

SPARSE RECOVERY PROPERTIES OF DISCRETE RANDOM MATRICES

ASAF FERBER, ASHWIN SAH, MEHTAAB SAWHNEY, AND YIZHE ZHU

ABSTRACT. Motivated by problems from compressed sensing, we determine the threshold behavior of a random $n \times d$ ± 1 matrix $M_{n,d}$ with respect to the property “every s columns are linearly independent”. In particular, we show that for every $0 < \delta < 1$ and $s = (1 - \delta)n$, if $d \leq n^{1+1/2(1-\delta)-o(1)}$ then whp every s columns of $M_{n,d}$ are linearly independent, and if $d \geq n^{1+1/2(1-\delta)+o(1)}$ then whp there are some s linearly dependent columns.

1. INTRODUCTION

Compressed sensing is a modern technique of data acquisition, which is at the intersection of mathematics, electrical engineering, computer science, and physics, and has tremendously grown in recent years. Mathematically, we define an unknown signal as a vector $\mathbf{x} \in \mathbb{R}^d$, and we have access to *linear measurements*: that is, for any vector $\mathbf{a} \in \mathbb{R}^d$, we have access to $\mathbf{a} \cdot \mathbf{x} = \sum_{i=1}^d a_i x_i$. In particular, if $\mathbf{a}^{(1)}, \dots, \mathbf{a}^{(n)} \in \mathbb{R}^d$ are the measurements we make, then we have an access to the vector $\mathbf{b} := A\mathbf{x}$, where

$$A := \begin{pmatrix} - & \mathbf{a}^{(1)} & - \\ & \vdots & \\ - & \mathbf{a}^{(n)} & - \end{pmatrix}.$$

The tasks of compressed sensing are: (i) to recover \mathbf{x} from A and \mathbf{b} as accurately as possible, and (ii) doing so in an efficient way. In practice, one would like to recover a high dimensional signal (that is, d is large) from as few measurements as possible (that is, n is small). In this regime, for an arbitrary vector $x \in \mathbb{R}^d$ the problem is ill-posed: for any given \mathbf{b} , the solution of $\mathbf{b} = A\mathbf{x}$, if exists, forms a (translation of) linear subspace of dimension at least $d - n$, and therefore there is no way to uniquely recover the original \mathbf{x} .

A key quantity to look at to guarantee the success of (unique) recovery is the *sparsity* of the vector \mathbf{x} , and we say that a vector is s -sparse if its *support* is of size at most s . That is, if

$$|\text{supp}(\mathbf{x})| = \{i : x_i \neq 0\} \leq s.$$

A neat observation is that having at most one s -sparse solution to $A\mathbf{x} = \mathbf{b}$ for every \mathbf{b} is equivalent to saying that A is $2s$ -robust (that is, every $2s$ columns of A are linearly independent). Indeed, if we have two s -sparse vectors $\mathbf{x} \neq \mathbf{y}$ such that $A\mathbf{x} = A\mathbf{y}$ then $\mathbf{x} - \mathbf{y}$ is a nonzero $2s$ -sparse vector in the kernel of A . For the other direction, if there is a nonzero $2s$ -sparse vector in the kernel of A , one can split its support into two disjoint sets of size at most s each and consider the vectors restricted to these sets, one of which is multiplied by -1 .

If we take A to be a random Gaussian matrix A (or any other matrix drawn from some “nice” continuous distribution), then we clearly have that with probability one A is s -robust for $n = s$ and any $d \in \mathbb{N}$ (and in particular, one can uniquely recover $s/2$ -sparse vectors). Moreover, in their seminal work, Candes and Tao [3] showed that it is possible to efficiently reconstruct \mathbf{x} with very high accuracy by solving a simple linear program if we take $n = O(s \log(d/s))$.

Sah and Sawhney were supported by NSF Graduate Research Fellowship Program DGE-1745302. Sah was supported by the PD Soros Fellowship. Zhu was supported by NSF-Simons Research Collaborations on the Mathematical and Scientific Foundations of Deep Learning.

In this paper, we are interested in the compressed sensing problem with integer-valued measurement matrices and with entries of magnitude at most k . Integer-valued measurement matrices have found applications in measuring gene regulatory expressions, wireless communications, and natural images [1, 4, 12], and they are quick to generate and easy to store in practice [13, 14]. Under this setting, for integer-valued signal \mathbf{x} , we can have exact recovery even if we allow some noise \mathbf{e} with $\|\mathbf{e}\|_\infty < 1/2$ (for more details, see [10]).

The first step is to understand when the compressed sensing problem is well-posed for given s, n, k , and d . Namely, for which values of s, n, k and d does an s -robust $n \times d$ integer-valued matrix with entries in $\{-k, \dots, k\}$ exist? For $s = n$, observe that if $d \geq (2k + 1)^2 n$, then by pigeonhole one can find n columns for which their first two rows are proportional and therefore are not linearly independent. In particular, we have $d = O_k(n)$. In [10], Fukshansky, Needell, and Sudakov showed that there exists an s -robust A with $d = \Omega(\sqrt{kn})$, using the result of Bourgain, Vu and Wood [2] on the singularity of discrete random matrices (in fact, the more recent result by Tikhomirov [17] gives a better bound for $k = 1$). Konyagin and Sudakov [15] improved the upper bound to $d = O(k\sqrt{\log kn})$, and they gave a deterministic construction of A when $d \geq \frac{1}{2}k^{n/(n-1)} > n$.

When $1 \leq s \leq n - 1$ and $k = 2$, Fukshansky and Hsu [9] gave a deterministic construction such that $d \geq \left(\frac{n+2}{2}\right)^{1+\frac{2}{3s-2}}$. When $s = o(\log n)$, this implies we can take $d = \omega(n)$. This result hints that if we allow s to be “separated away” from n , then one could take d to be “very large”. A natural and nontrivial step to understand the s -robustness property of matrices is to investigate the *typical* behavior. For convenience, we will focus on the case $k = 1$ (even though our argument can be generalized to all fixed k), and we define, for all $n, d \in \mathbb{N}$, the random variable $M_{n,d}$ which corresponds to an $n \times d$ matrix with independent entries chosen uniformly from $\{\pm 1\}$. For $1 \leq s \leq n$, we would like to investigate the *threshold* behavior of $M := M_{n,d}$ with respect to being s -robust. That is, we wish to find some $d^* := d(s, n)$ such that

$$\lim_{n \rightarrow \infty} \mathbb{P}[M \text{ is } s\text{-robust}] = \begin{cases} 0 & d/d^* \rightarrow \infty \\ 1 & d/d^* \rightarrow 0. \end{cases}$$

It is trivial to show (deterministically) that if $s = n$ and M is s -robust, then $d \leq 2n$. What if we allow s to be “separated away” from n ? That is, what if $s = (1 - \delta)n$ for some $0 < \delta < 1$? It is not hard to show (and it follows from the proof of Lemma 3.3) that the probability for a random $n \times n$ matrix to have rank at least $(1 - \delta)n$ is at least $1 - 2^{-\Omega(\delta^2 n^2)}$. Therefore, one could think that a typical $M_{n,d}$ might $(1 - \delta)n$ -robust for some $d = 2^{n^{1-o(1)}}$. This turns out to be wrong as we show in the following simple theorem:

Theorem 1.1. *For any fixed $0 < \delta < 1$ there exists $C > 0$ such that for sufficiently large $n \in \mathbb{N}$ the following holds. If $s = (1 - \delta)n$ and $d \geq Cn^{1+1/(1-\delta)}$, then every ± 1 $n \times d$ matrix M is not s -robust.*

Proof. Given any subset $\mathbf{v}_1, \dots, \mathbf{v}_{s/2} \in \{\pm 1\}^n$, by Spencer’s “six standard deviations suffice” [16], there exist some $x_1, \dots, x_s \in \{\pm 1\}$ for which $\|\sum_{i=1}^s x_i \mathbf{v}_i\|_\infty = O(\sqrt{n})$ (a simple Chernoff bound suffices if one is willing to lose a $\sqrt{\log n}$ factor). Fix such a combination for each $s/2$ -subset of columns. Since there are at most $(3C'\sqrt{n})^n$ integer-valued vectors in the box $[-C'\sqrt{n}, C'\sqrt{n}]^n$, and since

$$\binom{d}{s/2} \geq \left(\frac{d}{s}\right)^{s/2} = \left(\frac{Cn^{1/(1-\delta)}}{1-\delta}\right)^{(1-\delta)n/2} > (3C'\sqrt{n})^n,$$

by pigeonhole as long as C is large enough, there are two $s/2$ -subsets with some signed sum equal to the same vector. Subtracting the corresponding kernel vectors leads to a nonzero s -sparse kernel vector of M (since their supports are not the same), proving the result. \square

In our main result we determine the (typical) asymptotic behavior up to a window of $(\log n)^{\omega(1)}$.

Theorem 1.2. For any fixed $0 < \delta < 1$, let $n \in \mathbb{N}$ be sufficiently large, let $s = (1 - \delta)n$, and let $\varepsilon = \omega(\log \log n / \log n)$. We have that:

- (1) If $d \leq n^{1+1/(2-2\delta)-\varepsilon}$ then whp $M_{n,d}$ is s -robust.
- (2) If $d \geq n^{1+1/(2-2\delta)+\varepsilon}$ then whp $M_{n,d}$ is not s -robust.

We believe that by optimizing our bounds/similar methods one would be able push the bounds in [Theorem 1.2](#) up to a constant factor of $n^{1+1/(2-2\delta)}$ (though we did not focus on this aspect). It would be interesting to obtain the $1 + o(1)$ multiplicative threshold behavior.

2. PROOF OUTLINE

We first outline the proof of [Theorem 1.2](#). We will prove it over \mathbb{F}_p for some prime $p = e^{\omega(\log^2 n)}$ to be chosen later (a stronger statement). Our strategy, at large, is to generate M as

$$M = \begin{pmatrix} M_1 \\ M_2 \end{pmatrix}$$

where $M_1 = M_{n_1,d}$ and $M_2 = M_{n_2,d}$, with $n_1 \approx n$ and $n_2 = o(n)$. The proof consists of the following two phases:

- (1) **Phase 1:** Given any vector $\mathbf{a} \in \mathbb{F}_p^d$, we let

$$\rho_{\mathbb{F}_p}(\mathbf{a}) = \max_{x \in \mathbb{F}_p} \mathbb{P} \left[\sum_{i=1}^d a_i \xi_i = x \right], \quad (2.1)$$

where the ξ_i s are i.i.d. Rademacher random variables. In this phase we will show that

- (a) M_1 is whp such that for all $\mathbf{a} \in \mathbb{F}_p^d$, if $|\text{supp } \mathbf{a}| \leq s := (1 - \delta)n$ and $M_1 \mathbf{a} = \mathbf{0}$, then $\rho_{\mathbb{F}_p}(\mathbf{a}) = e^{-\omega(\log^2 n)}$, and
- (b) M_1 is whp such that every s -subset of its columns has rank $s - o(s)$.
- (2) **Phase 2:** Conditioned on the above properties, we will use the extra randomness of M_2 to show that for a specific set of s columns, after exposing M_2 , the probability that it does not have full rank is $o\left(1/\binom{d}{s}\right)$, and hence a simple union bound will give us the desired result.

In this strategy, it turns out that **Phase 1(a)** is the limiting factor, i.e., ruling out structured kernel vectors.

For the proof of the upper bound in [Theorem 1.2](#), we exploit this observation. We show using the second-moment method that it is highly likely that some $2\lfloor(1 - \delta)n/2\rfloor$ columns sum to the zero vector (corresponding to an all 1s, highly structured kernel vector).

3. PROOF OF THE LOWER BOUND IN [THEOREM 1.2](#)

In this section we prove [Theorem 1.2](#). Let (say) $p \approx e^{\log^3 n}$ be a prime, let $d = n^{1+1/(2-2\delta)-\varepsilon}$ and $s = (1 - \delta)n$ as given, and $n_1 = (1 - \beta)n$ where $\beta = \omega(1/\log n)$ and $\beta = o(\log \log n / \log n)$. As described in [Section 2](#), our proof consists of two phases, each of which will be handled separately.

3.1. Phase 1: no sparse structured vectors in the kernel of M_1 . Our first goal is to prove the following proposition.

Proposition 3.1. $M_{n_1,d}$ is whp such that for every $(1 - \delta)n$ -sparse vector $\mathbf{a} \in \mathbb{F}_p^d \setminus \{\mathbf{0}\}$, if $M_1 \mathbf{a} = \mathbf{0}$ then $\rho_{\mathbb{F}_p}(\mathbf{a}) = e^{-\omega(\log^2 n)}$.

In order to prove the above proposition, we need some auxiliary results.

Lemma 3.2. $M_{n_1,d}$ is whp $n/\log^4 n$ -robust over \mathbb{F}_p .

Proof. Observe that for any $\mathbf{a} \in \mathbb{F}_p^d \setminus \{\mathbf{0}\}$ we trivially have that $\mathbb{P}[M_1 \mathbf{a} = \mathbf{0}] \leq 2^{-n_1} = 2^{-\Theta(n)}$. Since there are at most

$$\binom{d}{n/\log^4 n} p^{n/\log^4 n} \leq \left(\frac{edp \log^4 n}{n} \right)^{n/\log^4 n} = 2^{o(n)}$$

$n/\log^4 n$ -sparse vectors $\mathbf{a} \in \mathbb{F}_p^d$, by a simple union bound we obtain that the probability for such an \mathbf{a} to satisfy $M_1 \mathbf{a} = \mathbf{0}$ is $o(1)$. This completes the proof. \square

In particular, by combining the above lemma with the Erdős-Littlewood-Offord inequality [5], we conclude that if $\mathbf{a} \in \mathbb{F}_p^d$ is $(1 - \delta)n$ -sparse and $M_1 \mathbf{a} = \mathbf{0}$, then $\rho_{\mathbb{F}_p}(\mathbf{a}) = O(\log^2 n/n^{1/2})$. However, to prove Proposition 3.1, we need a stronger estimate.

The following lemma asserts that every subset of s columns in M_1 has large rank. It will be crucial in Phase 2.

Lemma 3.3. *Let $t = \omega(\log n)$. Then, whp $M_1 = M_{n_1, d}$ is such that every subset of s columns contains at least $s - t$ linearly independent columns.*

Proof. Consider the event that one such subset has rank at most $s - t$. There are $\binom{d}{s} \leq d^s \leq n^n$ possible choices of columns. For each such choice, there are at most $2^s \leq 2^n$ ways to choose a spanning set of $r \leq s - t$ columns. Such a subset has span containing at most 2^s many $\{\pm 1\}$ vectors (indeed, consider a full-rank $r \times r$ sub-block; any $\{\pm 1\}$ vector in the span of the columns is determined by its value on these r coordinates), so the probability that the remaining at least $t = \omega(\log n)$ columns are in the span is at most $(2^s/2^{n_1})^t \leq (2^{-(\delta-\beta)n})^t = o(n^{-n})$. Taking a union bound, the result follows. \square

Next, we state a version of Halász's inequality ([11, Theorem 3]) as well as a ‘‘counting inverse Littlewood-Offord theorem’’ as was developed in [7].

Definition 3.4. Let $\mathbf{a} \in \mathbb{F}_p^n$ and $k \in \mathbb{N}$. We define $R_k^*(\mathbf{a})$ to be the number of solutions to

$$\pm a_{i_1} \pm a_2 \pm \dots \pm a_{i_{2k}} \equiv 0 \pmod{p}$$

with $|\{i_1, \dots, i_{2k}\}| > 1.01k$.

Theorem 3.5 ([7, Theorem 1.4]). *Given an odd prime p , integer n , and vector $\mathbf{a} = (a_1, \dots, a_n) \in \mathbb{F}_p^n \setminus \{\mathbf{0}\}$, suppose that an integer $0 \leq k \leq n/2$ and positive real L satisfy $30L \leq |\text{supp}(\mathbf{a})|$ and $80kL \leq n$. Then*

$$\rho_{\mathbb{F}_p}(\mathbf{a}) \leq \frac{1}{p} + C_{3.5} \frac{R_k^*(\mathbf{a}) + ((40k)^{0.99} n^{1.01})^k}{2^{2k} n^{2k} L^{1/2}} + e^{-L}.$$

Theorem 3.6 ([7, Theorem 1.7]). *Let p be a prime, let $k, n \in \mathbb{N}$, $s \in [n]$ and $t \in [p]$. Define $\mathbf{B}_{k, m, \geq t}(s, d)$ as the following set:*

$$\left\{ \mathbf{a} \in \mathbb{F}_p^d : |\text{supp}(\mathbf{a})| \leq s, \text{ and } R_k^*(\mathbf{b}) \geq t \cdot \frac{2^{2k} \cdot |\mathbf{b}|^{2k}}{p} \text{ for every } \mathbf{b} \subseteq \mathbf{a} \text{ with } |\mathbf{b}| \geq m \right\}.$$

We have

$$|\mathbf{B}_{k, m, \geq t}(s, d)| \leq \binom{d}{s} \left(\frac{m}{s} \right)^{2k-1} (1.01t)^{m-s} p^s.$$

We now are in position to prove Proposition 3.1. The proof is quite similar to the proofs in [6–8].

Proof of Proposition 3.1. Let $k = \log^3 n$ and $m = n/\log^4 n, p \approx e^{\log^3 n}$.

First we use Lemma 3.2 to rule out vectors \mathbf{a} with a support of size less than $n/\log^4 n$. Next, let (say) $L = n/\log^{10} n$ and let $\sqrt{L} \leq t \leq p$.

Consider a fixed $\mathbf{a} \in \mathbf{B}_{k,m,\geq t}(s,d) \setminus \mathbf{B}_{k,m,\geq 2t}(s,d)$ and we wish to bound the probability that $M_1 \mathbf{a} = \mathbf{0}$. By definition, there is a set $S \subseteq \text{supp}(\mathbf{a})$ of size at least m such that

$$R_k^*(\mathbf{a}|_S) < 2t \cdot \frac{2^{2k}|S|^{2k}}{p}. \quad (3.1)$$

Since the rows are independent and since $\rho_{\mathbb{F}_p}(\mathbf{a}) \leq \rho_{\mathbb{F}_p}(\mathbf{a}|_S)$, the probability that $M_1 \mathbf{a} = \mathbf{0}$ is at most $\rho_{\mathbb{F}_p}(\mathbf{a}|_S)^{n_1}$. Furthermore, by [Theorem 3.5](#) and the given conditions, which guarantee $30L \leq m \leq |\text{supp}(\mathbf{a}|_S)|$ and $80kL \leq m \leq |S|$, and by $\sqrt{L} \leq t \leq p$, we have

$$\begin{aligned} \rho_{\mathbb{F}_p}(\mathbf{a}|_S) &\leq \frac{1}{p} + C_{3.5} \frac{R_k^*(\mathbf{a}|_S) + ((40k)^{0.99}|S|^{1.01})^k}{2^{2k}|S|^{2k}L^{1/2}} + e^{-L} \\ &\leq \frac{1}{p} + \frac{2C_{3.5}t}{p\sqrt{L}} + \frac{10^k C_{3.5}}{L^{1/2}} \left(\frac{k}{|S|}\right)^{0.99k} + e^{-L} \\ &\leq \frac{Ct}{p\sqrt{L}} \end{aligned} \quad (3.2)$$

for all sufficiently large n by [\(3.1\)](#). All in all, taking a union bound over all the possible choices of \mathbf{a} ([Theorem 3.6](#)), and using the fact that $s = (1 - \delta)n$ and $n_1 = (1 - \beta)n$ with $\beta = \omega(1/\log n)$, we obtain the bound

$$\begin{aligned} \binom{d}{s} \left(\frac{m}{s}\right)^{2k-1} (1.01t)^{m-s} p^s \left(\frac{Ct}{p\sqrt{L}}\right)^{n_1} &\leq \left(\frac{ed}{s}\right)^s (1.01t)^m \left(\frac{p}{1.01t}\right)^s \left(\frac{Ct}{p\sqrt{L}}\right)^{(1-\beta)n} \\ &\leq \left(\frac{ed}{(1-\delta)n}\right)^{(1-\delta)n} 2^{o(n)} \left(\frac{1.01t}{p}\right)^{(\delta-\beta)n} \left(\frac{C(\log n)^5}{\sqrt{n}}\right)^{(1-\beta)n} \\ &= o(1/p) \end{aligned}$$

on the probability M_1 has such a kernel vector for sufficiently large n . Here we used the bounds $d \leq n^{1+1/(2-2\delta)-\varepsilon}$, $\varepsilon = \omega(\log \log n / \log n)$ and $\beta = o(\varepsilon)$. Union bounding over all possible values of t shows that there is an appropriately small chance of having such a vector for any $t \geq \sqrt{L}$.

Finally, note that $B_{k,m,\geq p}(s,d)$ is empty and thus the above shows that kernel vectors \mathbf{a} cannot be in $\mathbf{B}_{k,m,\geq \sqrt{L}}(s,d)$. A similar argument as in [\(3.1\)](#) and [\(3.2\)](#) shows that

$$\rho_{\mathbb{F}_p}(\mathbf{a}) \leq \frac{C'}{p},$$

and the result follows. \square

3.2. Phase 2: boosting the rank using M_2 . Here we show that, conditioned on the the conclusions of [Proposition 3.1](#) and [Lemma 3.3](#), after exposing M_2 whp $M = \begin{pmatrix} M_1 \\ M_2 \end{pmatrix}$ is s -robust.

To analyze the probability that a given subset of s columns is not of full rank, we will use the following procedure:

Fix any subset of s columns in M_1 , and let $C := (\mathbf{c}_1, \dots, \mathbf{c}_s)$ be the submatrix in M_1 that consists of those columns. We reveal M_2 according to the following steps:

- (1) Let $I \subseteq [s]$ be the largest subset of indices such that the columns $\{\mathbf{c}_i \mid i \in I\}$ are linearly independent. By [Lemma 3.3](#) we have that $T := |I| \geq s - t = (1 - \delta)n - t$, where $t = \omega(\log n)$. Without loss of generality we may assume that $I := \{\mathbf{c}_1, \dots, \mathbf{c}_T\}$ and $T \leq s - 1$ (otherwise we have already found s independent columns of M). By maximality, we know that \mathbf{c}_{T+1} can be written (uniquely) as a linear combination of $\mathbf{c}_1, \dots, \mathbf{c}_T$. That is, there exists a

unique combination for which $\sum_{i=1}^T x_i \mathbf{c}_i = \mathbf{c}_{T+1}$. In particular, this means that

$$\sum_{i=1}^T x_i \mathbf{c}_i - \mathbf{c}_{T+1} = 0,$$

and hence the vector $\mathbf{x} = (0, \dots, x_1, \dots, x_T, -1, \dots, 0)^T \in \mathbb{F}_q^d$ is $(T+1)$ -sparse and satisfies $M_1 \mathbf{x} = 0$. Since $T+1 \leq s$, by [Proposition 3.1](#) we know that $\rho_{\mathbb{F}_p}(\mathbf{x}) = 2^{-\omega(\log^2 n)}$.

- (2) Expose the row vector of dimension $T+1$ from M_2 below the matrix $(\mathbf{c}_1, \dots, \mathbf{c}_{T+1})$. We obtain a matrix of size $(n_1+1) \times (T+1)$. Denote the new row as (y_1, \dots, y_{T+1}) .
- (3) If the new matrix is of rank $T+1$, then consider this step as a “success”, expose the entire row and start over from (1). Otherwise, consider this step as a “failure” (As we failed to increase the rank) and observe that if $\begin{bmatrix} \mathbf{c}_1 & \cdots & \mathbf{c}_{T+1} \\ y_1 & \cdots & y_{T+1} \end{bmatrix}$ is not of full rank, then we must have

$$x_1 y_1 + x_2 y_2 + \dots - y_{T+1} = 0.$$

The probability to expose such a vector y is at most $\rho_{\mathbb{F}_p}(\mathbf{x}) = e^{-\omega(\log^2 n)}$.

- (4) All in all, the probability for more than $\beta n - t$ failures is at most $\binom{\beta n}{t} \left(e^{-\omega(\log^2 n)} \right)^{\beta n - t} = e^{-\omega(n \log n)} = o\left(\binom{d}{s}^{-1}\right)$. Therefore, by the union bound we obtain that whp M is s -robust.

This completes the proof.

4. PROOF OF THE UPPER BOUND IN [THEOREM 1.2](#)

We first perform preliminary computations to compute a certain correlation. This boils down to estimating binomial sums. Let ξ_i, ξ'_i be independent Rademacher variables and define

$$\alpha(n, m) = \frac{\mathbb{P}[\xi_1 + \dots + \xi_n = \xi_1 + \dots + \xi_m + \xi'_{m+1} + \dots + \xi'_n = 0]}{\mathbb{P}[\xi_1 + \dots + \xi_n = 0]^2}.$$

Clearly $\alpha(n, m) \leq \alpha(n, n) \leq 10\sqrt{n}$ by [\[5\]](#).

Lemma 4.1. *Fix $\lambda > 0$. If n is even and $0 \leq m \leq (1 - \varepsilon)n$ we have*

$$\alpha(n, m) = 1 + O(m/(\varepsilon n)).$$

Proof. We have

$$\alpha(n, m) \leq \frac{\sup_k \mathbb{P}[\xi_1 + \dots + \xi_{n-m} = k]}{\mathbb{P}[\xi_1 + \dots + \xi_n = 0]^2} \leq \frac{2^{-(n-m)} \binom{n-m}{\lfloor (n-m)/2 \rfloor}}{2^{-n} \binom{n}{n/2}} = 1 + O(m/(n-m)). \quad \square$$

We will also need a more refined bound when m is small.

Lemma 4.2. *If n is even and $0 \leq m \leq n^{1/2}$, we have*

$$\alpha(n, m) = 1 + O(m^2/n^2).$$

Proof. Using the approximation $1 - x = \exp(-x - x^2/2 + O(x^3))$ for $|x| \leq 1/2$ we see that if y is an integer satisfying $1 \leq y \leq x/2$ then

$$\begin{aligned} x(x-1)\cdots(x-y+1) &= x^y \exp\left(-\sum_{i=0}^{y-1} \frac{i}{x} - \sum_{i=0}^{y-1} \frac{i^2}{2x^2} + O\left(\frac{y^4}{x^3}\right)\right) \\ &= x^y \exp\left(-\frac{y(y-1)}{2x} - \frac{y(y-1)(2y-1)}{12x^2} + O\left(\frac{y^4}{x^3}\right)\right). \end{aligned} \quad (4.1)$$

We now apply this to the situation at hand. We see $\alpha(n, m)$ is equal to

$$\begin{aligned}
& \frac{2^{-(2n-m)} \sum_{k=0}^s \binom{m}{k} \binom{n-m}{n/2-k}^2}{2^{-2n} \binom{n}{n/2}^2} \\
&= 2^m \sum_{k=0}^m \binom{m}{k} \left(\frac{(n/2)(n/2-1) \cdots (n/2-k+1) \times (n/2)(n/2-1) \cdots (n/2-(m-k)+1)}{n(n-1) \cdots (n-m+1)} \right)^2 \\
&= 2^m \sum_{k=0}^m \binom{m}{k} \left(\frac{(n/2)^m e^{-\frac{k(k-1)}{n} - \frac{k(k-1)(2k-1)}{3n^2} - \frac{(m-k)(m-k-1)}{n} - \frac{(m-k)(m-k-1)(2m-2k-1)}{3n^2} + O(m^4/n^3)}}{n^m e^{-\frac{m(m-1)}{2n} - \frac{m(m-1)(2m-1)}{12n^2} + O(m^4/n^3)}} \right)^2 \\
&= 2^{-m} \sum_{k=0}^m \binom{m}{k} \exp \left(-\frac{m^3 - 4mk(m-k) + n(2k-m)^2 - nm}{2n^2} + O(m^2/n^2) \right) \\
&= 2^{-m} \sum_{k=0}^m \binom{m}{k} \left(1 - \frac{m^3 - 4mk(m-k) - nm}{2n^2} + O(m^2/n^2) \right) \left(1 - \frac{(2k-m)^2}{2n} + O\left(\frac{(2k-m)^4}{n^2}\right) \right) \\
&= 2^{-m} \sum_{k=0}^m \binom{m}{k} \left(1 - \frac{m^3 - 4mk(m-k) - nm}{2n^2} \right) \left(1 - \frac{(2k-m)^2}{2n} \right) + O(m^2/n^2).
\end{aligned}$$

In the third line we used (4.1) and in the fourth line we simplified the expression and used $k \leq m \leq n^{1/2}$ to subsume many terms into an error of size $O(m^2/n^2)$. The fifth line used $\exp(x) = 1 + x + O(x^2)$ for $|x| \leq 1$ and the sixth line uses $2^{-m} \binom{m}{k} (2k-m)^4 \leq 2m^2 \exp(-(2k-m)^2/100)$. Finally, this sum equals

$$\alpha(n, m) = 1 - \frac{3nm^2 - 3m^3 + 2m^2}{4n^3} + O(m^2/n^2) = 1 + O(m^2/n^2). \quad \square$$

We are ready to prove the upper bound in [Theorem 1.2](#).

Proof of the upper bound in [Theorem 1.2](#). We are given $\delta \in (0, 1)$ and $\varepsilon = \omega(\log \log n / \log n)$, with $d = n^{1+1/(2-2\delta)+\varepsilon}$. Let $s = 2\lfloor(1-\delta)n/2\rfloor$. We consider an $n \times d$ random matrix with independent Rademacher entries and wish to show it is not s -robust whp. We may assume $\varepsilon < 1/2$ as increasing d makes the desired statement strictly easier.

For an s -tuple of columns labeled by index set $S \subseteq [d]$, let X_S be the indicator of the event that these columns sum to the zero vector. Let $X = \sum_{S \in \binom{[d]}{s}} X_S$, and let (ξ_1, \dots, ξ_d) be a vector of independent Rademachers. We have

$$\mathbb{E}X = \binom{d}{s} \mathbb{E}X_{[s]} = \binom{d}{s} \mathbb{P}[\xi_1 + \cdots + \xi_s = 0]^n = \binom{d}{s} \left(2^{-s} \binom{s}{s/2} \right)^n$$

and

$$\begin{aligned}
\text{Var } X &= \mathbb{E}X^2 - (\mathbb{E}X)^2 = \sum_{S, T \in \binom{[d]}{s}} \left(\mathbb{P} \left[\sum_{i \in S} \xi_i = \sum_{j \in T} \xi_j = 0 \right]^n - \mathbb{P}[\xi_1 + \cdots + \xi_s = 0]^{2n} \right) \\
&= (\mathbb{E}X)^2 \cdot \frac{1}{\binom{d}{s}^2} \sum_{S, T \in \binom{[d]}{s}} \left(\frac{\mathbb{P} \left[\sum_{i \in S} \xi_i = \sum_{j \in T} \xi_j = 0 \right]^n}{\mathbb{P}[\xi_1 + \cdots + \xi_n = 0]^{2n}} - 1 \right) \\
&= (\mathbb{E}X)^2 \sum_{m=0}^s \frac{\binom{s}{m} \binom{d-s}{s-m}}{\binom{d}{s}} \cdot (\alpha(s, m)^n - 1).
\end{aligned}$$

For every $\eta > 0$ and $m \leq c_\eta n^{1/2}$, where c_η is a sufficiently small absolute constant in terms of η , we see $|\alpha(s, m)^n - 1| \leq \eta$ by [Lemma 4.2](#). For $c_\eta n^{1/2} < m \leq (1-\varepsilon/8)s$ we have $\alpha(s, m)^n \leq \exp(O(m/\varepsilon))$

by Lemma 4.1. For this range we have, since $m/s \geq n^{\delta/2}s/d$,

$$\frac{\binom{s}{m}\binom{d-s}{s-m}}{\binom{d}{s}} \leq (s+1)\mathbb{P}[\text{Bin}(s, s/d) \geq m] \leq \exp(-sD(m/(2s)||s/d)) \leq \exp(-m(\delta/4)\log n)$$

by Chernoff–Hoeffding (the fact that $\text{Bin}(n, p)$ exceeds nq for $q \geq p$ with probability at most $\exp(-nD(q||p))$, where this is the KL-divergence). Thus

$$\sum_{m=c\sqrt{n}}^{(1-\varepsilon)s} \frac{\binom{s}{m}\binom{d-s}{s-m}}{\binom{d}{s}} \cdot (\alpha(s, m)^n - 1) \leq \sum_{m=c\sqrt{n}}^{(1-\varepsilon)s} \exp(O(m/\varepsilon)) \cdot \exp(-m(\delta/4)\log n) = o(1)$$

as $\varepsilon = \omega(\log \log n / \log n)$.

Finally for $(1 - \varepsilon/8)s \leq m \leq s$ we have

$$\sum_{m=(1-\varepsilon)s}^s \frac{\binom{s}{m}\binom{d-s}{s-m}}{\binom{d}{s}} \cdot (\alpha(s, m)^n - 1) \leq \sum_{m=(1-\varepsilon)s}^s \frac{\binom{s}{m}\binom{d-s}{s-m}}{\binom{d}{s}} (10\sqrt{n})^n \leq 2^s \frac{\binom{d}{\varepsilon s/8}}{\binom{d}{s}} (10\sqrt{n})^n.$$

Thus

$$\sum_{m=(1-\varepsilon)s}^s \frac{\binom{s}{m}\binom{d-s}{s-m}}{\binom{d}{s}} \cdot (\alpha(s, m)^n - 1) \leq \left(\frac{10s}{\varepsilon d}\right)^{(1-\varepsilon/8)s} (10\sqrt{n})^n \leq (n^{-\frac{1}{2-2\delta}-\varepsilon/2})^{(1-\varepsilon/8)(1-\delta)n} (10\sqrt{n})^n,$$

since $d = n^{1+1/(2-2\delta)+\varepsilon}$ and $s = 2\lfloor(1 - \delta)n/2\rfloor$ along with $\varepsilon = \omega(\log \log n / \log n)$. We see that this is $o(1)$. Thus

$$\text{Var } X \leq (\mathbb{E}X)^2 \cdot \left(\eta + o(1) + o(1)\right) \leq 2\eta(\mathbb{E}X)^2$$

for n sufficiently large, and thus $X > 0$ with probability at least $1 - 2\eta$. \square
