Abstract

In this work, we study fixed point algorithms for finding a zero in the sum of $n \geq 2$ maximally monotone operators by using their resolvents. More precisely, we consider the class of such algorithms where each resolvent is evaluated only once per iteration. For any algorithm from this class, we show that the underlying fixed point operator is necessarily defined on a d-fold Cartesian product space with $d \geq n-1$. Further, we show that this bound is unimprovable by providing a family of examples for which $d = n-1$ is attained. This family includes the Douglas–Rachford algorithm as the special case when $n = 2$. Applications of the new family of algorithms in distributed decentralised optimisation and multi-block extensions of the alternation direction method of multipliers (ADMM) are discussed.

1   Introduction

In this work, we study fixed point algorithms for finding a zero in the sum of finitely many maximally monotone operators defined on a real Hilbert space $\mathcal{H}$. That is, we consider problems of the form

$$\text{find } x \in \mathcal{H} \text{ such that } 0 \in \sum_{i=1}^{n} A_i(x), \tag{1}$$

where the set-valued operator $A_i \colon \mathcal{H} \rightrightarrows \mathcal{H}$ is maximally monotone for all $i \in \{1, \dots, n\}$. We focus on so-called *backward schemes* for solving (1). That is, we assume the operator A_i is only available through its resolvent $J_{A_i} := (\mathrm{Id} + A_i)^{-1}$. Such methods are the backbone of modern optimisation [8]. Although resorting exclusively to the use of resolvents for (1) may seem restrictive, it is worth noting that algorithms have interpretations as the resolvents of appropriately choosen monotone operators [11, 15].

To be more precise, this work considers the class of so-called *frugal resolvent splittings* in the sense of Ryu [22] which form a special class of backward schemes. Roughly speaking, a fixed point algorithm for solving (1) is a member of this class if it can be described using only vector addition, scalar multiplication, and each of the resolvents $J_{A_1}, \dots, J_{A_n}$ once per iteration. The best known examples of frugal resolvent splittings are the *proximal point algorithm* [21] for $n = 1$ and the *Douglas–Rachford algorithm* [16, 11] for $n = 2$.

The memory requirements of a fixed point algorithm can be measured using the notion of *lifting* [22]. A fixed point algorithm has *d-fold lifting* if its underlying fixed point operator can be defined on the d-fold Cartesian product $\mathcal{H}^d := \mathcal{H} \times \overset{(d)}{\dots} \times \mathcal{H}$. Since the amount of memory needed to

work with vectors in $\mathcal{H}^d$ is d-times larger than vectors in $\mathcal{H}$, the quantity d can be used to compare different algorithms. In practice, algorithms with less lifting (*i.e.,* smaller d for given n) can be desirable as they allow for larger problems to be solved with less computational resources. The best algorithms according to this criteria are said to have *minimal lifting*. That is, the smallest amount of lifting (for a given n) while still solving all feasible instance of (1).

Motivated by this property, this work studies the relationship between the number of monotone operators in (1), as specified by n, and the minimal amount of lifting in frugal resolvent splitting for solving (1), denoted by $d^*(n)$. The first few values of $d^*(n)$ are known in the existing literature, as we now explain. For $n = 1$, the proximal point algorithm is a frugal resolvent splitting with 1-fold lifting (which is necessarily a minimal lifting), so $d^*(1) = 1$. For $n = 2$, the Douglas–Rachford algorithm is a frugal resolvent splitting with 1-fold lifting, so $d^*(2) = 1$. For $n = 3$, Ryu [22, 2] devised a scheme with 2-fold lifting and established its minimality in [22, Theorem 3]. As a consequence, $d^*(3) = 2$. For $n \geq 4$, the value of $d^*(n)$ has remained an open problem. Indeed, Ryu's scheme for $n = 3$ does not seem to generalise to the $n \geq 4$ setting (see Remark 4.7). Nevertheless, the pattern provided by the first few terms does suggest that $d^*(n) = n - 1$ for $n \geq 2$.

In the first part of this work, we fully resolve the aforementioned open question by showing that it is indeed the case that $d^*(n) = n - 1$ for $n \geq 2$. This is established in two steps: we first show that $d^*(n) \geq n - 1$ for $n \geq 2$ using techinques inspired by [22], and we then show the bound cannot be improved by providing a new family of frugal resolvent splittings for (1) with $(n-1)$-fold lifting. We believe this family of algorithms, which does not rely on the usual product space reformulation (see Remark 2.7), to be of interest in its own right. Indeed, in the second part of this work, we investigate implications and applications of the new family of algorithms for structured optimisation problems. More precisely, we use the family to devise two novel schemes: a method for distributed optimisation which is decentralised in the sense that it does not require a "central coordinator", and a multi-block extension of the *alternating direction method of multipliers (ADMM)*. Numerical examples are included to illustrate the methods, although this is not our main focus.

The remainder of this work is structured as follows. In Section 2, we recall the necessarily preliminaries on fixed point algorithms. In Section 3, we establish the purported lower bound for $d^*(n)$ and, in Section 4, we introduce the new family of frugal resolvent splittings and proof convergence. In Section 5, we devise a scheme for distributed decentralised optimisation which uses resolvents and, in Section 6, we present our multi-block extension of ADMM. Finally, Section 7 concludes by outlining a number of directions and open questions for future research.

2 Fixed Point Encodings

Throughout this work, $\mathcal{H}$ denotes a real Hilbert space with inner-product $\langle\cdot,\cdot\rangle$ and induced norm $\|\cdot\|$. A set-valued operator $B\colon \mathcal{H} \rightrightarrows \mathcal{H}$ is said to be *monotone* if

$$\langle x - y, u - v \rangle \geq 0 \qquad \forall (x,u),(y,v) \in \operatorname{gra} B := \big\{(x,u) : u \in B(x)\big\}.$$

A monotone operator is *maximally monotone* if no proper extension is monotone. The *resolvent* of an operator $B\colon \mathcal{H} \rightrightarrows \mathcal{H}$ is the operator given by $J_B := (I+B)^{-1}$. When B is maximally monotone, its resolvent J_B is single-valued with full domain, and firmly nonexpansive [17].

Let $\mathcal{A}_n$ denote the set of all n-tuples of maximally monotone operators on $\mathcal{H}$. In other words, $A = (A_1,\ldots,A_n) \in \mathcal{A}_n$ if and only if $A_i\colon \mathcal{H} \rightrightarrows \mathcal{H}$ is maximally monotone for all $i \in \{1,\ldots,n\}$. Each $A \in \mathcal{A}_n$ induces an instance of the n-operator monotone inclusion problem given by

$$\text{find } x \in \mathcal{H} \text{ such that } 0 \in \sum_{i=1}^{n} A_i(x). \tag{2}$$

Note that the definition of $\mathcal{A}_n$ does not require the existence of a solution to (2). Further, due to commutativity of vector addition in $\mathcal{H}$, all cyclic permutations of an n-tuple $A \in \mathcal{A}_n$ induce the same instance of (2).

In the first part of this work, we study the structure of fixed point iterations for solving (2) whose update step can be defined in terms of the resolvents of the monotone operators $A_1,\ldots,A_n$.

Following Ryu [22], we formalise this idea in terms of two operators both parameterised by $A \in \mathcal{A}_n$: a *fixed point operator*, denoted T_A, and a *solution operator*, denoted S_A. The fixed point operator can be thought of as the basis for an iterative algorithm with the corresponding solution operator mapping its fixed points to solutions.

Definition 2.1 (Fixed point encoding [22])**.** *A pair of operators (T_A, S_A) is a* fixed point encoding *for $\mathcal{A}_n$ if, for all $A \in \mathcal{A}_n$,*

$$\text{Fix}\, T_A \neq \varnothing \iff \text{zer}\left(\sum_{i=1}^n A_i\right) \neq \varnothing \quad and \quad \mathbf{z} \in \text{Fix}\, T_A \implies S_A(\mathbf{z}) \in \text{zer}\left(\sum_{i=1}^n A_i\right).$$

Example 2.2. The *proximal point algorithm* is the fixed point encoding for $\mathcal{A}_1$ defined by $T_A = J_{A_1}$ and $S_A = \text{Id}$. The *Douglas–Rachford algorithm* is the fixed point encoding for $\mathcal{A}_2$ defined by

$$T_A = \text{Id} + J_{A_2}(2J_{A_1} - \text{Id}) - J_{A_1} \quad and \quad S_A = J_{A_1}. \tag{3}$$

Let $\mathbf{z} = (z_1, z_2) \in \mathcal{H}^2$. Then *Ryu's splitting algorithm* [2, 22] is the fixed point encoding for $\mathcal{A}_3$ defined by

$$T_A(\mathbf{z}) = \mathbf{z} + \frac{1}{2}\begin{bmatrix} J_{A_3}\big(J_{A_1}(z_1) - z_1 + J_{A_2}(J_{A_1}(z_1) + z_2) - z_2\big) - J_{A_1}(z_1) \\ J_{A_3}\big(J_{A_1}(z_1) - z_1 + J_{A_2}(J_{A_1}(z_1) + z_2) - z_2\big) - J_{A_2}\big(J_{A_1}(z_1) + z_2\big) \end{bmatrix}$$

and $S_A(\mathbf{z}) = J_{A_1}(z_1)$.

Definition 2.3 (Resolvent splitting [22])**.** *A fixed point encoding (T_A, S_A) is a* resolvent splitting *if, for all $A \in \mathcal{A}_n$, there is a finite procedure that evaluates T_A and S_A at a given point that uses only vector addition, scalar multiplication, and the resolvents of $A_1, \ldots, A_n$.*

Definition 2.3 does not specify the number of times per iteration that the resolvents of $A_1, \ldots, A_n$ can be used. Thus, without further restrictions, the computational cost per iteration of two different resolvent splittings need not be the same. The following definition provides a slight refinement as one way to address this.

Definition 2.4 (Frugality [22])**.** *A resolvent splitting (T_A, S_A) is* frugal *if, for all $A \in \mathcal{A}_n$, there is a finite procedure that evaluates T_A and S_A at a given point that uses only vector addition, scalar multiplication, and each of the resolvents of $A_1, \ldots, A_n$ exactly once.*

It is worth emphasising that, given a point z, the procedure for evaluating T_A and S_A described in Definition 2.4 must compute both $T_A(z)$ and $S_A(z)$ using each of the resolvents precisely once. In other words, the resolvent evaluations used to compute $S_A(z)$ must be the same as those used to compute $T_A(z)$. As will be demonstrated in Section 3, every frugal resolvent splitting can be expressed and analysed in terms of six coefficient matrices which fully define such a method.

Example 2.5. All fixed point encodings in Example 2.2 are frugal resolvent splittings. For an example of a resolvent splitting for $A = (A_1) \in \mathcal{A}_1$ which is not frugal, consider (T_A, S_A) given by

$$T_A = \text{Id} + J_{A_1}(2J_{A_1} - \text{Id}) - J_{A_1} \quad and \quad S_A = J_{A_1},$$

which coincides with the Douglas–Rachford algorithm applied to inclusion $0 \in (A_1 + A_1)(x)$. The resolvent splitting (T_A, S_A) is not frugal in general because any procedure for computing T_A requires the resolvent J_{A_1} to be evaluated twice.

Definition 2.6 (Lifting [22])**.** *Let $d \in \mathbb{N}$. A fixed point encoding (T_A, S_A) is a d-fold lifting for $\mathcal{A}_n$ if $T_A \colon \mathcal{H}^d \to \mathcal{H}^d$ and $S_A \colon \mathcal{H}^d \to \mathcal{H}$.*

Using the well-known product space reformulation, it is straightforward to derive a frugal resolvent splitting for $\mathcal{A}_n$ with n-fold lifting. In what follows, denote the *diagonal subspace* in $\mathcal{H}^n$ by

$$\Delta_n := \big\{\mathbf{z} = (z_1 \ldots, z_n) \in \mathcal{H}^n : z_1 = \cdots = z_n\big\}.$$

3

Example 2.7 (Product space formulation). Let $A = (A_1, \dots, A_n) \in \mathcal{A}_n$. Then

$$x \in \text{zer}\left(\sum_{i=1}^{n} A_i\right) \iff \mathbf{x} = (x, \dots, x) \in \text{zer}\left(A + N_{\Delta_n}\right),$$

where N_{Δ_n} denotes the (convex) normal cone to Δ_n. Consider the operators $T_A \colon \mathcal{H}^n \to \mathcal{H}^n$ and $S_A \colon \mathcal{H}^n \to \mathcal{H}$ given by

$$T_A = \text{Id} + J_A(2P_{\Delta_n} - \text{Id}) - P_{\Delta_n} \quad \text{and} \quad S_A = P_1 P_{\Delta_n},$$

where P_{Δ_n} denotes the projection onto Δ_n, $J_A = (J_{A_1}, \dots, J_{A_n})$, and P_1 denotes the projection onto the first product coordinate of a vector in $\mathcal{H}^n$. Then (T_A, S_A) is a frugal resolvent splitting of $\mathcal{A}_n$ with n-fold lifting. In fact, T_A coincides with the Douglas–Rachford operator applied to the monotone operators N_{Δ_n} and A.

In light of Example 2.7, it is natural to ask if there exists a frugal resolvent splitting for $\mathcal{A}_n$ with d-fold lifting for $d < n$. Indeed, this will be the main question we consider in the following section.

3   Frugal Resolvent Splittings with Lifting

Suppose (T_A, S_A) is a frugal resolvent splitting for $\mathcal{A}_n$ with d-fold lifting where $d \leq n$. By definition, there exists a finite procedure for evaluating T_A and S_A using only vector addition, scalar multiplication and the resolvents of $A_1, \dots, A_n$ precisely once. The form of such a procedure may be completely described in terms of a number of matrices, as we now explain.

Consider evaluation of T_A at an arbitrary point $\mathbf{z} = (z_1, \dots, z_d) \in \mathcal{H}^d$. By frugality, each of the resolvents $J_{A_1}, \dots, J_{A_n}$ is evaluated precisely once in the computation of $T_A(\mathbf{z})$. Thus there exist points $\mathbf{x} = (x_1, \dots, x_n) \in \mathcal{H}^n$ and $\mathbf{y} = (y_1, \dots, y_n) \in \mathcal{H}^n$ used in the procedure such that

$$\mathbf{x} = J_A(\mathbf{y}) \iff 0 \in \mathbf{x} - \mathbf{y} + A(\mathbf{x}). \tag{4}$$

The resolvents in (4) are computed in some order in the evaluation of $T_A(\mathbf{z})$. Without loss of generality, we assume they are computed in the order $J_{A_1}(y_1), \dots, J_{A_n}(y_n)$. Since T_A is a resolvent splitting, y_i is a linear combination of points already computed in the process of evaluating $T_A(\mathbf{z})$. Thus, we must have $y_1 \in \text{span}\{z_1, \dots, z_d\}$ and

$$y_i \in \text{span}\{z_1, \dots, z_d, x_1, \dots, x_{i-1}, y_1, \dots, y_{i-1}\} = \text{span}\{z_1, \dots, z_d, x_1, \dots, x_{i-1}\} \quad \forall i \geq 2,$$

with the coefficients in these linear combinations independent of z, x and y. Thus, in a slight abuse of notation,[1] we may express this compactly as

$$\mathbf{y} = B\mathbf{z} + L\mathbf{x}. \tag{5}$$

where $B \in \mathbb{R}^{n \times d}$ contains the coefficients of $z_1, \dots, z_n$ and $L \in \mathbb{R}^{n \times n}$ is a lower-triangular matrix with zeros on the diagonal which contains the coefficients of x. Since T_A is a frugal resolvent splitting, we also have

$$T_A(\mathbf{z}) \in \text{span}\{z_1, \dots, z_d, x_1, \dots, x_n, y_1, \dots, y_n\} = \text{span}\{z_1, \dots, z_d, x_1, \dots, x_n\},$$

where, as before, the coefficients in the linear combinations independent of $\mathbf{z}$ and $\mathbf{x}$. Hence there exists $T_z \in \mathbb{R}^{d \times d}$ and $T_x \in \mathbb{R}^{d \times n}$ such that[2]

$$T_A(\mathbf{z}) = T_z \mathbf{z} + T_x \mathbf{x}. \tag{6}$$

---

[1]Strictly speaking, (5) should be written as $\mathbf{y} = (B \otimes \text{Id})\mathbf{z} + (L \otimes \text{Id})\mathbf{x}$ where $\otimes$ denotes the Kronecker product. In the special case when $\mathcal{H} = \mathbb{R}$, $B \otimes \text{Id} = B$ and $L \otimes \text{Id} = L$, and the two expressions coincide.

[2]We emphasise that the coefficient matrices T_z and T_x are constant and do not have any dependence on $\mathbf{z}$ or $\mathbf{x}$. The subscripts are merely labels to indicate which variables the coefficients belong to. An analogous remark applies to the coefficient matrices S_z and S_x in (7).

Similarly, frugality also ensures

$$S_A(\mathbf{z}) \in \operatorname{span}\{z_1, \dots, z_d, x_1, \dots, x_n, y_1, \dots, y_n\} = \operatorname{span}\{z_1, \dots, z_d, x_1, \dots, x_n\},$$

hence there exists matrices $S_z \in \mathbb{R}^{1 \times d}$ and $S_x \in \mathbb{R}^{1 \times n}$ such that

$$S_A(\mathbf{z}) = S_z \mathbf{z} + S_x \mathbf{x}. \tag{7}$$

Thus, altogether, any frugal resolvent splitting for $\mathcal{A}_n$ with d-fold lifting is completed described by (4), (5), (6) and (7), and the matrices B, L, T_z, T_x, S_z, S_x. With this in mind, the results in this section are formulated in terms of these matrices.

We shall require the following technical lemma.

Lemma 3.1. *Let (T_A, S_A) be a frugal resolvent splitting for $\mathcal{A}_n$. Let M denote the block matrix given by*

$$M := \begin{bmatrix} 0 & \operatorname{Id} & -\operatorname{Id} & \operatorname{Id} \\ B & L & -\operatorname{Id} & 0 \\ T_z - \operatorname{Id} & T_x & 0 & 0 \end{bmatrix}.$$

If $\mathbf{z} \in \operatorname{Fix} T_A$, then there exists $\mathbf{v} = \begin{bmatrix} \mathbf{z} & \mathbf{x} & \mathbf{y} & \mathbf{a} \end{bmatrix}^\top \in \ker M$ with $\mathbf{a} \in A(\mathbf{x})$. Conversely, if $\mathbf{v} = \begin{bmatrix} \mathbf{z} & \mathbf{x} & \mathbf{y} & \mathbf{a} \end{bmatrix}^\top \in \ker M$ and $\mathbf{a} \in A(\mathbf{x})$, then $\mathbf{z} \in \operatorname{Fix} T_A$, $\mathbf{x} = J_A(\mathbf{y})$ and $S_A(\mathbf{z}) = S_z \mathbf{z} + S_x \mathbf{x}$.

Proof. Suppose $\mathbf{z} \in \operatorname{Fix} T_A$. Then there exists $\mathbf{x}, \mathbf{y} \in \mathcal{H}^n$ defined by (4)–(6) such that

$$\begin{bmatrix} \mathbf{x} - \mathbf{y} + A(\mathbf{x}) \\ B\mathbf{z} + L\mathbf{x} - \mathbf{y} \\ (T_z - \operatorname{Id})\mathbf{z} + T_x \mathbf{x} \end{bmatrix} = M \begin{bmatrix} \mathbf{z} \\ \mathbf{x} \\ \mathbf{y} \\ A(\mathbf{x}) \end{bmatrix} \ni 0.$$

Consequently, there exists $\mathbf{a} \in A(\mathbf{x})$ such that $\mathbf{v} := \begin{bmatrix} \mathbf{z} & \mathbf{x} & \mathbf{y} & \mathbf{a} \end{bmatrix}^\top \in \ker M$.

Conversely, suppose $\mathbf{v} = \begin{bmatrix} \mathbf{z} & \mathbf{x} & \mathbf{y} & \mathbf{a} \end{bmatrix}^\top \in \ker M$ and $\mathbf{a} \in A(\mathbf{x})$. The first row of M gives $0 = \mathbf{x} - \mathbf{y} + \mathbf{a} \in \mathbf{x} - \mathbf{y} + A(\mathbf{x}) \implies \mathbf{x} = J_A(\mathbf{y})$, the second row of M gives $\mathbf{y} = B\mathbf{z} + L\mathbf{x}$, and the last row of M together with (6) gives $\mathbf{z} = T_z \mathbf{z} + T_x \mathbf{x} = T_A(\mathbf{z}) \implies \mathbf{z} \in \operatorname{Fix} T_A$. Thus, as $\mathbf{z}, \mathbf{x}, \mathbf{y}$ satisfy (4)–(6), (7) implies $S_A(\mathbf{z}) = S_z \mathbf{z} + S_x \mathbf{x}$. $\square$

The following result shows that the solution mapping of a frugal resolvent splitting is necessarily of a specific form.

Proposition 3.2 (Solution mappings). *Let (T_A, S_A) be a frugal resolvent splitting for $\mathcal{A}_n$. Then, for all $\bar{\mathbf{z}} \in \operatorname{Fix} T_A$ and $\bar{\mathbf{x}} = J_A(\bar{\mathbf{y}})$, we have*

$$S_A(\bar{\mathbf{z}}) = \frac{1}{n} \sum_{i=1}^{n} \bar{y}_i = \bar{x}_1 = \cdots = \bar{x}_d.$$

Proof. Let $A \in \mathcal{A}_n$, let $\bar{\mathbf{z}} \in \operatorname{Fix} T_A$ and set $x^* = S_A(\bar{\mathbf{z}})$. By Lemma 3.1, there exists a vector $\mathbf{v} := \begin{bmatrix} \bar{\mathbf{z}} & \bar{\mathbf{x}} & \bar{\mathbf{y}} & \bar{\mathbf{a}} \end{bmatrix}^\top \in \ker M$ with $\bar{\mathbf{a}} \in A(\bar{\mathbf{x}})$ and $x^* = S_A(\bar{\mathbf{z}}) = S_z \bar{\mathbf{z}} + S_x \bar{\mathbf{x}}$. Next, consider the n-tuples of operators $A^{(0)}, A^{(1)}, \dots, A^{(n)} \in \mathcal{A}_n$ given by

$$A^{(0)}(\mathbf{x}) = \bar{\mathbf{a}} \quad \text{and} \quad A^{(j)}(\mathbf{x}) = \bar{\mathbf{a}} + \begin{bmatrix} 0 \\ \vdots \\ x_j - \bar{x}_j \\ \vdots \\ 0 \end{bmatrix} \quad \forall j = 1, \dots, n.$$

5

Since $\mathbf{v} \in \ker M$ and $\bar{\mathbf{a}} = A^{(j)}(\bar{\mathbf{x}})$, Lemma 3.1 implies $\bar{\mathbf{z}} \in \operatorname{Fix} T_{A^{(j)}}$ and $\bar{\mathbf{x}} = J_{A^{(j)}}(\bar{\mathbf{y}})$ and $S_{A^{(j)}}(\bar{\mathbf{z}}) = S_z\bar{\mathbf{z}} + S_x\bar{\mathbf{x}} = x^*$. Consequently, we have $0 = \sum_{i=1}^n A_i^{(0)}(x^*) = \sum_{i=1}^n \bar{a}_i$ and

$$0 = \sum_{i=1}^n A_i^{(j)}(x^*) = \sum_{i=1}^n \bar{a}_i + x^* - \bar{x}_j = x^* - \bar{x}_j \quad \forall j = 1, \ldots, n,$$

from which it follows that $x^* = \bar{x}_1 = \cdots = \bar{x}_n$. Finally, since $\bar{\mathbf{x}} = J_{A^{(0)}}(\bar{\mathbf{y}})$, we have $\bar{\mathbf{y}} - \bar{\mathbf{x}} = A^{(0)}(\bar{\mathbf{x}}) = \bar{\mathbf{a}}$ and hence $\sum_{i=1}^n \bar{y}_i - nx^* = \sum_{i=1}^n \bar{a}_i = 0$. The proof is now complete. $\qquad\square$

Thanks to Example 2.7, we know that there exists a frugal resolvent splitting for $\mathcal{A}_n$ with d-fold lifting with $d = n$. The following propositions show that there are no frugal resolvent splittings with lifting when $d \leq n - 2$, and thereby extends [22, Theorem 3] beyond the setting with $n = 3$.

Theorem 3.3 (Minimal lifting). *Let (T_A, S_A) be a frugal resolvent splitting for $\mathcal{A}_n$ with d-fold lifting. If $n \geq 2$, then $d \geq n - 1$.*

Proof. Suppose, by way of a contradiction, that (T_A, S_A) is a frugal resolvent splitting for $\mathcal{A}_n$ with d-fold lifting such that $d \leq n - 2$. Let $A \in \mathcal{A}_n$ with $\operatorname{zer}(\sum_{i=1}^n A_i) \neq \varnothing$ and $\mathbf{z} \in \operatorname{Fix} T_A$. By Lemma 3.1, there exists $\mathbf{v} = \begin{bmatrix} \mathbf{z} & \mathbf{x} & \mathbf{y} & \mathbf{a} \end{bmatrix}^\top \in \ker M$ with $\mathbf{a} \in A(\mathbf{x})$. In particular, the last row of M implies that $0 = (T_z - \operatorname{Id})\mathbf{z} + T_x\mathbf{x}$. Since $T_x \in \mathbb{R}^{d \times n}$ and $d \leq n - 2$, the rank-nullity theorem implies $\dim \ker T_x = n - \operatorname{rank} T_x \geq n - d \geq 2$. Thus, since $\dim \Delta_n = 1$, there exists $\bar{\mathbf{x}} \notin \Delta_n$ such that $T_x\mathbf{x} = T_x\bar{\mathbf{x}}$.

Set $\bar{\mathbf{z}} := \mathbf{z}$, $\bar{\mathbf{y}} := B\bar{\mathbf{z}} + L\bar{\mathbf{x}}$, $\bar{\mathbf{a}} := \bar{\mathbf{y}} - \bar{\mathbf{x}}$ and consider $\bar{A} \in \mathcal{A}_n$ given by $\bar{A}(\mathbf{x}) = \bar{\mathbf{a}}$. Then $\bar{\mathbf{v}} = \begin{bmatrix} \bar{\mathbf{z}} & \bar{\mathbf{x}} & \bar{\mathbf{y}} & \bar{\mathbf{a}} \end{bmatrix}^\top \in \ker M$ with $\bar{\mathbf{a}} \in \bar{A}(\bar{\mathbf{x}})$. By the Lemma 3.1, $\bar{\mathbf{z}} \in \operatorname{Fix} T_{\bar{A}}$ and $\bar{\mathbf{x}} = J_{\bar{A}}(\bar{\mathbf{y}})$. On the other hand, Proposition 3.2 implies $\bar{\mathbf{x}} \in \Delta_n$. Thus a contradiction is obtained and so completes the proof. $\qquad\square$

Theorem 3.3 provides a lower bound on the value of d for frugal resolvent splittings with d-folding lifting, but says nothing about whether this bound is tight. In the following section, we address this question by showing that it is indeed unimprovable for $\mathcal{A}_n$.

Remark 3.4. The definition of a resolvent splitting (Definition 2.3) only allows the resolvents $J_{A_1}, \ldots, J_{A_n}$ to be used in evaluation of T_A and S_A. Since the resolvent $J_{\omega_i A_i}$ for parameter $\omega_i > 0$ is typically no more difficult to compute than the resolvent J_{A_i}, a natural generalisation of Definition 2.3 is to allow the resolvents $J_{\omega_1 A_1}, \ldots, J_{\omega_n A_n}$ for parameters $\omega_1, \ldots, \omega_n > 0$, not necessarily all equal. After the publication of this work, this setting has been considered in [1] under the name "paramterised resolvent splittings". In the same work, it was shown that the conclusion of Theorem 3.3 also holds for parameterised resolvents splitting [1, Theorem 2.10]. Examples of frugal parameterised resolvents splitting which attain this bound can be found in [10, 5].

4 A Family of Resolvent Splitting

In this section, we provide an example of a frugal resolvent splitting for $\mathcal{A}_n$ with $(n-1)$-fold lifting, assuming $n \geq 2$. Due to Theorem 3.3 this is unimprovable for this problem class. In what follows, the set of integers between $k, l \in \mathbb{N}$ is denoted

$$[\![k, l]\!] := \begin{cases} \{k, k+1, \ldots, l\} & \text{if } k \leq l, \\ \varnothing & \text{otherwise.} \end{cases}$$

Let $\gamma \in (0, 1)$ and $A = (A_1, \ldots, A_n) \in \mathcal{A}_n$. Consider the operator $T_A \colon \mathcal{H}^{n-1} \to \mathcal{H}^{n-1}$ given by

$$T_A(\mathbf{z}) := \mathbf{z} + \gamma \begin{pmatrix} x_2 - x_1 \\ x_3 - x_2 \\ \vdots \\ x_n - x_{n-1} \end{pmatrix} \tag{8}$$

6

where $\mathbf{x} = (x_1, \ldots, x_n) \in \mathcal{H}^n$ depends on $\mathbf{z} = (z_1, \ldots, z_{n-1}) \in \mathcal{H}^{n-1}$ and is given by

$$\begin{cases} x_1 = J_{A_1}(z_1), \\ x_i = J_{A_i}(z_i + x_{i-1} - z_{i-1}) & \forall i \in [\![2, n-1]\!], \\ x_n = J_{A_n}(x_1 + x_{n-1} - z_{n-1}). \end{cases} \tag{9}$$

Remark 4.1. For $n = 2$, the operator T_A described by (8)–(9) is an under-relaxation of the standard Douglas–Rachford algorithm. Indeed, in this case, $T_A \colon \mathcal{H} \to \mathcal{H}$ can be expressed as

$$T_A(z) = z + \gamma(x_2 - x_1) = z + \gamma \left(J_{A_2}(2J_{A_1}(z) - z) - J_{A_1}(z) \right) = \left(1 - \frac{\gamma}{2} \right) \mathrm{Id} + \frac{\gamma}{2} R_{A_2} R_{A_1}, \tag{10}$$

where $R_{A_i} = 2J_{A_i} - \mathrm{Id}$ denotes the *reflected resolvent* of the monotone operator A_i. The (unrelaxed) Douglas–Rachford algorithm in (3) corresponds to the limiting case with $\gamma = 1$. For $n = 3$, the operator T_A is different than the one described by Ryu in [22, Theorem 4] (see also [2, Theorem 8]), which in the notation used in this section, corresponds to

$$\mathbf{z} \mapsto \mathbf{z} + \gamma \begin{pmatrix} x_3 - x_1 \\ x_3 - x_2 \end{pmatrix} \quad \text{where} \quad \begin{cases} x_1 = J_{A_1}(z_1) \\ x_2 = J_{A_2}(z_2 + x_1) \\ x_3 = J_{A_3}(x_1 - z_1 + x_2 - z_2). \end{cases} \tag{11}$$

As we will discuss in Remark 4.7, it is currently not obvious how to extend this method to the setting where $n \geq 4$.

Let Ω denote the set of all points $(\bar{\mathbf{z}}, \bar{x}) \in \mathcal{H}^{n-1} \times \mathcal{H}$ where $\bar{\mathbf{z}} = (\bar{z}_1, \ldots, \bar{z}_{n-1})$ satisfying

$$\begin{cases} \bar{x} = J_{A_1}(\bar{z}_1), \\ \bar{x} = J_{A_i}(\bar{z}_i - \bar{z}_{i-1} + \bar{x}) & i \in [\![2, n-1]\!], \\ \bar{x} = J_{A_n}(2\bar{x} - z_{n-1}). \end{cases}$$

Lemma 4.2. *Let $n \geq 2$, $A = (A_1, \ldots, A_n) \in \mathcal{A}_n$ and $\gamma > 0$. The following assertions hold.*

(a) If $\bar{\mathbf{z}} \in \mathrm{Fix}\, T_A$, then there exists $\bar{x} \in \mathcal{H}$ such that $(\bar{\mathbf{z}}, \bar{x}) \in \Omega$.

(b) If $\bar{x} \in \mathrm{zer}\left(\sum_{i=1}^n A_i\right)$, then there exists $\bar{\mathbf{z}} \in \mathcal{H}$ such that $(\bar{\mathbf{z}}, \bar{x}) \in \Omega$.

(c) If $(\bar{\mathbf{z}}, \bar{x}) \in \Omega$, then $\bar{\mathbf{z}} \in \mathrm{Fix}\, T_A$ and $\bar{x} \in \mathrm{zer}\left(\sum_{i=1}^n A_i\right)$.

Consequently,

$$\mathrm{Fix}\, T_A \neq \varnothing \iff \Omega \neq \varnothing \iff \mathrm{zer}\left(\sum_{i=1}^n A_i\right) \neq \varnothing.$$

Proof. (a): Let $\bar{\mathbf{z}} \in \mathrm{Fix}\, T_A$ and set $\bar{x} := J_{A_1}(\bar{z}_1)$. Since $T_A(\bar{\mathbf{z}}) = \bar{\mathbf{z}}$, (8) implies $(\bar{\mathbf{z}}, \bar{x}) \in \Omega$.

(b): Let $\bar{x} \in \mathrm{zer}\left(\sum_{i=1}^n A_i\right)$. Then there exists $\mathbf{v} = (v_1, \ldots, v_n) \in \mathcal{H}^n$ such that $v_i \in A_i(\bar{x})$ and $\sum_{i=1}^n v_i = 0$. Define the vector $\bar{\mathbf{z}} = (z_1, \ldots, z_{n-1}) \in \mathcal{H}^{n-1}$ according to

$$\begin{cases} \bar{z}_1 := \bar{x} + v_1 \in (\mathrm{Id} + A_1)\bar{x}, \\ \bar{z}_i := v_i + \bar{z}_{i-1} = (\bar{x} + v_i) - \bar{x} + \bar{z}_{i-1} \in (\mathrm{Id} + A_i)(\bar{x}) - \bar{x} + \bar{z}_{i-1} & \forall i \in [\![2, n-1]\!]. \end{cases}$$

Then $\bar{x} = J_{A_1}(z_1)$ and $\bar{x} = J_{A_i}(\bar{z}_i - \bar{z}_{i-1} + \bar{x})$ for $i \in [\![2, n-1]\!]$. Furthermore, we have

$$(\mathrm{Id} + A_n)(\bar{x}) \ni \bar{x} + v_n = \bar{x} - \sum_{i=1}^{n-1} v_i = \bar{x} - (\bar{z}_1 - \bar{x}) - \sum_{i=2}^{n-1} (\bar{z}_i - \bar{z}_{i-1}) = 2\bar{x} - \bar{z}_{n-1},$$

which implies that $\bar{x} = J_{A_n}(2\bar{x} - \bar{z}_{n-1})$. Altogether, we have $(\bar{\mathbf{z}}, \bar{x}) \in \Omega$.

(c): Let $(\bar{\mathbf{z}}, \bar{x}) \in \Omega$. It follows that $\bar{\mathbf{z}} \in \mathrm{Fix}\, T$. Further, the definition of the resolvent implies

$$\begin{cases} A_1(\bar{x}) \ni \bar{z}_1 - \bar{x} \\ A_i(\bar{x}) \ni \bar{z}_i - \bar{z}_{i-1} & \forall i \in [\![2, n-1]\!] \\ A_n(\bar{x}) \ni \bar{x} - z_{n-1}. \end{cases}$$

Summing together the above inclusions gives $\bar{x} \in \mathrm{zer}\left(\sum_{i=1}^n A_i\right)$, which completes the proof. $\qquad\square$

Lemma 4.3. *Let $n \geq 2$, $A = (A_1, \ldots, A_n) \in \mathcal{A}$ and $\gamma > 0$. Then, for all $\mathbf{z} = (z_1, \ldots, z_n) \in \mathcal{H}^{n-1}$ and $\bar{\mathbf{z}} = (\bar{z}_1, \ldots, \bar{z}_n) \in \mathcal{H}^{n-1}$, we have*

$$\|T_A(\mathbf{z}) - T_A(\bar{\mathbf{z}})\|^2 + \frac{1 - \gamma}{\gamma}\|(\mathrm{Id} - T_A)(\mathbf{z}) - (\mathrm{Id} - T_A)(\bar{\mathbf{z}})\|^2$$

$$+ \frac{1}{\gamma}\|\sum_{i=1}^{n-1}(\mathrm{Id} - T_A)(\mathbf{z})_i - \sum_{i=1}^{n-1}(\mathrm{Id} - T_A)(\bar{\mathbf{z}})_i\|^2 \leq \|\mathbf{z} - \bar{\mathbf{z}}\|^2. \quad (12)$$

In particular, if $\gamma \in (0, 1)$, then T_A is γ-averaged nonexpansive.

Proof. For convenience, denote $\mathbf{z}^+ := T_A(\mathbf{z})$ and $\bar{\mathbf{z}}^+ := T_A(\bar{\mathbf{z}})$. Further, let $\mathbf{x} = (x_1, \ldots, x_n) \in \mathcal{H}^n$ be given by (9) and let $\bar{\mathbf{x}} = (\bar{x}_1, \ldots, \bar{x}_n) \in \mathcal{H}^n$ be given analogously. Since $z_1 - x_1 \in A_1(x_1)$ and $\bar{z}_1 - \bar{x}_1 \in A_1(\bar{x}_1)$, monotonicity of A_1 implies

$$0 \leq \langle x_1 - \bar{x}_1, (z_1 - x_1) - (\bar{z}_1 - \bar{x}_1)\rangle$$
$$= \langle x_2 - \bar{x}_1, (z_1 - x_1) - (\bar{z}_1 - \bar{x}_1)\rangle + \langle x_1 - x_2, (z_1 - x_1) - (\bar{z}_1 - \bar{x}_1)\rangle. \quad (13)$$

For $i \in [\![2, n-1]\!]$, $z_i - z_{i-1} + x_{i-1} - x_i \in A_i(x_i)$ and $\bar{z}_i - \bar{z}_{i-1} + \bar{x}_{i-1} - \bar{x}_i \in A_i(\bar{x}_i)$. Thus monotonicity of A_i yields

$$0 \leq \langle x_i - \bar{x}_i, (z_i - z_{i-1} + x_{i-1} - x_i) - (\bar{z}_i - \bar{z}_{i-1} + \bar{x}_{i-1} - \bar{x}_i)\rangle$$
$$= \langle x_i - \bar{x}_i, (z_i - x_i) - (\bar{z}_i - \bar{x}_i)\rangle - \langle x_i - \bar{x}_i, (z_{i-1} - x_{i-1}) - (\bar{z}_{i-1} - \bar{x}_{i-1})\rangle$$
$$= \langle x_{i+1} - \bar{x}_i, (z_i - x_i) - (\bar{z}_i - \bar{x}_i)\rangle + \langle x_i - x_{i+1}, (z_i - x_i) - (\bar{z}_i - \bar{x}_i)\rangle$$
$$- \langle x_i - \bar{x}_{i-1}, (z_{i-1} - x_{i-1}) - (\bar{z}_{i-1} - \bar{x}_{i-1})\rangle - \langle \bar{x}_{i-1} - \bar{x}_i, (z_{i-1} - x_{i-1}) - (\bar{z}_{i-1} - \bar{x}_{i-1})\rangle.$$

Summing this inequality for $i \in [\![2, n-1]\!]$ and simplifying gives

$$0 \leq \langle x_n - \bar{x}_{n-1}, (z_{n-1} - x_{n-1}) - (\bar{z}_{n-1} - \bar{x}_{n-1}\rangle - \langle x_2 - \bar{x}_1, (z_1 - x_1) - (\bar{z}_1 - \bar{x}_1)\rangle$$

$$+ \sum_{i=2}^{n-1}\langle x_i - x_{i+1}, (z_i - x_i) - (\bar{z}_i - \bar{x}_i)\rangle - \sum_{i=1}^{n-2}\langle \bar{x}_i - \bar{x}_{i+1}, (z_i - x_i) - (\bar{z}_i - \bar{x}_i)\rangle. \quad (14)$$

Since $x_1 + x_{n-1} - x_n - z_{n-1} \in A_n(x_n)$ and $\bar{x}_1 + \bar{x}_{n-1} - \bar{x}_n - \bar{z}_{n-1} \in A_n(\bar{x}_n)$, monotonicity of A_n gives

$$0 \leq \langle x_n - \bar{x}_n, (x_1 + x_{n-1} - x_n - z_{n-1}) - (\bar{x}_1 + \bar{x}_{n-1} - \bar{x}_n - \bar{z}_{n-1})\rangle$$
$$= \langle x_n - \bar{x}_n, (x_{n-1} - z_{n-1}) - (\bar{x}_{n-1} - \bar{z}_{n-1})\rangle + \langle x_n - \bar{x}_n, (x_1 - \bar{x}_1) - (x_n - \bar{x}_n)\rangle$$
$$= -\langle x_n - \bar{x}_{n-1}, (z_{n-1} - x_{n-1}) - (\bar{z}_{n-1} - \bar{x}_{n-1})\rangle$$
$$- \langle \bar{x}_n - \bar{x}_{n-1}, (z_{n-1} - x_{n-1}) - (\bar{z}_{n-1} - \bar{x}_{n-1})\rangle$$
$$+ \frac{1}{2}\left(\|x_1 - \bar{x}_1\|^2 - \|x_n - \bar{x}_n\|^2 - \|(x_1 - x_n) - (\bar{x}_1 - \bar{x}_n)\|^2\right). \quad (15)$$

Adding (13), (14) and (15) and rearranging gives

$$0 \leq \sum_{i=1}^{n-1}\langle (x_i - \bar{x}_i) - (x_{i+1} - \bar{x}_{i+1}), \bar{x}_i - x_i\rangle - \sum_{i=1}^{n-1}\langle (x_i - \bar{x}_i) - (x_{i+1} - \bar{x}_{i+1}), z_i - \bar{z}_i\rangle$$

$$+ \frac{1}{2}\left(\|x_1 - \bar{x}_1\|^2 - \|x_n - \bar{x}_n\|^2 - \|(x_1 - x_n) - (\bar{x}_1 - \bar{x}_n)\|^2\right). \quad (16)$$

The first term in (16) can be expressed as

$$\sum_{i=1}^{n-1}\langle (x_i - \bar{x}_i) - (x_{i+1} - \bar{x}_{i+1}), \bar{x}_i - x_i\rangle$$

$$= \frac{1}{2}\sum_{i=1}^{n-1}\left(\|x_{i+1} - \bar{x}_{i+1}\|^2 - \|x_i - \bar{x}_i\|^2 - \|(x_i - x_{i+1}) - (\bar{x}_i - \bar{x}_{i+1})\|^2\right)$$

$$= \frac{1}{2}\left(\|x_n - \bar{x}_n\|^2 - \|x_1 - \bar{x}_1\|^2 - \frac{1}{\gamma^2}\sum_{i=1}^{n-1}\|(z_i - z_i^+) - (\bar{z}_i - \bar{z}^+)\|^2\right)$$

$$= \frac{1}{2}\left(\|x_n - \bar{x}_n\|^2 - \|x_1 - \bar{x}_1\|^2 - \frac{1}{\gamma^2}\|(\mathbf{z} - \mathbf{z}^+) - (\bar{\mathbf{z}} - \bar{\mathbf{z}}^+)\|^2\right), \quad (17)$$

8

and the second term in (16) can be expressed as

$$
\begin{aligned}
\sum_{i=1}^{n-1} &\langle (x_i - x_{i+1}) - (\bar{x}_i - \bar{x}_{i+1}), z_i - \bar{z}_i \rangle \\
&= \frac{1}{\gamma} \sum_{i=1}^{n-1} \langle (z_i - z_i^+) - (\bar{z}_i - \bar{z}_i^+), z_i - \bar{z}_i \rangle \\
&= \frac{1}{\gamma} \langle (\mathbf{z} - \mathbf{z}^+) - (\bar{\mathbf{z}} - \bar{\mathbf{z}}^+), \mathbf{z} - \bar{\mathbf{z}} \rangle \\
&= \frac{1}{2\gamma} \left(\| (\mathbf{z} - \mathbf{z}^+) - (\bar{\mathbf{z}} - \bar{\mathbf{z}}^+) \|^2 + \| \mathbf{z} - \bar{\mathbf{z}} \|^2 - \| \mathbf{z}^+ - \bar{\mathbf{z}}^+ \|^2 \right).
\end{aligned}
\tag{18}
$$

Thus, substituting (17) and (18) into (16) and simplifying gives

$$
\| \mathbf{z}^+ - \bar{\mathbf{z}}^+ \|^2 + \left(\frac{1}{\gamma} - 1 \right) \| (\mathbf{z} - \mathbf{z}^+) - (\bar{\mathbf{z}} - \bar{\mathbf{z}}^+) \|^2 + \gamma \| (x_1 - x_n) - (\bar{x}_1 - \bar{x}_n) \|^2 \leq \| \mathbf{z} - \bar{\mathbf{z}} \|^2.
\tag{19}
$$

Note that (9) implies

$$
\gamma(x_1 - x_n) - \gamma(\bar{x}_1 - \bar{x}_n) = \gamma \sum_{i=1}^{n-1} (x_i - x_{i+1}) - \gamma \sum_{i=1}^{n} (\bar{x}_i - \bar{x}_{i+1}) = \sum_{i=1}^{n-1} (z_i - z_i^+) - \sum_{i=1}^{n-1} (\bar{z}_i - \bar{z}_i^+).
$$

Substituting this into (19) gives (12), which completes the proof. $\qquad\square$

Remark 4.4. In general, Lemma 4.3 cannot be improved in the sense that T_A need not be averaged nonexpansive if $\gamma \geq 1$. Indeed, consider the setting with $n \geq 3$, $\gamma = 1$, and $A_1 = \cdots = A_n = 0$. Then $J_{A_1} = J_{A_2} = \cdots = J_{A_n} = \mathrm{Id}$ and hence

$$
T_A(\mathbf{z}) = T_A \begin{pmatrix} z_1 \\ z_2 \\ \vdots \\ z_{n-2} \\ z_{n-1} \end{pmatrix} = \begin{pmatrix} z_2 \\ z_3 \\ \vdots \\ z_{n-1} \\ z_1 \end{pmatrix}.
$$

Consequently, T_A is an isometry and hence not averaged nonexpansive.

However, in the special case when $n = 2$, Lemma 4.3 recovers the known result that T_A is averaged nonexpansive when $\gamma \in (0, 2)$. Indeed, if $n = 2$, then

$$
\left\| \sum_{i=1}^{n-1} (z_i - z_i^+) - \sum_{i=1}^{n-1} (\bar{z}_i - \bar{z}_i^+) \right\|^2 = \left\| (z_1 - z_1^+) - (\bar{z}_1 - \bar{z}_1^+) \right\|^2.
$$

Consequently, the second and third terms in (12) can be combined to give

$$
\| T_A(z) - T_A(\bar{z}) \|^2 + \frac{2 - \gamma}{\gamma} \| (\mathrm{Id} - T_A)(z) - (\mathrm{Id} - T_A)(\bar{z}) \|^2 \leq \| z - \bar{z} \|^2.
$$

Thus, if $n = 2$ and $\gamma \in (0, 2)$, then T_A is $\frac{\gamma}{2}$-averaged nonexpansive.

The following theorem, which is concerned with convergence of Algorithm 1, is our main result for this section.

Theorem 4.5. *Let $n \geq 2$, let $A = (A_1, \ldots, A_n) \in \mathcal{A}_n$ with $\mathrm{zer}\left(\sum_{i=1}^{n} A_i \right) \neq \varnothing$, and let $\gamma \in (0, 1)$. Given $\mathbf{z}^0 \in \mathcal{H}^{n-1}$, let $(\mathbf{z}^k) \subseteq \mathcal{H}^{n-1}$ and $(\mathbf{x}^k) \subseteq \mathcal{H}^n$ be the sequences given by (20) and (21), respectively. Then the following assertions hold.*

(a) The sequence $(\mathbf{z}^k)$ converges weakly to a point $\mathbf{z} \in \mathrm{Fix}\, T_A$.

(b) The sequence $(\mathbf{x}^k)$ converges weakly to a point $(x, \ldots, x) \in \mathcal{H}^n$ with $x \in \mathrm{zer}\left(\sum_{i=1}^{n} A_i \right)$.

Algorithm 1: Minimal resolvent splitting for finding a zero of $\sum_{i=1}^n A_i$ when $n \geq 2$.

Input: Choose $\mathbf{z}^0 = (z_1^0, \ldots, z_{n-1}^0) \in \mathcal{H}^{n-1}$ and $\gamma \in (0, 1)$.

for $k = 1, 2, \ldots$ **do**

Compute $\mathbf{z}^{k+1} = (z_1^{k+1}, \ldots, z_{n-1}^{k+1}) \in \mathcal{H}^{n-1}$ according to

$$\mathbf{z}^{k+1} = T_A(\mathbf{z}^k) = \mathbf{z}^k + \gamma \begin{pmatrix} x_2^k - x_1^k \\ x_3^k - x_2^k \\ \vdots \\ x_n^k - x_{n-1}^k \end{pmatrix}, \tag{20}$$

where $\mathbf{x}^k = (x_1^k, \ldots, x_n^k) \in \mathcal{H}^n$ is given by

$$\begin{cases} x_1^k = J_{A_1}(z_1^k), \\ x_i^k = J_{A_i}(z_i^k - z_{i-1}^k + x_{i-1}^k) & \forall i \in [\![2, n-1]\!], \\ x_n^k = J_{A_n}(x_1^k + x_{n-1}^k - z_{n-1}^k). \end{cases} \tag{21}$$

Proof. Since $\mathrm{zer}\left(\sum_{i=1}^n A_i\right) \neq \varnothing$, Lemma 4.2(b) implies $\mathrm{Fix}\, T_A \neq \varnothing$. Since $\gamma \in (0, 1)$, Lemma 4.3 implies T_A is γ-averaged nonexpansive. By applying [3, Theorem 5.15], we therefore deduce that $(\mathbf{z}^k)$ converges weakly to a point $\mathbf{z} \in \mathrm{Fix}\, T_A$ and that $\lim_{k \to \infty} \|\mathbf{z}^{k+1} - \mathbf{z}^k\| = 0$.

By Lemma 4.2(a), there exists $\bar{x} \in \mathcal{H}$ such that $(\mathbf{z}, \bar{x}) \in \Omega$. By nonexpansivity of resolvents and boundedness of $(\mathbf{z}^k)$, it follows that $(\mathbf{x}^k)$ is also bounded. Further, (20) and the fact that $\lim_{k \to \infty} \|\mathbf{z}^{k+1} - \mathbf{z}^k\| = 0$ implies that

$$\lim_{k \to \infty} \|x_i^k - x_{i-1}^k\| = 0 \quad \forall i = 2, \ldots, n. \tag{22}$$

Next, using the definition of the resolvent, (21) implies

$$\begin{cases} A_1^{-1}(z_1^k - x_1^k) & \ni x_1^k \\ A_i^{-1}((z_i^k - x_i^k) - (z_{i-1}^k - x_{i-1}^k)) & \ni x_i^k \\ A_n(x_n^k) & \ni x_1^k - x_n^k - (z_{n-1}^k - x_{n-1}^k) \end{cases} \quad \forall i \in [\![2, n-1]\!]$$

which can be written as the inclusion

$$\left[\begin{pmatrix} A_1^{-1} \\ A_2^{-1} \\ \vdots \\ A_{n-1}^{-1} \\ A_n \end{pmatrix} + \begin{pmatrix} 0 & 0 & \ldots & 0 & -\mathrm{Id} \\ 0 & 0 & \ldots & 0 & -\mathrm{Id} \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \ldots & 0 & -\mathrm{Id} \\ \mathrm{Id} & \mathrm{Id} & \ldots & \mathrm{Id} & 0 \end{pmatrix} \right] \begin{pmatrix} z_1^k - x_1^k \\ (z_2^k - x_2^k) - (z_1^k - x_1^k) \\ \vdots \\ (z_{n-1}^k - x_{n-1}^k) - (z_{n-2}^k - x_{n-2}^k) \\ x_n^k \end{pmatrix} \ni \begin{pmatrix} x_1^k - x_n^k \\ x_2^k - x_n^k \\ \vdots \\ x_{n-1}^k - x_n^k \\ x_1^k - x_n^k \end{pmatrix}. \tag{23}$$

Note that the operator in the inclusion (23) is maximally monotone as the sum of two maximally monotone operators, the latter having full domain [3, Corollary 24.4(i)]. Consequently, it is demiclosed [3, Proposition 20.32]. That is, its graph is sequentially closed in the weak-strong topology.

Let $\mathbf{w} \in \mathcal{H}^n$ be an arbitrary weak cluster point of the sequence $(\mathbf{x}^k)$. As a consequence of (22), $\mathbf{w} = (x, \ldots, x)$ for some $x \in \mathcal{H}$. Taking the limit along a subsequence of $(\mathbf{x}^k)$ which converges weakly to $\mathbf{w}$ in (23), using demiclosedness and unravelling the resulting expression gives

$$\begin{cases} A_1(x) & \ni z_1 - x \\ A_i(x) & \ni z_i - z_{i-1} \quad \forall i \in [\![2, n-1]\!] \\ A_n(x) & \ni x - z_{n-1}, \end{cases}$$

which implies $(\mathbf{z}, x) \in \Omega$. In particular, $\mathbf{z} \in \mathrm{Fix}\, T_A$ and $x = J_{A_1}(z_1) \in \mathrm{zer}\left(\sum_{i=1}^n A_i\right)$.

In other words, $\mathbf{w} = (x, \ldots, x) \in \mathcal{H}^n$ with $x := J_{A_1}(z_1)$ is the unique weak sequential cluster point of the bounded sequence $(\mathbf{x}^k)$. We therefore deduce that $(\mathbf{x}^k)$ converges weakly to $\mathbf{w}$, which completes the proof. $\qquad\square$

The following corollary, which attains the lower bound given in Theorem 3.3, is an immediate consequence of Theorem 4.5. Thus, in the terminology of Ryu [22], the scheme described by Theorem 4.5 has "minimal lifting".

Corollary 4.6. *Let $n \geq 2$. There exists a frugal resolvent splitting (T_A, S_A) for $\mathcal{A}_n$ with $(n-1)$-fold lifting. Moreover, there exists no frugal resolvents splitting for $\mathcal{A}_n$ with d-fold lifting for $d \leq n - 2$.*

The following remark comments on the difficulties of extending [22, Theorem 4] to a four operator scheme. Such an extension seems not to be straightforward without additional assumptions.

Remark 4.7 (Extensions of Ryu splitting). Let $A = (A_1, A_2, A_3, A_4) \in \mathcal{A}_4$ and $\gamma \in (0,1)$. Consider the operator $T \colon \mathcal{H}^3 \to \mathcal{H}^3$ given by

$$T(\mathbf{z}) = \mathbf{z} + \gamma \begin{pmatrix} x_4 - x_1 \\ x_4 - x_2 \\ x_4 - x_3 \end{pmatrix} \quad \text{where} \quad \begin{cases} x_1 = J_{A_1}(z_1) \\ x_2 = J_{A_2}(z_2 + x_1) \\ x_3 = J_{A_3}(z_3 + x_2 - x_1) \\ x_4 = J_{A_4}(x_1 - z_1 + x_2 - z_2 + x_3 - z_3), \end{cases} \tag{24}$$

which can be considered as a four operator extension of (11). By using the definition of the resolvents, it can be shown that for this scheme

$$\mathbf{z} \in \operatorname{Fix} T \implies x_1 = x_2 = x_3 = x_4 \in \operatorname{zer}(A_1 + A_2 + A_3 + A_4).$$

However, its fixed point iteration does not converge for all $A = (A_1, A_2, A_3, A_4) \in \mathcal{A}_4$ with $\operatorname{zer}(A_1 + A_2 + A_3 + A_4) \neq \varnothing$. To see this, let $\mathcal{H} = \mathbb{R}$ and take $A_1 = A_2 = A_3 = A_4 = 0$, so that $J_{A_1} = J_{A_2} = J_{A_3} = J_{A_4} = \operatorname{Id}$. In this case, $T(\mathbf{z})$ simplifies to

$$T(\mathbf{z}) = \mathbf{z} + \gamma \begin{pmatrix} z_2 \\ 0 \\ z_1 + z_3 \end{pmatrix} = P\mathbf{z} \quad \text{where} \quad P := \begin{bmatrix} 1 & \gamma & 0 \\ 0 & 1 & 0 \\ 1 & 0 & 1+\gamma \end{bmatrix}.$$

In particular, if $\mathbf{z} = (0,0,1)$, then $T^k(\mathbf{z}) = P^k \mathbf{z} = (1+\gamma)^k \mathbf{z}$ which diverges as $k \to \infty$.

Interestingly, the operator described by (24) can be shown to be γ-averaged nonexpansive if the fourth operator A_4 is 1-strongly monotone, rather than just monotone. Further, if A_4 is β-strongly monotone for some $\beta \in (0,1)$, then $\frac{1}{\beta} A_4$ is 1-strongly monotone. In this case, (24) can instead be applied the operators $\frac{1}{\beta} A_1, \frac{1}{\beta} A_2, \frac{1}{\beta} A_3, \frac{1}{\beta} A_4$ where we note that $\operatorname{zer}\left(\sum_{i=1}^4 A_i\right) = \operatorname{zer}\left(\sum_{i=1}^4 \frac{1}{\beta} A_i\right)$.

Remark 4.8. Since the sequence $(\mathbf{x}^k)$ is weakly convergent to $(x, \ldots, x)$, it follows that $x_i^k - x_j^k \rightharpoonup 0$ as $k \to +\infty$ for all $i, j \in \{1, \ldots, n\}$. However, (22) shows convergence is actually strong. That is, we have

$$\lim_{k \to \infty} \|x_i^k - x_j^k\| = 0 \quad \forall i, j \in \{1, \ldots, n\}.$$

4.1 The Limiting Case under Uniform Monotonicity

We conclude this section with the following theorem which deals with the limiting case in Theorem 4.5. That is, the case where $\gamma = 1$.

Theorem 4.9. *Let $n \geq 2$, let $A = (A_1, \ldots, A_n) \in \mathcal{A}_n$ with $\operatorname{zer}\left(\sum_{i=1}^n A_i\right) \neq \varnothing$, and let $\gamma \in (0,1]$. Further suppose $A_i \colon \mathcal{H} \rightrightarrows \mathcal{H}$ is uniformly monotone with modulus ϕ_i for all $i \in \{2, \ldots, n\}$. Given $\mathbf{z}^0 \in \mathcal{H}^{n-1}$, let $(\mathbf{z}^k) \subseteq \mathcal{H}^{n-1}$ and $(\mathbf{x}^k) \subseteq \mathcal{H}^n$ be the sequences given by (20) and (21), respectively. Then the following assertions hold.*

(a) The sequence $(\mathbf{z}^k)$ converges weakly to a point $\mathbf{z} \in \operatorname{Fix} T_A$.

11

(b) The sequence $(\mathbf{x}^k)$ converges strongly to a point $(x, \ldots, x) \in \mathcal{H}^n$ with $x \in \operatorname{zer}\left(\sum_{i=1}^{n} A_i\right)$.

Proof. Since $\operatorname{zer}\left(\sum_{i=1}^{n} A_i\right) \neq \varnothing$, Lemma 4.2(a) implies there exists $(\bar{\mathbf{z}}, x) \in \Omega$ which implies $\bar{\mathbf{z}} \in \operatorname{Fix} T_A$ and $x \in \operatorname{zer}\left(\sum_{i=1}^{n} A_j\right)$. By repeating the proof of Lemma 4.3 but using uniform monotonicity in place of monotonicity, we obtain

$$\|\mathbf{z}^{k+1} - \bar{\mathbf{z}}\|^2 + \frac{1-\gamma}{\gamma}\|\mathbf{z}^k - \mathbf{z}^{k+1}\|^2 + \frac{1}{\gamma}\|x_1^k - x_n^k\|^2 + 2\gamma\sum_{i=2}^{n}\phi_i(\|x_i^k - x\|) \leq \|\mathbf{z}^k - \bar{\mathbf{z}}\|^2 \quad \forall k \in \mathbb{N}.$$

Since $\gamma \in (0,1]$ this implies

$$\|\mathbf{z}^{k+1} - \bar{\mathbf{z}}\|^2 + \frac{1}{\gamma}\|x_1^k - x_n^k\|^2 + 2\gamma\sum_{i=2}^{n}\phi_i(\|x_i^k - x\|) \leq \|\mathbf{z}^k - \bar{\mathbf{z}}\|^2 \quad \forall k \in \mathbb{N}. \tag{25}$$

It follows that $(\|\mathbf{z}^k - \bar{\mathbf{z}}\|^2)$ is non-increasing and hence convergent. Taking the limit as $k \to +\infty$ in (25) then gives that $x_1^k - x_n^k \to 0$ and $x_i^k \to x$ for all $i \in \{2, \ldots, n\}$. Hence the sequence $(\mathbf{x}^k)$ converges strongly to $(x, \ldots, x) \in \mathcal{H}^n$, which establishes (b).

To establish (a), first note that T_A is nonexpansive due to Lemma 4.3. Let $\mathbf{z}'$ be an arbitrary weak cluster point of the bounded sequence $(\mathbf{z}^k)$. Since $\mathbf{x}^k \to (x, \ldots, x)$, (20) implies that $(\operatorname{Id} - T_A)(\mathbf{z}^k) \to 0$ which, since $\operatorname{Id} - T_A$ is demiclosed [3, Theorem 4.27], implies $\mathbf{z}' \in \operatorname{Fix} T_A$. Thus, applying [3, Theorem 5.5], gives that $(\mathbf{z}^k)$ converges weakly to a point in $\operatorname{Fix} T_A$ as claimed. $\qquad\square$

Remark 4.10. The limiting case (*i.e.,* $\gamma = 2$) of Douglas–Rachford splitting (10) for a finding a zero in the sum of $n = 2$ operators is known as *Peaceman–Rachford splitting* [20]. Theorem 4.9 can be considered as an extension of Peaceman–Rachford splitting for $n \geq 2$ operators, in the sense that it represents the limiting case of our proposed method. For $n \geq 2$, a zero in the sum of n operators can be found using Peaceman–Rachford splitting applied to the product formulation (Example 2.7) provided that all n operators are uniformly monotone. In contrast, Theorem 4.9 only requires $n-1$ of the operators to be uniformly monotone.

5 Distributed Decentralised Optimisation

The structure of the update step in Algorithm 1 is especially well suited to being performed in a distributed decentralised way, without the need for a "central coordinator" to enforce consensus. Specifically, we consider a cycle graph with n nodes labelled 1 through n. Each node in the graph represents a device, and two devices can communicate with one another only if their nodes are adjacent. In our setting, this means that node i can communicate with nodes $i-1$ and $i+1$ (mod n). For each $i \in \{1, \ldots, n\}$, we assume that node i only knows the operator A_i. In addition, we assign updating of $z_1, \ldots, z_{n-1}$ to nodes $2, \ldots, n$, respectively. With this in mind, we give the following protocol (Algorithm 2) for distributed decentralised implementation of Algorithm 1.

In total, the protocol described in Algorithm 2 requires each node to send exactly two messages per iteration; node i sends one message to node $i-1$ and one to node $i+1$ (mod n). As node i is responsible for computing the sequence (x_i^k) (which converges to a solution) in this protocol, each node always keeps track of its own approximate solution. Also note that not all steps in Algorithm 2 must be completed in the stated order. For example, after completing Step 3, nodes $2, \ldots, n-1$ can commence Step 1 of the next iteration without waiting for node n to complete Step 4.

5.1 Numerical Example: ℓ_1-Consensus

To illustrate the method, consider the simple unconstrained optimisation problem given by

$$\min_{x \in \mathbb{R}} |x - c_1| + \cdots + |x - c_n|, \tag{26}$$

Algorithm 2: Protocol for distributed decentralised implementation of Algorithm 1.

Input: Let $\gamma \in (0,1)$. For each $i \in \{2, \dots, n\}$, node i chooses $z_i^0 \in \mathcal{H}$.

for $k = 1, 2, \dots$ **do**

    1. For each $i \in \{2, \dots, n\}$, node i sends z_{i-1}^k to Node $i - 1$;

    2. Node 1 computes $x_1^k = J_{A_1}(z_1^k)$ and sends x_1^k to nodes 2 and n;

    3. For each $i \in \{2, \dots, n-1\}$, node i computes

$$x_i^k = J_{A_i}(z_i^k - z_{i-1}^k + x_{i-1}^k),$$

    sends x_i^k to node $i + 1$, and updates $z_{i-1}^{k+1} = z_{i-1}^k + \gamma(x_i^k - x_{i-1}^k)$;

    4. Node n computes

$$x_n^k = J_{A_n}(x_1^k - z_{n-1}^k + x_{n-1}^k)$$

    and updates $z_{n-1}^{k+1} = z_{n-1}^k + \gamma(x_n^k - x_{n-1}^k)$;

---

where $c_1, \dots, c_n \in \mathbb{R}$ are given. Through its first order optimality condition, this problem is equivalent to the monotone inclusion

$$\text{find } x \in \mathbb{R} \text{ such that } 0 \in \sum_{i=1}^n A_i(x), \quad \text{where } A_i := \partial |\cdot - c_i|.$$

We solve this in the decentralised way described above. Since the resolvent of A_i has an explicit form, Algorithm 1 is straightforward to implement (using the protocol described in Algorithm 2).

Alternatively, we can rewrite (26) as the constrained minimisation problem given by

$$\min_{\mathbf{x}=(x_1,\dots,x_n)\in\mathbb{R}^n} |x_1 - c_1| + \cdots + |x_n - c_n| \quad \text{subject to} \quad L\mathbf{x} = 0, \tag{27}$$

where $L \in \mathbb{R}^{n \times n}$ is the *Laplacian* of the cycle graph, that is $L_{ii} = 2$ for all $i \in [\![1, n]\!]$ and $L_{ij} = -1$ if $|i - j| = 1 \pmod{n}$ and 0 otherwise. In words, $L\mathbf{x}$ amounts to the exchange of the coordinates of $\mathbf{x}$ between nodes in the way permitted by the network topology. Formulation (27) can be solved using the *primal dual hybrid gradient (PDHG)* algorithm [6, 9] given by

$$\begin{cases} \mathbf{x}^{k+1} = \text{prox}_{\tau f}(\mathbf{x}^k - \tau L^* \mathbf{y}^k) \\ \mathbf{y}^{k+1} = \mathbf{y}^k + \sigma L(2\mathbf{x}^{k+1} - \mathbf{x}^k), \end{cases} \tag{28}$$

where $f(\mathbf{x}) := \|\mathbf{x} - \mathbf{c}\|_1$ and $\tau\sigma\|L\|^2 \leq 1$.

However, (28) turns out not to be the best way to use the PDHG to solve (27). Instead, one can first replace the constraint in (27) with the constraint $\sqrt{L}\mathbf{x} = 0$, where $\sqrt{L}$ is the unique positive semidefinite matrix such that $(\sqrt{L})^2 = L$. Then, after making the change of variables $\mathbf{v}^k = \sqrt{L}\mathbf{y}^k$, the PDHG scheme (28) with $\sqrt{L}$ in place of L can be expressed as

$$\begin{cases} \mathbf{x}^{k+1} = \text{prox}_{\tau f}(\mathbf{x}^k - \tau \mathbf{v}^k) \\ \mathbf{v}^{k+1} = \mathbf{v}^k + \sigma L(2\mathbf{x}^{k+1} - \mathbf{x}^k), \end{cases} \tag{29}$$

where τ and σ are only required to satisfy the weaker inequality $\tau\sigma\|L\| \leq 1$.

Both Algorithm 1 and the PDHG algorithm (29) use approximately the same number of variables and have approximately the same amount of computation/communication per iteration. To compare their performance, we measure the residuals of the two algorithms: $\frac{1}{\gamma}\|\mathbf{z}^{k+1} - \mathbf{z}^k\|$ for Algorithm 1 and $\left(\frac{1}{\tau}\|\mathbf{x}^{k+1} - \mathbf{x}^k\|^2 + \frac{1}{\sigma}\|\mathbf{y}^{k+1} - \mathbf{y}^k\|^2 - 2\langle\sqrt{L}(\mathbf{x}^{k+1} - \mathbf{x}^k), \mathbf{y}^{k+1} - \mathbf{y}^k\rangle\right)^{1/2}$ for PDHG. The latter residual comes from the interpretation of PDHG as the proximal point algorithm and after some algebra it can be written simply as $\left(\frac{1}{\tau}\|\mathbf{x}^{k+1} - \mathbf{x}^k\|^2 + \langle\mathbf{v}^{k+1} - \mathbf{v}^k, \mathbf{x}^k\rangle\right)^{1/2}$. Comparison of
Figure 1: Results for problem (26). x-axis: iterations, y-axis: residuals

these two residuals is justified because they corresponds to successive iterations of the underlying fixed point operators.

For $n \in \{10, 100, 1000\}$, we generated the numbers c_i randomly by sampling the standard normal distribution. The initial point for Algorithm 1 was taken as $\mathbf{z}^0 = \mathbf{0} \in \mathbb{R}^{n-1}$ and for PDHG as $(\mathbf{x}^0, \mathbf{y}^0) = (\mathbf{0}, \mathbf{0}) \in \mathbb{R}^n \times \mathbb{R}^n$. Algorithm 1 was run with $\gamma = 0.9$ and PDHG with stepsizes given by

$$(\tau, \sigma) \in \left\{ \Big(\frac{1}{\sqrt{\|L\|}}, \frac{1}{\sqrt{\|L\|}}\Big), \Big(\frac{1}{10\sqrt{\|L\|}}, \frac{10}{\sqrt{\|L\|}}\Big), \Big(\frac{10}{\sqrt{\|L\|}}, \frac{1}{10\sqrt{\|L\|}}\Big) \right\}$$

(we refer to these choices as PDHG versions 1, 2, and 3, respectively). The results are shown in Figure 1 and suggest favourable performance of Algorithm 1, but further investigation is needed.

6   Multi-block ADMM

The *alternating direction method of multipliers (ADMM)* is an algorithm for solving minimisation problems of the form

$$\min_{\mathbf{w}=(w_1,w_2)} f_1(w_1) + f(w_2) \;\; \text{subject to} \;\; A_1 w_1 + A_2 w_2 = b, \tag{30}$$

where $f_1 \colon \mathcal{H}_1 \to (-\infty, +\infty]$ and $f_2 \colon \mathcal{H}_2 \to (-\infty, +\infty]$ are proper lsc convex functions, $A_1 \colon \mathcal{H}_1 \to \mathcal{H}$ and $A_2 \colon \mathcal{H}_2 \to \mathcal{H}$ are bounded linear opeartors, and $b \in \mathcal{H}$ is a given vector. ADMM is known to be equvialent to applying the Douglas–Rachford method to the Fenchel dual of (30) [12, 11]. As the family of resolvent splitting introduced in Section 4 includes the Douglas–Rachford method as the special case when $n = 2$ (see Remark 4.1), it is natural to investigate an analogous equivalence in the setting when $n \geq 3$.

Before proceeding, we recall some notation. The *Fenchel conjugate* of an extended real-valued function g is denoted $g^*(x) := \sup_y\{\langle x, y \rangle - g(y)\}$. Given a set C, its *indicator function*, denoted ι_C, is the function which takes the value 0 on C and $+\infty$ outside C.

Consider the separable minimisation problem

$$\min_{\mathbf{w}=(w_1,\dots,w_n)} \sum_{i=1}^n f_i(w_i) \;\; \text{subject to} \;\; \sum_{i=1}^n A_i w_i = b, \tag{31}$$

where $f_1, \dots, f_n$ are proper lsc convex functions, $A_1, \dots, A_n$ are bounded linear operators, and $b \in \mathcal{H}$ is a given vector. Denote $f(\mathbf{w}) := \sum_{i=1}^n f_i(w_i)$ and $\mathbf{A} := \begin{bmatrix} A_1 & \dots & A_n \end{bmatrix}$. Then (31) can be expressed as the Fenchel primal problem given by

$$p := \min_{\mathbf{w}}\{f(\mathbf{w}) + \iota_{\{b\}}(\mathbf{A}\mathbf{w})\}. \tag{32}$$

which has Fenchel dual given by

$$d := \sup_x\{-f^*(\mathbf{A}^*x) - \iota_{\{b\}}^*(-x)\}.$$

14

Since $f^* = \bigoplus_{i=1}^n f_i^*$, $\iota_{\{b\}}^* = \langle b, \cdot \rangle$ and $\mathbf{A}^* = \begin{bmatrix} A_1^* \\ \vdots \\ A_n^* \end{bmatrix}$, this dual problem is equivalent to

$$\inf_x \{ \sum_{i=1}^{n-1} f_i^*(-A_i^* x) + g^*(x) \} \quad \text{where} \quad g^*(x) := f_n^*(-A_n^* x) - \langle b, x \rangle. \tag{33}$$

In what follows, we derive a multi-block extension of the ADMM algorithm by applying the new resolvent splitting from Section 4 to the dual problem (33). Such an extension is of interest because, even when $n = 3$, the natural "direct extension of ADMM" need not converge [7].

We begin by examining the so-called "averaged operator" form of our proposed ADMM extension. To simplify the presentation of our derivation, we will use the following lemmas.

Lemma 6.1. *Let $h_1 \colon \mathcal{H}' \to (-\infty, +\infty]$ and $h_2 \colon \mathcal{H} \to (-\infty, +\infty]$ be proper lsc convex functions, and let $A \colon \mathcal{H}' \to \mathcal{H}$ be a bounded linear operator. Denote $h(z) := h_1^*(-A^* z) + h_2^*(z)$. If*

$$\begin{aligned}
(\hat{x}, \hat{y}) &\in \arg\min_{x,y} \left\{ h_1(x) + h_2(y) + \langle z, Ax - y \rangle + \frac{1}{2} \| Ax - y \|^2 \right\} \\
&= \arg\min_{x,y} \left\{ h_1(x) + h_2(y) + \frac{1}{2} \| Ax - y + z \|^2 \right\},
\end{aligned} \tag{34}$$

then $\operatorname{prox}_h(z) = z + (A\hat{x} - \hat{y})$. Moreover, the minimum in (34) is attained provided that: (a) h_1 is coercive or A^*A is invertible, and (b) $h_2^* = \langle b, \cdot \rangle$ for some vector $b \in \mathcal{H}'$.

Proof. Suppose the minimum in (34) is attained at $(\hat{x}, \hat{y})$ and denote $w := z + (A\hat{x} - \hat{y})$. By first-order optimality in (34), we have $-A^* w \in \partial h_1(\hat{x})$ and $w \in \partial h_2(\hat{y})$. Since $(\partial h_1)^{-1} = \partial h_1^*$ and $(\partial h_2)^{-1} = \partial h_2^*$, it follows that $0 \in (-A)\partial h_1^*(-A^* w) + \partial h_2^*(w) + (w - z)$ which, in turn, implies

$$w \in \arg\min_u \{ h_1^*(-A^* u) + h_2^*(u) + \frac{1}{2} \| u - z \|^2 \} = \arg\min_u \{ h(u) + \frac{1}{2} \| u - z \|^2 \}.$$

Thus, $\operatorname{prox}_h(z) = w = z + (A\hat{x} - \hat{y})$, which establishes the first claim.

Further, suppose $h_2^* = \langle b, \cdot \rangle$ for some $b \in \mathcal{H}$. Then $h_2 = h_2^{**} = \iota_{\{b\}}$, and hence $(\hat{x}, \hat{y})$ attains the minimum in (34) if and only if $\hat{y} = b$ and

$$\hat{x} \in \arg\min_x \left\{ \phi(x) := h_1(x) + \frac{1}{2} \| Ax - b + z \|^2 \right\}. \tag{35}$$

If h_1 is coercive, then ϕ is also coercive due to nonnegativity $\| \cdot \|^2$. If A^*A is invertible, then $x \mapsto \frac{1}{2} \| Ax - b + z \|^2 = \frac{1}{2} \langle x, A^*Ax \rangle + \langle x, A^*(z - b) \rangle + \frac{1}{2} \| z - b \|^2$ is supercoercive by [3, Exercise 17.1] and hence ϕ is cocercive by [3, Proposition 11.14]. Thus, in either case, ϕ is coercive, and so the minimum in (35) is attained due to [3, Proposition 11.15]. This establishes the second claim and completes the proof. $\square$

Lemma 6.2. *Let $h \colon \mathcal{H} \to (-\infty, +\infty]$ be a proper lsc convex function, let $A \colon \mathcal{H}' \to \mathcal{H}$ be a bounded linear operator, and let $(u^k) \subseteq \mathcal{H}$ be a bounded sequence. Suppose that h is coercive or A^*A is invertible. Then, any sequence $(w^k) \subseteq \mathcal{H}'$ satisfying*

$$w^k \in \arg\min_w \left\{ h(w) + \frac{1}{2} \| Aw + u^k \|^2 \right\} \quad \forall k \in \mathbb{N}, \tag{36}$$

is bounded.

Proof. Suppose, by way of a contradiction, that (w^k) is not bounded. Then, without loss of generality, we assume that $\| w^k \| \to +\infty$ as $k \to +\infty$. Using the same argument as in the second part of the proof of Lemma 6.1, we deduce that function $\phi(w) := h(w) + \frac{1}{4} \| Aw \|^2$ is coercive and hence $\phi(w^k) \to +\infty$ as $k \to +\infty$. Since h is proper, (36) implies

$$+\infty > h(w^1) + \frac{1}{2} \| Aw^1 + u^k \|^2 \geq h(w^k) + \frac{1}{2} \| Aw^k + u^k \|^2 \geq h(w^k) + \frac{1}{4} \| Aw^k \|^2 - \frac{1}{2} \| u^k \|^2 \quad \forall k \in \mathbb{N}.$$

Since (u^k) is bounded, this inequality implies that the sequence $(h(w^k) + \frac{1}{4} \| Aw^k \|^2)$ is bounded above. This is a contradiction, and so the proof is complete. $\square$

Algorithm 3: Multi-block ADMM for (31) in averaged operator form.

Input: Choose $\mathbf{z}^0 = (z_1^0, \ldots, z_{n-1}^0)$ and $\gamma \in (0,1)$.

for $k = 1, 2, \ldots$ **do**

    1. Compute $\mathbf{w}^k = (w_1^k, \ldots, w_n^k)$ according to

$$
\begin{cases}
w_1^k \in \underset{w_1}{\arg\min}\{f_1(w_1) + \dfrac{1}{2}\|A_1 w_1 + z_1^k\|^2\} & \text{(37a)} \\[2ex]
w_i^k \in \underset{w_i}{\arg\min}\{f_i(w_i) + \dfrac{1}{2}\|\sum_{j=1}^{i-1} A_j w_j^k + A_i w_i + z_i^k\|^2\} & \forall i \in [\![2, n-1]\!] \quad \text{(37b)} \\[2ex]
w_n^k \in \underset{w_n}{\arg\min}\{f_n(w_n) + \dfrac{1}{2}\|2A_1 w_1^k + \sum_{j=2}^{n-1} A_j w_j^k + A_n w_n - b + z_1^k\|^2\} & \text{(37c)}
\end{cases}
$$

    2. Update $\mathbf{z}^{k+1} = (z_1^{k+1}, \ldots, z_{n-1}^{k+1})$ according to

$$
\begin{cases}
z_i^{k+1} = z_i^k + \gamma(z_{i+1}^k - z_i^k) + \gamma A_{i+1} w_{i+1}^k & \forall i \in [\![1, n-2]\!] \quad \text{(37d)} \\[1ex]
z_{n-1}^{k+1} = z_{n-1}^k + \gamma(z_1^k - z_{n-1}^k) + \gamma(A_1 w_1^k + A_n w_n^k - b). & \text{(37e)}
\end{cases}
$$

Recall that $(\mathbf{w}, x)$ is a *Kuhn–Tucker pair* for (32) if $-\mathbf{A}^* x \in \partial f(\mathbf{w})$ and $x \in \partial \iota_{\{b\}}(\mathbf{Aw})$. In particular, when such a pair exists, $\mathbf{w}$ is a primal solution and x is a dual solution. Moreover, by using properties of the Fenchel conjugate, it can be seen that $(\mathbf{w}, x)$ being a Kuhn–Tucker pair is equivalent to $\mathbf{w} \in \partial f^*(-\mathbf{A}^* x)$ and $\mathbf{Aw} \in \partial \iota_{\{b\}}^*(x)$ which implies

$$
\begin{aligned}
0 \in (-\mathbf{A})\partial f^*(-\mathbf{A}^* x) + \partial \iota_{\{b\}}^*(x) &= \sum_{i=1}^n (-A_i)\partial f_i^*(-A_i^* x) + \partial \langle b, \cdot \rangle(x) \\
&\subseteq \sum_{i=1}^{n-1} \partial(f_i^* \circ (-A_i^*))(x) + \partial g^*(x),
\end{aligned}
\tag{38}
$$

We are ready to derive our multi multi-block extension of ADMM and analyse its convergence. The averaged operator form of our proposed algorithm is given in Algorithm 3 and its convergence analysed in Theorem 6.3.

Theorem 6.3 (Multi-block ADMM – averaged operator form)**.** *Let $n \geq 2$. Suppose (32) has a Kuhn–Tucker pair, and that, for each $i \in \{1, \ldots, n\}$, either f_i is coercive or $A_i^* A_i$ is invertible. Let $\gamma \in (0,1)$. Given $\mathbf{z}^0 = (z_1^0, \ldots, z_{n-1}^0)$, consider the sequences $(\mathbf{z}^k)$ and $(\mathbf{w}^k)$ given by Algorithm 3. Then:*

(a) The sequence $(\mathbf{w}^k)$ is bounded and every weak limit point is a solution of the primal problem (32). Moreover, if $A_i^* A_i$ is invertible for all $i \in \{1, \ldots, n\}$, then $(\mathbf{w}^k)$ converges strongly.

(b) For each $i \in \{1, \ldots, n-1\}$, the sequence $(z_i^k + \sum_{j=1}^i A_j w_j^k)$ converges weakly to a solution of the dual problem (33).

(c) The residual sequence converges strongly to zero. That is, $\sum_{i=1}^n A_i w_i^k \to b$ as $k \to +\infty$.

Proof. Let $F := (F_1, \ldots, F_n) \in \mathcal{A}_n$ denote the n-tuple of maximally monotone operators given by

$$
F_i := \begin{cases} \partial(f_i^* \circ (-A_i^*)) & i = 1, \ldots, n-1, \\ \partial g^* & i = n. \end{cases}
\tag{39}
$$

Since (32) has a Kuhn–Tucker pair, (38) shows that $\mathrm{zer}(\sum_{i=1}^n F_i) \neq \varnothing$. Hence $F = (F_1, \ldots, F_n)$ satisfies all the assumptions required to apply Theorem 4.5. To this end, let $(\mathbf{z}^k)$ denote the

sequence given by

$$\mathbf{z}^{k+1} := T_F(\mathbf{z}^k) = \mathbf{z}^k + \gamma \begin{pmatrix} x_2^k - x_1^k \\ x_3^k - x_2^k \\ \vdots \\ x_n^k - x_{n-1}^k \end{pmatrix}, \tag{40}$$

where the sequence $(\mathbf{x}^k)$ is given by

$$\begin{cases} x_1^k = J_{F_1}(z_1^k) = \operatorname{prox}_{f_1^* \circ (-A_1^*)}(z_1^k), \\ x_i^k = J_{F_i}(z_i^k + x_{i-1}^k - z_{i-1}^k) = \operatorname{prox}_{f_i^* \circ (-A_i^*)}(z_i^k + x_{i-1}^k - z_{i-1}^k) & \forall i \in [\![2, n-1]\!], \\ x_n^k = J_{F_n}(x_1^k + x_{n-1}^k - z_{n-1}^k) = \operatorname{prox}_{g^*}(x_1^k + x_{n-1}^k - z_{n-1}^k). \end{cases} \tag{41}$$

Using Theorem 4.5 applied to $F \in \mathcal{A}_n$, we deduce that $(\mathbf{z}^k)$ converges weakly to a point $\mathbf{z} \in \operatorname{Fix} T_F$ and that $(\mathbf{x}^k)$ converges weakly to a point $(x, \dots, x)$ with $x \in \operatorname{zer}(\sum_{i=1}^n F_i)$. Moreover, Remark 4.8 gives that $\|x_i^k - x_j^k\| \to 0$ as $k \to \infty$ for all $i, j \in \{1, \dots, n\}$.

Next, using Lemma 6.1, we express (41) as

$$\begin{cases} x_1^k = z_1^k + A_1 w_1^k, \\ x_i^k = z_i^k + (x_{i-1}^k - z_{i-1}^k) + A_i w_i^k & \forall i \in [\![2, n-1]\!] \\ x_n^k = x_1^k + (x_{n-1}^k - z_{n-1}^k) + A_n w_n^k - b \end{cases} \tag{42}$$

for some sequence $(\mathbf{w}^k)$ satisfying

$$\begin{cases} w_1^k \in \operatorname*{arg\,min}_{w_1} \left\{ f_1(w_1) + \frac{1}{2}\|A_1 w_1 + z_1^k\|^2 \right\} \\ w_i^k \in \operatorname*{arg\,min}_{w_i} \left\{ f_i(w_i) + \frac{1}{2}\|A_i w_i + z_i^k + x_{i-1}^k - z_{i-1}^k\|^2 \right\} & \forall i \in [\![2, n-1]\!] \\ w_n^k \in \operatorname*{arg\,min}_{w_n} \left\{ f_n(w_n) + \frac{1}{2}\|A_n w_n - b + x_1^k + x_{n-1}^k - z_{n-1}^k\|^2 \right\}. \end{cases} \tag{43}$$

By substituting (42) into (43) and (40), we obtain (37). Thus, to complete the proof, it remains to establish assertions (a), (b) and (c), which we do in reverse order.

(c) Summing the system of equations in (42) gives

$$A_1 w_1^k + \cdots + A_n w_n^k - b = x_n^k - x_1^k \to 0 \quad \text{as} \quad k \to +\infty.$$

(b) Follows by combining weak convergence of $(\mathbf{x}^k)$ to $(x, \dots, x)$ with (42).

(a) Since $(\mathbf{z}^k)$ and $(\mathbf{x}^k)$ are bounded, Lemma 6.2 implies that $(\mathbf{w}^k)$ given by (43) is also bounded. Let $\mathbf{w} = (w_1, \dots, w_n)$ be a weak cluster point $(\mathbf{w}^k)$. Combining (42) and (43) gives

$$\partial f_i(w_i^k) \ni -A_i^* x_i^k \quad \forall i \in \{1, \dots, n\} \implies \partial f(\mathbf{w}^k) + \mathbf{A}^* x_1^k \ni \begin{pmatrix} 0 \\ A_2^*(x_1^k - x_2^k) \\ \vdots \\ A_n^*(x_1^k - x_n^k) \end{pmatrix}. \tag{44}$$

Since $\iota_{\{b\}}^* = \langle b, \cdot \rangle$, we have $(\partial \iota_{\{b\}})^{-1} = b$. Thus, using the equality in (44), we deduce that

$$(\partial \iota_{\{b\}})^{-1}(x_1^k) = b = \mathbf{A}\mathbf{w}^k + x_1^k - x_n^k \implies (\partial \iota_{\{b\}})^{-1}(x_1^k) - \mathbf{A}\mathbf{w}^k \ni x_1^k - x_n^k. \tag{45}$$

By combining (44) and (45), we obtain the maximally monotone inclusion

$$\left[\begin{pmatrix} \partial f \\ (\partial \iota_{\{b\}})^{-1} \end{pmatrix} + \begin{pmatrix} 0 & A^* \\ -A & 0 \end{pmatrix} \right] \begin{pmatrix} \mathbf{w}^k \\ x_1^k \end{pmatrix} \ni \begin{pmatrix} 0 \\ A_2^*(x_1^k - x_2^k) \\ \vdots \\ A_n^*(x_1^k - x_n^k) \\ x_1^k - x_n^k \end{pmatrix}.$$

17

Since the graph of a maximally monotone operators is demiclosed [3, Proposition 20.32], taking the limit along a subsequence of $(\mathbf{w}^k)$ which converges to $\mathbf{w}$ and unravelling the resulting expression gives

$$-\mathbf{A}^*x \in \partial f(\mathbf{w}) \quad \text{and} \quad \mathbf{A}\mathbf{w}(\partial \iota_{\{b\}})^{-1}(x) \iff x \in \partial \iota_{\{b\}}(\mathbf{A}\mathbf{w}).$$

That is, $(\mathbf{w}, x)$ is a Kuhn-Tucker pair for (32) and so, in particular, $\mathbf{w}$ solves the primal problem (32). Moreover, if $A_i^*A_i$ are invertible for all $i \in \{1, \ldots, n\}$, then $\mathbf{A}^*\mathbf{A}$ is also invertible [3, Example 3.29]. Consequently, $\mathbf{A}\mathbf{w}^k \to b$ implies that $\mathbf{w}^k = (\mathbf{A}^*\mathbf{A})^{-1}\mathbf{A}^*\mathbf{A}\mathbf{w}^k \to (\mathbf{A}^*\mathbf{A})^{-1}\mathbf{A}^*b$.

The proof is now complete. $\qquad\square$

Remark 6.4. The form of ADMM in Theorem 6.3 is a a multi-block version of the "averaged operator" form of two-block ADMM as it appears in [13, Equations (77)–(79)]. In the two-block setting, Theorem 6.3 includes [4, Proposition 5.4.1] as a special case.

Next, we express the multi-block ADMM extension in Theorem 6.3 in terms of the *augmented Lagrangian*. Recall that the *augmented Lagrangian* of (32) is the function $\mathcal{L}$ given by

$$\mathcal{L}(w_1, \ldots, w_n, \mu) := \sum_{i=1}^{n} f(w_i) + \left\langle \mu, \sum_{i=1}^{n} A_i w_i - b \right\rangle + \frac{1}{2} \left\| \sum_{i=1}^{n} A_i w_i - b \right\|^2.$$

The augmented Lagrangian form of our proposed algorithm in terms of $\mathcal{L}$ is given in Algorithm 4 and its converged analysed in Corollary 6.5.

Algorithm 4: Multi-block ADMM for (31) in augmented Lagrangian form.

Input: Choose $\boldsymbol{\mu}^0 = (\mu_1^0, \ldots, \mu_n^0)$ and $\gamma \in (0, 1)$.

for $k = 1, 2, \ldots$ **do**

   1. Compute $\mathbf{w}^k = (w_1^k, \ldots, w_n^k)$ according to

$$\begin{cases} w_1^{k+1} = \underset{w_1}{\arg\min}\ \mathcal{L}(w_1, w_2^k, \ldots, w_n^k, \mu_1^k) & \text{(46a)} \\[2mm] w_i^{k+1} = \underset{w_i}{\arg\min}\ \mathcal{L}(w_1^{k+1}, \ldots, w_i^{k+1}, w_i, w_{i+1}^k \ldots, w_n^{k-1}, \mu_i^k) & \forall i \in [\![2, n-1]\!] \quad \text{(46b)} \\[2mm] w_n^{k+1} = \underset{w_n}{\arg\min}\ \mathcal{L}(w_1^{k+1}, \ldots, w_{n-1}^{k+1}, w_n, \mu_n^k) & \text{(46c)} \end{cases}$$

   2. Update $\boldsymbol{\mu}^{k+1} = (\mu_1^{k+1}, \ldots, \mu_{n-1}^{k+1})$ according to

$$\begin{cases} \mu_i^{k+1} = \mu_{i+1}^k + \displaystyle\sum_{j=i+2}^{n} \left(A_j w_j^k - A_j w_j^{k+1} \right) & \forall i \in [\![1, n-1]\!] \quad \text{(46d)} \\[1mm] \qquad\qquad + (1-\gamma)(\mu_i^k - \mu_{i+1}^k + A_{i+1}w_{i+1}^k - A_{i+1}w_{i+1}^{k+1}) & \\[2mm] \mu_n^{k+1} = \mu_1^{k+1} + \left(\displaystyle\sum_{j=1}^{n} A_j w_j^{k+1} - b \right) & \text{(46e)} \end{cases}$$

Corollary 6.5 (Multi-block ADMM – augmented Lagrangian form). *Let $n \geq 2$. Suppose (32) has a Kuhn–Tucker pair, and that, for each $i \in \{1, \ldots, n\}$, either f_i is coercive or $A_i^*A_i$ is invertible. Let $\gamma \in (0, 1)$. Given $\boldsymbol{\mu}^0 = (\mu_1^0, \ldots, \mu_n^0)$, consider the sequences $(\mathbf{w}^k)$ and $(\boldsymbol{\mu}^k)$ given by Algorithm 4. Then:*

(a) *The sequence $(\mathbf{w}^k)$ is bounded and every weak limit point is a solution of the primal problem (32). Moreover, if $A_i^*A_i$ is invertible for all $i \in \{1, \ldots, n\}$, then $(\mathbf{w}^k)$ converges strongly.*

(b) *The sequences $(\mu_1^k), \ldots, (\mu_n^k)$ converge weakly to a solution of the dual problem (33).*

(c) *The residual sequence converges strongly to zero. That is,* $\sum_{i=1}^{n} A_i w_i^k \to b$ *as* $k \to +\infty$.

Proof. The proof is a continuation of the proof of Theorem 6.3. To this end, let $(\mathbf{z}^k)$, $(\mathbf{x}^k)$ and $(\mathbf{w}^k)$ be as in the proof of Theorem 6.3. Define $\boldsymbol{\mu}^k = (\mu_1^k, \ldots, \mu_n^k)$ according to

$$\mu_i^k = \begin{cases} z_i^{k+1} - \left(\sum_{j=i+1}^{n} A_j w_j^k - b\right) & i = 1, \ldots, n-1, \\ z_1^{k+1} + A_1 w_1^{k+1} & i = n. \end{cases} \tag{47}$$

Substituting (47) into (37a)-(37c) gives

$$\begin{cases} w_1^{k+1} = \underset{w_1}{\arg\min}\{f_1(w_1) + \frac{1}{2}\|A_1 w_1 + \sum_{j=2}^{n} A_j w_j^k - b + \mu_1^k\|^2\} \\ w_i^{k+1} = \underset{w_i}{\arg\min}\{f_i(w_i) + \frac{1}{2}\|\sum_{j=1}^{i-1} A_j w_j^{k+1} + A_i w_i + \sum_{j=i+1}^{n} A_j w_j^k - b + \mu_i^k\|^2\} \quad \forall i \in [\![2, n-1]\!] \\ w_n^{k+1} = \underset{w_n}{\arg\min}\{f_n(w_n) + \frac{1}{2}\|\sum_{j=1}^{n-1} A_j w_j^{k+1} + A_n w_n - b + \mu_n^k\|^2\}, \end{cases}$$

which is equivalent to (46a)-(46c). Similarly, substituting (47) into (37d) & (37e) gives (46d) & (46e).

We therefore have that assertions (a) and (c) follow immediately from Theorem 6.3(a) & (c). To establish assertion (b), observe that

$$\mu_i^k = \begin{cases} \left(z_i^{k+1} + \sum_{j=1}^{i} A_j w_j^{k+1}\right) + \sum_{j=1}^{i}\left(A_j w_j^k - A_j w_j^{k+1}\right) - \left(\sum_{j=1}^{n} A_j w_j^k - b\right) & i \in [\![1, n-1]\!] \\ z_1^{k+1} + A_1 w_1^{k+1} & i = n. \end{cases} \tag{48}$$

Convergence of (μ_i^k) to a dual solution of (33) follows with the help of Theorem 6.3(b) & (c) by taking the limit as $k \to +\infty$ in (48). In taking this limit, we note that $\|A_j w_j^k - A_j w_j^{k+1}\| \to 0$ for all $j \in \{1, \ldots, n\}$ as a consequence of combining (42) with the fact that $\|\mathbf{z}^{k+1} - \mathbf{z}^k\| \to 0$ and that $\|x_i^k - x_j^k\| \to 0$ for all $i, j \in \{1, \ldots, n\}$. $\qquad\square$

Remark 6.6. If the operators $F_2, \ldots, F_n$ in (39) are uniformly monotone, then Theorem 4.9 can be used in place of Theorem 4.5 to allow the limiting case with $\gamma = 1$. In this case, setting $i = n-1$ in (46d) gives $\mu_{n-1}^k = \mu_n^k$ for all $k \in \mathbb{N}$, which can be substituted into (46e) to eliminate the sequence (μ_n^k) from Algorithm 3. In particular, in the case when $\gamma = 1$ and $n = 2$, (46) reduces to the standard form of two-block ADMM given by

$$\begin{cases} w_1^{k+1} = \underset{w_1}{\arg\min}\ \mathcal{L}(w_1, w_2^k, \mu_1^k) \\ w_2^{k+1} = \underset{w_2}{\arg\min}\ \mathcal{L}(w_1^{k+1}, w_2, \mu_1^k) \\ \mu_1^{k+1} = \mu_1^{k+1} + \left(A_1 w_1^{k+1} + A_2 w_2^{k+1} - b\right). \end{cases}$$

6.1 Numerical Example: Robust PCA with Partial Information

In this section, we provide a numerical illustration of our multi-block ADMM method in robust principle component analysis. Given a matrix $M \in \mathbb{R}^{m \times n}$, the *robust principle component analysis (PCA)* problem is to find two matrices $L, S \in \mathbb{R}^{m \times n}$ such that L is low rank and S is sparse. In [25], this problem is formulated as the convex minimisation problem

$$\min_{L,S \in \mathbb{R}^{m \times n}} \|L\|_* + \lambda \|S\|_1 \quad \text{subject to} \quad L + S = M. \tag{49}$$

where $\|\cdot\|_*$ denotes the nuclear norm, $\|\cdot\|_1$ denotes the ℓ_1-norm, and $\lambda > 0$. The parameter λ is chosen to balance the competing effects of the nuclear norm, which promotes low rankedness of L, and the ℓ_1-norm, which promotes sparsity in S.

In practice, it is not always possible to observe all the entries of the matrix $M \in \mathbb{R}^{m \times n}$. Instead, one observes only entries of M corresponding to some index set $\Omega \subseteq \{1, \ldots, m\} \times \{1, \ldots, n\}$. That is, the entry M_{ij} is known if $(i,j) \in \Omega$. To deal with robust PCA problem having only partial knowledge of M, [24] proposed an extension of (49) given by

$$\min_{L,S,P \in \mathbb{R}^{m \times n}} \|L\|_* + \lambda \|S\|_1 \quad \text{subject to} \quad \|P_\Omega(M - L - S)\|_F \leq \delta,$$

where P_Ω denotes the orthogonal projection onto matrices supported by Ω and $\delta > 0$. By setting $C := \{D \in \mathbb{R}^{m \times n} : \|P_\Omega(D)\|_F \leq \delta\}$, this problem can be expressed as given by

$$\min_{L,S,D \in \mathbb{R}^{m \times n}} \|L\|_* + \lambda \|S\|_1 + \iota_C(D) \quad \text{subject to} \quad L + S + D = M. \tag{50}$$

The problem (50) can be solved using a three block ADMM-type method known as *alternating splitting augmented Lagrangian method (ASALM)* [24]. This method is given by

$$\begin{cases} D^{k+1} = \arg\min_{D \in C}\{\frac{1}{2}\|L^k + S^k + D - M + \mu^k\|^2\} \\ S^{k+1} = \arg\min_{S \in \mathbb{R}^{m \times n}}\{\lambda\|S\|_1 + \frac{1}{2}\|L^k + S + D^{k+1} - M + \mu^k\|^2\} \\ L^{k+1} = \arg\min_{L \in \mathbb{R}^{m \times n}}\{\|L\|_* + \frac{1}{2}\|L + S^{k+1} + D^{k+1} - M + \mu^k\|^2\} \\ \mu^{k+1} = \mu^k + (L^{k+1} + S^{k+1} + D^{k+1} - M). \end{cases} \tag{51}$$

Despite its numerical performance, the theoretical underpinnings of ASALM are not completely understood. Indeed, the authors of [24] were only able to showed boundedness of the ASALM iterates in a special case. This is consistent with counter-examples for convergence of the direct extension of ADMM to three blocks [7].

Remark 6.7. Noting that (50) is of the form specified by (31), we may apply the three block version of our multi-block ADMM developed in Section 6. It is interesting to compare the similarities of (51) with (46) in limiting case with $\gamma = 1$ which can be expressed as

$$\begin{cases} D^{k+1} = \arg\min_{D \in C}\{\frac{1}{2}\|L^k + S^k + D - M + \mu_1^k\|^2\} \\ S^{k+1} = \arg\min_{S \in \mathbb{R}^{m \times n}}\{\lambda\|S\|_1 + \frac{1}{2}\|L^k + S + D^{k+1} - M + \mu_2^k\|^2\} \\ L^{k+1} = \arg\min_{L \in \mathbb{R}^{m \times n}}\{\|L\|_* + \frac{1}{2}\|L + S^{k+1} + D^{k+1} - M + \mu_2^k\|^2\} \\ \mu_1^{k+1} = \mu_2^k + (L^k - L^{k+1}) \\ \mu_2^{k+1} = \mu_1^{k+1} + (L^{k+1} + S^{k+1} + D^{k+1} - M). \end{cases}$$

As compared to (51), (46) has two copies of the the "dual variable" in its update. The μ_1^k-update in (46) allows for correction by $L^k - L^{k+1}$ not present in (51).

We now compare (51) and the multi-block ADMM in Algorithm 3 on randomly generated test problems. We took L to be a binary "checker-board" matrix, generated S by sampling the standard normal distribution in approximately 15% of its entries, and generated the set Ω to be approximately 40% of entries. The partial matrix M was then computed elementwise according to $M_{ij} = L_{ij} + S_{ij}$ for all $(i,j) \in \Omega$. A random examples of L, M and Ω generated in this way is shown in Figure 2.

We ran both methods for a 20×20 and a 40×40 instance of (50). The best parameters in (50) for this instance were found by trial and error to be $\lambda = 0.25$ and $\delta = 0.1$. For Algorithm 3, the stepsize γ was chosen as $\gamma = 0.8$. All methods were initialised with the zero matrices. After 2000 iterations, the reconstructions of L for both algorithms were inspected and were visually indistinguishable.
Figure 2: A random instance of (49) for $m = n = 20$: (left) the low rank matrix L, (center) the noisy partial matrix M, and (right) the set Ω representing the observed entries.

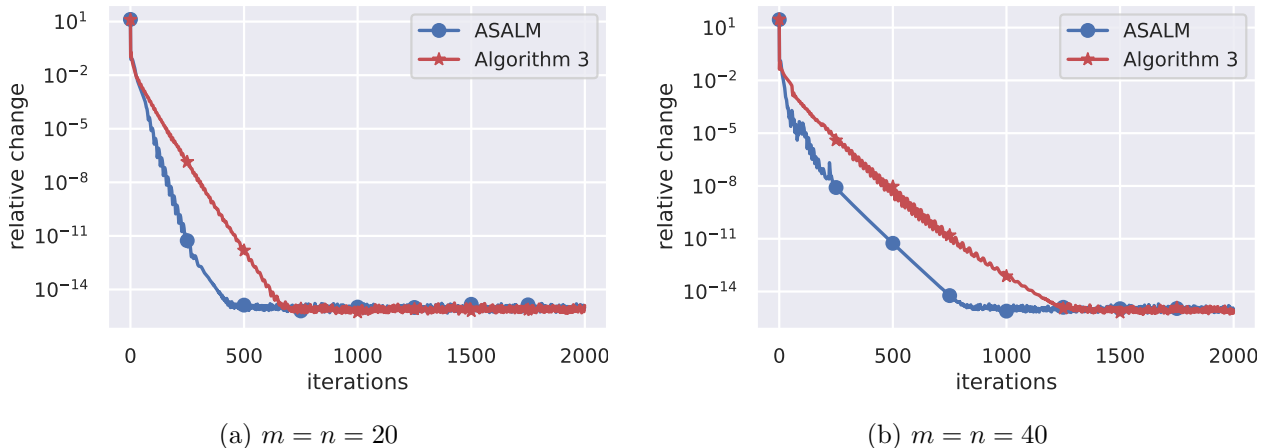

(a) $m = n = 20$

(b) $m = n = 40$

Figure 3: Results for problem (49).

We compared the progress of both algorithms as a function of iterations in Figure 3. To do so, we monitored the relative change of the recovered low rank and sparse components of the solution which is given by

$$\frac{\|(L^{k+1}, S^{k+1}) - (L^k, S^k)\|}{\|(L^k, S^k)\| + 1}.$$

This quantity was used in [24, Section 9] as a stopping criteria for ASALM. Although the relative change for both methods decays to the same final value, Figure 3 shows that ASALM is faster in terms of iterations. However, its poorer theoretical properties, as compared to Algorithm 3, may counterbalance this is in some situations.

7   Conclusions

In this work, we have introduced a family of frugal resolvent splittings with minimial lifting in the sense of Ryu [22]. We investigated applications of this family in distributed decentralised optimisation and in multi-block ADMM. To conclude, we outline possible directions for further research arising from this work.

Characterising frugal resolvent splittings for n operators. The proximal point algorithm and the Douglas–Rachford algorithm are the unique frugal resolvent splittings for $n = 1$ and $n = 2$, respectively [22]. For $n \geq 3$, there seems to be multiple distinct schemes (*i.e.,* this work and [22, 2]). It would be interesting to characterise and enumerate all possible frugal resolvents splittings for a given number of monotone operators. Iterations with different structure will be potentially useful for distributed decentralised optimisation with non-cyclic network topologies.

Behaviour on infeasible and pathological problems. In this work, we only analysed our frugal resolvent splitting and our multi-block ADMM in the consistent, non-pathological setting. In the literature, the behaviour of the Douglas–Rachford method and two-block ADMM applied to infeasible and/or pathological problems is relatively well understood [23] within the framework of Pazy's trichotomy theorem [19]. It would be interesting to analyse the behaviour our methods in potentially infeasible and/or pathological settings.

Iteration complexity of the multi-block ADMM. In our analysis of ADMM, Theorem 6.3 focused on convergence of the iterates generated by the algorithm, but did not consider iteration complexity. The worst-case iteration complexity of two-block ADMM is known to be $O(1/k)$ in the ergodic sense [14, 18]. It would be interesting to investigate the iteration complexity of our multi-block ADMM extension to see if it is still $O(1/k)$.

Interpretations in terms of the PPA. The Douglas–Rachford algorithm can be interpreted as a proximal point algorithm applied to the so-called "splitting operator" (see [11]). Since our proposed framework is a generalisation of the Douglas-Rachford algorithm to n operators, it is natural to ask if it can also be understood as an instance of the proximal point algorithm.
