

UNIVERSAL AUTOHOMEOMORPHISMS OF \mathbb{N}^*

KLAAS PIETER HART AND JAN VAN MILL

To the memory of Cor Baayen, who taught us many things

ABSTRACT. We study the existence of universal autohomeomorphisms of \mathbb{N}^* . We prove that CH implies there is such an autohomeomorphism and show that there are none in any model where all autohomeomorphisms of \mathbb{N}^* are trivial.

INTRODUCTION

This paper is concerned with universal autohomeomorphisms on \mathbb{N}^* , the Čech-Stone remainder of \mathbb{N} .

In very general terms we say that an autohomeomorphism h on a space X is universal for a class of pairs (Y, g) , where Y is a space and g is an autohomeomorphism of Y , if for every such pair there is an embedding $e : Y \rightarrow X$ such that $f \circ e = e \circ g$, that is, h extends the copy of g on $e[Y]$.

In [1, Section 3.4] one finds a general way of finding universal autohomeomorphisms. If X is homeomorphic to X^ω then the shift mapping $\sigma : X^\mathbb{Z} \rightarrow X^\mathbb{Z}$ defines a universal autohomeomorphism for the class of all pairs (Y, g) , where Y is a subspace of X . One embeds Y into $X^\mathbb{Z}$ by mapping each $y \in Y$ to the sequence $\langle g^n(y) : n \in \mathbb{Z} \rangle$.

Thus, the Hilbert cube carries an autohomeomorphism that is universal for all autohomeomorphisms of separable metrizable spaces and the Cantor set carries one for all autohomeomorphisms of zero-dimensional separable metrizable spaces. Likewise the Tychonoff cube $[0, 1]^\kappa$ carries an autohomeomorphism that is universal for all autohomeomorphisms of completely regular spaces of weight at most κ , and the Cantor cube 2^κ has a universal autohomeomorphism for all zero-dimensional such spaces.

Our goal is to have an autohomeomorphism h on \mathbb{N}^* that is universal for all autohomeomorphisms of all *closed* subspaces of \mathbb{N}^* . The first result of this paper is that there is no trivial universal autohomeomorphism of \mathbb{N}^* , and hence no universal autohomeomorphism at all in any model where all autohomeomorphisms of \mathbb{N}^* are trivial. On the other hand, the Continuum Hypothesis implies that there is a universal autohomeomorphism of \mathbb{N}^* . The proof of this will have to be different from the results mentioned above because \mathbb{N}^* is definitely not homeomorphic to its power $(\mathbb{N}^*)^\omega$; it will use group actions and a homeomorphism extension theorem.

We should mention the dual notion of universality where one requires the existence of a surjection $s : X \rightarrow Y$ such that $g \circ s = s \circ h$. For the space \mathbb{N}^* this was investigated thoroughly in [2] for general group actions.

Key words and phrases. autohomeomorphism, \mathbb{N}^* , universality.

1. SOME PRELIMINARIES

Our notation is standard. For background information on \mathbb{N}^* we refer to [5].

We denote by Aut the autohomeomorphism group of \mathbb{N}^* . We call a member h of Aut *trivial* if there are cofinite subsets A and B of \mathbb{N} and a bijection $b : A \rightarrow B$ such that h is the restriction of βb to \mathbb{N}^* .

In both sections we shall use the G_δ -topology on a given space (X, τ) ; this is the topology τ_δ on X generated by the family of all G_δ -subsets in the given space. It is well-known that $w(X, \tau_\delta) \leq w(X, \tau)^{\aleph_0}$; we shall need this estimate in Section 3.

2. WHAT IF ALL AUTOHOMEOMORPHISMS ARE TRIVIAL?

To begin we observe that fixed-point sets of trivial autohomeomorphism of \mathbb{N}^* are clopen. Therefore, to show that no trivial autohomeomorphism is universal it would suffice to construct a compact space that can be embedded into \mathbb{N}^* and that has an autohomeomorphism whose fixed-point set is not clopen.

The example. We let L be the ordinal $\omega_1 + 1$ endowed with its G_δ -topology. Thus all points other than ω_1 are isolated and the neighbourhoods of ω_1 are exactly the co-countable sets that contain it. Then L is a P -space of weight \aleph_1 and hence, by the methods in [4, Section 2], its Čech-Stone compactification βL can be embedded into \mathbb{N}^* .

We define $f : L \rightarrow L$ such that ω_1 is the only fixed point of βf . We put

$$\begin{aligned} f(\omega_1) &= \omega_1, \\ f(2 \cdot \alpha) &= 2 \cdot \alpha + 1, \text{ and} \\ f(2 \cdot \alpha + 1) &= 2 \cdot \alpha. \end{aligned}$$

This defines a continuous involution on L .

If $p \in \beta L \setminus L$ then $p \in \text{cl } \alpha$ for some $\alpha < \omega_1$ and then either $E = \{2 \cdot \beta : \beta < \alpha\}$ or $O = \{2 \cdot \beta + 1 : \beta < \alpha\}$ belongs to the ultrafilter p . But $f[E] \cap E = \emptyset = f[O] \cap O$, hence $\beta f(p) \neq p$.

Since ω_1 is not an isolated point of βL , no matter how this space is embedded into \mathbb{N}^* there is no trivial autohomeomorphism of \mathbb{N}^* that would extend βf .

3. THE CONTINUUM HYPOTHESIS

Under the Continuum Hypothesis the space \mathbb{N}^* is generally very well-behaved and one would expect it to have a universal autohomeomorphism as well. We shall prove that this is indeed the case. We need some well-known facts about closed subspaces of \mathbb{N}^* .

First we have Theorem 1.4.4 from [5] which characterizes the closed subspaces of \mathbb{N}^* under CH: they are the compact zero-dimensional F -spaces of weight \mathfrak{c} , and, in addition: every closed subset of \mathbb{N}^* can be re-embedded as a nowhere dense closed P -set.

Second we have the homeomorphism extension theorem from [3]: CH implies that every homeomorphism between nowhere dense closed P -sets of \mathbb{N}^* can be extended to an autohomeomorphism of \mathbb{N}^* .

Step 1. We consider the natural action of \mathbf{Aut} on \mathbb{N}^* , that is the map $\sigma : \mathbf{Aut} \times \mathbb{N}^* \rightarrow \mathbb{N}^*$ given by $\sigma(f, p) = f(p)$. This action is continuous when \mathbf{Aut} carries the compact-open topology τ and hence also when \mathbf{Aut} carries the G_δ -modification τ_δ of τ . For the rest of the construction we consider the topology τ_δ .

Using this action we define an autohomeomorphism $h : \mathbf{Aut} \times \mathbb{N}^* \rightarrow \mathbf{Aut} \times \mathbb{N}^*$ by $h(f, p) = (f, f(p))$. The map h is continuous because its two coordinates are and it is a homeomorphism because its inverse $(f, p) \mapsto (f, f^{-1}(p))$ is continuous as well.

Now if X is a closed subset of \mathbb{N}^* and $g : X \rightarrow X$ is an autohomeomorphism then we can re-embed X as a nowhere dense closed P -set and we can then find an $f \in \mathbf{Aut}$ such that $f \upharpoonright X = g$. We transfer this embedded copy of X to $\{f\} \times \mathbb{N}^*$ in $\mathbf{Aut} \times \mathbb{N}^*$; for this copy of X we then have $h \upharpoonright X = g$. It follows that h satisfies the universality condition.

Step 2. We embed $\mathbf{Aut} \times \mathbb{N}^*$ into \mathbb{N}^* in such a way that there is an autohomeomorphism H of \mathbb{N}^* such that $H \upharpoonright (\mathbf{Aut} \times \mathbb{N}^*) = h$. Then H is the desired universal autohomeomorphism of \mathbb{N}^* .

To this end we list a few properties of this product.

Weight. The weight of the product is equal to \mathfrak{c} , as both factors have weight \mathfrak{c} . For \mathbb{N}^* this is clear and for \mathbf{Aut} this follows because the topology τ has weight \mathfrak{c} and one obtains a base for τ_δ by taking the intersections of all countable subfamilies of a base for τ .

Zero-dimensional and F . The product is a zero-dimensional F -space as the product of the P -space \mathbf{Aut} and the compact zero-dimensional F -space \mathbb{N}^* , see [6, Theorem 6.1].

Strongly zero-dimensional. The product $\mathbf{Aut} \times \mathbb{N}^*$ is not compact, but we shall construct a compactification of it that is also a zero-dimensional F -space of weight \mathfrak{c} .

For this we need to prove that $\mathbf{Aut} \times \mathbb{N}^*$ is actually strongly zero-dimensional. We prove more: the product is ultraparacompact, meaning that every open cover has a *pairwise disjoint* open refinement.

Let \mathcal{U} be an open cover of the product consisting of basic clopen rectangles.

For each $f \in \mathbf{Aut}$ there is a finite subfamily \mathcal{U}_f of \mathcal{U} that covers $\{f\} \times \mathbb{N}^*$, say $\mathcal{U}_f = \{C_i \times D_i : i < k_f\}$. Let $C_f = \bigcap_{i < k_f} C_i$ and $D_{f,i} = D_i \setminus \bigcup_{j < i} D_j$ for $i < k_f$. Then $\mathcal{C}_f = \{C_f \times D_{f,i} : i < k_f\}$ is a disjoint family of clopen rectangles that covers $\{f\} \times \mathbb{N}^*$ and refines \mathcal{U} .

Because \mathbf{Aut} has weight \mathfrak{c} , and we assume CH, there is a sequence $\langle f_\alpha : \alpha \in \omega_1 \rangle$ in \mathbf{Aut} such that $\{C_{f_\alpha} : \alpha \in \omega_1\}$ covers \mathbf{Aut} . Next we let $V_\alpha = C_{f_\alpha} \setminus \bigcup_{\beta < \alpha} C_{f_\beta}$ for all α . Because \mathbf{Aut} is a P -space the family $\{V_\alpha : \alpha \in \omega_1\}$ is a disjoint open cover of \mathbf{Aut} .

The family $\{V_\alpha \times D_{f_\alpha,i} : i < k_{f_\alpha}, \alpha \in \omega_1\}$ then is a disjoint open refinement of \mathcal{U} .

A compactification. To complete Step 2 we construct a compactification of $\mathbf{Aut} \times \mathbb{N}^*$ that is a zero-dimensional F -space of weight \mathfrak{c} and that has an autohomeomorphism that extends h . The Čech-Stone compactification would be the obvious candidate, were it not for the fact that its weight is equal to $2^{\mathfrak{c}}$. More precisely, using some continuous onto function from (\mathbf{Aut}, τ) onto $[0, 1]$ one obtains a clopen partition of $(\mathbf{Aut}, \tau_\delta)$ of cardinality \mathfrak{c} . This shows that $\beta(\mathbf{Aut} \times \mathbb{N}^*)$ admits a continuous surjection onto the space $\beta\mathfrak{c}$ (where \mathfrak{c} carries the discrete topology).

To create the desired compactification we build, either by transfinite recursion or by an application of the Löwenheim-Skolem theorem, a subalgebra \mathbb{B} of the algebra of clopen subsets of $\text{Aut} \times \mathbb{N}^*$ that is closed under h and h^{-1} , of cardinality \mathfrak{c} , and that has the property that for every pair of countable subsets A and B of \mathbb{B} such that $a \cap b = \emptyset$ whenever $a \in A$ and $b \in B$ there is a $c \in \mathbb{B}$ such that $a \subseteq c$ and $c \cap b = \emptyset$ for all $a \in A$ and $b \in B$. The latter condition can be fulfilled because $\text{Aut} \times \mathbb{N}^*$ is an F -space — $\bigcup A$ and $\bigcup B$ have disjoint closures — and strongly zero-dimensional — the closures can be separated using a clopen set.

The Stone space $\text{St}(\mathbb{B})$ of \mathbb{B} is then a compactification of $\text{Aut} \times \mathbb{N}^*$ that is a compact zero-dimensional F -space of weight \mathfrak{c} , with an autohomeomorphism \bar{h} that extends h . We embed $\text{St}(\mathbb{B})$ into \mathbb{N}^* as a nowhere dense P -set and extend \bar{h} to an autohomeomorphism H of \mathbb{N}^* .
