## Abstract

Keyword Spotting (KWS) remains challenging to achieve the trade-off between small footprint and high accuracy. Recently proposed metric learning approaches improved the generalizability of models for the KWS task, and 1D-CNN based KWS models have achieved the state-of-the-arts (SOTA) in terms of model size. However, for metric learning, due to data limitations, the speech anchor is highly susceptible to the acoustic environment and speakers. Also, we note that the 1D-CNN models have limited capability to capture long-term temporal acoustic features. To address the above problems, we propose to utilize text anchors to improve the stability of anchors. Furthermore, a new type of model (LG-Net) is exquisitely designed to promote long-short term acoustic feature modeling based on 1D-CNN and self-attention. Experiments are conducted on Google Speech Commands Dataset version 1 (GSCDv1) and 2 (GSCDv2). The results demonstrate that the proposed text anchor based metric learning method shows consistent improvements over speech anchor on representative CNN-based models. Moreover, our LG-Net model achieves SOTA accuracy of 97.67% and 96.79% on two datasets, respectively. It is encouraged to see that our lighter LG-Net with only 74k parameters obtains 96.82% KWS accuracy on the GSCDv1 and 95.77% KWS accuracy on the GSCDv2.

**Index Terms:** keyword spotting, long-term information, metric learning, small-footprint, text anchor

## 1. Introduction

With speech technology development, speech assistants can help people solve affairs more efficiently, such as querying weather and controlling air conditioning. People increasingly enjoy the convenience of the hands-free experience. Keyword Spotting (KWS) is the beginning of the human-computer speech interaction, aims at distinguishing between each of the target keywords of interest and non-target sounds such as general speech (non-target words) and noises [1].

Recently, researchers have improved the generalization performance of models in terms of data enhancement [2], loss function [3, 4], automatic gain control [5], negative sample mining [6], and metric learning [1, 7]. In particular, the metric learning based on triplet loss [1, 7] has demonstrated excellent performance. The KWS models are trained using triplet consists of an *anchor* sample, a *positive* sample from the same class with the *anchor*, and a *negative* sample from a different class. The objective of the network training is to minimize the distance between the embeddings of the *anchor* and the *positive* sample while maximizing the distance between the embeddings of the *anchor* and the *negative* sample. It can be seen that the performance is much dependent on the choice of

the anchor. However, due to data limitations, the speech anchor is highly susceptible to the acoustic environment and speakers, making the anchor embedding more variant during training. In addition, deviated speech anchors may make the KWS models suffering from a local optimality issue, which leads to the degradation of the performance.

On the other hand, Deep neural networks (DNNs) have recently proven to yield efficient small-footprint solutions for KWS [8, 9, 10, 11, 12, 13, 14, 15, 16]. In particular, more advanced architectures, such as Convolutional Neural Networks (CNNs), have been applied to solve KWS problems under limited memory footprint as well as computational resource scenarios, showing excellent accuracy. Most CNN-based KWS models receive features, such as Mel-Frequency Cepstral Coefficient (MFCC), as a 2D input. However, such 2D CNN-based KWS models struggle with capturing the dependency between low and high frequencies with the relatively shallow network. To address this problem, [13, 15] utilize temporal convolution to capture low and high-frequency features in a shallow network, which achieves the best KWS performance. Despite their success, due to local region perception and weight sharing characteristics of CNNs, the long-term temporal information may not be considered. Figure 1a shows the feature maps produced by a representative 1D-CNN-based KWS model, TC-ResNet14-1.5 [13]. It is noted that the saliency regions are distributed sparsely, which implies that 1D-CNN focuses on the short-term temporal information. In fact, it is crucial to capture the long-term temporal information for KWS, considering that the characteristics of keywords are usually different on the time scale.

In this study, we aim at boosting the performance of the small-footprint KWS model. To improve the stability of the anchor, we replace the speech anchor with the text anchor and propose a text anchor based metric learning method for KWS. Specifically, target keywords and non-target words are encoded in the text anchors by pretraining models (like BERT [17]). Moreover, the local-global network (LG-Net) is designed to model local and global information. Specifically, the self-attention layer [18] is stacked to the 1D temporal convolution layer to capture the long-term and short-term temporal information. Experimental results demonstrate that the proposed text anchor based metric learning method shows consistent improvements over speech anchor on representative CNN-based models. Besides, our LG-Net model achieves SOTA accuracy of 97.67% and 96.79% on Google Speech Commands Dataset version 1 (GSCDv1) and version 2 (GSCDv2), respectively.

## 2. Proposed Method

### 2.1. Data Process

The raw audio is decomposed into a sequence of frames where the window length is 25 ms and the stride is 10 ms for feature extraction. We use 40 Mel-Frequency Cepstral Coeffi-

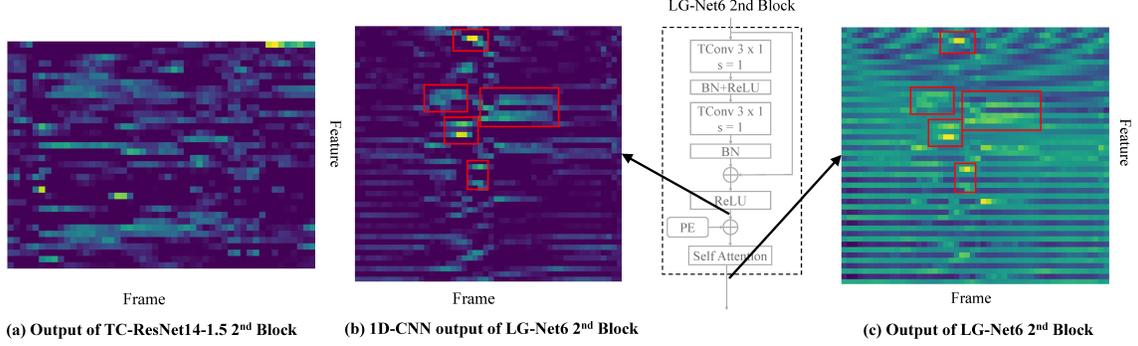

Figure 1: Feature maps produced by the TC-ResNet14-1.5 and proposed model LG-Net using a benchmark image, saliency for each feature is represented by brightness. (a) and (b) shows that the feature maps outputs by 1D-CNN are sparse, representing that 1D-CNN focuses on short-term temporal information. (c) shows the self-attention layer modeling the long-term information while preserving the short-term temporal information captured by the 1D-CNN.

cient (MFCC) features for each frame and stack them over the time-axis, denote as  $M \in \mathbb{R}^{T \times F}$  where  $F$  represents the dimension of the MFCC feature, and  $T$  denotes the number of frames. The text anchor is extracted by BERT-base [17] denoted as  $V \in \mathbb{R}^D$ , where  $D$  represents the dimension of the text anchor (*i.e.*  $D = 768$ ).

## 2.2. Text anchor based metric learning method

As mentioned in Section 1, the susceptibility of the speech anchor leads to the poor performance of the model. Therefore, we propose a text anchor based metric learning method for KWS, illustrated in Figure 2b. The input triplet is denoted as  $(M^+, M^-, V)$ , where  $M^+$  and  $M^-$  are input MFCCs from different classes, and  $V$  as the input text vector corresponding to  $M^+$ . The speech embeddings  $E_S^{M^+} \in \mathbb{R}^{D'}$  and  $E_S^{M^-} \in \mathbb{R}^{D'}$  are extracted from  $M^+$  and  $M^-$  by the speech embedding extraction module  $f_S$ , respectively, where  $D'$  represents the dimension of the speech embedding (*i.e.*  $D' = 128$ ). In parallel,  $V$  is mapped as a text embedding  $E_T \in \mathbb{R}^{D'}$ . The triplet loss is employed to decrease the distance between the  $E_T$  and  $E_S^{M^+}$  and increases the distance between  $E_T$  and  $E_S^{M^-}$ . For a single sample, the triplet loss is thus

$$L_{tri} = \max \left( d \left( E_S^{M^+}, E_T \right) - d \left( E_S^{M^-}, E_T \right) + \alpha, 0 \right) \quad (1)$$

where  $d(x, y) = \|x - y\|_p$  is the pairwise-distance between  $x$  and  $y$  (*i.e.*  $p = 2$ );  $\alpha$  is a constant margin (*i.e.*  $\alpha = 1$ ).

Note that the phone embeddings extracted by the text encoder in [7] is fundamentally different from the text anchor proposed in this paper. In [7], a pronunciation dictionary is used to map words to their sequence of phonemes. Therefore, the phone embeddings do not contain the information about other words, although it is not influenced by factors such as acoustic environment and speaker. The text anchor in this paper is extracted from the BERT [17] which is trained on the large-scale text corpus, it contains information about other words.

## 2.3. Local-global Neural Network

As mentioned in Section 1, for KWS, long-term temporal information is crucial because the characteristics of keywords are usually different on the time scale. In this work, we utilize the

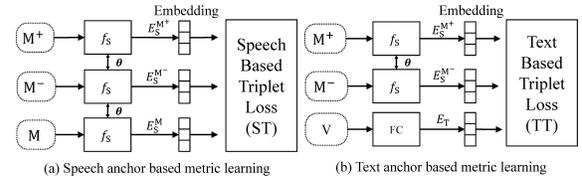

Figure 2: (a) Speech anchor based metric learning and (b) proposed text anchor based metric learning.  $M^+$  and  $M^-$  are input MFCCs from different classes,  $M$  is input MFCC from the same class of  $M^+$ , and  $V$  as the input text vector encoded by BERT [17] corresponding  $M^+$ .  $E_S$  represents the speech embedding output from the speech embedding extraction module  $f_S$ .  $E_T$  represents the text embedding.

self-attention [18] layer to capture long-term temporal information. The temporal convolution with residual structure [13] is adopted in this paper, which is one of the most widely used 1D-CNN architectures for KWS. To reduce the number of parameters,  $3 \times 1$  kernels are utilized instead of  $9 \times 1$  kernels. As Figure 3 shows, and the self-attention layer is stacked to the 1D-CNN layers, denoted as LG-Block. Following the design of the previous study [13], the identity shortcuts can be directly used when the input and output have matching dimensions (Figure 3a); otherwise, we use an extra  $1 \times 1$  convolution with a stride to match the dimensions (Figure 3b). Local-global neural network (LG-Net) can be easily constructed by stacking LG-Blocks. We select LG-Net6 (Figure 3c), which has 6 LG-Blocks as our base model. To establish a small-footprint model, we compress the LG-Net6 by taking out three LG-Blocks and reducing the number of channels, named LG-Net3.

Considering the variation in feature maps due to speaking style, speed of speech, we use an averaging pooling strategy on the time dimension. The output of the average pooling layer is given to a fully connected layer to generate speech embedding  $E_S \in \mathbb{R}^{D'}$ .

$$E_S = f_S(M; \theta_S) \quad (2)$$

where  $\theta_S$  denote the parameters of the  $f_S$ .

Finally, the predicted score,  $\hat{y} \in \mathbb{R}^C$  where  $C$  denote the

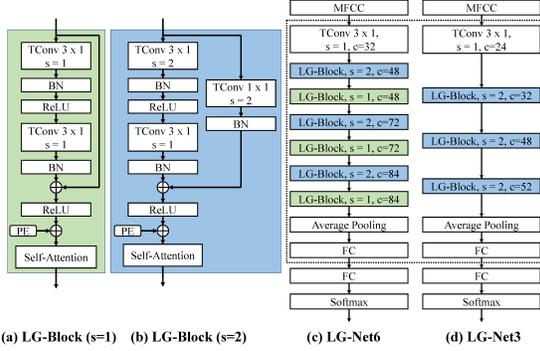

Figure 3: The local-global block (LG-Block) when (a) stride = 1 and (b) stride = 2 and two implementations of local-global neural network (LG-Net) when (c) LG-Net6 and (d) LG-Net3. TConv means the temporal convolution layer, “s” and “c” indicates stride and channel of TConv, respectively. PE means the position encoding [18]. BN and FC denote batch normalization and fully connected layer. The part inside the dotted line is regarded as the speech embedding extraction module.

number of class, is obtained from  $E_S$

$$\hat{y} = \sigma(f_{FC}(E_S; \theta_{FC})) \quad (3)$$

where  $\sigma$  is the sigmoid function;  $\theta_{FC}$  denotes the parameters of the fully connected layer  $f_{FC}$ . KWS as a multi-classification problem, the cross entropy (CE) loss is adopted to optimize the model, for the given ground truth  $y \in \mathbb{R}^C$  (where  $y^{(i)} = \{0, 1\}$  denotes whether label  $i$  appears or not), the loss  $L$  is calculated using binary cross-entropy:

$$L_{CE} = \sum_{i=1}^C y^{(i)} \log(\hat{y}^{(i)}) + (1 - y^{(i)}) \log(1 - \hat{y}^{(i)}) \quad (4)$$

In this work, the networks are optimized by the loss  $L$ , which is calculated by weighted sum of  $L_{tri}$  and  $L_{CE}$

$$L = \beta L_{tri} + (1 - \beta) L_{CE} \quad (5)$$

where  $\beta$  is the balanced weight between  $L_{tri}$  and  $L_{CE}$ .

Except for the cases of target keywords and non-target words, a “silence” class is considered to indicate the case when no speech is detected [19]. However, in this work, the text vector of “silence” does not match the definition in KWS, so the model cannot be trained directly using the text vector of “silence”. To address the problem, we first train the network without the “silence” sample and then finetune the two FC layers on the full dataset with only CE loss.

### 3. Experiments

#### 3.1. Datasets

The proposed models are trained and evaluated with Google Speech Commands Dataset version 1 (GSCDv1<sup>1</sup>) and version 2 (GSCDv2<sup>2</sup>) [19]. Following the implementation of Google [19], we seek to discriminate among 12 classes for GSCDv1: “yes”, “no”, “up”, “down”, “left”, “right”, “on”,

Table 1: The number of samples in training, validation and test set of google speech commands dataset version 1 and version 2.

Dataset	Train	Valid	Test	Total
GSCDv1	55287	7218	7242	69747
GSCDv2	89043	10401	11413	110857

“off”, “stop”, “go”, unknown, or silence, and 16 classes for GSCDv2 which add 4 keywords of GSCDv1: “backward”, “forward”, “follow”, and “learn”. In order to generate background noise, we randomly sample and crop background noises provided in the dataset. For a fair comparison, in our test set, the “silence” class test samples are taken from open source speech commands dataset test set version 2<sup>3</sup> [19], and test samples of other classes are written in the officially released *testing.list*<sup>12</sup>. Table 1 shows the number of samples in training, validation, and test sets. Note that to make it easy for other researchers to reproduce the model and results in this paper, we do not use any data augmentation methods.

#### 3.2. Implementation Details

Our implementation was done with Pytorch [20] deep learning toolkit.

**Training.** All the models are trained with a mini-batch of 256 samples using stochastic gradient descent with weight decay of 0.001 and momentum of 0.9. For formula (5), the  $L_{tri}$  and  $L_{CE}$  weights to be the same, *i.e.*  $\beta = 0.5$ ,  $L = 0.5L_{CE} + 0.5L_{tri}$ . The initial learning rate is set to be 0.01 and decayed by a factor of 3 when the validation accuracy does not increase for 3 epochs. The training is terminated when validation accuracy does not increase for 10 epochs. For the fine-tuning stage mentioned in Section 2.3, the training setup is the same as the text anchor based metric learning method, except that  $\beta$  is set as 0.

**Evaluation.** The primary metric in our experiments is classification accuracy, the proportion of correct decisions out of the total number of samples. We also report the number of parameters and the false reject rate (FRR) at 0.5% false alarm rate (FAR). We train each model 10 times and report its average performance.

#### 3.3. Baselines

To demonstrate the consistent performance improvement of our proposed text anchor based metric learning method, we reproduce CnnTradFpool3 [9], CnnOneFstride4 [9], TDNNWSA [14], TC-ResNet8 [13], and TC-ResNet14-1.5 [13], which are representative CNN-based KWS models.

We use three loss functions for training and comparison. First, the CE loss, which is the most widely used loss function in the KWS task. Second, the triplet loss based on speech anchor (ST) is used to evaluate the performance gains from the triplet loss. As shown in Figure 2a, the input triplet is denoted as  $(M^+, M^-, M)$ , where  $M$  is input MFCC randomly sampled from the training set with the same class of  $M^+$ . Third, the triplet loss based on text anchor (TT). As mentioned in Section 2.3, we employ CE loss accompanied by the ST and the TT, denote as  $CE+ST$  and  $CE+TT$ , respectively. Also, to evaluate the performance improvement brought by our proposed LG-Net model, we selected several CNN-based KWS models trained with CE loss functions for direct comparison [10, 15, 16].

		CE+ST	4.31%
		CE+TT	<b>3.56%</b>

### 3.4. Experimental Results and Analysis

**Impact of text anchor based metric learning method.** As Table 2 shows, for each model, training with *CE+TT* loss shows consistent improvements over training with *CE+ST* loss, since that BERT provides informative and robust text anchors, which alleviates the effects of the acoustic environment and speakers. Furthermore, We find that training with *CE+ST* loss yields a performance gain compared to CE loss because triplet loss increases the distinguishability of features. From Table 3, we can see that LG-Net6 achieves a lower FRR at 0.5% FAR. Note that there is no increase in memory footprint and computational resource at inference compared with the corresponding baseline. As Figure 4 shows, we randomly sample speech embeddings and use the t-SNE algorithm [23] to visualize the embeddings. We can see that keywords with similar pronunciation are difficult to distinguish (e.g. “go” and “no”), but are easily distinguished in the feature space after using our proposed text anchor based metric learning method.

**Impact of other text vectors.** We make a step forward to

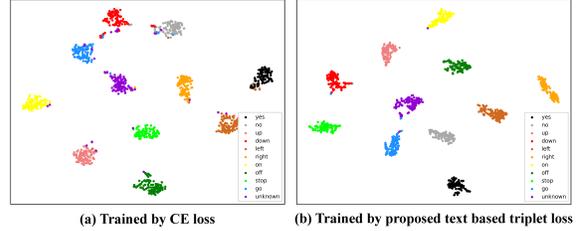

Figure 4: t-SNE visualization of speech embeddings extracted by LG-Net6.

Table 4: Comparison of other text embeddings on GSCDv2

Model	Text Embedding	Acc.
TC-ResNet14-1.5 [13] (Choi <i>et al.</i> 2019)	glove.840B.300d [21]	96.21%
	BERT-Layer 1 [17]	<b>96.27%</b>
	BERT-Layer 2 [17]	96.23%
LG-Net6 (ours)	BERT-Layer 12 [17]	96.22%
	glove.840B.300d [21]	96.47%
	BERT-Layer 1 [17]	<b>96.79%</b>
	BERT-Layer 2 [17]	96.52%
	BERT-Layer 12 [17]	96.50%

study how other text vectors influence the performance of our proposed method. Comparison experiments among the different layers of BERT and Glove [21] are performed. Referring to Table 4, both models, TC-ResNet14-1.5 [13] and LG-Net6, achieve the best performances by employing the output of the first layer from BERT as the text anchor. The results indicate that the lower layer of BERT can mostly capture word-level information, which is consistent with the statement in [22].

**Impact of the local-global block.** As shown in Table 2, compared to models trained using CE loss, LG-Nets achieve a balance between model size and accuracy. Compared to TC-ResNet14-1.5 [13], our LG-Net6 achieves better accuracy of 97.03% and 96.45% on GSCDv1 and GSCDv2, respectively. Compared to NAS2 [9], our proposed LG-Net6 achieves comparable results using only 35% (313K/886K) of the number of parameters. The small-footprint model LG-Net3 obtains 95.71% KWS accuracy in GSCDv1 and 95.35% KWS accuracy in GSCDv2. Visualization results (Figure 1b and Figure 1c) show that the self-attention layer helps the network capture long-term temporal information while preserving the short-term temporal information captured by the 1D-CNN.

## 4. Conclusion

In this paper, we propose text anchor based metric learning method and design a neural network LG-Net for small-footprint keyword spotting (KWS). The experimental results show that the proposed text anchor based metric learning method shows consistent improvements over the speech anchor based method. Moreover, our LG-Net model achieves SOTA accuracy on the Google Speech Commands Dataset version 1 and version 2.

## Abstract

For your paper to be published in the conference proceedings, you must use this document as both an instruction set and as a template into which you can type your own text. If your paper does not conform to the required format, you will be asked to fix it.

Please do not reuse your past papers as a template. To prepare your paper for submission, please always download a fresh copy of this template from the conference website and please read the format instructions in this template before you use it for your paper.

Conversion to PDF may cause problems in the resulting PDF or expose problems in your source document. Before submitting your final paper in PDF, check that the format in your paper PDF conforms to this template. Specifically, check the appearance of the title and author block, the appearance of section headings, document margins, column width, column spacing, and other features such as figure numbers, table numbers and equation number. In summary, you must proofread your final paper in PDF before submission.

The maximum number of pages is 5. The 5<sup>th</sup> page is reserved for references, exclusively. However, the references may begin on an earlier page immediately after the Acknowledgements section, and continue onto the 5<sup>th</sup> page. If no space is available on an earlier page, then the references may begin on the 5<sup>th</sup> page.

Index terms should be included as shown below.

**Index Terms:** speech recognition, human-computer interaction, computational paralinguistics

## 1. Introduction

This template can be found on the conference website. Templates are provided for Microsoft Word®, and L<sup>A</sup>T<sub>E</sub>X. However, we highly recommend using L<sup>A</sup>T<sub>E</sub>X when preparing your submission. Information for full paper submission is available on the conference website.

## 2. Page layout and style

Authors should observe the following rules for page layout. A highly recommended way to meet these requirements is to use a given template (Microsoft Word® or L<sup>A</sup>T<sub>E</sub>X) and check details against the corresponding example PDF file. Given templates, Microsoft Word® or L<sup>A</sup>T<sub>E</sub>X, can be adapted/imported easily in other software such as LibreOffice, Apple Pages, LuaL<sup>A</sup>T<sub>E</sub>X, and XeL<sup>A</sup>T<sub>E</sub>X, but please be careful to match the layout of the provided PDF example.

### 2.1. Basic layout features

- Proceedings will be printed in DIN A4 format. Authors must submit their papers in DIN A4 format.

- Two columns are used except for the title section and for large figures that may need a full page width.
- Left and right margin are 20 mm each.
- Column width is 80 mm.
- Spacing between columns is 10 mm.
- Top margin is 25 mm (except for the first page which is 30 mm to the title top).
- Bottom margin is 35 mm.
- Text height (without headers and footers) is maximum 235 mm.
- Headers and footers must be left empty.
- Check indentations and spacings by comparing to this example file (in PDF).

### 2.1.1. Headings

Section headings are centered in boldface with the first word capitalized and the rest of the heading in lower case. Sub-headings appear like major headings, except they start at the left margin in the column. Sub-sub-headings appear like sub-headings, except they are in italics and not boldface. See the examples in this file. No more than 3 levels of headings should be used.

### 2.2. Text font

Times or Times Roman font is used for the main text. Font size in the main text must be 9 points, and in the References section 8 points. Other font types may be used if needed for special purposes. It is VERY IMPORTANT that while making the final PDF file, you embed all used fonts! To embed the fonts, you may use the following instructions:

1. For Windows users, the bullzip printer can convert any PDF to have embedded and subsetted fonts.
2. For Linux/Mac users, you may use  
pdftops file.pdf  
pstopdf -dPDFSETTINGS=/prepress file.pdf

L<sup>A</sup>T<sub>E</sub>X users: users should use Adobe Type 1 fonts such as Times or Times Roman. These are used automatically by the INTERSPEECH2021.sty style file. Authors must not use Type 3 (bitmap) fonts.

### 2.3. Figures

All figures must be centered on the column (or page, if the figure spans both columns). Figure captions should follow each figure and have the format given in Figure 1.

Figures should be preferably line drawings. If they contain gray levels or colors, they should be checked to print well on a high-quality non-color laser printer.

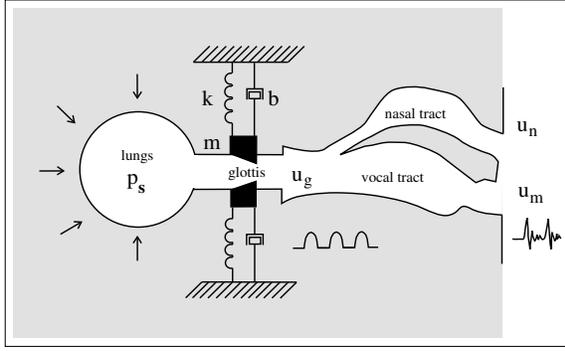

Figure 1: Schematic diagram of speech production.

Graphics (i. e., illustrations, figures) must not use stipple fill patterns because they will not reproduce properly in Adobe PDF. Please use only SOLID FILL COLORS.

Figures which span 2 columns (i. e., occupy full page width) must be placed at the top or bottom of the page.

#### 2.4. Tables

An example of a table is shown in Table 1. The caption text must be above the table.

Table 1: This is an example of a table

Ratio	Decibels
1/10	-20
1/1	0
2/1	$\approx 6$
3.16/1	10
10/1	20
100/1	40
1000/1	60

#### 2.5. Equations

Equations should be placed on separate lines and numbered. Examples of equations are given below. Particularly,

$$x(t) = s(f_\omega(t)) \quad (1)$$

where  $f_\omega(t)$  is a special warping function

$$f_\omega(t) = \frac{1}{2\pi j} \oint_C \frac{\nu^{-1k} d\nu}{(1 - \beta\nu^{-1})(\nu^{-1} - \beta)} \quad (2)$$

A residue theorem states that

$$\oint_C F(z) dz = 2\pi j \sum_k \text{Res}[F(z), p_k] \quad (3)$$

Applying (3) to (1), it is straightforward to see that

$$1 + 1 = \pi \quad (4)$$

Finally we have proven the secret theorem of all speech sciences. No more math is needed to show how useful the result is!

Table 2: Main predefined styles in Word

Style Name	Entities in a Paper
Title	Title
Author	Author name
Affiliation	Author affiliation
Email	Email address
AbstractHeading	Abstract section heading
Body Text	First paragraph in abstract
Body Text Next	Following paragraphs in abstract
Index	Index terms
1. Heading 1	1 <sup>st</sup> level section heading
1.1 Heading 2	2 <sup>nd</sup> level section heading
1.1.1 Heading 3	3 <sup>rd</sup> level section heading
Body Text	First paragraph in section
Body Text Next	Following paragraphs in section
Figure Caption	Figure caption
Table Caption	Table caption
Equation	Equations
• List Bullet	Bulleted lists
[1] Reference	References

#### 2.6. Information for Word users only

For ease of formatting, please use the styles listed in Table 2. The styles are defined in this template file and are shown in the order in which they would be used when writing a paper. When the heading styles in Table 2 are used, section numbers are no longer required to be typed in because they will be automatically numbered by Word. Similarly, reference items will be automatically numbered by Word when the “Reference” style is used.

If your Word document contains equations, you must not save your Word document from “.docx” to “.doc” because when doing so, Word will convert all equations to images of unacceptably low resolution.

#### 2.7. Hyperlinks

For technical reasons, the proceedings editor will strip all active links from the papers during processing. Hyperlinks can be included in your paper, if written in full, e. g. “http://www.foo.com/index.html”. The link text must be all black. Please make sure that they present no problems in printing to paper.

#### 2.8. Multimedia files

The INTERSPEECH organizing committee offers the possibility to submit multimedia files. These files are meant for audio-visual illustrations that cannot be conveyed in text, tables and graphs. Just like you would when including graphics, make sure that you have sufficient author rights to the multimedia materials that you submit for publication. The proceedings media will NOT contain readers or players, so be sure to use widely accepted file formats, such as MPEG, Windows WAVE PCM (.wav) or Windows Media Video (.wmv) using standard codecs.

Your multimedia files must be submitted in a single ZIP file for each separate paper. Within the ZIP file you can use folders and filenames to help organize the multimedia files. In the ZIP file you should include a TEXT or HTML index file which describes the purpose and significance of each multimedia file. From within the manuscript, refer to a multimedia illustration

by its filename. Use short file names without blanks for clarity.

The ZIP file you submit will be included as-is in the proceedings media and will be linked to your paper in the navigation interface of the proceedings. Causal Productions (the publisher) and the conference committee will not check or change the contents of your ZIP file.

Users of the proceedings who wish to access your multimedia files will click the link to the ZIP file which will then be opened by the operating system of their computer. Access to the contents of the ZIP file will be governed entirely by the operating system of the user's computer.

## 2.9. Page numbering

Final page numbers will be added later to the document electronically. *Do not make any footers or headers!*

## 2.10. References

The reference format is the standard IEEE one. References should be numbered in order of appearance, for example [?], [?], [?, pp. 417–422], and [?].

## 2.11. Abstract

The total length of the abstract is limited to 200 words. The abstract included in your paper and the one you enter during web-based submission must be identical. Avoid non-ASCII characters or symbols as they may not display correctly in the abstract book.

## 2.12. Author affiliation

Please list country names as part of the affiliation for each country.

## 2.13. Number of authors in the author list

The maximum number of authors in the author list is twenty. If the number of contributing authors is more than twenty, they should be listed in a footnote or in acknowledgement section, as appropriate.

## 2.14. Submitted files

Authors are requested to submit PDF files of their manuscripts. You can use commercially available tools or for instance <http://www.pdfforge.org/products/pdfcreator>. The PDF file should comply with the following requirements: (a) there must be no PASSWORD protection on the PDF file at all; (b) all fonts must be embedded; and (c) the file must be text searchable (do CTRL-F and try to find a common word such as “the”). The proceedings editors (Causal Productions) will contact authors of non-complying files to obtain a replacement. In order not to endanger the preparation of the proceedings, papers for which a replacement is not provided in a timely manner will be withdrawn.

# 3. Discussion

This is the discussion. This is the discussion. This is the discussion. Is there any discussion?

Lorem ipsum dolor sit amet, consectetur adipiscing elit. Cras consequat mollis odio, nec venenatis enim auctor sed. Integer tincidunt fringilla lectus eget condimentum. In eget sapien id eros dapibus interdum vel ac quam. Aenean vitae rutrum erat.

## 4. Conclusions

Authors must proofread their PDF file prior to submission to ensure it is correct. Authors should not rely on proofreading the Word file. Please proofread the PDF file before it is submitted.

## 5. Acknowledgements

The ISCA Board would like to thank the organizing committees of the past INTERSPEECH conferences for their help and for kindly providing the template files.

Note to authors: Authors should not use logos in the acknowledgement section; rather authors should acknowledge corporations by naming them only.
