbf{Z}$  by linearly extending the definition

$$
\psi(e_{1j_1},\ldots,e_{kj_k})=\psi_{j_1\cdots j_k}.
$$

The maps  $\psi|_{pA_1 \times A_{[2,k]}}$  and  $p\varphi$  agree on generators, so they are the same. (2) Write

$$
\varphi_{j_1\cdots j_k} = \varphi(e_{1j_1}, e_{2j_2}, \ldots, e_{kj_k}) \in \mathbf{Z}/q\mathbf{Z}.
$$

For each  $j_1, \ldots, j_k$ , let  $\psi_{j_1\cdots j_k} \in \mathbf{Z}/(pq)\mathbf{Z}$  be an arbitrary solution to

$$
\psi_{j_1\cdots j_k} \equiv \varphi_{j_1\cdots j_k} \pmod{q}.
$$

Suppose  $p^n$  is the order of one of the generators  $e_{ij_i}$ . Then  $p^{n-1}\varphi_{j_1\cdots j_k} = 0 \pmod{q}$ , so  $p^n \psi_{j_1 \cdots j_k} = 0 \pmod{pq}$ . Hence we may define  $\psi : A_{[k]} \to \mathbf{Z}/(pq)\mathbf{Z}$  by linearly extending the definition

$$
\psi(e_{1j_1},\ldots,e_{kj_k})=\psi_{j_1\cdots j_k}.
$$

Then  $\psi$  mod q and  $\varphi$  agree on generators, so they are the same.

(3) By assumption  $\varphi = m_q(\varphi_1, \varphi_2)$  where  $\varphi_1$  is defined on  $pA_1 \times A_I$  for some  $I \subsetneq [2, k]$  and  $\varphi_2$  is defined on  $A_{[2,k] \setminus I}$ . By (1),  $\varphi_1$  may be extended to  $\psi_1$ :  $A_1 \times A_I \to \mathbf{Z}/(pq)\mathbf{Z}$  in such a way that  $\psi_1|_{pA_1 \times A_I} = p\varphi_1$ . By (2),  $\varphi_2$  may be extended to  $\psi_2$ :  $A_{[2,k]\setminus I} \to \mathbf{Z}/(pq)\mathbf{Z}$  in such a way that  $\psi_2$  mod  $q = \varphi_2$ . Let  $\psi = m_{pq}(\psi_1, \psi_2)$ . Then for  $x \in pA_1 \times A_{[2,k]}$  we have

$$
\psi(x) = \psi_1(x)\psi_2(x)/(pq) \text{ mod } 1 = \varphi_1(x)\varphi_2(x)/q \text{ mod } 1 = \varphi(x),
$$

so  $\psi$  extends  $\varphi$ .

We can now prove Theorem [1.2.](#page-1-1)

*Proof of Theorem [1.2.](#page-1-1)* Let the exponent of  $A_i$  be  $p^{n_i}$ . We will prove the theorem by induction on  $n_1 + \cdots + n_k$ . If  $n_i = 1$  for each i then each  $A_i$  is elementary abelian, hence a vector space over  $\mathbf{F}_p$ . In this case the result follows from Theorem [1.1.](#page-1-0) Hence assume  $n_1 > 1$  without loss of generality. Then  $pA_1$  and  $A_1/pA_1$  both have smaller exponent than  $A_1$ .

The restriction  $\varphi_1$  of  $\varphi$  to  $pA_1 \times A_{[2,k]}$  factors through a map  $\varphi'_1$  defined on  $pA_1 \times \prod_{i \in [2,k]} A_i/A_i[p]$ , as in the following diagram:

$$
pA_1 \times A_{[2,k]} \xrightarrow{\qquad} pA_1 \times \prod_{i \in [2,k]} A_i/A_i[p]
$$
\n
$$
A_{[k]} \xrightarrow{\qquad \varphi_1} \downarrow \varphi_1'
$$
\n
$$
A_{[k]}
$$

.

By Corollary [2.7,](#page-4-2)  $bias(\varphi_1') = bias(\varphi_1) \ge \epsilon$ , so by induction

$$
\varphi_1' = \psi_1' + \dots + \psi_r'
$$

for  $r = O_{\epsilon}(1)$  and some

$$
\psi'_1,\ldots,\psi'_r: pA_1 \times \prod_{i \in [2,k]} A_i/A_i[p] \to \mathbf{T}
$$

where each  $\psi'_i$  factors through  $m_{q_i}$  for some  $q_i \leq O_{\epsilon}(1)$ . By Lemma [3.1,](#page-6-0) each  $\psi'_i$ extends to a multilinear map  $\psi_i: A_{[k]} \to \mathbf{T}$  factoring through  $m_{pq_i}$ . Let

$$
\varphi_2 = \varphi - (\psi_1 + \cdots + \psi_r).
$$

Then  $\varphi_2$  also has bias bounded away from zero (by Lemma [2.3](#page-3-1) and Corollary [2.6\)](#page-4-3), and  $\varphi_2$  factors through  $(A_1/pA_1) \times A_{[2,k]}$ . By induction again there are multilinear maps  $\psi_{r+1}, \ldots, \psi_{r_2} : (A_1/pA_1) \times A_{[2,k]} \to \mathbf{T}$ , where  $r_2 = O(1)$ , such that each  $\psi_i$ factors through  $m_q$  for some bounded q, and such that

$$
\varphi_2=\psi_{r+1}+\cdots\psi_{r_2}.
$$

Hence

$$
\varphi=\psi_1+\cdots+\psi_{r_2},
$$

and the induction is complete.  $\Box$ 

We end by deducing Corollary [1.3.](#page-2-4)

*Proof of Corollary [1.3.](#page-2-4)* Let  $A_k = \widehat{B}$  and let  $\varphi(x) = x_k(F(x_1, \ldots, x_{k-1}))$ . Then  $\varphi$ is multilinear and bias( $\varphi$ ) =  $P(f = 0) \ge \epsilon > 0$ , so Theorem [1.2](#page-1-1) implies that  $\varphi$  is the sum of  $O_\epsilon(1)$  multilinear functions of the form

$$
\psi(x) = m_q(\varphi_1(x_I), \varphi_2(x_{I^c})),
$$

where  $0 < |I| < k$  and  $q \leq O_{\epsilon}(1)$ . Assume without loss of generality that  $k \in I^c$ . Since  $\psi$  is linear in  $x_k$  and  $\widehat{A}_k \cong B$ , there is some  $b = b(x_{[k-1]}) \in B$  such that

$$
\psi(x) = x_k(b(x_{[k-1]})).
$$

Moreover, b must be multilinear in  $x_{[k-1]}$ , and b can depend on  $x_I$  only through  $\varphi_1(x_I)$ . Hence  $\psi$  has the form

$$
\psi(x) = x_k(G(g(x_I), x_{[k-1]\setminus I})),
$$

where  $g = \varphi_1$ . This implies that F is the sum of  $O_\epsilon(1)$  maps of the form  $G(g(x_1), x_{[k-1]\setminus I})$ . Now fix I and suppose the terms of the form  $G(g(x_I), x_{[k-1]\setminus I})$  are

$$
G_j(g_j(x_I), x_{[k-1]\setminus I}) \qquad (1 \le j \le n).
$$

Let  $g = (g_1, \ldots, g_n)$ , and note that  $|\text{cod}(g)|$  is still bounded and  $G_j(g_j(x_I), x_{[k-1]\setminus I}) =$  $G'_{j}(g(x_{I}), x_{[k-1]\setminus I}),$  where  $G'_{j}$  is the composite of  $G_{j}$  and the projection  $\pi_{j}$ . Let  $G = G'_1 + \cdots + G'_n$ . Then

$$
\sum_{j=1}^{n} G_j(g_j(x_I), x_{[k-1]\setminus I}) = G(g(x_I), x_{[k-1]\setminus I}).
$$

<span id="page-8-0"></span>Hence  $F$  has the claimed form.

#### 4. Possible biases

Let  $\Phi_k$  be the set of all multilinear maps  $\varphi: A_{[k]} \to \mathbf{T}$  for any finite abelian groups  $A_1, \ldots, A_k$ . In this section we probe the set of all possible biases

$$
B_k = \{\text{bias}(\varphi) : \varphi \in \Phi_k\}.
$$

For example,

$$
B_1 = \{0, 1\}, \qquad \qquad B_2 = \{1/n : n \ge 1\}.
$$

By [\(3\)](#page-2-2),  $B_k \subseteq [0,1]$ . We will show that Theorem [1.2](#page-1-1) implies that  $B_k$  is a small subset of  $[0, 1]$  in various senses. The results of this section are analogous to those

proved in  $[E]$  essentially for  $B_3$  and for the set of commuting probabilities of finite groups.

A slight generalization is useful. Call  $\varphi: A_{[k]} \to \mathbf{T}$  multiaffine if  $\varphi(x)$  is affinelinear in each variable  $x_i$  separately. Equivalently,  $\varphi$  is multiaffine if and only if it can be written

$$
\varphi=\sum_{I\subseteq [k]}\varphi_I,
$$

where  $\varphi_I$  is a multilinear map  $A_I \to \mathbf{T}$ . The greatest  $d = |I|$  such that  $\varphi_I$  is nontrivial is the *degree* of  $\varphi$ . Let  $\Phi_{k,d}$  be the set of all multiaffine maps  $\varphi: A_{[k]} \to \mathbf{T}$ (for any  $A_1, \ldots, A_k$ ) of degree at most d and zero constant term, and let

$$
B_{k,d} = \{\text{bias}(\varphi) : \varphi \in \Phi_{k,d}\}.
$$

Thus  $B_{k,d}$  is a subset of the unit disc  $D = \{z \in \mathbf{C} : |z| \leq 1\}.$ 

**Example 4.1** (Gauss sums). Let  $A_1 = A_2 = A_3 = \mathbf{F}_p$ , where p is an odd prime, and let

$$
\varphi(x,y,z)=(xy+xz+yz)/p \bmod 1 \qquad (x,y,z\in \mathbf{F}_p)
$$

Thus  $\varphi \in \Phi_{3,2}$ . Then

bias
$$
(\varphi)
$$
 =  $\mathbf{E}_{x,y,z \in \mathbf{F}_p} e((xy + xz + yz)/p) = p^{-2} \overline{G(p)},$ 

where  $G(p)$  is the Gauss sum

$$
G(p) = \sum_{x \in \mathbf{F}_p} e(x^2/p).
$$

It was proved by Gauss that  $G(p) = p^{1/2}$  or  $ip^{1/2}$  according to whether p is 1 or 3 mod 4. Hence  $B_{3,2}$  includes  $i^{\pm (p-1)^2/4} p^{-3/2}$  for every odd prime p.

If X is a subset of a compact metric space, let  $X'$  be the set of limit points of X. We iterate this operation transfinitely according to the following rules:

If X is countable then there is a countable ordinal  $\beta$  such that  $X^{(\beta)} = \emptyset$ . The smallest such  $\beta$  must be a successor ordinal, say  $\alpha + 1$ , and this ordinal  $\alpha$  is called the *Cantor–Bendixson rank* of X and denoted  $CB(X)$ . It is the unique ordinal such that  $X^{(\alpha)}$  is finite and nonempty.<sup>[1](#page-9-0)</sup>

<span id="page-9-1"></span>**Theorem 4.2.** The set  $B_{k,d}$  has the following smallness properties.

- (1) All limit points of  $B_{k,d}$  are algebraic (in fact, rational linear combinations of roots of unity).
- <span id="page-9-2"></span>(2) CB $(B_{k,d}) \in \{1, \omega, \ldots, \omega^{d-2}\}\$  for  $d \geq 2$ .

In particular, Item [\(1\)](#page-9-1) shows that  $\overline{B_{k,d}}$  is countable, so in particular it is nowhere dense and measure-zero.

*Proof.* For  $\epsilon > 0$  let

$$
B_{k,d,\epsilon}=B_{k,d}\cap\{z\in D:|z|\geq\epsilon\}.
$$

<span id="page-9-0"></span><sup>&</sup>lt;sup>1</sup>More often  $\beta$  itself is called the Cantor–Bendixson rank, but the present usage is a common variant for countable sets.

Let  $\varphi \in \Phi_{k,d,\epsilon}$ , so  $\varphi: A_{[k]} \to \mathbf{T}$  is a multiaffine map of degree d and zero constant term defined on some finite abelian groups  $A_1, \ldots, A_k$  and  $|\text{bias}(\varphi)| \geq \epsilon$ . Write

$$
\varphi = \sum_{I \subseteq [k]} \varphi_I,
$$

where  $\varphi_I : A_I \to \mathbf{T}$  is multilinear. Let  $\varphi_d$  be the sum of the terms with  $|I| = d$ . By Lemma [2.2,](#page-3-0) for each  $I \subseteq [k]$  of size d we have

$$
bias(\varphi_I) \ge | bias(\varphi)| \ge \epsilon,
$$

so by Theorem [1.2](#page-1-1) there is an expression for  $\varphi_I$  as the sum of  $O_\epsilon(1)$  maps factoring through  $m_q$  for some bounded prime power q. Hence there is an expression for  $\varphi_d$ of the form

$$
\varphi_d = \sum_{i=1}^r m_{q_i}(\varphi_i^L, \varphi_i^R),
$$

where  $r = O_{\epsilon}(1)$  and, for each i,  $\varphi_i^L$  and  $\varphi_i^R$   $(1 \leq i \leq r)$  are multilinear maps with disjoint sets of variables and codomain  $\mathbf{Z}/q_i\mathbf{Z}$ , where  $q_i = O_{\epsilon}(1)$ . Hence

$$
e(\varphi_d) = F(\varphi_1^L, \dots, \varphi_r^L, \varphi_1^R, \dots, \varphi_r^R),
$$

where

$$
F(x_1,...,x_r,y_1,...,y_1) = e(x_1y_1/q_1 + \cdots + x_ry_r/q_r)
$$

Let  $\Gamma = \left(\prod_{i=1}^r \mathbf{Z}/q_i \mathbf{Z}\right)^2$  and let  $Q = q_1 \cdots q_r = |\Gamma|^{1/2}$ . The Fourier expansion of F is

$$
F(x_1,...,x_r,y_1,...,y_s) = \frac{1}{Q} \sum_{(u,v) \in \Gamma} e \left( \sum_{i=1}^r (-u_i v_i + u_i x_i + v_i y_i) / q_i \right).
$$

Hence

$$
e(\varphi_d) = \frac{1}{Q} \sum_{(u,v) \in \Gamma} e\left(\sum_{i=1}^r (-u_i v_i + u_i \varphi_i^L + v_i \varphi_i^R)/q_i\right)
$$

and

bias
$$
(\varphi)
$$
 =  $\frac{1}{Q}$  $\sum_{(u,v)\in\Gamma} e(-u_1v_1/q_1 - \cdots - u_rv_r/q_r)$  bias $(\psi_{u,v}),$ 

where

<span id="page-10-0"></span>
$$
\psi_{u,v} = \sum_{i=1}^r (u_i \varphi_i^L + v_i \varphi_i^R) / q_i + (\varphi - \varphi_d).
$$

Note that  $\psi_{u,v}$  is multi-affine of degree at most  $d-1$  with zero constant term. Since  $|\Gamma| \leq O_{\epsilon}(1)$ , we have proved that

(4) 
$$
B_{k,d,\epsilon} \subseteq O_{\epsilon}(1)H_{O_{\epsilon}(1)}B_{k,d-1},
$$

where  $H_X$  is the (finite) set of all complex numbers of the form  $\zeta/m$  where  $\zeta$  is a root of unity of order at most X and  $m$  is a positive integer of size at most X. Here we are also using the standard notation  $ST = \{st : s \in S, t \in T\}$  for the product of sets S and T and  $nS = S + \cdots + S$  for the sum of n copies of a set S.

We will now use induction on  $d$  to prove Items  $(1)$  and  $(2)$ . As the base of the induction, note that an affine linear map with zero constant term is just a linear map, so  $B_{k,1} = B_1 = \{0,1\}$ . Hence, for  $d = 2$ , [\(4\)](#page-10-0) shows that  $B_{k,2,\epsilon}$  is finite for all  $\epsilon > 0$ , so  $B'_{k,2} \subseteq \{0\}$ . Hence we may assume  $d > 2$ .

Let z be a limit point of  $B_{k,d}$ . Then either  $z = 0$  or z is a limit point of  $B_{k,d,\epsilon}$ for  $\epsilon = |z|/2$ . In the latter case [\(4\)](#page-10-0) shows that

$$
z \in O_{\epsilon}(1)H_{O_{\epsilon}(1)}\overline{B_{k,d-1}}.
$$

By induction on  $d$  this shows that  $z$  is a rational linear combination of roots of unity. This proves Item [\(1\).](#page-9-1)

Let  $\alpha = \text{CB}(B_{k,d})$ . Then it follows from [\(4\)](#page-10-0) that

$$
B_{k,d,\epsilon}^{(\alpha O_\epsilon(1))}=\emptyset.
$$

Since this holds for all  $\epsilon > 0$ , it follows that

$$
B_{k,d}^{(\alpha\omega)} \subseteq \{0\}.
$$

Hence

$$
CB(B_{k,d}) \leq CB(B_{k,d-1})\omega,
$$

and this proves  $CB(B_{k,d}) \leq \omega^{d-2}$  by induction. Finally, since  $B_{k,d}$  is closed under multiplication, the argument of [\[E,](#page-11-8) Lemma 5.1] shows that  $CB(B_{k,d}) = \omega^{\gamma}$  for some ordinal  $\gamma$ , so  $CB(B_{k,d}) \in \{1, \omega, \ldots, \omega^{d-2}\}.$ 

- Since  $B_k \subseteq B_{k,k}$ , the theorem applies in particular to  $B_k \subseteq [0,1]$  and shows
- (1) all limit points of  $B_k$  are algebraic,
- (2) CB $(B_k) \in \{1, \omega, \ldots, \omega^{k-2}\}.$

It is very likely that all limit points of  $B_k$  are actually rational, but a slightly more sophisticated analysis is required to prove this. As to the Cantor–Bendixson rank, basic examples demonstrate that  $CB(B_k) > 1$  for  $k > 2$ , so

$$
CB(B_1) = 0, \qquad CB(B_2) = 1, \qquad CB(B_3) = \omega,
$$

but the value of  $CB(B_k)$  for  $k > 3$  is unclear. Relatedly, it is plausible that  $B_k$  is well-ordered by the reverse of the natural order, i.e., for every  $x \in B_k$  there is some  $\epsilon > 0$  such that  $(x - \epsilon, x) \cap B_k = \emptyset$ ; if this is the case it follows that  $B_k$  has order type  $\omega^{\text{CB}(B_k)}$ . We leave these questions as open problems.

### Problem 4.3.

- (1) Prove that all limit points of  $B_k$  are rational.
- (2) Determine the Cantor–Bendixson rank of  $B_k$ . In particular, determine whether CB( $B_4$ ) is  $\omega$  or  $\omega^2$ .
- (3) Determine whether  $B_k$  is reverse-well-ordered.
