A mathematical modeling of biochemical processes makes it possible to determine the adaptation of a biosystem to open environmental conditions. The mass-balance equations incorporate the nonlinear cooperative nature of the transformation processes. As a result, we have a self-regulation problem for dynamic systems far from equilibrium. The phase-portrait method, in particular the Poincare mapping, is effective for studying such nonlinear problems. In the present we wish to propose a model of this type, which is defined by the following system of nonlinear differential equations:

$$\partial_t S = \frac{S_0 K}{K + S + \Psi^4} - l_1 V(S) V(S_6) - \alpha_S S \qquad (1)$$

$$\partial_t S_1 = l_1 V(S) V(S_6) - l_2 V(N^2) V(S_1^2)$$
(2)

$$\partial_t S_2 = l_2 V(N^2) V(S_1^2) - l_3 V(N) V(S_2)$$
(3)

$$\partial_t S_3 = l_3 V(N) V(S_2) - 4l_4 V(L_1 - T) V(S_3)$$
 (4)

$$\partial_t S_4 = 4l_4 V (L_1 - T) V(S_3) - l_5 V(N) \frac{S_4}{1 + S_4^2 + MS_6}$$
(5)

$$\partial_t S_5 = l_5 V(N) \frac{S_4}{1 + S_4^2 + MS_6} - l_6 V(N) V(S_5) \tag{6}$$

$$\partial_t S_6 = l_6 V(N) V(S_5) - l_1 V(S) V(S_6) \tag{7}$$

$$\partial_t N = k_5 V(E_1) V(L_2 - N) - l_2 V(N^2) V(S_1^2) -k_3 V(T^4) \frac{E_3}{1 + E_3 + O_2} - l_5 V(N) \frac{S_4}{1 + S_4^2 + MS_6} -l_6 V(N) V(S_5) + l_7 V(Q) V(L_2 - N)$$
(8)

$$\partial_t Q = 6k_2 \frac{V(O_2)V(L_1 - Q)}{1 + \Psi^2} - l_7 V(Q)V(L_2 - N) \quad (9)$$

$$\partial_t T = k_4 V(N_2) V(\Psi^4) \frac{E_4}{1 + E_4 + H_2/2} + l_8 V(L_1 - T) V(\Psi^4) - 4k_3 V(T^4) \frac{E_3}{1 + E_3 + O_2} - 2k_6 \frac{E_3}{E_3 + K_{11}} V(T^2) V(\Psi^2)$$
(10)

$$\partial_t \Psi = 4l_7 V(Q) V(L_2 - N) - 4l_8 V(L_1 - T) V(\Psi^4)$$

-k_1 V(E_1) V(\Psi) - 4k_4 V(N_2) V(\Psi^4) \frac{E_4}{1 + E_4 + H_2/2}
-2k_6 $\frac{E_3}{E_3 + K_{11}} V(T^2) V(\Psi^2) - \alpha_{\Psi} \Psi$ (11)

$$\partial_t O_2 = O_{20} \frac{K_5}{K_5 + O_2} - k_2 \frac{V(O_2)V(L_1 - Q)}{1 + \Psi^2}$$
(12)

$$\partial_t E_1 = E_{10} \frac{A}{A + \beta_1} \frac{K_1}{K_1 + A^4} - k_1 V(E_1) V(\Psi)$$

+ $k_4 V(N_2) V(\Psi^4) \frac{E_4}{1 + E_4 + H_2/2} - k_5 V(E_1) V(L_2 - N)$
+ $k_6 \frac{E_3}{E_3 + K_{11}} V(T^2) V(\Psi^2) - k_7 V(E_1) V(H_2) - \alpha_{E_1} E_1$ (13)

$$\partial_t E_3 = k_1 V(E_1) V(\Psi) - k_3 V(T^4) \frac{E_3}{1 + E_3 + O_2} + k_5 V(E_1) V(L_2 - N) - k_6 \frac{E_3}{E_3 + K_{11}} V(T^2) V(\Psi^2) + k_7 V(E_1) V(H_2)$$
(14)

$$\partial_t E_4 = k_3 V(T^4) \frac{E_3}{1 + E_3 + O_2} -k_4 V(N_2) V(\Psi^4) \frac{E_4}{1 + E_4 + H_2/2}$$
(15)
$$\partial_t N_2 = N_{22} \frac{K_2}{K_2} = -$$

$$\partial_t N_2 = N_{20} \frac{E_2}{K_2 + N_2} - \frac{E_4}{K_2 + N_2} - \alpha_{N_2} N_2$$
(16)

$$\partial_t A = k_4 V(N_2) V(\Psi^4) \frac{E_4}{1 + E_4 + H_2/2} - \alpha_A A \quad (17)$$

$$\partial_t H_2 = k_6 \frac{E_3}{E_3 + K_{11}} V(T^2) V(\Psi^2) -k_7 V(E_1) V(H_2) - \alpha_{H_2} H_2$$
(18)

where V(x) = x/(x + 1). The dynamic variables $S(t), ..., S_6(t)$ describe the Krebs cycle. The variables $Q(t), \Psi(t), T(t), O_2(t)$ describe the respiratory chain, the kinetic membrane potential, the ATP concentration, and the concentration of molecular oxygen, respectively [1, 2].

This block of the model is responsible for the describing the bioenergetics of a cell. The crucial enzyme nitrogenase participates in its three forms [3–5] E_1 , E_3 , E_4 . Its activity is regulated by molecular hydrogen H_2 and molecular nitrogen N_2 , while the biosynthesis is regulated by ammonia A, which is present in the biosystem.

Serving as an electron donor here is $NAD \cdot H_2 \equiv N$.

The optimal regime of the biosystem is described by the following set of parameter values:

$$\begin{split} l_1 &= 0.3, \ l_2 = 0.3, \ l_3 = 0.3, \\ l_4 &= 0.03, \ l_5 = 0.3, \ l_6 = 0.3, \\ l_7 &= 0.4, \ l_8 = 0.2, \ k_1 = 0.01, \\ k_2 &= 0.05, \ k_3 = 0.05, \ k_4 = 0.06, \\ k_5 &= 0.05, \ k_6 = 0.03, \ k_7 = 0.003, \\ L_1 &= 3, \ L_2 &= 2, \ L_3 &= 2, \\ K &= 0.3, \ K_1 &= 0.006, \ K_2 &= 0.3, \\ \alpha_S &= 0.005, \ \alpha_A &= 0.0045, \ O_{20} &= 0.02, \\ E_{10} &= 0.02, \ \beta &= 0.1, \ N_{20} &= 0.2. \end{split}$$

The kinetics of the biosystem exhibits a self-regulation. Under the open environmental conditions conditions described by the parameters $S_0, O_{20}, N_{20}, \alpha_S, \alpha_1, \alpha_2, ...$ the phase-portrait of the biosystem includes a structural adapter characterized by stable oscillations and does not dependent from a initial state of the biosystem (Cauchy data).

The presence of oscillations in the biosystem is determined primarily by the interaction of self-regulated subsystems: the Krebs cycle, the respiratory chain, and the nitrogenase complex.

Furthermore, the process of biosynthesis of nitrogenase in form of E_1 depends on the ammonia concentration in a nonmonotonic way. This circumstance is expressed by the nonlinear term in (13):

$$E_{10}\frac{A}{A+\beta_1}\frac{K_1}{K_1+A^4}$$

At small values of A, the synthesis of E_1 is induced, while a large value of A results in a repression of E_1 .

At the pumping parameter value $S_0 = 0.07$, a strange attractor exists in the phase space of the system. Figure 1 shows a projection of the phase portrait of a strange attractor in the coordinates (A, Ψ) .

The given regime forms form a limiting-cycle regime through an infinite sequence of period-doubling bifurcations. [6].

Figure 2 shows the kinetics of simple periodic oscillations of the variables from a Krebs cycle. Figure 3 shows the kinetic behavior of the respiratory chain, of the kinetic membrane potential, of the ATP, and of molecular oxygen. Figure 4 shows the time evolution of the biosynthesis of the nitrogenase complex. We see from these figures that we have a self-regulation of the biosystem in an oscillatory regime: At high values of A AA, we have low levels of E_1 , E_3 , E_4 ; low values of Acorresponds to high values of E_1 , E_3 , E_4 . This situation determines the kinetic behavior of the other reactants.

At the parameter value $S_0 = 0.063$ the attractor is a limiting cycle. At the point $S_0 = 0.065$ this limiting cycle undergoes a bifurcation into a limiting cycle with a period t twice the original period. The limiting cycle which is generated at $S_0 = 0.0689$ again doubles through a period-doubling bifurcation. The next bifurcation point found is $S_0 = 0.06932$. After an infinite sequence of doubling bifurcations of the limiting cycle, an aperiodic oscillatory attractive regime - a strangeattractor regime - appears in the phase space.
