# FLAG-TRANSITIVE, POINT-IMPRIMITIVE SYMMETRIC $2-(v, k, \lambda)$ DESIGNS WITH $k>\lambda(\lambda-3) / 2$ 

ALESSANDRO MONTINARO<br>Dedicated to Mauro Biliotti, professor emeritus at the University of Salento

#### Abstract

Let $\mathcal{D}=(\mathcal{P}, \mathcal{B})$ be a symmetric $2-(v, k, \lambda)$ design admitting a flagtransitive, point-imprimitive automorphism group $G$ that leaves invariant a nontrivial partition $\Sigma$ of $\mathcal{P}$. Praeger and Zhou [40 have shown that, there is a constant $k_{0}$ such that, for each $B \in \mathcal{B}$ and $\Delta \in \Sigma$, the size of $|B \cap \Delta|$ is either 0 or $k_{0}$. In the present paper we show that, if $k>\lambda(\lambda-3) / 2$ and $k_{0} \geqslant 3, \mathcal{D}$ is isomorphic to one of the known flag-transitive, point-imprimitive symmetric 2-designs with parameters $(45,12,3)$ or $(96,20,4)$.

## 1. Introduction and Main Result

A 2- $(v, k, \lambda)$ design $\mathcal{D}$ is a pair $(\mathcal{P}, \mathcal{B})$ with a set $\mathcal{P}$ of $v$ points and a set $\mathcal{B}$ of blocks such that each block is a $k$-subset of $\mathcal{P}$ and each two distinct points are contained in $\lambda$ blocks. We say $\mathcal{D}$ is non-trivial if $2<k<v$, and symmetric if $v=b$. All $2-(v, k, \lambda)$ designs in this paper are assumed to be non-trivial. An automorphism of $\mathcal{D}$ is a permutation of the point set which preserves the block set. The set of all automorphisms of $\mathcal{D}$ with the composition of permutations forms a group, denoted by $\operatorname{Aut}(\mathcal{D})$. For a subgroup $G$ of $\operatorname{Aut}(\mathcal{D}), G$ is said to be point-primitive if $G$ acts primitively on $\mathcal{P}$, and said to be point-imprimitive otherwise. In this setting we also say that $\mathcal{D}$ is either point-primitive or point-imprimitive respectively. A flag of $\mathcal{D}$ is a pair $(x, B)$ where $x$ is a point and $B$ is a block containing $x$. If $G \leqslant \operatorname{Aut}(\mathcal{D})$ acts transitively on the set of flags of $\mathcal{D}$, then we say that $G$ is flag-transitive and that $\mathcal{D}$ is a flag-transitive design.

Flag-transitive symmetric designs are widely studied. If $\lambda=1$, that is, $\mathcal{D}$ is a projective plane of order $n$, Kantor [25] proved that either $\mathcal{D}$ is Desarguesian and $P S L_{3}(n) \unlhd G$, or $G$ is a sharply flag-transitive Frobenius group of order $\left(n^{2}+n+\right.$ 1) $(n+1)$, and $n^{2}+n+1$ is a prime. In both cases the action of G is point-primitive. For $\lambda>1$, flag-transitive, point-imprimitive symmetric designs do exist. In 1945 Hussain [21] and, independently, in 1946 Nandi [37] discovered that there are exactly three symmetric 2-(16, 6, 2)-designs. In 2006 O'Reilly Regueiro [42 showed that, if $\lambda \leqslant 4$ then the parameters of $\mathcal{D}$ are $(16,2,2),(45,12,3),(15,8,4),(96,20,4)$ and that exactly two of the three 2 -designs discovered by Hussain and Nandi are flag-transitive and point-imprimitive. In 2006 Praeger and Zhou [40] proved that there is exactly one flag-transitive, point-imprimitive symmetric $2-(15,8,3)$ design, in 2007 Praeger [38] showed that there is exactly one flag-transitive, point-imprimitive symmetric 2 - $(45,12,3)$ design, and in 2009, Law, Praeger and Reichard [28] proved that there

[^0]are exactly four transitive, point-imprimitive symmetric 2-(96, 40, 4) designs. Apart from two possible numerical exceptions, the classification of the flag-transitive pointimprimitive symmetric 2 -designs has been recently extended to $\lambda \leqslant 10$ by Mandić and Šubasić (33].
It is worth noting that one of the four $2-(96,40,4)$ designs is a special case of a beautiful, general construction of transitive, point-imprimitive symmetric 2-designs due to Cameron and Praeger [7] based on a previous work of Sane [43]. It is an open problem whether the remaining three 2-designs arise or not from the CameronPraeger construction.
An upper bound on $k$, when $\mathcal{D}$ is flag-transitive and point-imprimitive, was given by O'Reilly Regueiro in [42] and subsequently refined by Praeger and Zhou in [40]. Among the other results, the authors determined the parameters of $\mathcal{D}$ as functions of $\lambda$ when $k>\lambda(\lambda-3) / 2$. Recently, the flag-transitive 2 -designs with $\lambda=2$ have been investigated by Devillers, Liang, Praeger and Xia in [12], where, it is shown that, apart from the two known symmetric $2-(16,6,2)$ designs, $G$ is primitive of affine or almost simple type.
The present paper is a contribution to the problem of classifying flag-transitive, point-imprimitive symmetric $2-(v, k, \lambda)$ designs. We classify those with $k>\lambda(\lambda-3) / 2$ and such that a block of the 2-design intersects a block of imprimitivity in at least 3 points. More precisely, our result is the following.

Theorem 1.1. Let $\mathcal{D}=(\mathcal{P}, \mathcal{B})$ be a symmetric $2-(v, k, \lambda)$ design admitting a flagtransitive, point-imprimitive automorphism group $G$ that leaves invariant a nontrivial partition $\Sigma$ of $\mathcal{P}$. If $k>\lambda(\lambda-3) / 2$ and there is block of $\mathcal{D}$ intersecting an element of $\Sigma$ in at least 3 points, then one of the following holds:
(1) $\mathcal{D}$ is isomorphic to the $2-(45,12,3)$ design of [38, Construction 4.2].
(2) $\mathcal{D}$ is isomorphic to one of the four $2-(96,20,4)$ designs constructed in [28].

The outline of the proof is as follows. The group $G$ preserves a set of imprimitivity $\Sigma$ on the point set of $\mathcal{D}$ consisting of $d$ blocks of imprimitivity each of size $c$. By [40] each block $B$ of $\mathcal{D}$ intersects any block of imprimitivity either in 0 or in a constant number $k_{0}$ of points. In Lemma [2.1] we show that the number of blocks intersecting a block of imprimitivity in the same $k_{0}$-set of points is constant and is independent on the choice of the block of $\mathcal{D}$ and of the element of $\Sigma$. We call such a number the overlap number of $\mathcal{D}$ and we denote it by $\theta$.
If $k_{0} \geqslant 3$, in Theorems 2.3 and 2.4 we show that the blocks of imprimitivity have the structure of flag-transitive $2-\left(c, k_{0}, \lambda / \theta\right)$ designs, where $\left(c, k_{0}\right)$ is either $\left(\lambda^{2}, \lambda\right)$, or $(\lambda+$ $6,3)$ with $\lambda \equiv 1,3(\bmod 6)$. Moreover, in Lemma 2.6 we prove that, such 2 -designs are also point-primitive. Flag-transitive, point-primitive $2-\left(\lambda^{2}, \lambda, \lambda / \theta\right)$ designs are classified in [34, 35, 36], whereas flag-transitive, point-primitive $2-(\lambda+6,3, \lambda / \theta)$ designs, with $\lambda \equiv 1,3(\bmod 6)$ are classified in the Appendix of this paper (Theorem (7.1). Finally, we complete the proof of Theorem 1.1 by combining the previous information on the structure of the blocks of imprimitivity with the constraints on the action of $G$ on $\mathcal{D}$ provided in [27] and on the structure of $G$ essentially provided in [1].

## 2. The overlap number of $\mathcal{D}$

Let $\mathcal{D}=(\mathcal{P}, \mathcal{B})$ be a symmetric $2-(v, k, \lambda)$ design admitting a flag-transitive, pointimprimitive automorphism group $G$ that leaves invariant a non-trivial partition $\Sigma$ of $\mathcal{P}$ with $d$ classes of size $c$. Then there is a constant $k_{0}$ such that, for each $B \in \mathcal{B}$ and $\Delta_{i} \in \Sigma, i=1, \ldots, d$, the size $\left|B \cap \Delta_{i}\right|$ is either 0 or $k_{0}$ by [40, Theorem 1.1]. If we pick two distinct points $x, y$ in a block of imprimitivity, then there are exactly $\lambda$ blocks of $\mathcal{D}$ incident with them. Thus $k_{0} \geqslant 2$. Moreover, since $\mathcal{D}$ is non-trivial, $v>k$ and hence $k_{0}<c$ by [40, (4) and (7)]. Therefore, $2 \leqslant k_{0}<c$. If $k_{0}=2$ the flag-transitivity of $G$ on $\mathcal{D}$ implies the 2-transitivity of $G_{\Delta_{i}}^{\Delta_{i}}$ on $\Delta_{i}$ for each $i=1, \ldots, d$.

Let $\mathcal{B}_{i}=\left\{B \in \mathcal{B}: B \cap \Delta_{i} \neq \varnothing\right\}$, where $i=1, \ldots, d$. For any $B \in \mathcal{B}_{i}$ define

$$
\mathcal{B}_{i}(B)=\left\{B^{\prime} \in \mathcal{B}_{i}: B^{\prime} \cap \Delta_{i}=B \cap \Delta_{i}\right\} \quad \text { and } \theta(i, B)=\left|\mathcal{B}_{i}(B)\right| .
$$

Clearly, $1 \leqslant \theta(i, B) \leqslant \lambda$.
Lemma 2.1. $\theta(i, B)=\theta\left(j, B^{\prime}\right)$ for each $i, j \in\{1, \ldots, d\}$ and for each $B \in \mathcal{B}_{i}$ and $B^{\prime} \in \mathcal{B}_{j}$.
Proof. Let $B \in \mathcal{B}_{i}$ and $B^{\prime} \in \mathcal{B}_{j}$, where $i, j \in\{1, \ldots, d\}$, and let $x \in B \cap \Delta_{i}$ and $x^{\prime} \in B^{\prime} \cap \Delta_{j}$. Then there is $\psi \in G$ such that $(x, B)^{\psi}=\left(x^{\prime}, B^{\prime}\right)$ since $G$ is flagtransitive. Hence $\left(B \cap \Delta_{i}\right)^{\gamma}=B^{\prime} \cap \Delta_{j}$.
Let $C \in \mathcal{B}_{i}(B)$, then $C \cap \Delta_{i}=B \cap \Delta_{i}$ and hence

$$
C^{\gamma} \cap \Delta_{j}=\left(C \cap \Delta_{i}\right)^{\gamma}=\left(B \cap \Delta_{i}\right)^{\gamma}=B^{\prime} \cap \Delta_{j} .
$$

Thus $C^{\gamma} \in \mathcal{B}_{j}\left(B^{\prime}\right)$ and hence $\theta(i, B) \leqslant \theta\left(j, B^{\prime}\right)$. Now, switching the role of $B$ and $B^{\prime}$ in the previous argument we get $\theta\left(j, B^{\prime}\right) \leqslant \theta(i, B)$. Thus $\theta(i, B)=\theta\left(j, B^{\prime}\right)$, which is the assertion.

In view of the previous lemma, we may denote $\theta(i, B)$ simply by $\theta$ and call it the overlap number of $\mathcal{D}$.

Corollary 2.2. Let $B \in \mathcal{B}_{i}$ and let $x \in B \cap \Delta_{i}$, then $\theta=\left[G_{x, B \cap \Delta_{i}}: G_{x, B}\right]$.
Proof. Let $B \in \mathcal{B}_{i}$ and let $x \in B \cap \Delta_{i}$. Then $G_{x, B} \leqslant G_{x, B \cap \Delta_{i}}$. Thus $\left[G_{x, B \cap \Delta_{i}}: G_{x, B}\right] \leqslant$ $\theta$.

Let $B^{\prime} \in \mathcal{B}_{i}(B)$. Then there is $\varphi \in G_{x}$ such that $B^{\varphi}=B^{\prime}$. Thus $\left(B \cap \Delta_{i}\right)^{\varphi}=$ $B^{\prime} \cap \Delta_{i}=B \cap \Delta_{i}$ and hence $\varphi \in G_{x, B \cap \Delta_{i}}$ and $G_{x, B} \varphi \subseteq G_{x, B \cap \Delta_{i}}$. Therefore $\left[G_{x, B \cap \Delta_{i}}: G_{x, B}\right] \geqslant \theta$ and hence $\left[G_{x, B \cap \Delta_{i}}: G_{x, B}\right]=\theta$.
Theorem 2.3. If $k_{0} \geqslant 3$, then $\mathcal{D}_{i}=\left(\Delta_{i}, \mathcal{B}_{i}^{*}\right)$, where $\mathcal{B}_{i}^{*}=\left\{B \cap \Delta_{i}: B \in \mathcal{B}_{i}\right\}$, is a non-trivial $2-\left(c, k_{0}, \lambda / \theta\right)$ design, with $\theta \mid \lambda$, admitting $G_{\Delta_{i}}^{\Delta_{i}}$ as a flag-transitive automorphism group.

Proof. Clearly the number of points in $\mathcal{D}_{i}$ is $c$ and each element of $\mathcal{B}_{i}^{*}$ contains $k_{0}$ points of $\Delta_{i}$. Let $x_{1}, x_{2} \in \Delta_{i}$, with $x_{1} \neq x_{2}$, then there are precisely $\lambda$ blocks of $\mathcal{D}$ incident with them, say $B_{1}, \ldots, B_{\lambda}$. For each $B_{j}$ there are precisely $\theta$ blocks among $B_{1}, \ldots, B_{\lambda}$ whose intersection set with $\Delta_{i}$ is $B_{j} \cap \Delta_{i}$, hence there are exactly $\lambda / \theta$ distinct elements of $\mathcal{B}_{i}^{*}$ incident with $x_{1} \neq x_{2}$. Thus $\mathcal{D}_{i}$ is a $2-\left(c, k_{0}, \lambda / \theta\right)$ design.

Also, $\mathcal{D}_{i}$ is non-trivial since $k_{0}<c$ by [40, (4) and (7)], and since $k_{0} \geqslant 3$ by our assumption. Finally, the flag-transitivity of $G$ on $\mathcal{D}$ implies the flag-transitivity of $G_{\Delta_{i}}^{\Delta_{i}}$ on $\mathcal{D}_{i}$.

The following theorem is an improvement of [40, Theorem 1.1] on the basis of Theorem 2.3,

Theorem 2.4. Let $\mathcal{D}=(\mathcal{P}, \mathcal{B})$ be a symmetric 2 -design admitting a flag-transitive, point-imprimitive automorphism group $G$ that leaves invariant a non-trivial partition $\Sigma=\left\{\Delta_{1}, \ldots, \Delta_{d}\right\}$ of $\mathcal{P}$ such that $\left|\Delta_{i}\right|=c$ for each $i=1, \ldots, d$. Then the following hold:
I. There is a constant $k_{0}$ such that, for each $B \in \mathcal{B}$ and $\Delta_{i} \in \Sigma$, the size $\left|B \cap \Delta_{i}\right|$ is either 0 or $k_{0}$.
II. There is a constant $\theta$ such that, for each $B \in \mathcal{B}$ and $\Delta_{i} \in \Sigma$ with $\left|B \cap \Delta_{i}\right|>$ 0 , the number of blocks of $\mathcal{D}$ whose intersection set with $\Delta_{i}$ coincides with $B \cap \Delta_{i}$ is $\theta$.
III. If $k_{0}=2$ then $G_{\Delta_{i}}^{\Delta_{i}}$ acts 2 -transitively on $\Delta_{i}$ for each $i=1, \ldots, d$.
IV. If $k_{0} \geqslant 3$ then $\mathcal{D}_{i}=\left(\Delta_{i},\left(B \cap \Delta_{i}\right)^{G_{\Delta_{i}}^{\Delta_{i}}}\right)$ is a flag-transitive non-trivial 2$\left(c, k_{0}, \lambda / \theta\right)$ design for each $i=1, \ldots, d$.
Moreover, if $k>\lambda(\lambda-3) / 2$ then one of the following holds:
V. $k_{0}=2$ and one of the following holds:

1. $\mathcal{D}$ is a symmetric $2-\left(\lambda^{2}(\lambda+2), \lambda(\lambda+1), \lambda\right)$ design and $(c, d)=\left(\lambda+2, \lambda^{2}\right)$.
2. $\mathcal{D}$ is a symmetric $2-\left(\left(\frac{\lambda+2}{2}\right)\left(\frac{\lambda^{2}-2 \lambda+2}{2}\right), \frac{\lambda^{2}}{2}, \lambda\right)$ design, $(c, d)=\left(\frac{\lambda+2}{2}, \frac{\lambda^{2}-2 \lambda+2}{2}\right)$, and either $\lambda \equiv 0(\bmod 4)$, or $\lambda=2 u^{2}$, where $u$ is odd, $u \geqslant 3$, and $2\left(u^{2}-1\right)$ is a square.
VI. $k_{0} \geqslant 3$ and one of the following holds:
3. $\mathcal{D}$ is a symmetric $2-\left(\lambda^{2}(\lambda+2), \lambda(\lambda+1), \lambda\right)$ design, $d=\lambda+2$, and $\mathcal{D}_{i}$ is a 2- $\left(\lambda^{2}, \lambda, \lambda / \theta\right)$ design, with $\theta \mid \lambda$, for each $i=1, \ldots, d$.
4. $\mathcal{D}$ is a symmetric $2-\left((\lambda+6) \frac{\lambda^{2}+4 \lambda-1}{4}, \lambda \frac{\lambda+5}{2}, \lambda\right)$ design, with $\lambda \equiv 1,3$ $(\bmod 6), d=\frac{\lambda^{2}+4 \lambda-1}{4}$, and $\mathcal{D}_{i}$ is a $2-(\lambda+6,3, \lambda / \theta)$ design, with $\theta \mid \lambda$, for each $i=1, \ldots, d$.
Proof. The assertion follows from [40, Theorem 1.1] and from Theorem [2.3,
From now on we assume that $k>\lambda(\lambda-3) / 2$ and $k_{0} \geqslant 3$. Hence, we will focus on the symmetric 2-designs in (VI.1) and (VI.2) of Theorem [2.4, and we will refer to them as 2-designs of type 1 and 2 respectively.

Lemma 2.5. $\lambda \geqslant 3$.
Proof. If $\lambda=2$, then $k_{0}=2$ by [40, Corollary 1.3 and Table 1], which is contrary to our assumption. Thus $\lambda \geqslant 3$.

Lemma 2.6. If $k>\lambda(\lambda-3) / 2$ and $k_{0} \geqslant 3$, then $G_{\Delta_{i}}^{\Delta_{i}}$ acts point-primitively on $\mathcal{D}_{i}$. Proof. The assertion follows from [10, 2.3.7.(c)] or [22, Theorem 4.8.(i)].

Lemma 2.7. Let $N$ be a minimal normal subgroup of $G$. Then one of the following holds:
(1) $\Sigma$ is the $N$-orbit decomposition of the point set of $\mathcal{D}$;
(2) $N$ acts point-transitively on $\mathcal{D}$;
or, for $c=\lambda+2$ and $d=\lambda^{2}$ the following additional possibility arises:
(3) The $N$-orbit decomposition of the point set of $\mathcal{D}$ is a further $G$-invariant partition $\Sigma^{\prime}=\left\{\Delta_{1}^{\prime}, \ldots, \Delta_{\lambda^{2}}^{\prime}\right\}$ such that the following hold:
(a) $\left|\Delta_{j}^{\prime}\right|=\lambda+2$ for each $j=1, \ldots, \lambda^{2}$;
(b) For each $B \in \mathcal{B}$ and $\Delta_{j}^{\prime} \in \Sigma^{\prime}$, the size $\left|B \cap \Delta_{j}^{\prime}\right|$ is either 0 or 2 ;
(c) For each $\Delta_{i} \in \Sigma$ and $\Delta_{j}^{\prime} \in \Sigma^{\prime},\left|\Delta_{i} \cap \Delta_{j}^{\prime}\right|=1$.
(d) $G_{\Delta_{j}^{\prime}}^{\Delta_{j}^{\prime}}$ acts 2 -transitively on $\Delta_{j}^{\prime}$ for each $j=1, \ldots, \lambda^{2}$.

Proof. Let $N$ be a minimal normal subgroup of $G$. Assume that $G_{\Delta_{i}} N$ acts pointtransitively on $\mathcal{D}$. Then $N$ acts transitively on $\Sigma$. If there is $j_{0} \in\{1, \ldots, d\}$ such that $N_{\Delta_{j_{0}}}^{\Delta_{j_{0}}}=1$, then $N_{\Delta_{j_{0}}} \leqslant G\left(\Delta_{j_{0}}\right)$. Hence $N_{\Delta_{i}} \leqslant G\left(\Delta_{i}\right)$ for each $i$, since $G$ acts transitively on $\Sigma$ and $N \unlhd G$. Thus the point set of $\mathcal{D}$ is split into $c^{\prime}$ orbits under $N$ each of length $d^{\prime}$, where $\left(c^{\prime}, d^{\prime}\right)=(d, c)$, since $N$ acts transitively on $\Sigma$. Hence $\Sigma^{\prime}=\left\{\Delta_{1}^{\prime}, \ldots, \Delta_{c}^{\prime}\right\}$, where $\Delta_{j}^{\prime}=x_{j}^{N}$ for each $j=1, \ldots, c$, is a set of imprimitivity for $G$. Moreover, $N_{x_{i}}=N\left(\Delta_{i}\right)$ for each $x_{i} \in \Delta_{i}$ and for each $i=1, \ldots, c$. By Theorem 2.4 there is a constant $k_{0}^{\prime}$ such that, for each $B \in \mathcal{B}$ and $\Delta_{i}^{\prime} \in \Sigma^{\prime}$, the size $\left|B \cap \Delta_{i}^{\prime}\right|$ is either 0 or $k_{0}^{\prime}$.
If $k_{0}^{\prime}=2$, then either $\left(c^{\prime}, d^{\prime}\right)=\left(\lambda+2, \lambda^{2}\right)$, or $\left(c^{\prime}, d^{\prime}\right)=\left(\frac{\lambda+2}{2}, \frac{\lambda^{2}-2 \lambda+2}{2}\right)$ and either $\lambda \equiv 0(\bmod 4)$, or $\lambda=2 u^{2}$, where $u$ is odd, $u \geqslant 3$, and $2\left(u^{2}-1\right)$ is a square by Theorem [2.4. On the other hand, we know that $\left(c^{\prime}, d^{\prime}\right)=(d, c)$ and either $(d, c)=$ $\left(\lambda+2, \lambda^{2}\right)$, or $\left(\frac{\lambda^{2}+4 \lambda-1}{4}, \lambda+6\right)$ and $\lambda \equiv 1,3(\bmod 6)$ again by by Theorem [2.4, since $k_{0} \geqslant 3$. By comparing the values of $\left(c^{\prime}, d^{\prime}\right)$ we see that the unique admissible value is $\left(c^{\prime}, d^{\prime}\right)=(d, c)=\left(\lambda+2, \lambda^{2}\right)$, and we obtain (3a) and (3b).
Let $\Delta_{i} \in \Sigma$ and $\Delta_{j}^{\prime} \in \Sigma^{\prime}$. Since $N_{x_{i}}=N\left(\Delta_{i}\right)$ for each $x_{i} \in \Delta_{i}$ and for each $i=1, \ldots, \lambda+2$, and since $\Delta_{j}^{\prime}$ is a $N$-orbit for each $j=1, \ldots, \lambda^{2}$, it follows that $\left|\Delta_{i} \cap \Delta_{j}^{\prime}\right|=1$. Also $G_{\Delta_{j}^{\prime}}^{\Delta_{j}^{\prime}}$ acts 2-transitively on $\Delta_{j}^{\prime} \in \Sigma^{\prime}$, since $k_{0}^{\prime}=2$. Thus we get (3c) and (3d).
If $k_{0}^{\prime} \geqslant 3$, then either $\left(c^{\prime}, d^{\prime}\right)=\left(\lambda^{2}, \lambda+2\right)$ or $\left(c^{\prime}, d^{\prime}\right)=\left(\lambda+6, \frac{\lambda^{2}+4 \lambda-1}{4}\right)$ and $\lambda \equiv 1,3$ $(\bmod 6)$ by Theorem [2.4. On the other hand, we know that $\left(c^{\prime}, d^{\prime}\right)=(d, c)$ and either $(d, c)=\left(\lambda+2, \lambda^{2}\right)$, or $\left(\frac{\lambda^{2}+4 \lambda-1}{4}, \lambda+6\right)$ and $\lambda \equiv 1,3(\bmod 6)$. By comparing the values of $\left(c^{\prime}, d^{\prime}\right)$ no admissible $\lambda$ 's arise, since $\lambda \geq 3$ by Lemma 2.5.

Assume that $N_{\Delta_{i}}^{\Delta_{i}} \neq 1$ for each $i=1, \ldots, d$. Hence $N_{\Delta_{i}}^{\Delta_{i}}$ acts point-transitively on $\mathcal{D}_{i}$ for each $i=1, \ldots, d$, since $G_{\Delta_{i}}^{\Delta_{i}}$ acts point-primitively on $\mathcal{D}_{i}$ by Lemma 2.6, Therefore $N$ acts point-transitively on $\mathcal{D}$, as $N$ acts transitively on $\Sigma$, which is (2).

Assume that $G_{\Delta_{i}} N$ acts point-intransitively on $\mathcal{D}$. Hence $G_{\Delta_{i}} N \neq G$. Then $\Delta_{i} \subseteq \Delta_{i}^{\prime \prime}$, where $\Delta_{i}^{\prime \prime}=x^{G_{\Delta_{i}} N}=\Delta_{i}^{N}$ and $x \in \Delta_{i}$. Also $\Sigma^{\prime \prime}=\left\{\left(\Delta_{i}^{\prime \prime}\right)^{g}: g \in G\right\}$ is a set of imprimitivity for $G$ by [13, Theorem 1.5 A ]. If $B \in \mathcal{B}$ is such that $B \cap \Delta_{i}^{\prime \prime} \neq \varnothing$, then $k_{0}^{\prime \prime}=\left|B \cap \Delta_{i}^{\prime \prime}\right| \geqslant\left|B \cap \Delta_{i}\right|=k_{0} \geqslant 3$ and hence we may apply Theorem [2.4] referred to the set of imprimitivity $\Sigma^{\prime \prime}$, and we obtain that $\mathcal{D}_{i}^{\prime \prime}=\left(\Delta_{i}^{\prime \prime},\left(B \cap \Delta_{i}^{\prime \prime}\right)^{G_{\Delta_{i}^{\prime \prime}}^{\Delta_{i}^{\prime \prime}}}\right)$
is a flag-transitive non-trivial $2-\left(c^{\prime \prime}, k_{0}^{\prime \prime}, \lambda / \theta^{\prime \prime}\right)$ design. Moreover, either $c^{\prime \prime}=\lambda^{2}$ or $c^{\prime \prime}=\lambda+6$ since $k>\lambda(\lambda-3) / 2$. It is easily seen that $c^{\prime \prime}=c$, since $c \mid c^{\prime \prime}$, being $\Delta_{i}^{\prime \prime}=\Delta_{i}^{N}$. Thus $\Delta_{i}=\Delta_{i}^{\prime \prime}$ and hence $N \unlhd G_{\Delta_{i}}$ for each $i=1, \ldots, d$. If there $i_{0}$ such that $N$ fixes a point in $\Delta_{i_{0}}$, then $N$ fixes each point of $\mathcal{D}$, since $N \unlhd G$ and $G$ acts point-transitively on $\mathcal{D}$, and we reach a contradiction. Thus $N^{\Delta_{i}} \neq 1$ for each $i=1, \ldots, d$, and hence $N$ acts point-transitively on $\mathcal{D}_{i}$, since $N^{\Delta_{i}} \unlhd G_{\Delta_{i}}^{\Delta_{i}}$ and since $G_{\Delta_{i}}^{\Delta_{i}}$ acts point-primitively on $\mathcal{D}_{i}$ by Lemma 2.6. Therefore, $\Sigma$ is the orbit decomposition of the point set of $\mathcal{D}$ under $N$, which is (1).

Let $\Delta \in \Sigma$ and $x \in \Delta$. Since $G(\Sigma) \unlhd G_{\Delta}$ and $G(\Delta) \unlhd G_{x}$ it is immediate to verify that $\left(G^{\Sigma}\right)_{\Delta}=\left(G_{\Delta}\right)^{\Sigma}$ and that $\left(G_{\Delta}^{\Delta}\right)_{x}=\left(G_{x}\right)^{\Delta}$. Hence, in the sequel, $\left(G^{\Sigma}\right)_{\Delta}$ and $\left(G_{\Delta}^{\Delta}\right)_{x}$ will simply be denoted $G_{\Delta}^{\Sigma}$ and $G_{x}^{\Delta}$ respectively.

## 3. The case where $\mathcal{D}$ Is of type 1

In this section we assume that $\mathcal{D}$ is of type 1 . Hence $\mathcal{D}$ is a symmetric $2-\left(\lambda^{2}(\lambda+\right.$ 2), $\lambda(\lambda+1), \lambda)$ design with $d=\lambda+2$. Moreover, $\mathcal{D}_{i}$ is a $2-\left(\lambda^{2}, \lambda, \lambda / \theta\right)$ design, with $\theta \mid \lambda$, admitting $G_{\Delta_{i}}^{\Delta_{i}}$ as a flag-transitive, point-primitive automorphism group for each $i=1, \ldots, d$. Our aim is to prove the following result.

Theorem 3.1. If $\mathcal{D}$ is of type 1 , one of the following holds:
(1) $\mathcal{D}$ is isomorphic to the $2-(45,12,3)$ design of [38, Construction 4.2].
(2) $\mathcal{D}$ is isomorphic to one of the four $2-(96,20,4)$ designs constructed in [28].

Proposition 3.2. $G$ induces a 2 -transitive group on $\Sigma$.
Proof. It is clear that $G$ acts transitively on $\Sigma$. Let $B$ be any block of $\mathcal{D}$ and define $\Sigma(B)=\left\{\Delta_{i} \in \Sigma: \Delta_{i} \cap B \neq \varnothing\right\}$. Then $\left|\Delta_{i} \cap B\right|=\lambda$ for each $\Delta_{i} \in \Sigma(B)$, $|\Sigma(B)|=\lambda+1$ and $\Sigma \backslash \Sigma(B)=\left\{\Delta_{i_{0}}\right\}$ for some $i_{0} \in\{1, \ldots, \lambda+2\}$, since $k=\lambda(\lambda+1)$ and $|\Sigma|=\lambda+2$. Since $G_{B}$ acts transitively on $B$ and preserves $\Sigma$, it follows that $G_{B}$ acts transitively on $\Sigma(B)$. Thus $G_{B}$ preserves $\Delta_{i_{0}}$ and hence $G_{B} \leqslant G_{\Delta_{i_{0}}}$. Therefore $G_{\Delta_{i_{0}}}$ acts transitively on $\Sigma \backslash\left\{\Delta_{i_{0}}\right\}$ and hence $G$ induces a 2 -transitive group on $\Sigma$.

Lemma 3.3. If $G\left(\Delta_{i}\right) \neq 1$, then either the primes dividing the order of $G\left(\Delta_{i}\right)$ divide $\lambda$, or $\mathcal{D}_{i}$ is a translation plane.
Proof. Assume that $G\left(\Delta_{i}\right) \neq 1$ and let $W$ be any Sylow $w$-subgroup of $G\left(\Delta_{i}\right)$ where $w$ is a prime not dividing $\lambda$. Clearly $W$ fixes the $\frac{\lambda^{2}}{\theta}(\lambda+1)$ blocks of $\mathcal{D}_{i}$. Let $B$ be any block of $\mathcal{D}$ such that $B \cap \Delta_{i}$ is a block of $\mathcal{D}_{i}$. Then $W$ preserves $B \cap \Delta_{i}$ and there are $\theta$ blocks of $\mathcal{D}$ whose intersection set with $\Delta_{i}$ is $B \cap \Delta_{i}$. Therefore $W$ fixes at least one of these $\theta$ blocks, as $w \nmid \lambda$ and $\theta \mid \lambda$, and hence $W$ fixes at least $\frac{\lambda^{2}}{\theta}(\lambda+1)$ blocks of $\mathcal{D}$. Then any non-trivial element of $W$ fixes at least $\frac{\lambda^{2}}{\theta}(\lambda+1)$ points of $\mathcal{D}$ by [27, Theorem 3.1] and hence $\frac{\lambda^{2}}{\theta}(\lambda+1) \leqslant \frac{\lambda}{k-\sqrt{(k-\lambda)}} v$ by [27, Corollary 3.7]. Since $k=\lambda(\lambda+1)$ and $v=\lambda^{2}(\lambda+2)$, it follows that $\frac{\lambda^{2}}{\theta}(\lambda+1) \leqslant \lambda(\lambda+2)$. Thus $\theta=\lambda$ and hence $\mathcal{D}_{i}$ is a 2- $\left(\lambda^{2}, \lambda, 1\right)$ design, that is, an affine plane. Then $\mathcal{D}_{i}$ is a translation plane by [46], since $G_{\Delta_{i}}^{\Delta_{i}}$ acts flag-transitively on $\mathcal{D}_{i}$.

The following theorem classifies the flag-transitive $2-\left(\lambda^{2}, \lambda, \lambda / \theta\right)$ designs $\mathcal{D}_{i}$.

Theorem 3.4. If $\mathcal{D}_{i}$ is a $2-\left(\lambda^{2}, \lambda, \lambda / \theta\right)$ design admitting a flag-transitive automorphism group $G_{\Delta_{i}}^{\Delta_{i}}$, then one of the following holds
(1) $G_{\Delta_{i}}^{\Delta_{i}}$ is almost simple and one of the following holds:
(a) $\mathcal{D}_{i}$ is isomorphic to the $2-\left(6^{2}, 6,2\right)$ design constructed in [34], $\theta=3$ and $P S L_{2}(8) \unlhd G_{\Delta_{i}}^{\Delta_{i}} \leqslant P \Gamma L_{2}(8)$.
(b) $\mathcal{D}_{i}$ is isomorphic to one of the three $2-\left(6^{2}, 6,6\right)$ designs constructed in [34], $\theta=1$ and $G_{\Delta_{i}}^{\Delta_{i}} \cong P \Gamma L_{2}(8)$.
(c) $\mathcal{D}_{i}$ is isomorphic to the $2-\left(12^{2}, 12,3\right)$ design constructed in [35], $\theta=4$ and $G_{\Delta_{i}}^{\Delta_{i}} \cong P S L_{3}(3)$.
(d) $\mathcal{D}_{i}$ is isomorphic to the $2-\left(12^{2}, 12,6\right)$ design constructed in [35], $\theta=2$ and $G_{\Delta_{i}}^{\Delta_{i}} \cong P S L_{3}(3): Z_{2}$.
(2) $G_{\Delta_{i}}^{\Delta_{i}}=T: G_{0}^{\Delta_{i}}, \lambda=p^{m}$, p prime, $m \geqslant 1$, and one of the following holds:
(a) $\mathcal{D}_{i}$ is a translation plane of order $p^{m}, \theta=p^{m}$, and one of the following holds:
(i) $\mathcal{D}_{i} \cong A G_{2}\left(p^{m}\right)$ and the possibilities $G_{0}^{\Delta_{i}}$ are given [15, 31].
(ii) $\mathcal{D}_{i}$ is the Lüneburg plane of order $2^{m}, m \equiv 2(\bmod 4), m \geqslant 6$, and $S z\left(2^{m / 2}\right) \unlhd G_{0}^{\Delta_{i}} \leqslant\left(Z_{2^{m / 2}-1} \times S z\left(2^{m / 2}\right)\right) . Z_{m / 2}$;
(iii) $\mathcal{D}_{i}$ is the Hall plane of order $3^{2}$ and the possibilities for $G_{0}^{\Delta_{i}}$ are given [16];
(iv) $\mathcal{D}_{i}$ is the Hering plane of order $3^{3}$ and $G_{0}^{\Delta_{i}} \cong S L_{2}(13)$.
(b) $\mathcal{D}_{i}$ is a $2-\left(p^{2 m}, p^{m}, p^{m-t}\right)$ design, $\theta=p^{t}$, where $0 \leqslant t \leqslant m$, the blocks are subspaces of $A G_{2 m}(p)$ and $G_{0}^{\Delta_{i}} \leqslant \Gamma L_{1}\left(p^{2 m}\right)$;
(c) $\mathcal{D}_{i}$ is isomorphic to one of the following 2-designs constructed in [36]:
(i) a 2-( $\left.p^{2 m}, p^{m}, p^{m / 2}\right)$ design, $m$ even, $\theta=p^{m / 2}$, and $S L_{2}\left(p^{m}\right) \unlhd$ $G_{0}^{\Delta_{i}} \leqslant\left(Z_{p^{m / 2}-1} \circ S L_{2}\left(p^{m}\right)\right) . Z_{m} ;$
(ii) a $2-\left(p^{2 m}, p^{m}, p^{2 m / 3}\right)$ design, $p$ odd and $m \equiv 0(\bmod 3), \theta=p^{m / 3}$, and $S U_{3}\left(p^{m / 3}\right) \unlhd G_{0}^{\Delta_{i}} \leqslant\left(Z_{p^{m / 3}-1} \times S U_{3}\left(p^{m / 3}\right)\right) . Z_{2 m / 3}$.
(iii) $\mathcal{D}$ is a $2-\left(p^{2 m}, p^{m}, p^{m}\right)$ design, $m$ even, $\theta=1$, and $S p_{4}\left(p^{m / 2}\right) \unlhd$ $G_{0}^{\Delta_{i}} \leqslant \Gamma S p_{4}\left(p^{m / 2}\right)$.
(iv) a $2-\left(2^{2 m}, 2^{m}, 2^{m} / \theta\right)$ design, $m \equiv 2(\bmod 4)$ and either $\theta=2^{m / 2}$ and $S z\left(2^{m / 2}\right) \unlhd G_{0}^{\Delta_{i}} \leqslant\left(Z_{2^{m / 2}-1} \times S z\left(2^{m / 2}\right)\right) . Z_{m / 2}$, or $\theta=1,2$ and $S z\left(2^{m / 2}\right) \unlhd G_{0}^{\Delta_{i}} \leqslant S z\left(2^{m / 2}\right) . Z_{m / 2} ;$
(v) a $2-\left(2^{2 m}, 2^{m}, 2^{m}\right)$ design, $m \equiv 0(\bmod 3), \theta=1$ and $G_{2}\left(2^{m / 3}\right) \unlhd$ $G_{0}^{\Delta_{i}} \leqslant\left(Z_{2^{m / 3}-1} \times G_{2}\left(2^{m / 3}\right)\right) . Z_{m / 3} ;$
(vi) a 2-( $\left.3^{4}, 3^{2}, 3\right)$ design, $\theta=3$, and $S L_{2}(5) \unlhd G_{0}^{\Delta_{i}} \leqslant\left(Z_{2} \cdot S_{5}^{-}\right): Z_{2}$;
(vii) one of the two 2-( $\left.2^{6}, 2^{3}, 2^{2}\right)$-designs, $\theta=2$, and either $G_{0}$ is one of the groups $3^{1+2}: Q_{8}, 3^{1+2}: Z_{8}$ or $3^{1+2}: S D_{16}$, or $3^{1+2}: Z_{8} \leqslant$ $G_{0}^{\Delta_{i}} \leqslant P S U_{3}(3) ;$
(viii) a $2-\left(2^{6}, 2^{3}, 2^{3}\right)$-design, $\theta=1$, and $G_{0}^{\Delta_{i}}$ is one of the groups $3^{1+2}$ : $Q_{8}, 3^{1+2}: C_{8}, 3^{1+2}: S D_{16},\left(3^{1+2}: Q_{8}\right): 3: 2$.
See [34, 35, 36] for a proof.
Proposition 3.5. $G_{\Delta_{i}}^{\Delta_{i}}$ is of affine type and $\lambda=p^{m}$.

Proof. Assume that $G_{\Delta_{i}}^{\Delta_{i}}$ is almost simple. Then either $P S L_{2}(8) \unlhd G_{\Delta_{i}}^{\Delta_{i}} \leqslant P \Gamma L_{2}(8)$ and $\lambda=6$, or $P S L_{3}(3) \unlhd G_{\Delta_{i}}^{\Delta_{i}} \leqslant P S L_{3}(3): Z_{2}$ and $\lambda=12$ by Theorem 3.4,
Assume that the former occurs. Since $G^{\Sigma}$ acts 2 -transitively on $\Sigma$ by Proposition 3.2, and $|\Sigma|=8$, one of the following holds by [24, Section 2, (A) and (B)]:
(1) $A G L_{1}(8) \unlhd G^{\Sigma} \leqslant A \Gamma L_{1}(8)$;
(2) $G^{\Sigma} \cong E_{8}: S L_{3}(2)$;
(3) $P S L_{2}(7) \unlhd G^{\Sigma} \leqslant P G L_{2}(7)$;
(4) $A_{8} \unlhd G^{\Sigma} \leqslant S_{8}$.

Assume that (4) holds. Since $G(\Sigma) G\left(\Delta_{i}\right) \unlhd G_{\Delta_{i}}$ and $A_{7} \unlhd G_{\Delta_{i}}^{\Sigma} \leqslant S_{7}$, either $G\left(\Delta_{i}\right) \unlhd G(\Sigma)$ or $G\left(\Delta_{i}\right) /\left(G\left(\Delta_{i}\right) \cap G(\Sigma)\right)$ contains a subgroup isomorphic to $A_{7}$. The latter is ruled out by Lemma 3.3, since $\lambda=6$, whereas the former implies that a quotient group of $G_{\Delta_{i}}^{\Delta_{i}}$ is isomorphic to $A_{7}$, which is impossible as $P S L_{2}(8) \unlhd$ $G_{\Delta_{i}}^{\Delta_{i}} \leqslant P \Gamma L_{2}(8)$. Thus (4) is ruled out.
Assume that one of (1)-(3) occurs. Since $G(\Sigma) G\left(\Delta_{i}\right) \unlhd G_{\Delta_{i}}$ and $P S L_{2}(8) \unlhd G_{\Delta_{i}}^{\Delta_{i}} \leqslant$ $P \Gamma L_{2}(8)$, either $G(\Sigma) \unlhd G\left(\Delta_{i}\right)$ or $P S L_{2}(8) \unlhd G(\Sigma) /\left(G(\Sigma) \cap G\left(\Delta_{i}\right)\right)$. The former implies $G_{\Delta_{i}}^{\Delta_{i}} \cong G_{\Delta_{i}}^{\Sigma} / G\left(\Delta_{i}\right)^{\Sigma}$ and hence a quotient group of $G_{\Delta_{i}}^{\Sigma}$ has a subgroup isomorphic to $P S L_{2}(8)$, but this is clearly impossible. So $P S L_{2}(8) \unlhd G(\Sigma) /(G(\Sigma) \cap$ $\left.G\left(\Delta_{i}\right)\right)$ and $A_{7} \unlhd G_{\Delta_{i}}^{\Sigma}$. Hence, if $W$ is any Sylow 7 -subgroup of $G_{\Delta_{i}}, 7^{2}| | W \mid$. Then $7\left|\left|W\left(\Delta_{i}\right)\right|\right.$, since $P S L_{2}(8) \unlhd G_{\Delta_{i}}^{\Delta_{i}} \leqslant P \Gamma L_{2}(8)$, but this contradicts Lemma 3.3.

Assume that $P S L_{3}(3) \unlhd G_{\Delta_{i}}^{\Delta_{i}} \leqslant P S L_{3}(3): Z_{2}$ and $\lambda=12$. Since $G^{\Sigma}$ acts 2transitively on $\Sigma$, with $|\Sigma|=14$, one of the following holds by [24, Section 2, (A) and (B)]:
(1) $P S L_{2}(13) \unlhd G^{\Sigma} \leqslant P G L_{2}(13)$;
(2) $A_{14} \unlhd G^{\Sigma} \leqslant S_{14}$.

We may proceed as the $P S L_{2}$ (8)-case to rule out (1) and (2), this time $W$ is a Sylow 13 -subgroup of $G_{\Delta_{i}}$.

Lemma 3.6. The following hold:
(1) $G\left(\Delta_{i}\right) \unlhd G(\Sigma) \leqslant G_{\Delta_{i}}$ for each $i=1, \ldots, p^{m}+2$.
(2) $G\left(\Delta_{i}\right) \cap G\left(\Delta_{j}\right)=1$ for each $i, j=1, \ldots, p^{m}+2$ with $i \neq j$.

Proof. Since $G_{\Delta_{i}}$ acts transitively on $\Sigma \backslash\left\{\Delta_{i}\right\}$ by Proposition 3.2, and since $G\left(\Delta_{i}\right) \unlhd$ $G_{\Delta_{i}}$, it follows that $\Sigma \backslash\left\{\Delta_{i}\right\}$ is union of $G\left(\Delta_{i}\right)$-orbits of the equal length $z$, where $z$ is a divisor of $p^{m}+1$ by Proposition [3.5. Assume that $z>1$. Then $\mathcal{D}_{i}$ is a translation plane of order $p^{m}$ by Lemma 3.3, Let $U$ be a Sylow $u$-subgroup of $G\left(\Delta_{i}\right)$, where $u$ is a prime divisor of $z$. Arguing as in Lemma 3.3, with $U$ in the role of $W$, we see that $U$ fixes at least $p^{m}\left(p^{m}+1\right)$ blocks of $\mathcal{D}$ and each of these intersects $\Delta_{i}$ in $p^{m}$ points, since $\mathcal{D}$ is a translation plane and $\theta=p^{m}$. Let $B$ be any of such blocks. Then $U$ preserves $\Delta_{i}$ and at least one the $p^{m}$ elements of $\Sigma \backslash\left\{\Delta_{i}\right\}$ intersecting $B$, say $\Delta_{j}$. Then $\left|\Delta_{j}^{G\left(\Delta_{i}\right)}\right|$ is coprime to $u$, whereas $\left|\Delta_{j}^{G\left(\Delta_{i}\right)}\right|=z$ and $u \mid z$. Thus $G\left(\Delta_{i}\right)$ preserves each element of $\Sigma$ and hence $G\left(\Delta_{i}\right) \leqslant G(\Sigma)$. Actually, $G\left(\Delta_{i}\right) \unlhd G(\Sigma)$ as $G(\Sigma) \leqslant G_{\Delta_{i}}$.

Let $\gamma \in G\left(\Delta_{i}\right) \cap G\left(\Delta_{i}\right)$, with $i \neq j$, then $\gamma$ fixes $2 p^{2 m}$ points of $\mathcal{D}$. If $\gamma \neq 1$ then $2 p^{2 m} \leqslant p^{m}\left(p^{m}+2\right)$ by [27. Corollary, 3.7]. So $\lambda=p^{m} \leqslant 2$, which is contrary to Lemma 2.5. Thus $\gamma=1$ and hence $G\left(\Delta_{i}\right) \cap G\left(\Delta_{j}\right)=1$ for $i \neq j$.

Corollary 3.7. $G(\Sigma) \neq 1$.
Proof. Suppose that $G(\Sigma)=1$. Then $G(\Delta)=1$ for each $\Delta \in \Sigma$ by Lemma 3.6(1) and hence $\operatorname{Soc}\left(G_{\Delta}\right)$ is elementary abelian of order $p^{2 m}$ by Proposition 3.5. Then $\Sigma \backslash\{\Delta\}$ is partitioned in $\operatorname{Soc}\left(G_{\Delta}\right)$-orbits of equal length $p^{h}$, with $h>0$, since $G_{\Delta}$ acts transitively on $\Sigma \backslash\{\Delta\}, \operatorname{Soc}\left(G_{\Delta}\right) \unlhd G_{\Delta}$ and $G(\Sigma)=1$. Then $p$ divides $|\Sigma \backslash\{\Delta\}|$, thus contradicting $|\Sigma \backslash\{\Delta\}|=p^{m}+1$.

Proposition 3.8. Let $V$ be a minimal normal subgroup of $G$ contained in $G(\Sigma)$.
(1) $V^{\Delta_{i}} \cong \operatorname{Soc}\left(G_{\Delta_{i}}^{\Delta_{i}}\right)$ for each $i=1, \ldots, p^{m}+2$.
(2) $V$ is an elementary abelian $p$-group of order $p^{2 m+t}$, where $0 \leqslant t \leqslant 2 m$.
(3) $C_{G}(V) \cap G(\Sigma)$ is an elementary abelian $p$-group order $p^{2 m+y}$, where $t \leqslant y \leqslant$ $2 m$, containing $V$.

Proof. Let $V$ be a minimal normal subgroup of $G$ contained in $G(\Sigma)$. Then $V$ acts transitively on $\Delta_{i}$ for each $i=1, \ldots, p^{m}+2$ by Lemma 2.7. Moreover, $V^{\Delta_{i}} \unlhd G_{\Delta_{i}}^{\Delta_{i}}$. If $R$ is a minimal normal subgroup of $G_{\Delta_{i}}^{\Delta_{i}}$ contained in $V^{\Delta_{i}}$, then $\operatorname{Soc}\left(G_{\Delta_{i}}^{\Delta_{i}}\right)=R \unlhd V^{\Delta_{i}}$ by [13, Theorem 4.3B(i)], since $G_{\Delta_{i}}^{\Delta_{i}}$ acts primitively on $\Delta_{i}$ by Lemma 2.6 and since $\operatorname{Soc}\left(G_{\Delta_{i}}^{\Delta_{i}}\right)$ is an elementary abelian group of order $p^{m}$ by Proposition 3.5. Thus $V^{\Delta_{i}}$ contains a normal subgroup isomorphic to $\operatorname{Soc}\left(G_{\Delta_{i}}^{\Delta_{i}}\right)$, and hence $V$ is an elementary abelian $p$-group, since $V$ is a minimal normal subgroup of $G$. Therefore $V^{\Delta_{i}} \cong$ $\operatorname{Soc}\left(G_{\Delta_{i}}^{\Delta_{i}}\right)$, which is (1).
It follows from (1) that $\left|V^{\Delta_{i}}\right|=p^{2 m}$. Let $p^{t}=\left|V\left(\Delta_{i_{0}}\right)\right|$, with $t \geqslant 0$, for some $i_{0}$, then $\left|V\left(\Delta_{i}\right)\right|=p^{t}$ for each $i=1, \ldots, p^{m}+2$, since $V \unlhd G$ and $G$ acts transitively on $\Sigma$. Moreover, it follows from Lemma 3.6(2) that, $V\left(\Delta_{s}\right) \cap V\left(\Delta_{s^{\prime}}\right)=1$ for each $s, s^{\prime}=1, \ldots p^{m}+2$ with $s \neq s^{\prime}$. Thus $V\left(\Delta_{s}\right)$ is isomorphic to a subgroup of $V^{\Delta_{s^{\prime}}}$. Therefore $p^{t} \leqslant p^{2 m}$ and hence $0 \leqslant t \leqslant 2 m$. So $|V|=p^{2 m+t}$, with $0 \leqslant t \leqslant 2 m$, and we obtain (2).
Set $C=C_{G}(V)$ and $K=G(\Sigma)$ and recall that $G$ is permutationally isomorphic to a subgroup of $G_{\Delta}^{\Delta} \imath G^{\Sigma}$ by [39, Theorem 5.5]. Since

$$
C \cap K \leqslant \prod_{\Delta \in \Sigma}(C \cap K)^{\Delta} \leqslant \prod_{\Delta \in \Sigma} C_{K^{\Delta}}\left(V^{\Delta}\right)=\prod_{\Delta \in \Sigma} V^{\Delta}
$$

it follows $C \cap K$ is an elementary abelian $p$-group. By repeating the final part of the argument in (2) with $C \cap K$ in the role of $V$, we see that the order of $C \cap K$ is $p^{2 m+y}$, where $t \leqslant y \leqslant 2 m$, as $V \leqslant C$, and we obtain (3).

Remark 3.9. The proof of (3) is a slight modification of an argument contained in the proof of [28, Lemma 3.2]: here we consider a minimal normal subgroup of $G$ instead of $O_{p}(G(\Sigma))$, the largest normal $p$-subgroup of $G(\Sigma)$. In this way $G / C_{G}(V)$ is an irreducible subgroup of $G L(V)$, and this will play an important role in completing the proof of Theorem 3.1.

Corollary 3.10. Let $\Delta \in \Sigma$ and $x \in \Delta$, then $G_{\Delta}^{\Sigma}$ is isomorphic to a quotient group of $G_{x}^{\Delta}$.

Proof. It follows from Lemma 3.6(1) and Proposition 3.8(1) that $G_{\Delta}=G(\Sigma) G_{x}$ with $G(\Delta) \unlhd G(\Sigma)_{x}$. Thus

$$
\begin{equation*}
G_{\Delta}^{\Sigma} \cong G_{x} / G(\Sigma)_{x} \cong G_{x}^{\Delta} / G(\Sigma)_{x}^{\Delta} \tag{3.1}
\end{equation*}
$$

which is the assertion.
Lemma 3.11. If $u=p^{m}+2$, with $u$ prime and $u \geqslant 5$, divides $p^{z}-1$, where $0<z \leqslant 4 m$, then either $\left(p^{m}, u, z\right)=(3,5,4)$ or $\left(p^{m}, u, z\right)=(9,11,5)$.
Proof. Clearly $z>m$. Set $z=m+w$, where $w>0$. Then $u$ divides $p^{w}\left(p^{m}+\right.$ 2) $-2 p^{w}-1$ and hence $2 p^{w}+1$. Then $p^{w} \geqslant p^{m} / 2+1 / 2$ and hence $w=m+y$ for some $y \geqslant 0$, as $p$ is odd. Thus $u$ divides $2 p^{y}\left(p^{m}+2\right)-\left(4 p^{y}-1\right)$ and hence $4 p^{y}-1$. Then either $p^{m}+2=4 p^{y}-1$ or $2\left(p^{m}+2\right) \leqslant 4 p^{y}-1$. The former yields $p^{y}=3, p^{m}=3^{2}$ and hence $\left(p^{m}, u, z\right)=(9,11,5)$, the latter implies $p^{y} \geqslant p^{m} / 2+5 / 4$ and hence $y=m+x$ for some $0 \leqslant x \leqslant 2 m$, since $z \leqslant 4 m$. Therefore $u$ divides $\left(4 p^{m}+8\right) p^{x}-\left(8 p^{x}+1\right)$ and hence $8 p^{x}+1$. Thus $a\left(p^{m}+2\right)=8 p^{x}+1$ for some $a \geqslant 1$. If $x<m$, then $\left(a p^{m-x}-8\right) p^{x}+2 a-1=0$. Therefore $a p^{m-x}<8$ and hence either $a=1$ and $p^{m-x}=3,5$ or 7 , or $a=2$ and $p^{m-x}=3$, since $p$ is odd. It is easy to verify that no solutions arise in these cases, since $u$ is a prime. Thus $x=m$ and hence $(8-a) p^{m}=2 a-1$, with $1 \leqslant a<8$. Thus either $a=3$ and $p^{m}=3$, or $a=7$ and $p^{m}=13$. However the latter cannot occur since $u=p^{m}+2$ and $u$ is a prime, hence $\left(p^{m}, u, z\right)=(3,5,4)$.

Proposition 3.12. One of the following holds:
(1) $C_{G}(V) \leqslant G(\Sigma)$.
(2) $C_{G}(V)=V \times U$, where $U$ is a minimal normal subgroup of $G$ of order $u^{h}$, with $u$ prime and $h \geqslant 1$, satisfying the following properties:
(a) $u^{h}=p^{m}+2$;
(b) The $U$-orbit decomposition of the point set of $\mathcal{D}$ is a $G$-invariant partition $\Sigma^{\prime}=\left\{\Delta_{1}^{\prime}, \ldots, \Delta_{p^{2 m}}^{\prime}\right\}$ such that $\left|\Delta_{j}^{\prime}\right|=p^{m}+2$ for each $j=1, \ldots, p^{2 m}$ and the following hold:
(i) For each $B \in \mathcal{B}$ and $\Delta_{j}^{\prime} \in \Sigma^{\prime}$, the size $\left|B \cap \Delta_{j}^{\prime}\right|$ is either 0 or 2 .
(ii) $\left|\Delta_{i} \cap \Delta_{j}^{\prime}\right|=1$ for each $\Delta_{i} \in \Sigma$ and $\Delta_{j}^{\prime} \in \Sigma^{\prime}$;
(iii) $G_{\Delta_{j}^{\prime}}^{\Delta_{j}^{\prime}}$ acts 2-transitively on $\Delta_{j}^{\prime}$ for each $\Delta_{j}^{\prime} \in \Sigma^{\prime}$;
(iv) $U^{\Delta_{j}^{\prime}}=\operatorname{Soc}\left(G_{\Delta_{j}^{\prime}}^{\Delta_{j}^{\prime}}\right)$ for each $\Delta_{j}^{\prime} \in \Sigma^{\prime}$.

Proof. Let $C=C_{G}(V)$ and assume that $C \not \leq G(\Sigma)$. Then $1 \neq C^{\Sigma} \unlhd G^{\Sigma}$. Thus $\operatorname{Soc}\left(G^{\Sigma}\right) \leqslant C^{\Sigma}$, as $G^{\Sigma}$ acts 2-transitively on $\Sigma$. Therefore, $C^{\Sigma}$ acts transitively on $\Sigma$.

Assume that $\left(C^{\Sigma}\right)_{\Delta_{1}} \neq 1$, where $\Delta_{1} \in \Sigma$. Then $V<C_{\Delta_{1}}$ as $V \leqslant C \cap G(\Sigma)$ by Proposition 3.8(3). So $C_{\Delta_{1}}=C_{x} V$, and hence $C_{x} \leqslant G\left(\Delta_{1}\right)$, since $V$ acts transitively on $\Delta_{1}$ and $C=C_{G}(V)$. Therefore, $C_{x} \leqslant G(\Sigma)$ by Lemma 3.6(1). So $C_{\Delta_{1}} \leqslant G(\Sigma)$, and hence $\left(C^{\Sigma}\right)_{\Delta_{1}}=1$, a contradiction.
Assume that $\left(C^{\Sigma}\right)_{\Delta_{1}}=1$. Thus $C^{\Sigma}$ acts regularly on $\Sigma$ and hence $C^{\Sigma}=\operatorname{Soc}\left(G^{\Sigma}\right)$, since $\operatorname{Soc}\left(G^{\Sigma}\right) \leqslant C^{\Sigma}$. Therefore $C /(C \cap G(\Sigma)) \cong \operatorname{Soc}\left(G^{\Sigma}\right)$, where $\left|\operatorname{Soc}\left(G^{\Sigma}\right)\right|=$ $p^{m}+2$, with $p^{m}+2 \equiv 1,2(\bmod 4)$ according to whether $p$ is odd or even respectively, since $p^{m} \geqslant 3$ by Lemma 2.5. Thus $\operatorname{Soc}\left(G^{\Sigma}\right)$ is an elementary abelian group of order
$u^{h}$, for some prime $u$ and some integer $h \geqslant 1$, since $G^{\Sigma}$ acts 2 -transitively on $\Sigma$. Therefore $u^{h}=p^{m}+2$ and hence $u \neq p$. Then $C=X: U$, where $X=C \cap G(\Sigma)$ and $U$ is an elementary abelian of order $u^{h}$, by [19, Theorem 6.2.1] since $C /(C \cap G(\Sigma)) \cong$ $\operatorname{Soc}\left(G^{\Sigma}\right)$ and since $X$ is an elementary abelian $p$-group by Proposition 3.8(3). In particular $U \leqslant G L(X)$. Then $X=X_{1} \oplus \cdots \oplus X_{\ell}$, with $\ell \geqslant 1$, where the $X_{s}$ 's, $s=1, \ldots, \ell$, are irreducible $U$-invariant subspaces of $X$ by [19, Theorem 3.3.1]. Moreover, for each $s=1, \ldots, \ell$ there is a subgroup of $U_{s}$ of $U$ of index at most $u$, fixing $X_{s}$ pointwise by [19, Theorem 3.2.3], since $U$ is elementary abelian.
Assume that $V<X$. Then there is $X_{s_{0}}$ containing an element, say $x$, such that $x \notin V$. If $h>1$, let $\psi$ an element of $U_{s_{0}}, \psi \neq 1$. Then $\psi$ centralizes $V,\langle x\rangle$ and hence $V \oplus\langle x\rangle$. Now $V \oplus\langle x\rangle$ acts on $\Delta_{1}$, and since it contains $p^{2 m+1}$ elements, there is an element $\alpha \in V \oplus\langle x\rangle, \alpha \neq 1$, such that $\alpha \in G\left(\Delta_{1}\right)$, and $\alpha$ and $\psi$ commute. On the other hand $U$ acts regularly on $\Sigma$, since $U^{\Sigma}=C /(C \cap G(\Sigma)) \cong \operatorname{Soc}\left(G^{\Sigma}\right)$, with $C \cap G(\Sigma)$ a $p$-group by Proposition 3.8(3). Hence, $\psi$ maps $\Delta_{1}$ onto $\Delta_{e}$ for some $e>1$. So $\alpha \in G\left(\Delta_{1}\right) \cap G\left(\Delta_{e}\right)$, with $\alpha \neq 1$, since $\alpha$ and $\psi$ commute, and this contradicts Lemma 3.6(2). Thus $h=1$ and hence $U \cong Z_{u}$. If $U$ fixes an element in $X \backslash V$, we reach a contradiction by using the previous argument. Thus $U$ does not fix points in $X \backslash V$ and hence $u \mid p^{2 m+y}-p^{2 m+t}$, with $0 \leqslant t<y \leqslant 2 m$ by Lemma 3.8(2),(3), since $V<X$. Then $u \mid p^{y-t}-1$, with $0<y-t \leqslant 2 m$, which is impossible for Lemma 3.11. Thus $X=V$ and hence $C=V \times U$, where $U$ is elementary abelian of order $u^{h}$, with $u^{h}=p^{m}+2$. Moreover $U \unlhd G$ as $C \unlhd G$.
Let $U^{*}$ be a minimal normal subgroup of $G$ contained in $U$. The set $\Sigma^{\prime}$ of all point-$U^{*}$-orbits is $G$-invariant partition of the point set of $\mathcal{D}$. If either $\Sigma^{\prime}=\Sigma$ or $U^{*}$ acts point-transitively on $\mathcal{D}$, then $c$ or $v$ is a power of $u$ respectively. However both these cases lead to a contradiction, since $c=p^{2 m}, v=p^{2 m}\left(p^{m}+2\right)$ and $u \neq p$. Thus, $\Sigma^{\prime}=\left\{\Delta_{1}^{\prime}, \ldots, \Delta_{p^{2 m}}^{\prime}\right\}$, with $\left|\Delta_{j}^{\prime}\right|=p^{m}+2=u^{h}$ for each $j=1, \ldots, p^{2 m}$, by Lemma 2.7. Hence $U^{*}=U$ and we obtain (2a). Moreover, for each $B \in \mathcal{B}$ and $\Delta_{j}^{\prime} \in \Sigma^{\prime}$, the size $\left|B \cap \Delta_{j}^{\prime}\right|$ is either 0 or $2, G_{\Delta_{j}^{\prime}}^{\Delta_{j}^{\prime}}$ acts 2-transitively on $\Delta_{j}^{\prime}$ and $U^{\Delta_{j}^{\prime}}=\operatorname{Soc}\left(G_{\Delta_{j}^{\prime}}^{\Delta_{j}^{\prime}}\right)$. Finally, $\left|\Delta_{i} \cap \Delta_{j}^{\prime}\right|=1$ for each $\Delta_{i} \in \Sigma$ and $\Delta_{j}^{\prime} \in \Sigma^{\prime}$. Thus (2b.i)-(2b.iv) follow.

The Diophantine equation in Proposition 3.12(2.a) is a special case of the Pillai Equation (e.g see [44]). It has at most one solution in positive integers ( $m, h$ ) by [44, Theorem 6]. Moreover, $p>3$ for $h>1$, and $\left(p^{m}, u^{h}\right)=\left(5^{2}, 3^{3}\right)$ for $h>1$ and $m$ even by [44, Lemmas 2 and 4].

## 4. Reduction to the case $C_{G}(V) \leqslant G(\Sigma)$

In this section we show that only (1) of Proposition 3.12 occurs. Hence, assume that $C_{G}(V)=V \times U$, where $U$ is a minimal normal elementary abelian $u$-subgroup of $G$ of order $u^{h}$, where $u^{h}=p^{m}+2$, satisfying properties (2b.i)-(2b.iv) of Proposition 3.12.

Lemma 4.1. Let $\Delta \in \Sigma$ and $\Delta^{\prime} \in \Sigma^{\prime}$ and let $x$ be their intersection point. Then the following hold:
(1) $G_{x}$ acts faithfully on $\Delta$;
(2) $G_{x}^{\Delta^{\prime}}$ is isomorphic to a quotient group of $G_{x}$.

Proof. Let $\Delta_{i} \in \Sigma$ and $\Delta_{j}^{\prime} \in \Sigma^{\prime}$ and let $x_{i j}$ be their (unique) intersection point. Since $G(\Delta) \leqslant G(\Sigma)$ by Lemma $3.6(1), G(\Delta)$ preserves each $\Delta_{i}$. On the other hand, $G(\Delta)$ preserves each $\Delta_{j}^{\prime}$ since these ones intersect $\Delta$ in a unique point and since $\Sigma^{\prime}$ is a $G$-invariant partition of the point set of $\mathcal{D}$. Thus $G(\Delta)$ fixes each $x_{i j}$, that is, $G(\Delta)$ fixes $\mathcal{D}$ pointwise. Hence $G(\Delta)=1$, which is (1). Finally, assertion (2) holds since $G\left(\Delta^{\prime}\right) \unlhd G_{x}$.
Lemma 4.2. The following hold:
(1) $\frac{p^{m}}{\theta}\left(p^{m}+1\right)$ divides $\left|G_{x}\right|$;
(2) $\theta\left(p^{m}+2\right)\left(p^{m}+1\right)$ divides $\left|G_{\Delta^{\prime}}^{\Delta^{\prime}}\right|$.

Proof. Let $\Delta \in \Sigma$ and $\Delta^{\prime} \in \Sigma^{\prime}$ and let $x$ be their intersection point. The replication number $r=\frac{p^{m}}{\theta}\left(p^{m}+1\right)$ divides $\left|G_{x}\right|$, since $\mathcal{D}_{i}$ is a flag-transitive $2-\left(p^{2 m}, p^{m}, \frac{p^{m}}{\theta}\right)$ design, hence (1) holds.

Since $G_{\Delta^{\prime}}^{\Delta^{\prime}}$ acts 2-transitively on $\Delta^{\prime}$ and $U^{\Delta^{\prime}}=\operatorname{Soc}\left(G_{\Delta^{\prime}}^{\Delta^{\prime}}\right)$, with $U^{\Delta^{\prime}}$ elementary abelian of order $p^{m}+2$, by Proposition 3.12(2a), (2.b.iii) and (2.b.iv), it follows that $\left(p^{m}+2\right)\left(p^{m}+1\right)$ divides $\left|G_{\Delta^{\prime}}^{\Delta^{\prime}}\right|$.

Let $B$ be any block of $\mathcal{D}$ such that $x \in B$. Then $B \cap \Delta^{\prime}=\{x, y\}$, for some $y \neq x$, by Proposition [3.12(2.b.i). Let $\gamma \in G_{x, B \cap \Delta} \cap G\left(\Delta^{\prime}\right)$. Then $B^{\gamma} \cap \Delta=B \cap \Delta$, and $y \in B^{\gamma}$ since $B \cap \Delta^{\prime}=\{x, y\}$. Thus $(B \cap \Delta) \cup\{y\} \subseteq B^{\gamma} \cap B$, where $y \notin B \cap \Delta$ as $y \in \Delta^{\prime}, y \neq x$, and $\Delta \cap \Delta^{\prime}=\{x\}$. Therefore $\left|B^{\gamma} \cap B\right| \geqslant \lambda+1$ and hence $B^{\gamma}=B$. So $\gamma \in G_{x, B}$, as $x^{\gamma}=x$. Thus $G_{x, B \cap \Delta} \cap G\left(\Delta^{\prime}\right) \leqslant G_{x, B}$ and hence $\theta$ divides $\left|\left(G_{x, B \cap \Delta}\right)_{\Delta^{\prime}}^{\Delta^{\prime}}\right|$, since $\left[G_{x, B \cap \Delta}: G_{x, B}\right]=\theta$ by Corollary [2.2. So, $\theta$ divides $\left|G_{\Delta^{\prime}}^{\Delta^{\prime}}\right|$. Hence, $\theta\left(p^{m}+2\right)\left(p^{m}+1\right)\left|\left|G_{\Delta^{\prime}}^{\Delta^{\prime}}\right|\right.$, which is (2), since $\left.\theta\right| p^{m}$ and $\left(p^{m}+2\right)\left(p^{m}+1\right)$ divides $\left|G_{\Delta^{\prime}}^{\Delta^{\prime}}\right|$.
Theorem 4.3. $C_{G}(V) \leqslant G(\Sigma)$.
Proof. Let $\Delta_{i} \in \Sigma$ and $\Delta^{\prime} \in \Sigma^{\prime}$ and let $x_{i}$ be their intersection point. Recall that $\mathcal{D}_{i}$ is isomorphic to one of the 2-designs listed in Theorem 3.4. Since $p^{m}+2=u^{h}$, with $u$ prime, by Proposition 3.12(2.a), and since $p^{m} \geqslant 3$ by Lemma 2.5, it follows that $p>2$. Thus (2.a.ii), (2.c.iv)-(2.c.v) and (2.c.vii)-(2.c.viii) are ruled out. Also, if $p^{m}=3^{2}$ or $3^{3}$ then $h=1$ and either $u=11$ or $u=29$ respectively. Hence $G_{\Delta^{\prime}}^{\Delta^{\prime}} \cong A G L_{1}(u)$ by Proposition 3.12(2.b.iii). Then $\theta=1$ by Lemma 4.2(2), and hence (2.a.iii)-(2.a.iv) and (2.c.vi) of Theorem 3.4 are ruled out.

Assume that (2.c.i) occurs. Then $p^{m}+2 \mid\left(p^{m / 2}+1\right)\left(p^{m / 2}-1\right)^{2} m$ by Lemma $4.2(2)$. Since $p^{m}+2$ is the power of an odd prime $u$, it follows that either $p^{m}+2 \mid$ $\left(p^{m / 2}+1\right) m / 2$ or $p^{m}+2 \mid\left(p^{m / 2}-1\right)^{2} m / 2$. In both case we get $p^{m}+2 \leqslant\left(p^{m / 2}-1\right)^{2} p^{m / 2}$, since $m / 2 \leqslant p^{m / 2}$, and we reach a contradiction.

Assume that (2.c.ii) occurs. Arguing as above, we see that either $p^{m}+2 \mid\left(p^{m / 3}+\right.$ 1) $m / 3$ or $p^{m}+2 \mid\left(p^{m / 3}-1\right)^{2} m / 3$, which is impossible since $m / 3 \leqslant p^{m / 3}$.

Assume that (2.c.iii) occurs. Then either $p^{m}+2 \mid\left(p^{m / 2}+1\right)^{2} m / 2$ or $p^{m}+2 \mid$ $\left(p^{m / 2}-1\right)^{3} m / 2$. Since $p>2$, it follows that $m / 2 \leqslant p^{m / 2}-2$ and hence the former is ruled out. Since $\left(p^{m}+2, p^{m / 2}-1\right) \mid 3$ forces $p^{m}+2=3^{h}$, with $h>1$, and since $m$ is even, it results $m=2$ and $p^{m / 2}=5$ by [44, Lemmas 4]. However, such values do not fulfill $p^{m}+2 \mid\left(p^{m / 2}-1\right)^{3} m / 2$. So this case is excluded. Therefore only cases (2.a.i) or (2.b) are admissible, and bearing in mind Lemma 4.1(1), one of the following holds:
(i). $\mathcal{D}_{i} \cong A G_{2}\left(p^{m}\right), p>2$ and $p^{m} \neq 3^{2}, 3^{3}, \lambda=\theta=p^{m}$ and $G_{x_{i}} \leqslant \Gamma L_{2}\left(p^{m}\right)$.
(ii). $\mathcal{D}_{i}$ is a $2-\left(p^{2 m}, p^{m}, p^{m-s}\right)$ design, $p>2$ and $p^{m} \neq 3^{2}, 3^{3}, \theta=p^{s}$ with $0 \leqslant s \leqslant$ $m$, the blocks are subspaces of $A G_{2 m}(p)$ and $G_{x_{i}} \leqslant \Gamma L_{1}\left(p^{2 m}\right)$.
Assume that (i) occurs. Then $p^{m}$ divides the order of $G_{x_{i}}^{\Delta^{\prime}}$, and hence that of $G_{x_{i}}$ by Lemmas 4.1(2) and 4.2(2), since $\theta=p^{m}$ and $\left[G_{\Delta^{\prime}}^{\Delta^{\prime}}: G_{x_{i}}^{\Delta^{\prime}}\right]=p^{m}+2$, with $p>2$. This fact, together with Lemma 4.2(1), implies $S L_{2}\left(p^{m}\right) \unlhd G_{x_{i}} \leqslant \Gamma L_{2}\left(p^{m}\right)$. Then $G_{x_{i}}^{\Delta^{\prime}}$ contains either $P S L_{2}\left(p^{m}\right)$ or $S L_{2}\left(p^{m}\right)$ as a normal subgroup by Lemma 4.1(2), since $p^{m}$ divides the order of $G_{x_{i}}^{\Delta^{\prime}}$. Then $p^{m}=3,5,13$ by [24, Section 2, (B)], since $p>2$ and $p^{m} \neq 3^{2}$, since $G_{\Delta^{\prime}}^{\Delta^{\prime}}$ is an affine 2 -transitive group by Proposition 3.12(2b.iii)(2b.iv). Actually $p^{m} \neq 13$ and $u^{h}=5,7$ for $p^{m}=3,5$ respectively, since $u^{h}=p^{m}+2$ and $u$ is a prime. The case $p^{m}=3$ cannot occur by [38, Proposition 5.1], the case $p^{m}=5$ is excluded since $G_{\Delta^{\prime}}^{\Delta^{\prime}} \cong A G L_{1}(5)$ in these cases, whereas $G_{x_{i}}^{\Delta^{\prime}}$ is non-solvable. Thus case (i) is ruled out.
Assume that (ii) occurs. Then $p^{m-s}$ divides the order of $G_{x_{i}}$ by Lemma 4.2(1). On the other hand, $p^{s}$ divides the order of $G_{x_{i}}^{\Delta^{\prime}}$, and hence that of $G_{x_{i}}$, by Lemmas 4.1 (2) and 4.2(2). Hence $p^{a}$ divides the order of $G_{x_{i}}$ and hence that $\Gamma L_{1}\left(p^{2 m}\right)$, where $a=\max \{s, m-s\} \geqslant m / 2$. So $p^{m / 2} \leqslant m$, which is a contradiction as $p$ is odd. Thus (2) of Proposition 3.12 is ruled out and hence the assertion follows.

## 5. Proof of Theorem 3.1

In this section we complete the proof of Theorem [3.1. In the sequel, $C_{G}(V)$ and $G / C_{G}(V)$ will simply be denoted by $C$ and $H$ respectively.

Proposition 5.1. $H$ is an irreducible subgroup of $G L_{2 m+t}(p)$, where $0 \leqslant t \leqslant 2 m$.
Proof. Since $V$ is a minimal normal elementary abelian subgroup of $G$ of order $p^{2 m+t}$, with $0 \leqslant t \leqslant 2 m$, by Proposition [3.8(2), the assertion follows.

For each divisor $n$ of $2 m+t$ the group $\Gamma L_{n}\left(p^{(2 m+t) / n}\right)$ has a natural irreducible action on $V$. By Proposition 5.1 we may choose $n$ to be minimal such that $H \leqslant$ $\Gamma L_{n}\left(p^{(2 m+t) / n}\right)$ in this action and write $q=p^{(2 m+t) / n}$.

Let $a, e$ be integers. A divisor $w$ of $a^{e}-1$ that is coprime to each $a^{i}-1$ for $1 \leqslant i<e$ is said to be a primitive divisor, and we call the largest primitive divisor $\Phi_{e}^{*}(a)$ of $a^{e}-1$ the primitive part of $a^{e}-1$. One should note that $\Phi_{e}^{*}(a)$ is strongly related to cyclotomy in that it is equal to the quotient of the cyclotomic number $\Phi_{e}(a)$ and $\left(n, \Phi_{e}(a)\right)$ when $e>2$. Also $\Phi_{e}^{*}(a)>1$ for $a \geqslant 2, e>2$ and $(q, e) \neq(2,6)$ by Zsigmondy's Theorem (for instance, see [41, P1.7]).

Since $G^{\Sigma}$ is a 2-transitive almost simple group by Proposition 3.2, either $G^{\Sigma}$ is of affine type or an almost simple group. We analyze the two cases separately.
5.1. $G^{\Sigma}$ is of affine type. In this subsection we assume that $G^{\Sigma}$ is of affine type. Hence $\operatorname{Soc}\left(G^{\Sigma}\right)$ is an elementary abelian $u$-group for some prime $u$. Let $u^{h}$ be the order of $\operatorname{Soc}\left(G^{\Sigma}\right)$, then $u^{h}=p^{m}+2$ as $|\Sigma|=p^{m}+2$. In the sequel $U$ will denote the pre-image of $\operatorname{Soc}\left(G^{\Sigma}\right)$ in $G$.
Lemma 5.2. The following hold:
(1) A quotient group of $H$ has a 2-transitive permutation representation of degree $q^{n / 2}+2$.
(2) $\left(q^{n / 2}+1\right)\left(q^{n / 2}+2\right)\left||H|\right.$. In particular $\left.\Phi_{2 m}^{*}(p)\right||H|$.
(3) Either $\Phi_{2 m}^{*}(p)>1$, or $\left(p^{m}, u^{h}\right)=(3,5)$ or $(7,9)$.

Proof. Since $C \leqslant G(\Sigma)$ by Theorem 4.3 and since $G^{\Sigma}$ acts 2-transitively on $\Sigma$ by Proposition 3.2, a quotient of $H$ is isomorphic to $G^{\Sigma}$. Thus (1) and (2) follow.

Suppose that $\Phi_{2 m}^{*}(p)=1$, then either $n=2$ and $q$ is a Mersenne prime, or $(q, n)=(2,6)$ by [41, P1.7]. The latter is ruled out since $q^{n / 2}+2=10$ in this case, the former yields $u^{h}=q^{n / 2}+2=2^{y}+1$, for some prime $y \geqslant 0$. Then either $\left(p^{m}, u^{h}, y\right)=(7,9,3)$, or $h=1$ by [41, B1.1]. If $h=1$, then $u$ is a Fermat prime and hence $y=2$, as $y$ is a prime and we obtain $\left(u^{h}, y\right)=(5,2)$. Thus either $\left(p^{m}, u^{h}\right)=(3,5)$ or $\left(p^{m}, u^{h}\right)=(7,9)$.

From now on, we assume that $\Phi_{2 m}^{*}(p)>1$. The cases $\left(p^{m}, u^{h}\right)=(3,5),(7,9)$ are tackled at the end of this subsection.

Lemma 5.3. $n>1$.
Proof. Suppose that $n=1$. Then $H \leqslant \Gamma L_{1}(q)$ and hence $\left(p^{m}+2\right) \Phi_{2 m}^{*}(p) \mid\left(p^{2 m+t}-\right.$ 1) $\cdot(2 m+t)$. Then $2 m \mid 2 m+t$ by [26, Proposition 5.2.15(i)] and hence either $t=0$ or $t=2 m$, since $0 \leqslant t \leqslant 2 m$. If $t=0$, then $p^{m}+2 \mid\left(p^{2 m}-1\right) \cdot 2 m$ and hence $p^{m}+2 \mid 3 m$, which is impossible since $p^{m}>3$ by our assumption. Thus $t=2 m$ and hence $\left(p^{m}+2\right) \mid\left(p^{4 m}-1\right) \cdot 4 m$. So $p^{m}+2 \mid 15 m$ and hence $p^{m}=3$, but this contradicts our assumption.
Proposition 5.4. Let $H^{*}=H \cap G L_{n}(q)$, then $\left.\Phi_{2 m}^{*}(p) \frac{p^{m}+2}{\left(p^{m}+2,(2 m+t) / n\right)}| | H^{*} \right\rvert\,$.
Proof. By Lemma 5.2(2) $\frac{\Phi_{2 m}^{*}(p)\left(p^{m}+2\right)}{\left(\Phi_{2 m}^{*}(p)\left(p^{m}+2\right),(2 m+t) / n\right)}\left|\left|H^{*}\right|\right.$. Assume that $\left(\Phi_{2 m}^{*}(p),(2 m+\right.$ $t) / n))>1$. Then there is a primitive prime divisor $w$ of $p^{2 m}-1$ dividing $(2 m+t) / n$. So $w \mid 2 m+t$. On the other hand, $w=2 m a+1$ for some $a \geqslant 1$ by [26, Proposition 5.2.15(ii)]. Hence $(2 m a+1) s=2 m+t$ for some $s \geqslant 1$ and hence $t=s=a=1$. So $w=n=2 m+1$ and $q=p$, whereas $w \mid(2 m+1) / n$, a contradiction. Thus $\left.\left(\Phi_{2 m}^{*}(p),(2 m+t) / n\right)\right)=1$ and the assertion follows, since $\left(\Phi_{2 m}^{*}(p), p^{m}+2\right)=1$.
Proposition 5.5. $n=4 m, q=p$ and one of the following holds:
(1) $H \leqslant G L_{2 m}(p) \imath Z_{2}$ and $H$ preserves a sum decomposition $V=V_{1} \oplus V_{2}$ with $\operatorname{dim} V_{1}=\operatorname{dim} V_{2}=2 m$.
(2) $H \leqslant G L_{2}(p) \circ G L_{2 m}(p), m>1$, and $H$ preserves a tensor decomposition $V=V_{1} \otimes V_{2}$ with $\operatorname{dim} V_{1}=2$ and $\operatorname{dim} V_{2}=2 m$.

Proof. Assume that $Y \unlhd H$, where $Y$ is isomorphic to one of the groups $S L_{n}(q)$, $S p_{n}(q)$ for $n$ even, $S U_{n}\left(q^{1 / 2}\right)$ for $q$ square, or $\Omega_{n}^{\varepsilon}(q)$ with $\varepsilon= \pm$ for $n$ even, and $\varepsilon=0$ for $n q$ odd. Then $H \leqslant(Z \circ Y)$. $\operatorname{Out}(\bar{Y})$, where $Z=Z\left(G L_{n}(q)\right)$ and $\bar{Y}=Y /(Y \cap Z)$,
and hence $|H / Y||(q-1)| \operatorname{Out}(\bar{Y}) \mid$.
Let $X$ be the pre-image of $Y$ in $G$. Then $X \unlhd G$ and hence $X^{\Sigma} \unlhd G^{\Sigma}$. Either $X^{\Sigma}=1$ or $U^{\Sigma} \unlhd X^{\Sigma}$, since $G^{\Sigma}$ acts 2-transitively on $\Sigma$ and since $U^{\Sigma}=\operatorname{Soc}\left(G^{\Sigma}\right)$. The latter implies that $U^{\Sigma}$ is isomorphic to a normal subgroup of $X /(X \cap G(\Sigma))$, with $C \leqslant X \cap G(\Sigma)$ by Theorem 4.3, So $X /(X \cap G(\Sigma))$ is a quotient group of the classical group $Y$ and contains a normal elementary abelian group of order $u^{h}$. Then $C \leqslant X \cap G(\Sigma) \leqslant W$, where $W$ is the pre-image of $Z(Y)$ in $G$, and hence the normal elementary abelian subgroup of order $u^{h}$ of $X /(X \cap G(\Sigma))$ is contained in $W /(X \cap G(\Sigma))$. Thus $u^{h}$ divides $|Z(Y)|$ and hence $q-1$, which is impossible since $u^{h}=q^{n / 2}+2 \geqslant 5$ by Lemma 2.5. Therefore $X^{\Sigma}=1$ and hence $X \leqslant G(\Sigma)$. Thus $Y \leqslant G(\Sigma) / C$ by Theorem 4.3. On the other hand, we have $G^{\Sigma} \cong H /(G(\Sigma) / C)$, where $H /(G(\Sigma) / C)$ is a quotient group of $H / Y$. Thus $\left|G^{\Sigma}\right|$ divides the order of $H / Y$ and hence $\left|G^{\Sigma}\right||(q-1)| O u t(\bar{Y}) \mid$.
Note that $|\bar{Y}| \mid 4 \cdot n \cdot \mu(2 m+t) / n$, where $\mu=2$ or 3 according to whether $X$ is isomorphic or not to $\Omega_{8}^{+}(q)$ respectively. Then

$$
\begin{equation*}
\Phi_{2 m}^{*}(p)\left(p^{m}+2\right) \left\lvert\, \mu\left(p^{\frac{2 m+t}{n}}-1\right)(2 m+t)\right. \tag{5.1}
\end{equation*}
$$

since $\Phi_{2 m}^{*}(p)\left(p^{m}+2\right)$ divides the order $G^{\Sigma}$ by Proposition 3.2 and since $\Phi_{2 m}^{*}(p)$ and $p$ are odd. Let $w$ be a primitive prime divisor of $p^{m}+1$. If $w \left\lvert\, p^{\frac{2 m+t}{n}}-1\right.$, then $2 m \left\lvert\, \frac{2 m+t}{n}\right.$ by [26, Proposition 5.2.15(i)], and hence $n=2$ and $t=2 m$ as $t \leqslant 2 m$ and as $n>1$ by Lemma 5.3. Thus $\mu=2$ and $p^{m}+2 \mid m\left(p^{m}-1\right)$ and hence $p^{m}+2 \mid 3 m$, since $p$ is odd, which is impossible by $p^{m} \geqslant 3$. Thus $w \mid \mu(2 m+t)$.

If $\mu=2$, then $w \mid 2 m+t$. If $\mu=3$, then $n=8$ and hence $m \geqslant 2$ since $n \mid 2 m+t$ with $t \leqslant 2 m$. Moreover, $w \equiv 1(\bmod 2 m)$ by [26, Proposition 5.2.15(ii)] and hence $w \neq 3$. Thus $w \mid 2 m+t$ also in this case. Again from [26, Proposition 5.2.15(ii)] it results that $w=2 m+1$ and $t=1$. Moreover $n=2 m+1$, and hence $q=p$, since $n \mid 2 m+1$, with $2 m+1$ prime, and since $n>1$ by Lemma 5.3. Then $\Phi_{2 m}^{*}(p)\left(p^{m}+2\right) \mid(p-1) \mu n$ by (5.1), with $n$ dividing $\Phi_{2 m}^{*}(p)$, hence $p^{m}+2 \mid 3 \mu$, which is impossible since $p$ is odd and since $p^{m} \neq 7$ by our assumption. Thus $Y \notin H$ and hence $H$ lies either in a member of $\mathcal{C}_{i}(\Gamma)$ for some $i$ such that $1 \leqslant i \leqslant 7$, or is a member of $\mathcal{S}(\Gamma)$, where $\Gamma$ denotes $\Gamma L_{n}(q)$, by the Aschbacher's Theorem (see [26]).

Assume that $H$ lies in $\mathcal{S}(\Gamma)$. Then $S \unlhd H /(H \cap Z) \leqslant \operatorname{Aut}(S)$, where $S$ is a non-abelian simple group and $Z$ is the centre of $G L_{n}(q)$. Then the pre-image $N$ of $S$ in $H$ is absolutely irreducible and $N$ is not a classical group over a subfield of $G F(q)$ in its natural representation. Let $M$ and $Q$ be the pre-images in $G$ of $N$ and of $Z(N)$ respectively. Since $M, U \unlhd G$, we may use the above argument with $M, Q, N$ and $Z(N)$ in the role of $X, W, Y$ and $Z$, respectively, to obtain that either a quotient of $Z(N)$ contains a normal elementary subgroup of order $u^{h}$, or $M \unlhd G(\Sigma)$ and $\left|G^{\Sigma}\right||(q-1)| O u t(S) \mid$. The former implies that there is a subgroup of the Schur multiplier of $S$ containing a normal elementary subgroup of order $u^{h}$. Then $h=1$ by [26, Theorem 5.1.4]. Let $\psi$ be an element of $Z(N)$ of order $u$. Then $\psi$ does not fix non-zero vectors of $V$ and so $u \mid p^{2 m+t}-1$, with $0<2 m+t \leqslant 4 m$. Thus $p^{m}=9$ by Lemma 3.11, since $p^{m}>3$ by our assumption, and hence $u=11$ divides $|Z(N)|$ and $n \leqslant 4 m=8$. Also, $H$ is an irreducible subgroup of $\Gamma L_{n}\left(3^{(4+t) / n}\right)$ of order divisible by 55 by Lemma 5.2(2). Then either $t=1, n=5, q=3$ and $H=N$, where $N$ is isomorphic to $P S L_{2}(11)$ or $M_{11}$, or $t=2, n=6, q=3$ and $H=N \cong Z_{2} . M_{12}$ by [5, Tables 8.2, 8.4, 8.9, 8.19. 8.25, 8.36 and 8.43]. However, 11
does not divide the order $Z(N)$ in any of these groups and hence they are ruled out． Thus $M \unlhd G(\Sigma)$ ．Moreover， $1 \neq M^{\Delta_{i}} \unlhd G_{\Delta_{i}}^{\Delta_{i}}$ for each $\Delta_{i} \in \Sigma$ ，since $C \leqslant M$ ，and $M \cap G\left(\Delta_{i}\right) \leqslant Q$ for each $\Delta_{i} \in \Sigma$ ，since $M / Q \cong N / Z(N) \cong S$ ，with $S$ non－abelian simple．Hence $T \triangleleft M^{\Delta_{i}}$ and a quotient group of $M^{\Delta_{i}}$ is non－abelian simple．

Since $M^{\Delta_{i}}$ is non－solvable and since $p^{m}+2=u^{h}$ with $u$ prime and $p^{m}>3$ ，by Theorem 3．4，$M^{\Delta_{i}}=T:\left(M^{\Delta_{i}}\right)_{0}$ and one of the following holds：
（1）$S L_{2}\left(p^{m}\right) \unlhd\left(M^{\Delta_{i}}\right)_{0} \leqslant \Gamma L_{2}\left(p^{m}\right)$ ；
（2）$S U_{3}\left(p^{m / 3}\right) \unlhd\left(M^{\Delta_{i}}\right)_{0} \leqslant\left(Z_{p^{m / 3}-1} \times S U_{3}\left(p^{m / 3}\right)\right) . Z_{2 m / 3}, m \equiv 0(\bmod 3)$ ；
（3）$S p_{4}\left(p^{m / 2}\right) \unlhd\left(M^{\Delta_{i}}\right)_{0} \leqslant \Gamma S p_{4}\left(p^{m / 2}\right), m$ even；
（4）$\left(M^{\Delta_{i}}\right)_{0} \leqslant\left(Q_{8} \circ D_{8}\right) \cdot S_{5}$ and $p^{m}=9$ ．
Note that，in the previous list some automorphism groups of non－isomorphic 2－ designs listed in Theorem 3.4 are brought together．Indeed，the group in（2．c．i）is a subgroup of $\Gamma L_{2}\left(p^{m}\right)$ as well as that is（2．c．vi）of Theorem 3.4 is a subgroup of the full translation complement of Hall plane of order，which is $\left(Q_{8} \circ D_{8}\right) \cdot S_{5}$ by［32， Theorem II．8．3］．Either $S \cong P S L_{2}\left(p^{m}\right)$ or $S \cong P S U_{3}\left(p^{m / 3}\right)$ or $S \cong P S p_{4}\left(p^{m / 2}\right)$ ， or $S \cong P S L_{2}(5)$ for $p^{m}=9$ ，since $M^{\Delta_{i}} \cong M /\left(M \cap G\left(\Delta_{i}\right)\right), M \cap G\left(\Delta_{i}\right) \leqslant Q$ and $M / Q \cong N / Z(N) \cong S$ ，with $S$ non－abelian simple．However，both cases are ruled out since they violates $\left|G^{\Sigma}\right||(q-1)| \operatorname{Out}(S) \mid$ ，being $\left|G^{\Sigma}\right|$ divisible by $p^{m}+2$ with $p^{m}>3$ ．Thus $H$ lies in a member of $\mathcal{C}_{i}(\Gamma)$ for some $i$ such that $1 \leqslant i \leqslant 7$ ．

The group $H$ does not lie in a member of $\mathcal{C}_{1}(\Gamma)$ ，since $H$ is irreducible subgroup of $\Gamma$ by Proposition 5.1 and subsequent remark，and does not lie in a member of $\mathcal{C}_{3}(\Gamma)$ by the definition of $q$ ．Also，$H$ does not lies in a member of $\mathcal{C}_{5}(\Gamma)$ ．Indeed，if not so，then $n<4 m$ since $q=p$ for $n=4 m$ ．Then $H^{*}$ lies in a member of $\mathcal{C}_{5}\left(G L_{n}(q)\right)$ ， but this is impossible by［1，Theorem 3．1］，since $\Phi_{2 m}^{*}(p)| | H^{*} \mid$ by Proposition 5．4． Assume that $H$ lies in a member of $\mathcal{C}_{2}(\Gamma)$ ．Then $H$ stabilizes a decomposition of $V=V_{1} \oplus \cdots \oplus V_{n_{0}}, n_{0}>1$ ，where $\operatorname{dim} V_{1}=\cdots=\operatorname{dim} V_{n_{0}}=m_{0} \geqslant 1$ ．Thus $n=m_{0} n_{0}$ and hence $H^{*} \leqslant G L_{m_{0}}(q)$ 亿 $S_{n_{0}}$ ．

If $n<4 m$ ，then $m_{0}=1, n_{0}=n, q=p$ ，and either $p^{m}=3^{2}$ and $n \leqslant 7$ ，or $p^{m}=3^{3}, 5^{3}$ ，and $n \leqslant 11$ by［1．Theorem 3．1］，since $\Phi_{2 m}^{*}(p)| | H^{*} \mid$ and since $p$ is odd．Then $u=11,29$ or 127 respectively．Since $u$ does not divide the order of the corresponding $G L_{1}(q)$ 亿 $S_{n}$ ，then $u$ does not divide the order of $H^{*}$ ，whereas $u$ must divide it by Proposition 5．4．Indeed，in each of these cases $(u,(2 m+t) / n)=1$ since $u$ a prime such that $u>4 m \leqslant(2 m+t) / n$ ．Hence，these cases are ruled out．

If $n=4 m$ ，then $q=p$ and hence $H=H^{*} \leqslant G L_{m_{0}}(p)$ 亿 $S_{n_{0}}$ ．Let $w$ be a prime divisor of $p^{2 m}-1$ ．Then $w$ divides either the order of $G L_{m_{0}}(p)$ or that of $S_{n_{0}}$ ．The former yields $2 m \leqslant m_{0}$ by［26，Proposition 5．2．15（i）］．Therefore $(2 m) n_{0} \leqslant m_{0} n_{0}=$ $n=4 m$ and hence $n_{0}=2$ and $m_{0}=2 m$ ，since $n_{0}>1$ ．

The case where $w$ divides the order of $S_{n_{0}}$ yields $w=2 m+1$ ，since $w \equiv 1$ $(\bmod 2 m)$ by［26，Proposition 5．2．15（ii）］，and $n_{0}=4 m$ and $m_{0}=1$ ，since $n_{0} \mid 4 m$ and $n_{0} \geqslant w=2 m+1>2$ ．Note that $n_{0}=2$ and $m_{0}=2 m$ is clearly not compatible with $n_{0}=4 m$ and $m_{0}=1$ ．Hence，in the latter case $\Phi_{2 m}^{*}(p)=(2 m+1)^{s}$ for some $s \geqslant 1$ and it is a divisor of $n_{0}!$ ．Then $s<\frac{n_{0}-1}{2 m}<4 m / 2 m=2$ by［13，Exercise 2．6．8］and hence $\Phi_{2 m}^{*}(p)=2 m+1$ ．Thus $p^{m}=3^{2}, 3^{3}, 5^{3}$ by［1，Lemma 6．1．（i）］，and hence $p^{m}+2=11,29,127$ respectively．Then $p^{m}+2$ does not divide the order of the corresponding $H$ ，since $H \leqslant G L_{1}(p)$ $S_{4 m}$ ，and hence these cases are ruled out by Lemma $5.2(2)$ ．Therefore $n_{0}=2, m_{0}=2 m$ and hence $H \leqslant G L_{2 m}(p)$ 亿 $S_{2}$ preserves a decomposition $V=V_{1} \oplus V_{2}$ ，which is（1）．

Assume that $H$ lies in a member of $\mathcal{C}_{4}(\Gamma)$. Then $H$ preserves a tensor decomposition $V=V_{1} \otimes V_{2}$, with $\operatorname{dim} V_{i}=n_{i}$ and $1 \leqslant n_{1}<n_{2}$. Therefore, $H^{*} \leqslant G L_{n_{1}}(q) \circ G L_{n_{2}}(q)$. No cases arise for $n<4 m$ by [1, Theorem 3.1], since $\Phi_{2 m}^{*}(p)| | H^{*} \mid$. Thus $n=4 m$ and $q=p$, hence $H=H^{*} \leqslant G L_{2}(p) \circ G L_{2 m}(p)$ and we obtain (2).

Assume that $H$ lies in a member of $\mathcal{C}_{6}(\Gamma)$. Then $H$ lies in the normalizer in $\Gamma L_{n}(q)$ of an absolutely irreducible symplectic type $s$-group $R$, with $s \neq p$. Hence $n=s^{y}$ for some $y \geqslant 1$ by [26, Definition (c) at p. 150.]

If $n<4 m$, then $(q, n)=(3,4)$ or $(3,8)$ by [1, Theorem 3.1], since $\Phi_{2 m}^{*}(p)| | H^{*} \mid$ and $u^{h}=q^{n / 2}+2$ with $q$ odd. Thus $h=1$. Moreover, $n=2 m+t$ since $q=p$, and therefore $(m, t)=(2,2)$ for $(q, n)=(3,4)$, and $(m, t)=(3,2),(4,0)$ for $(q, n)=$ $(3,8)$, since $n<4 m$. A similar argument to that of the $\mathcal{S}$-case yields $u \mid 3^{2 m+t-f}-1$, with $0<2 m+t-f \leqslant 4 m$, where $3^{f}$ is the number of fixed points of an element of order $u$ of $H$. Either $m=1$ and $2+t-f=4$, or $m=2$ and $4+t-f=5$ by Lemma 3.11, whereas $m=2$ or 3,4 respectively. Thus $H$ does not lie in a member of $\mathcal{C}_{6}(\Gamma)$ for $n<4 m$.
If $n=4 m$, then $q=p$ and hence $s=2$ and $y \geqslant 2$ as $n=s^{y}$. Therefore, $m=2^{y-2}$. Let $w$ be a primitive prime divisor of $p^{2 m}-1$. Then $w=2^{y-1} j+1=2 m j+1$ for some $j \geqslant 1$ by [26, Proposition 5.2.15(ii)]. On the other hand, $w$ divides he order of $H$, where $H /(H \cap Z)$ is a subgroup of one of the groups given in [26, Table 4.6.A] for $s=2$, and $Z$ is the center of $G L_{4 m}(p)$. It follows that $w$ divides the order of $S p_{2 y}(2)$ and hence it divides either $2^{i}-1$ or $2^{i}+1$ for some $1 \leqslant i \leqslant y$. Then either $w=2^{y-1}+1=2 m+1$ or $w=2^{y}+1=2(2 m)+1$, respectively, and hence $\Phi_{2 m}^{*}(p)$ is either $2 m+1$ or $2(2 m)+1$ or $(2 m+1)(2(2 m)+1)$. Then $p^{m}=3^{2}, 3^{3}, 5^{3}, 3^{9}$ or $17^{3}$ by [1, Lemma 6.1], since $q=p$ and $p$ is odd. Actually $p^{m} \neq 3^{9}, 17^{3}$, since they do not fulfill $u^{h}=p^{m}+2$, whereas $h=1$ in the remaining cases. Then $u \mid p^{4 m-f}-1$, and arguing as above we obtain $p^{m}=3^{2}, u=11$ and $f=3$ and $n=8$. Since $q=p=3$, it follows that $Z(R) \cong Z_{2}, R \cong D_{8} \circ Q_{8}$ and hence $n=2$ by [26, Definition (c) and Table 4.6.B at p. 150]. However, it contradicts $n=8$ and hence it is ruled out.

Assume that $H$ lies in a member of $\mathcal{C}_{7}(\Gamma)$. Then $H$ stabilizes a decomposition of $V=V_{1} \otimes \cdots \otimes V_{n_{0}}$, where $\operatorname{dim} V_{1}=\cdots=\operatorname{dim} V_{n_{0}}=m_{0}$. Hence $n=m_{0}^{n_{0}}$, with $m_{0} \geqslant 1$ and $n_{0} \geqslant 2$, and $H^{*} \leqslant\left(G L_{m_{0}}(p) \circ \cdots \circ G L_{m_{0}}(p)\right) . S_{n_{0}}$. If $m_{0}<3$, then $H$ lies in a member of $\mathcal{C}_{8}(\Gamma)$ (see remark before Proposition 4.7.3 in [26]), which is not the case. Hence $m_{0} \geqslant 3$. No cases arise for $n<4 m$ by [1, Theorem 3.1], since $\Phi_{2 m}^{*}(p)| | H^{*} \mid$ by Proposition 5.4. Thus $n=4 m$ and $q=p$ and hence $H=H^{*}$. A prime divisor $w$ of $p^{2 m}-1$ divides either the order of $G L_{m_{0}}(p)$ or that of $S_{n_{0}}$. Since $w \equiv 1(\bmod 2 m)$ by [26, Proposition 5.2.15(ii)], the latter implies $n_{0} \geqslant 2 m+1$ and hence $3^{2 m+1} \leqslant m_{0}^{2 m+1} \leqslant 4 m$, a contradiction. Thus $w$ divides the order of $G L_{m_{0}}(p)$. Then $2 m \leqslant n_{0}$ by [26, Proposition 5.2.15(i)], and hence $(2 m)^{n_{0}} \leqslant m_{0}^{n_{0}}=n=4 m$. So $n_{0}=m_{0}=2$, and we reach a contradiction as $m_{0} \geqslant 3$. This completes the proof.

Lemma 5.6. The following hold in case (1) of Proposition 5.5:
(1) $H_{V_{j}}^{V_{j}}$ acts irreducibly on $V_{j}$ for $j=1,2$;
$\left.\Phi_{2 m}^{*}(p) \frac{p^{m}+2}{\left(p^{m}+2,3\right)}| | H_{V_{j}}^{V_{j}} \right\rvert\,$ for $j=1,2$;
(3) $H_{V_{j}}^{V_{j}}$ contains a normal subgroup $Q_{j}$ of order divisible by $\frac{p^{m}+2}{\left(p^{m}+2,3\right)}$ and such that $\Phi_{2 m}^{*}(p) \mid\left[H_{V_{j}}^{V_{j}}: Q_{j}\right]$ for $j=1,2$.

Proof. The length of $V\left(\Delta_{i}\right)^{G}$ is $p^{m}+2$ since $G$ acts transitively on $\Sigma$ and $V \unlhd G$. Then the length of $V\left(\Delta_{i}\right)^{H}$ is $p^{m}+2$, since $C=C_{G}(V)$. Let $w$ be a primitive prime divisor of $p^{2 m}-1$, and since $G_{\Delta_{i}}^{\Delta_{i}}$ acts flag-transitively on $\mathcal{D}_{i}$, let $W_{i}$ be a Sylow $w$-subgroup of $G$ preserving $\Delta_{i}$. Then $W_{i}$ normalizes $V\left(\Delta_{i}\right)$. Moreover, $W_{i}$ acts faithfully on $V$ inducing a Sylow $w$-subgroup of $H$, since $C$ is a $p$-group by Proposition 3.8(3) and Theorem 4.3.
Assume that $W_{i}\left(V_{1}\right) \neq 1$. Then $W_{i}\left(V_{1}\right)$ acts irreducibly on $V_{2}$. If it is not so, there is $\zeta \in W_{i}\left(V_{1}\right), \zeta \neq 1$, fixing $V_{2}$ pointwise, since $\operatorname{dim} V_{2}=2 m$ and $\zeta$ is a $w$-element with $w$ a primitive prime divisor of $p^{2 m}-1$. Then $\zeta \in C$ and hence $\zeta$ is a $p$-element, since $C$ is a $p$-group, whereas $\zeta$ is a non-trivial $w$-element with $w \neq p$. Clearly $W_{i}\left(V_{1}\right)$ preserves $\left\langle x_{1}\right\rangle \oplus V_{2}$ for each $x_{1} \in V_{1}, x_{1} \neq 0$. Since $\operatorname{dim}\left\langle x_{1}\right\rangle \oplus V_{2}=2 m+1$ and $\operatorname{dim} V\left(\Delta_{i}\right)=2 m$, it follows that $V\left(\Delta_{i}\right) \cap\left(\left\langle x_{1}\right\rangle \oplus V_{2}\right) \neq 0$. Let $\lambda \in G F(p)$ and $x_{2} \in V_{2}$ such that $\lambda x_{1}+x_{2} \in V\left(\Delta_{i}\right) \cap\left(\left\langle x_{1}\right\rangle \oplus V_{2}\right)$. If $x_{2} \neq 0$, there is a non-trivial $\alpha \in W_{i}\left(V_{1}\right)$ such that $x_{2}^{\alpha} \neq x_{2}$. Then $\lambda x_{1}+x_{2}^{\alpha} \in V\left(\Delta_{i}\right) \cap\left(\left\langle x_{1}\right\rangle \oplus V_{2}\right)$, since $W_{i}\left(V_{1}\right)$, and hence $\alpha$, preserves $V\left(\Delta_{i}\right) \cap\left(\left\langle x_{1}\right\rangle \oplus V_{2}\right)$. Hence $x_{2}^{\alpha}-x_{2}$ is a non-zero element of $V\left(\Delta_{i}\right) \cap V_{2}$, since $x_{2}^{\alpha}-x_{2}=\left(\lambda x_{1}+x_{2}^{\alpha}\right)-\left(\lambda x_{1}+x_{2}\right)$ and $x_{2}^{\alpha} \neq x_{2}$. Thus $V\left(\Delta_{i}\right)=V_{2}$ since $W_{i}\left(V_{1}\right)$ acts irreducibly on $V_{2}$ and preserves $V\left(\Delta_{i}\right)$. So $p^{m}+2=2$, since the length of $V\left(\Delta_{i}\right)^{H}$ is $p^{m}+2$ and since $H$ switches $V_{1}$ and $V_{2}$, and we reach a contradiction. Thus $x_{2}=0$ and hence $\lambda x_{1} \in V\left(\Delta_{i}\right) \cap V_{1}$. Then $V\left(\Delta_{i}\right)=V_{1}$ and hence $\left|V\left(\Delta_{i}\right)^{H}\right|=p^{m}+2=2$, which is a contradiction. Thus $W_{i}$ acts faithfully and irreducibly on $V_{1}$. Similarly, we prove that $W_{i}$ acts faithfully and irreducibly on $V_{2}$. Thus $H_{V_{j}}^{V_{j}}$ acts irreducibly on $V_{j}$, which is (1), and $\Phi_{2 m}^{*}(p)| | H_{V_{j}}^{V_{j}} \mid$.

Recall that $U$ is the pre-image of $\operatorname{Soc}\left(G^{\Sigma}\right)$. Let $S$ be a Sylow $u$-subgroup of $U$, where $u^{h}=p^{m}+2$. Then $S$ acts faithfully on $V$ inducing a Sylow $u$-subgroup of $H$, since $C$ is a $p$-group. Assume that $S\left(V_{1}\right) \neq 1$. Since $\left(p^{m}+2, p^{2 m}-1\right) \mid 3$, there is a subgroup of $Y$ of $S\left(V_{1}\right)$ such that $\left[S\left(V_{1}\right): Y\right] \leqslant(3, u)$ fixing an non-zero element $z_{2}$ of $V_{2}$. Then $Y$ fixes $V_{1} \oplus\left\langle z_{2}\right\rangle$ pointwise. Since $V\left(\Delta_{i}\right) \cap\left(V_{1} \oplus\left\langle z_{2}\right\rangle\right) \neq 0$ for each $i=1, \ldots, p^{m}$, there is an element of $v_{i} \in V\left(\Delta_{i}\right), v_{i} \neq 0$, fixed by $Y$ for each $i=1, \ldots, p^{m}$.

Assume that $Y \not \leq G(\Sigma)$. Then there are $\eta \in Y$ and $i_{0} \in\left\{1, \ldots, p^{m}+2\right\}$ such that $\left[v_{i_{0}}, \eta\right]=1$ and $\Delta_{i_{0}}^{\eta} \neq \Delta_{i_{0}}$. Then $v_{i_{0}} \in V\left(\Delta_{i_{0}}\right) \cap V\left(\Delta_{i_{0}}^{\eta}\right)$, with $v_{i} \neq 0$, whereas $V\left(\Delta_{i_{0}}\right) \cap V\left(\Delta_{i_{0}}^{\eta}\right)=0$ by Lemma 3.6 (2), since $\Delta_{i_{0}}^{\eta} \neq \Delta_{i_{0}}$. Thus $Y \leqslant G(\Sigma)$ and hence $\left[S\left(V_{1}\right): S\left(V_{1}\right) \cap G(\Sigma)\right] \leqslant(3, u)$. Similarly, we have $\left[S\left(V_{2}\right): S\left(V_{2}\right) \cap G(\Sigma)\right] \leqslant(3, u)$. Thus

$$
\left|S^{V_{j}}\right|=\frac{|S|}{\left|S\left(V_{j}\right)\right|} \geqslant \frac{|S|}{(3, u)\left|S\left(V_{2}\right) \cap G(\Sigma)\right|} \geqslant \frac{|S|}{(3, u)|S \cap G(\Sigma)|}=\frac{\left|U^{\Sigma}\right|}{(3, u)}=\frac{p^{m}+2}{\left(p^{m}+2,3\right)},
$$

since $U=G(\Sigma) S$. Thus $\frac{p^{m}+2}{\left(p^{m}+2,3\right)}\left|\left|S^{V_{j}}\right|\right.$, since $u^{h}=p^{m}+2$ and $S^{V_{j}}$ is a $u$-group, and hence $\left.\Phi_{2 m}^{*}(p) \frac{p^{m}+2}{\left(p^{m}+2,3\right)}| | H_{V_{j}}^{V_{j}} \right\rvert\,$, since we have already proven that $\Phi_{2 m}^{*}(p)| | H_{V_{j}}^{V_{j}} \mid$. Therefore, we get (2). Moreover $S^{V_{j}} \leqslant Q_{j} \unlhd H^{V_{j}}$, where $Q_{j}=(U / C)^{V_{j}}$, since $C \unlhd G(\Sigma) \unlhd U$ by Theorem 4.3. Hence the order of $Q_{j}$ is divisible by $\frac{p^{m}+2}{\left(p^{m}+2,3\right)}$. Also, since $G^{\Sigma}$ acts 2-transitively on $\Sigma$, it follows that $\Phi_{2 m}^{*}(p)$ divides $\left[G^{\Sigma}: U^{\Sigma}\right]$ and
hence $[G: U]$. Then $\Phi_{2 m}^{*}(p)$ divides $[H: U / C]$, since $C \unlhd U$ and $C$ is a $p$-group, and hence $\left[H_{V_{j}}^{V_{j}}: Q_{j}\right]$ for each $j=1,2$, which is (3).

Lemma 5.7. The following hold in case (2) of Proposition 5.5:
(1) $H^{V_{2}}$ acts irreducibly on $V_{2}$;
(2) $\left.\Phi_{2 m}^{*}(p) \frac{p^{m}+2}{\left(p^{m}+2,3\right)}| | H^{V_{2}} \right\rvert\,$;
(3) $H^{V_{2}}$ contains a normal subgroup $Q_{2}$ of order divisible by $\frac{p^{m}+2}{\left(p^{m}+2,3\right)}$ and such that $\Phi_{2 m}^{*}(p) \mid\left[H^{V_{2}}: Q_{2}\right]$.

Proof. Set $M=G L_{2}(p) \circ G L_{2 m}(p)$. Let $w$ be primitive prime divisor of $p^{2 m}-1$ and let $W$ be a Sylow $w$-subgroup of $H$. Then $W^{V_{1}} \leqslant H^{V_{1}}$ and hence $W^{V_{1}}=1$, since $m>1$ by Proposition 5.5(2). Therefore, $W^{V_{2}} \cong W$, since $V=V_{1} \otimes V_{2}$ and $W \cap Z(M)=1$, being $Z(M) \leqslant Z_{p-1}$. Thus $H^{V_{2}}$ acts irreducibly on $V_{2}$, which is (1), and $\Phi_{2 m}^{*}(p)| | H^{V_{2}} \mid$.
Let $S$ be a Sylow $u$-subgroup of $U$, where $U \cong \operatorname{Soc}\left(G^{\Sigma}\right)$. Then $S$ acts faithfully on $V$ inducing a Sylow $u$-subgroup of $H$, where $u^{h}=p^{m}+2$ and $p$ is odd, since $C$ is a $p$ group by Proposition 3.8 (3) and Theorem 4.3. Note that $S^{V_{1}}$ is a subgroup of $G L_{2}(p)$ of order at most 9 , since $\left(p^{m}+2,(p-1)^{2}\right) \mid 9$. Hence $S=S\left(V_{1}\right)$ or $\left[S: S\left(V_{1}\right)\right] \leqslant 9$ according to whether 3 does not divide or does divide the order of $Z(M)$. Thus $\left|S^{V_{2}}\right| \geqslant \frac{|S|}{\left(p^{m}+2,3\right)}$ since $S\left(V_{1}\right) \cap S\left(V_{2}\right) \leqslant Z(M) \leqslant Z_{p-1}$. Then $\frac{p^{m}+2}{\left(p^{m}+2,3\right)}\left|\left|S^{V_{2}}\right|\right.$, since $u^{h}=p^{m}+2$ and $S^{V_{2}}$ is a $u$-group, hence $\left.\Phi_{2 m}^{*}(p) \frac{p^{m}+2}{\left(p^{m}+2,3\right)}| | H^{V_{2}} \right\rvert\,$, which is (2).
Since $C \unlhd G(\Sigma) \unlhd U$ by Theorem 4.3, let $Q_{2}=(U / C)^{V_{2}}$. Then the order of $Q_{2}$ is divisible by $\frac{p^{m}+2}{\left(p^{m}+2,3\right)}$, since $S^{V_{2}} \leqslant Q_{2} \unlhd H^{V_{2}}$. Now a similar argument to that of the proof of Lemma 5.6(3) can be used to obtain that $\Phi_{2 m}^{*}(p)$ divides [ $H^{V_{2}}: Q_{2}$ ]. Thus we obtain (3).

Remark 5.8. In view of Lemmas 5.6 and 5.7, in (1) and in (2) of Proposition 5.5 there is a quotient group $X$ of a subgroup of $H$ with the following properties:
(1) $X$ is an irreducible subgroup of $G L\left(V_{2}\right)$ of order divisible by $\Phi_{2 m}^{*}(p) \frac{p^{m}+2}{\left(p^{m}+2,3\right)}$;
(2) $X$ contains a normal subgroup $Q$ of order divisible by $\frac{p^{m}+2}{\left(p^{m}+2,3\right)}$ and such that $\Phi_{2 m}^{*}(p) \mid[X: Q] ;$
(3) $p^{m}+2=u^{h}$, where $u$ is a prime and $h \geqslant 1$.

We are going to show that a quotient group of $H$ with such constraints does not exist. We derive from this fact that $\Phi_{2 m}^{*}(p)=1$, hence $\left(p^{m}, u^{h}\right)=(3,5),(7,9)$ by Lemma 5.2(3).

For each divisor $\ell$ of $2 m$ the group $\Gamma L_{\ell}\left(p^{2 m / \ell}\right)$ has a natural irreducible action on $V_{2}$. By Proposition 5.1 we may choose $\ell$ to be minimal such that $X \leqslant \Gamma L_{\ell}\left(p^{2 m / \ell}\right)$ in this action and write $a=p^{2 m / \ell}$.

Lemma 5.9. The following hold
(1) $\ell>1$;
(2) $Q \not \leq Z\left(G L_{\ell}(a)\right)$.

Proof. Suppose that $\ell=1$. Then $X \leqslant \Gamma L_{1}(a)$ and hence $\left.\Phi_{2 m}^{*}(p) \frac{p^{m}+2}{\left(p^{m}+2,3\right)} \right\rvert\,\left(p^{2 m}-1\right)$. $(2 m)$. Then we obtain (1) by proceeding as in Lemma 5.3 (for $t=0$ ) with $\frac{p^{m}+2}{\left(p^{m}+2,3\right)}$ in the role of $p^{m}+2$ and bearing in mind that $p^{m} \neq 7$.

Suppose the contrary. Then $\left.\frac{p^{m}+2}{\left(p^{m}+2,3\right)} \right\rvert\, p^{2 m / \ell}-1$ and hence $p^{m}+2 \mid 9$. So $\left(p^{m}, u^{h}\right)=$ (7,9), since $p^{m} \geqslant 3$ by Lemma 2.5, but his case is ruled out since it contradicts the assumption $\Phi_{2 m}^{*}(p)>1$. Thus we obtain (2).

Let $X^{*}=X \cap G L_{\ell}(a)$. Then $\Phi_{2 m}^{*}(p)$ divides the order of $X^{*}$, since $\left(\Phi_{2 m}^{*}(p), \ell\right)=1$ by [26, Proposition 5.2.15.(ii)], being $\ell \mid 2 m$. Then one of the following holds by [1, Theorem 3.1] and by the minimality of $\ell$ :
(i). $X^{*}$ contains as a normal subgroup $Y$ isomorphic to one of the groups $S L_{\ell}(a)$ with $\ell \geqslant 2, S p_{\ell}(a)$ or $\Omega_{\ell}^{-}(a)$ with $\ell$ even and $\ell \geqslant 2$, or $S U_{\ell}\left(a^{1 / 2}\right) \unlhd X$ with $a$ square, $\ell$ odd and $\ell \geqslant 3$.
(ii). $X^{*} \leqslant\left(D_{8} \circ Q_{8}\right) \cdot S_{5}$ and $(\ell, a)=(4,3)$.
(iii). $X^{*}$ is nearly simple, that is, $S \unlhd X^{*} /\left(X^{*} \cap Z\right) \leqslant \operatorname{Aut}(S)$, where $Z$ is the center of $G L_{\ell}(a)$ and $S$ is a non-abelian simple group. Moreover, if $Y$ is the pre-image of $S$ in $X^{*}$, then $Y$ is absolutely irreducible on $V$ and $Y$ is not a classical group defined over a subfield of $G F(a)$ in its natural representation.

Theorem 5.10. $\left(p^{m}, u^{h}\right)=(3,5),(7,9)$.
Proof. Assume that (i) occurs. Then $X \leqslant\left(Z \circ X^{*}\right) . \operatorname{Out}\left(\bar{X}^{*}\right)$, with $\bar{X}^{*}=X^{*} /\left(X^{*} \cap\right.$ $Z$ ), where $Z=Z\left(G L_{\ell}(a)\right)$. It follows that $X^{*} \unlhd Q$ by Lemma 5.9(2), since $Q \unlhd X$. Then $\Phi_{2 m}^{*}(p)|(a-1)| \operatorname{Out}\left(X^{*}\right) \mid$, since $\Phi_{2 m}^{*}(p) \mid[X: Q]$ by Remark $[5.8(3)$, and hence $\Phi_{2 m}^{*}(p) \mid\left(p^{2 m / \ell}-1\right) 2 m$. However this impossible by [26, Proposition 5.2.15], since $\ell>1$ by Lemma 5.9(1).

Case (ii) is ruled out, since $a^{\ell / 2}+2=11$ does not divide the order of $X$
Assume that case (iii) occurs. Suppose that $S \cong A_{s}, s \geqslant 5$ and that $V_{2}$ is the fully deleted permutation module for $A_{s}$. Then $a=p, n=2 m, A_{s} \unlhd X^{*} \leqslant S_{s} \times Z$, where $Z$ is the center of $G L_{2 m}(p)$, and either $s=2 m+1$ or $s=2 m+2$ according to whether $p$ does not divide or does divide $s$, respectively, by [26, Lemma 5.3.4]. Moreover $p^{m}=3^{2}, 3^{3}, 5^{3}$ by [1, Theorem 3.1], since $p$ is odd, and hence $p^{m}+2=11,29,127$ respectively. However, such values of $p^{m}+2$ do not divide $|X|$ and hence they are ruled out (see Remark 5.8).

Assume that $S \cong A_{s}, s \geqslant 5$ and that $V_{2}$ is not the fully deleted permutation module for $A_{s}$. Then $(\ell, a)=(4,7), Z_{2} \cdot A_{7} \unlhd H \leqslant Z_{2} \cdot S_{7} \times Z_{3}$ and $V_{2}=V_{4}(7)$ by 1, Theorem 3.1], since $p$ is odd. However it is ruled out, since $7^{2}+2$ does not divide the order of $X$.

Assume that $S$ is sporadic. Then $S \cong J_{2}$ and $(\ell, a)=(6,5)$ by [1, Theorem 3.1], since $p$ is odd. However $a^{\ell / 2}+2=127$ does not divide the order of $X$ and hence this case is excluded.

Assume that $S$ is a Lie type simple group in characteristic $p^{\prime}$. Then $S$ is given in [1, Theorem 3.1] and recorded in Table 5.1. Since $\frac{a^{\ell / 2}+2}{\left(a^{\ell / 2}+2,3\right)}||X|$ and since $S \unlhd X^{*} /\left(X^{*} \cap Z\right) \leqslant \operatorname{Aut}(S)$, it follows that

$$
\varrho=\frac{a^{\ell / 2}+2}{\left(a^{\ell / 2}+2,3(a-1)|A u t(S)|\right)}
$$

TAble 1. Admissible $S$ and corresponding $\varrho$

| $S$ | $\ell$ | $a$ | $\varrho$ |
| :--- | :--- | :--- | :--- |
| $P S L_{2}(7)$ | 6 | 3 | 29 |
|  | 6 | 5 | 127 |
|  | 3 | 9 | 29 |
|  | 3 | $5^{2}$ | 127 |
| $P S L_{2}(13)$ | 6 | 3 | 29 |
| $P S L_{3}\left(2^{2}\right)$ | 6 | 3 | 29 |
| $P S U_{3}(3)$ | 6 | 5 | 127 |

must divide the order of $S$. However, the order of $S$ is divisible by the corresponding $\varrho$ in none of the cases listed in Table 5.1. Hence all the groups in Table 5.1 are excluded.

Assume that $S$ is a Lie type simple group in characteristic $p$. Then $p=2$ by [1, Theorem 3.1], whereas $p$ must be odd, and hence no cases arise. Thus $\Phi_{2 m}^{*}(p)=1$ and hence $\left(p^{m}, u^{h}\right)=(3,5),(7,9)$ by Lemma 5.2(3).
Theorem 5.11. If $G^{\Sigma}$ is of affine type, then $\mathcal{D}$ is isomorphic to the 2-(45, 12,3) design constructed in [38, Construction 4.2].

Proof of Theorem 3.1. It follows from Theorem 5.10 that $\left(p^{m}, u^{h}\right)=(3,5)$ or $(7,9)$, and the assertion follows in the former case by [38, Corollary 4.2]. Hence, in order to complete the proof we need to rule out $\left(p^{m}, u^{h}\right)=(7,9)$. We are going to prove this in a series of steps.
(1). Let $\Delta_{i} \in \Sigma$ and $x_{i} \in \Delta_{i}$. Then $G^{\Sigma} \cong A G L_{1}(9), G_{x_{i}}^{\Delta_{i}} \cong Z_{3^{j}} \times Z_{16}$ and $G(\Sigma)_{x_{i}}^{\Delta_{i}} \cong Z_{3^{j}} \times Z_{2}$ where $j=0,1$.
$G_{\Delta_{i}}^{\Sigma} \cong Z_{8}, Q_{8}, S D_{16}, S L_{2}(3), G L_{2}(3)$ by [24, Section 2, (B)], since $G^{\Sigma}$ is an affine group acting 2-transitively on $\Sigma$ by Proposition 3.2. On the other hand, since $\mathcal{D}_{i} \cong A G_{2}(7)$ by Theorem 3.4, since $m=1$, it follows from [15, Theorem 1 ' and Table II] that either $S L_{2}(7) \unlhd G_{x_{i}}^{\Delta_{i}} \leqslant G L_{2}(7)$, or $G_{x_{i}}^{\Delta_{i}} \leqslant \Gamma L_{1}\left(7^{2}\right)$ or $G_{x_{i}}^{\Delta_{i}} \cong$ $S L_{2}(3) . Z_{2}$. Moreover, if $G_{x_{i}}^{\Delta_{i}} \leqslant \Gamma L_{1}\left(7^{2}\right)$, it is not difficult to see that $G_{x_{i}}^{\Delta_{i}} \cong$ $Z_{3 j} \times Z_{16}, Z_{3^{j}} \times Q_{16}, Z_{3 j} \times S D_{32}$, with $j=0,1$. Using (3.1) in Corollary 3.10, with $G_{\Delta_{i}}^{\Sigma} \cong Z_{8}, Q_{8}, S D_{16}, S L_{2}(3), G L_{2}(3)$, we see that the unique possibilities are $G_{\Delta_{i}}^{\Sigma} \cong Z_{8}$ and either $G_{x_{i}}^{\Delta_{i}} \cong Z_{16}$ and $G(\Sigma)_{x_{i}}^{\Delta_{i}} \cong Z_{2}$, or $G_{x_{i}}^{\Delta_{i}} \cong Z_{48}$ and $G(\Sigma)_{x_{i}}^{\Delta_{i}} \cong Z_{8}$. Thus $G^{\Sigma} \cong A G L_{1}(9), G_{x_{i}}^{\Delta_{i}} \cong Z_{3^{j}} \times Z_{16}$ and $G(\Sigma)_{x_{i}}^{\Delta_{i}} \cong Z_{3^{j}} \times Z_{2}$ with $j=0,1$.
(2). $G\left(\Delta_{i}\right) \leqslant E_{7^{2}}:\left(Z_{3 j} \times Z_{2}\right)$ for each $i=1, \ldots, 9$.

Since $G\left(\Delta_{i}\right) \unlhd G(\Sigma)$ and $G\left(\Delta_{i}\right) \cap G\left(\Delta_{s}\right)=1$ for each $s \in\{1, \ldots, 9\}$, with $s \neq i$, by Lemma 3.6 (2), it follows that $G\left(\Delta_{i}\right)$ is isomorphic to a normal subgroup of $G(\Sigma)^{\Delta_{s}}$. On the other hand $G(\Sigma)^{\Delta_{s}} \cong E_{7^{2}}: Z_{3 j} \times Z_{2}$ with $j=0,1$, since $G(\Sigma)=G(\Sigma)_{x_{s}} V$ by Proposition 3.8(1)(3) and since $G(\Sigma)_{x_{s}}^{\Delta_{s}} \cong Z_{3 j} \times Z_{2}$ with $j=0,1$ by (1). Thus $G\left(\Delta_{i}\right) \leqslant E_{7^{2}}: Z_{3^{j}} \times Z_{2}$.
(3). $G$ is solvable.

It follows from (2) that $G\left(\Delta_{i}\right)$ is solvable. Thus $G(\Sigma)_{x_{i}}$ is solvable, since $G(\Sigma)_{x_{i}}^{\Delta_{i}} \cong$ $Z_{3 j} \times Z_{2}$ by (1), and hence $G(\Sigma)$ is solvable since $G(\Sigma)=G(\Sigma)_{x_{i}} V$. Therefore $G$ is solvable, since $G^{\Sigma} \cong A G L_{1}(9)$.
(4). $H$ is a solvable irreducible subgroup of $G L_{4}(7)$.

Recall that $H$ is an irreducible subgroup of $G L_{2+t}(7)$, with $t \leqslant 2$, by Proposition 5.1, and let $R$ be the pre-image of $H \cap S L_{2+t}(7)$ in $G$. Then $R \triangleleft G$. Therefore $R^{\Sigma} \triangleleft G^{\Sigma}$ and hence either $R^{\Sigma}=1$ or $E_{9} \unlhd R^{\Sigma}$, since $G^{\Sigma} \cong A G L_{1}(9)$. The former implies $R \leqslant G(\Sigma)$ and hence $9\left||G / R|\right.$. Then 9 divides the index of $S L_{2+t}(7)$ in $G L_{2+t}(7)$, since $G / R \cong H /\left(H \cap S L_{2+t}(7)\right)$, which is a contradiction. Thus $E_{9} \unlhd R^{\Sigma}$ and hence a quotient group of $H \cap S L_{2+t}(7)$ contains a normal subgroup isomorphic to $E_{9}$, since $C$ is a 7-group by Proposition 3.8(2) and Theorem 4.3,
Let $M$ be the pre-image of $H \cap Z\left(G L_{2+t}(7)\right)$ in $G$. Clearly $M \triangleleft G$. Therefore $M^{\Sigma} \triangleleft G^{\Sigma}$ and hence either $M^{\Sigma}=1$ or $9\left|\left|M^{\Sigma}\right|\right.$, since $G^{\Sigma} \cong A G L_{1}(9)$. The latter implies $9\left||M / C|\right.$, since $C$ is a 7 -group, whereas $M / C=H \cap Z\left(G L_{2+t}(V)\right) \leqslant Z_{6}$. Thus $M^{\Sigma}=1$ and hence $M \leqslant G(\Sigma)$.

Set $A=\left(H \cap S L_{2+t}(7)\right) /\left(H \cap Z\left(S L_{2+t}(7)\right)\right)$, then $A$ is isomorphic to a solvable subgroup of $P S L_{2+t}(7)$. Moreover, a quotient group of $A$ contains $E_{9}$ as a normal subgroup, since $A \cong R / M, E_{9} \unlhd R^{\Sigma}$ and $M \leqslant G(\Sigma)$. Thus $t \neq 0$.

Assume that $t=1$. Since $Z_{16} \leqslant G_{x_{i}}^{\Delta_{i}}$, then $H$ contains 2-elements of order at least 16 and hence $A$ contains elements of order at least 8 . Hence $A$ is isomorphic to a solvable subgroup of $P S L_{3}(7)$ of order divisible by 72 . Then $A \cong E_{9}: Q_{8}$ by [8], whereas $A$ contains elements of order at least 8 . Thus $t \neq 1$ and hence the claim follows from (3) and from Proposition 5.1.
(5). $G=C:(Q: J)$, where $|Q|=3^{2+j}$, with $0 \leqslant j \leqslant 1$, and $J \cong Z_{16}$.

Let $S$ be a Sylow 7 -subgroup of $G$ containing $C$. Since $G^{\Sigma} \cong A G L_{1}(9)$, it follows that $S \leqslant G(\Sigma)$. Since $G_{\Delta_{i}}^{\Delta_{i}} \cong E_{7^{2}}:\left(Z_{3^{j}} \times Z_{16}\right)$ and $G\left(\Delta_{i}\right) \leqslant E_{7^{2}}:\left(Z_{3^{j}} \times Z_{2}\right)$ by (1) and (2), it follows that $|S| \leqslant 7^{4}$. On the other hand, $7^{4} \leqslant|C| \leqslant|S|$ by (4) and by Proposition $3.8(3)$. Hence $S=C \unlhd G$. Moreover, $|H|=2^{4+e} \cdot 3^{2+f}$, where $e \leqslant 1$ and $j \leqslant f \leqslant 2$, again by (1) and (2). Then $G=C: K$, where $K$ is a group of order $2^{4+e} \cdot 3^{2+f}$ by [19, Theorem 6.2.1(i)].
Since $K^{\Sigma} \cong A G L_{1}(9)$, it results $|K(\Sigma)|=2^{1+e} \cdot 3^{f}$, with $e \leqslant 1$ and $j \leqslant f \leqslant 2$. Let $S$ be a Sylow $w$-subgroup of $K(\Sigma)$, where $w \in\{2,3\}$. If either $e=1$ or $f=2$, assume that $w$ is 2 or 3 respectively. Then $Z_{w} \leqslant S\left(\Delta_{i}\right)$ for each $i \in\{1, \ldots, 9\}$, since $|S|=w^{2}$, and since $G(\Sigma)_{x_{i}}^{\Delta_{i}} \cong Z_{3 j} \times Z_{2}$, with $j=0,1$, for each $i \in\{1, \ldots, 9\}$ by (1). Then $S\left(\Delta_{i}\right) \cap S\left(\Delta_{i^{\prime}}\right) \neq 1$ for some $i, i^{\prime} \in\{1, \ldots, 9\}$, with $i \neq i^{\prime}$, since the number of cyclic subgroup of $Q(\Sigma)$ is $w+1$, which is at most 4 , and $|\Sigma|=9$. Since it contradicts Lemma 3.6(2), this case is excluded. Thus $e=0, f \leqslant 1$ and hence $|K(\Sigma)|=2 \cdot 3^{f}$. From this fact and from $K^{\Sigma} \cong A G L_{1}(9)$, it results that the preimage $P$ in $K$ of $Z_{3} \times Z_{3}$ is $Q: Z_{2}$, where $Q$ a Sylow 3-subgroup of $K$. Moreover, the Frattini's argument implies $K=N_{K}(Q) P$ and hence $K=Q: J$, where $J$ is a Sylow 2-subgroup of $K$. Finally, $J \cong Z_{16}$, since $J$ is of order 16 and since $G_{x_{i}}^{\Delta_{i}} \cong Z_{3 j} \times Z_{16}$ by (1).
(6). $Q$ is abelian.

Suppose the contrary. Then $j=1$ and hence $Q$ is extraspecial. If there is an element $\phi$ in $Q$ of order 9. Then Fix $\left(\phi^{2}\right) \neq 1$, since $V=V_{4}(7)$. Then $K$ preserves Fix $\left(\phi^{2}\right)$, since $\left\langle\phi^{2}\right\rangle=Z(Q)$, whereas $K$ acts irreducibly on $V$ by (4), since $K=G / C=H$. Thus $Q$ is of exponent 3 . Now $Z(Q) \leqslant K(\Sigma)$, since $K^{\Sigma} \cong A G L_{1}(9)$, therefore $Z(Q)$ preserves each $\Delta_{i}$ in $\Sigma$ and hence it normalizes $V\left(\Delta_{i}\right)$. Then $Z(Q)$ is a reducible subgroup of $G L_{4}(7)$. Then $Q$ is reducible by [19, Theorem 3.4.1]. Then either $V=X_{1} \oplus X_{2} \oplus X_{3} \oplus X_{4}$, where $X_{s}, s=1,2,3,4$, is a $Q$-invariant 1-dimensional subspace of $V$, and $K \leqslant G L_{1}(7) 乙 S_{4}$, or $V=Y_{1} \oplus Y_{2}$, where $Y_{1}, Y_{2}$ are $Q$-invariant

2-dimensional subspaces of $V$, and $K \leqslant G L_{2}(7)$ 亿 $Z_{2}$. In each case there is a $Q$ invariant subspace of $V$ fixed pointwise by a non trivial normal subgroup of $Q$, since the order of $Q$ is $3^{3}$. Also such a group contains $Z(Q)$. So $F i x(Z(Q))$ is a $H$-invariant subspace of $V$ of dimension at least 1 , since $Z(Q) \unlhd K$, and we reach a contradiction since $K$ acts irreducibly on $V$. Thus $Q$ is abelian.

## (7). The final contradiction.

$Q$ acts reducibly on $V$ by [19, Theorem 3.2.3], since $Z_{3} \times Z_{3} \leqslant Q$, hence $K$ acts transitively on a $Q$-invariant decomposition of $V$ in subspaces of equal dimension by [19, Theorem 3.4.1], since $K$ acts irreducibly on $V$. Therefore either $K \leqslant G L_{1}(7)$ 亿 $S_{4}$ or $K \leqslant G L_{2}(7)$ \{ $Z_{2}$. However the former does not contain cyclic subgroups of order 16. Hence, $K \leqslant G L_{2}(7) \imath Z_{2}$ and $Q=\langle\alpha\rangle \times\langle\beta\rangle \times\langle\gamma\rangle$, where $o(\alpha)=3^{j}$ and $o(\beta)=o(\gamma)=3$. Also $\alpha \in Z(K)$, whereas $N_{K}(\langle\delta\rangle) \cong Z_{3}: Z_{4}$ for each $\delta \in Q \backslash\langle\alpha\rangle$. Let $V=V_{1} \oplus V_{2}$ be the decomposition preserved by $K$. Clearly $J_{V_{1}} \cong Z_{8}$ acts faithfully on $V_{1}$, since $J \cong Z_{16}$ switches $V_{1}$ and $V_{2}$. Also $Q$ preserves $V_{1}$ and $Q\left(V_{1}\right) \neq$ 1. If $Q\left(V_{1}\right)$ is of order 9 , then $Q\left(V_{1}\right) \cap Q\left(V_{2}\right) \neq 1$ since $Q \unlhd K$, the order of $Q$ is $3^{2+f}$, with $f \leqslant 1$, and since $K$ switches $V_{1}$ and $V_{2}$. However, this is impossible since it contradicts Lemma $3.6(2)$. Thus $Q\left(V_{1}\right)$ is of order 3 and hence $\left(Z_{3} \times Z_{3}\right): Z_{8} \leqslant$ $K_{V_{1}}^{V_{1}} \leqslant G L_{2}(7)$, which is also impossible. So this case is ruled out and the proof is completed.
5.2. $G^{\Sigma}$ is an almost simple group. In this subsection we assume that $\operatorname{Soc}\left(G^{\Sigma}\right)$ is a non-abelian simple group.

Proposition 5.12. One of the following holds:
I. $p^{m}=4$ and $\mathcal{D}$ is isomorphic to one of the four 2-(96, 20,4) designs constructed in [28].
II. $p^{m}=9$ and $G^{\Sigma} \cong P S L_{2}(11), M_{11}$.
III. $p^{m}=16$ and $G^{\Sigma} \cong P S L_{2}(17)$.

Proof. Suppose that $G^{\Sigma}$ is almost simple and let $S=\operatorname{Soc}\left(G_{\Sigma}^{\Sigma}\right)$. Since $G^{\Sigma}$ acts 2 transitively on $\Sigma$, and $|\Sigma|=p^{m}+2$, by [24, Section 2,(A)] one of the following holds:
(1) $S \cong A_{p^{m}+2}$ and $p^{m} \geqslant 3$;
(2) $S \cong P S L_{h}(u)$, with $h \geqslant 2,(h, u) \neq(2,2),(2,3)$ and $\frac{u^{h}-1}{u-1}=p^{m}+2$;
(3) $S \cong P S U_{3}(u)$, with $u \neq 2$ and $u^{3}+1=p^{m}+2$;
(4) $S \cong S z\left(2^{2 t+1}\right)$, with $t \geqslant 1$, and $2^{4 t+2}+1=p^{m}+2$;
(5) $S \cong{ }^{2} G_{2}\left(3^{2 t+1}\right)^{\prime}$, with $t \geqslant 1$, and $3^{6 t+3}+1=p^{m}+2$;
(6) $S \cong S p_{2 n}(2)$, with $n \geqslant 3$, and $2^{2 n-1} \pm 2^{n-1}=p^{m}+2$;
(7) $S \cong P S L_{2}(11), M_{11}$ and $p^{m}=9$;
(8) $S \cong A_{7}$ and $p^{m}=13$.

Assume that (1) occurs. Let $\Delta_{i} \in \Sigma$ and $x_{i} \in \Delta_{i}$, then $A_{p^{m}+1} \unlhd G_{\Delta_{i}}^{\Sigma} \leqslant S_{p^{m}+1}$ and hence a quotient group of $G_{x_{i}}^{\Delta_{i}}$ contains $A_{p^{m}+1}$ by Corollary 3.10. On the other hand, by Theorem [3.4] one of the following holds:
(i) $G_{x_{i}}^{\Delta_{i}} \leqslant \Gamma L_{2}\left(p^{m}\right)$;
(ii) $G_{x_{i}}^{\Delta_{i}} \leqslant\left(Q_{8} \circ D_{8}\right) \cdot S_{5}$ and $p^{m}=9$;
(iii) $G_{x_{i}}^{\Delta_{i}} \cong S L_{2}(13)$ and $p^{m}=27$;
(iv) $G_{x_{i}}^{\Delta_{i}} \leqslant\left(Z_{p^{m / 3}-1} \times S U_{3}\left(p^{m / 3}\right)\right) \cdot Z_{2 m / 3}$, with $m \equiv 0(\bmod 3)$.
(v) $G_{x_{i}}^{\Delta_{i}} \leqslant \Gamma S p_{4}\left(p^{m / 2}\right)$, with $m$ even.
(iv) $S z\left(2^{m / 2}\right) \unlhd G_{x_{i}}^{\Delta_{i}} \leqslant\left(Z_{2^{m / 2}-1} \times S z\left(2^{m / 2}\right)\right) . Z_{m / 2}$, with $m \equiv 2(\bmod 4)$;
(vii) $G_{2}\left(2^{m / 3}\right)^{\prime} \unlhd G_{x_{i}}^{\Delta_{i}} \leqslant\left(Z_{2^{m / 3}-1} \times G_{2}\left(2^{m / 3}\right)\right) . Z_{m / 3}$, with $m \equiv 0(\bmod 3)$.

Cases (i)-(viii) bring together some of the automorphism groups of the 2-designs listed in Theorem 3.4. For instance, $\Gamma L_{2}\left(p^{m}\right)$ contains $G_{x_{i}}^{\Delta_{i}}$ when this one is as in (2.a.i) or in (2.c.i) of Theorem [3.4, $\left(Q_{8} \circ D_{8}\right) . S_{5}$ contains $G_{x_{i}}^{\Delta_{i}}$ when this one is as in (2.b.iii) or in (2.c.vi) and the group in case (vii) contains the groups in (2.c.v) and for $q=2$ (2.c.vii) (the non solvable case) of Theorem 3.4.

It is easy to check that only groups in (i) for $p^{m}=2,3,4,5$ and in (vi) admit a quotient group containing $A_{p^{m}+1}$ as a normal subgroup. Actually, $p^{m} \neq 2$ by Lemma [2.5, and $p^{m} \neq 5$ since $A_{6}$ occurs only in (i) for $p^{m}=9$ and in (vi) for $p^{m}=4$. If $p^{m}=3$, then $G$ is solvable by [38] and also this case is ruled out. Thus $p^{m}=4$ and hence the assertion (I) follows from [28].

Assume that (2) occurs. Thus $\left[u^{h-1}\right]: S L_{h-1}(u) \unlhd G_{\Delta_{i}}^{\Sigma}$ (e.g. see [26, Proposition 4.1.17(II)]) and hence a quotient group of $G_{x_{i}}^{\Delta_{i}}$ contains $\left[u^{f(h-1)}\right]: S L_{h-1}\left(u^{f}\right)$ as a normal subgroup by Corollary 3.10. This is clearly impossible for $h \geqslant 3$, hence $h=2$. Then $u^{f}=p^{m}+1$. By [41, B1.1] either $\left(p^{m}, u^{f}\right)=\left(2^{3}, 3^{2}\right)$, or $f=1, p=2$ and $u$ is a Fermat prime, or $m=1, u=2$ and $p$ is a Mersenne prime. In each case $G_{\Delta_{i}}^{\Sigma}$ contains a normal Frobenius group of order $\left(p^{m}+1\right) \frac{p^{m}}{\left(p^{m}, 2\right)}$, with kernel of order $p^{m}+1$ and complement of order $\frac{p^{m}}{\left(p^{m}, 2\right)}$. Since a quotient group of $G_{x_{i}}^{\Delta_{i}}$ is isomorphic to $G_{\Delta_{i}}^{\Sigma}$ by Corollary 3.10, it follows that only $G_{x_{i}}^{\Delta_{i}}$ as in (i) is admissible. Moreover, either $\mathcal{D}_{i} \cong A G_{2}\left(p^{m}\right)$, where $p^{m}$ is either 8 , or $2^{2^{e}}$ with $e \geqslant 1$, or a Fermat prime, or $\mathcal{D}_{i}$ is as in (2.b), or $\mathcal{D}_{i}$ is as in (2.c.i) of Theorem 3.4. Assume that the former occurs. Then either $G_{x_{i}}^{\Delta_{i}} \leqslant \Gamma L_{1}\left(p^{2 m}\right)$, or $S L_{2}\left(p^{m}\right) \unlhd G_{x_{i}}^{\Delta_{i}}$, or $p^{m}=5$ and $S L_{2}(3) \unlhd G_{x_{i}}^{\Delta_{i}}$ by [15, 31]. If $S L_{2}\left(p^{m}\right) \unlhd G_{x_{i}}^{\Delta_{i}}$, then $\left(p^{m}+1\right) \frac{p^{m}}{\left(p^{m}, 2\right)}$ divides [ $\Gamma L_{2}\left(p^{m}\right): S L_{2}\left(p^{m}\right)$ ], and hence $\left(p^{m}-1\right) m$, since a quotient group of $G_{x_{i}}^{\Delta_{i}}$ contains a normal Frobenius group of order $\left(p^{m}+1\right) \frac{p^{m}}{\left(p^{m}, 2\right)}$. This is clearly is impossible. Case (2.c.i) of Theorem 3.4 is ruled out by the previous argument, since $S L_{2}\left(p^{m}\right) \unlhd G_{x_{i}}^{\Delta_{i}} \leqslant\left(Z_{q^{m / 2}-1} \circ S L_{2}\left(p^{m}\right)\right) . Z_{m}$. Finally, case $p^{m}=5$ and $S L_{2}(3) \unlhd G_{x_{i}}^{\Delta_{i}}$ is ruled out similarly. Thus $G_{x_{i}}^{\Delta_{i}} \leqslant \Gamma L_{1}\left(p^{2 m}\right)$ and hence $\left(p^{m}+1\right) \frac{p^{m}}{\left(p^{m}, 2\right)}$ divides the order of $\Gamma L_{1}\left(p^{2 m}\right)$. Then $\left.\frac{p^{m}}{\left(p^{m}, 2\right)} \right\rvert\, 2 m$ and hence $p^{m}=4,16$, since $p^{m} \geqslant 3$ by Lemma 2.5. We reach the same conclusion if $\mathcal{D}_{i}$ is either as in (2.b) of Theorem [3.4, since $G_{x_{i}}^{\Delta_{i}} \leqslant \Gamma L_{1}\left(p^{2 m}\right)$ in this case. Hence, $p^{m}=4,16$ in each case. If $p^{m}=4$, then $A_{5} \unlhd G^{\Sigma} \leqslant S_{5}$ and hence the assertion (I) follows from [28.

Assume that $p^{m}=16$. Then $P S L_{2}(17) \unlhd G^{\Sigma} \leqslant P G L_{2}(17)$. If $G^{\Sigma} \cong P G L_{2}(17)$, then a quotient group of $G_{x_{i}}^{\Delta_{i}}$ is isomorphic to to Frobenius group of order 17•16. However, this is impossible since $G_{x_{i}}^{\Delta_{i}} \leqslant \Gamma L_{1}\left(2^{8}\right)$. Thus $G^{\Sigma} \cong P S L_{2}(17)$, which is (III).

Cases (3), (4) and (5) yield an equation of type $u^{i}=p^{m}+1$, with $i=3,2,3$ respectively. Only (4) is admissible with $m=1$ and $u=2$ by [41, B1.1(2)], however it is ruled out since $u \neq 2$ in (4). Case (6) cannot occur, since $2^{2 n-1} \pm 2^{n-1}=p^{m}+2$ with $n \geqslant 3$ has no solutions. In (7), $G^{\Sigma} \cong P S L_{2}(11), M_{11}$ by 8 and hence (II) holds.

Finally, assume that (8) occurs. Then $G^{\Sigma} \cong A_{7}$ by [8]. Moreover $\mathcal{D}_{i} \cong A G_{2}(13)$ and $G_{x_{i}}^{\Delta_{i}} \leqslant G L_{2}(13)$ by Theorem 3.4. On the other hand, a quotient group of $G_{x_{i}}^{\Delta_{i}}$
contains $P S L_{2}(7)$ by Corollary 3.10, since $P S L_{2}(7) \unlhd G_{\Delta_{i}}^{\Sigma}$, being $|\Sigma|=15$, and we reach a contradiction. This completes the proof.

Theorem 5.13. If $G^{\Sigma}$ is almost simple, then $p^{m}=4$ and $\mathcal{D}$ is isomorphic to one of the four 2-(96, 20, 4) designs constructed in [28].

Proof. Assume that Case (II) of Proposition 5.12 occurs. Then $H$ is an irreducible subgroup of $G L_{8+t}(2)$, with $t \leqslant 8$, by Lemma 5.1. Moreover, a quotient group of $H$ is isomorphic either to $P S L_{2}(11)$ or to $M_{11}$, since $C \leqslant G(\Sigma)$ by Theorem 4.3. From [5, Tables 8.18-8.19, 8.25-8.26, 8.35-8.36, 8.44-8.45], it follows that either $H=G^{\Sigma}$ and $t=1,2$, or $H \cong S L_{2}(11)<Z_{2} . M_{12}$ for $t=2$. However, the action of $H$ on $V_{4+t}(3)$ is irreducible only for $t=1$ by [47]. Therefore $G(\Sigma)=C$ and hence $G(\Sigma)_{x}^{\Delta}=1$ for $\Delta \in \Sigma$ and $x \in \Delta$. It follows that $G_{\Delta}^{\Sigma} \cong G_{x}^{\Delta}$ by (3.1) of Corollary 3.10. Thus $G(\Sigma)_{x}^{\Delta}$ is isomorphic either to $A_{5}$ or to $P \Sigma L_{2}(9)$ according to whether $H$ is isomorphic to $P S L_{2}(11)$ or $M_{11}$ respectively by [8]. On the other hand, $G_{x}^{\Delta}$ is contained in one of the groups $\Gamma L_{2}(9), G S p_{4}(3)$, or $\left(D_{8} \circ Q_{8}\right) \cdot S_{5}$ according to whether either one of (2.a.i) or (2.c.i), or (2.c.iii), or one of (2.a.iii) or (2.c.vi) occurs, respectively, by Theorem [3.4, since $p^{m}=9$ and $G_{x}^{\Delta}$ is non-solvable. However, none of these groups contains $A_{5}$ or $P \Sigma L_{2}(9)$ (see [5, Tables 8.13-8.13]) and hence Case (II) is ruled out.

Assume that Case (III) occurs. Then $H$ is an irreducible subgroup of $G L_{8+t}(2)$, with $t \leqslant 8$, by Lemma 5.1. Moreover, a quotient group of $H$ is isomorphic to $P S L_{2}(17)$, since $C \leqslant G(\Sigma)$ by Theorem4.3. If $t<8$, then $t=0$ and $H \cong P S L_{2}(17)$ by [1, Theorem 3.1], since $\Phi_{8}^{*}(2)=17$ divides the order of $H$. Thus $|G|=2^{12} \cdot 3^{2} \cdot 17$ and hence $\left|G_{x}\right|=2^{3} \cdot 17$ since $v=2^{9} \cdot 3^{2}$. Then this case is excluded since $k=2^{4} \cdot 17$ does not divide the order of $G_{x}$. Therefore $t=8$ and hence $C=V$ by Proposition 3.8(3). It is easy to verify that $H$ is not a geometric subgroup of $G L_{16}(2)$ by using [26, Section 4]. Thus $H$ is a nearly simple subgroup of $G L_{16}(2)$ and hence $H \cong P S L_{2}(17)$ by 47.

Let $Q$ be a Sylow 17 -subgroup $G$. Simple computations with the aid of GAP [18] show that $Q$ preserves a decomposition of $V=V_{1} \oplus V_{2}$, where $V_{1}$ and $V_{2}$ are the unique $Q$-invariant proper subspaces of $V$. Moreover, $V_{1}^{H}$ and $V_{2}^{H}$ are two distinct orbits each of length 18 , and $\left|V_{2} \cap V_{1}^{\eta}\right|=2^{3}$ for each $\eta \in H \backslash H_{V_{1}}$ and $\left|V_{1} \cap V_{2}^{\sigma}\right|=2^{3}$ for each $\sigma \in H \backslash H_{V_{2}}$.

The group $Q$ fixes a point $x$ of $\mathcal{D}$, since $v=2^{17} \cdot 3^{2}$. Thus $Q$ preserves the unique element $\Delta$ of $\Sigma$ containing $x$ and hence normalizes $V(\Delta)$, being $V_{x}=V(\Delta)$. Then $V_{x}$ is either $V_{1}$ or $V_{2}$, as $V_{1}$ and $V_{2}$ are the unique $Q$-invariant proper subspaces of $V$. Dualizing, $Q$ preserves a block $B$ of $\mathcal{D}$ and hence also $V_{B}$ is either $V_{1}$ or $V_{2}$. Actually, $\left(V_{x}, V_{B}\right)$ is either $\left(V_{1}, V_{2}\right)$ or $\left(V_{2}, V_{1}\right)$, since $\left[G_{B}: G_{B, x}\right]=2^{4} \cdot 17$ and since $G_{x} / V_{x} \cong G_{B} / V_{B} \cong F_{136}$. In particular, $x$ and $B$ are the unique point and block of $\mathcal{D}$ fixed by $Q$ respectively. Moreover, $|B \cap \Delta|=0$ and $|B \cap \Delta|=2^{4}$ for each $\Delta^{\prime} \in \Sigma \backslash\{\Delta\}$, since $Q$ acts regularly on $\Sigma \backslash\{\Delta\}$.

Assume that $\left(V_{x}, V_{B}\right)=\left(V_{1}, V_{2}\right)$. Then $V_{1}^{H}=\left\{V\left(\Delta^{\prime}\right): \Delta^{\prime} \in \Sigma\right\}$ and hence $\left|V_{B} \cap V\left(\Delta^{\prime}\right)\right|=2^{3}$ for each $\Delta^{\prime} \in \Sigma \backslash\{\Delta\}$. On the contrary, $V_{B}=V_{B \cap \Delta^{\prime}}$ and hence $\left|V_{B} \cap V\left(\Delta^{\prime}\right)\right|=2^{4}$ for each $\Delta^{\prime} \in \Sigma \backslash\{\Delta\}$, since $V_{B}$ preserves each element of $\Sigma \backslash\{\Delta\}$ and since $\left|V_{B}\right|=2^{8}$ and $\left|B \cap \Delta^{\prime}\right|=2^{4}$. So, we obtain a contradiction and hence this case is excluded. The case $\left(V_{x}, V_{B}\right)=\left(V_{2}, V_{1}\right)$ is ruled out similarly, and the proof is thus completed.

## 6. The case where $\mathcal{D}$ is of type 2

In this section we assume that $\mathcal{D}$ is of type 2 . Hence $\mathcal{D}$ is a symmetric 2$\left((\lambda+6) \frac{\lambda^{2}+4 \lambda-1}{4}, \lambda \frac{\lambda+5}{2}, \lambda\right)$ design, with $\lambda \equiv 1,3(\bmod 6)$ admitting a flag-transitive automorphism group $G$ preserving a partition $\Sigma$ of the point set of $\mathcal{D}$ in $\frac{\lambda^{2}+4 \lambda-1}{4}$ classes each of size $\lambda+6$. Then $\mathcal{D}_{i}$ is a $2-(\lambda+6,3, \lambda / \theta)$ design, with $\theta \mid \lambda$, admitting $G_{\Delta_{i}}^{\Delta_{i}}$ as a flag-transitive, point-primitive automorphism group for each $i=1, \ldots, \frac{\lambda^{2}+4 \lambda-1}{4}$ by Theorem 2.4. Our aim is to prove the following result and hence completing the proof of Theorem 1.1.

Theorem 6.1. If $\mathcal{D}$ is of type 2 , then $\mathcal{D}$ is isomorphic to the $2-(45,12,3)$ design constructed in [38, Construction 4.2].

Our starting point is the following theorem which classifies $\mathcal{D}_{i}$. It is an application of Theorem 7.1 whose statement and proof are the content of the Appendix of the present paper.

Theorem 6.2. Let $\mathcal{D}_{i}$ be a $2-(\lambda+6,3, \lambda / \theta)$-design, with $\lambda \equiv 1,3(\bmod 6)$ and $\lambda \geqslant 3$, admitting a flag-transitive automorphism group $G_{\Delta_{i}}^{\Delta_{i}}$. Then $G_{\Delta_{i}}^{\Delta_{i}}$ acts point2 -transitively on $\mathcal{D}_{i}$, and one of the following holds:
(1) $\mathcal{D}_{i}$ is a $2-\left(\frac{q^{h}-1}{q-1}, 3, q-1\right)$ design, $q$ is even, $\frac{q^{h}-1}{q-1} \equiv 0,1(\bmod 3), q-1 \mid h-6$, $\theta=\frac{q^{h}-6 q+5}{(q-1)^{2}}$ and one of the following holds:
(a) $P S L_{h}(q) \unlhd G_{\Delta_{i}}^{\Delta_{i}} \leqslant P \Gamma L_{h}(q)$.
(b) $G_{\Delta_{i}}^{\Delta_{i}} \cong A_{7}$ and $(h, q)=(4,2)$.
(2) $\mathcal{D}_{i}$ is a $2-(31,3,25)$ design, $\theta=1$ and $P S L_{3}(5) \unlhd G_{\Delta_{i}}^{\Delta_{i}} \leqslant P G L_{3}(5)$.
(3) $\mathcal{D}_{i} \cong A G_{h}(3), h \geqslant 2, \lambda=\theta=3^{h}-6$ and $G_{\Delta_{i}}^{\Delta_{i}}$ is of affine type.

Recall that a group is called quasiprimitive if each of its non-trivial normal subgroups is transitive. More information on quasiprimitive groups can be found in [39].

Lemma 6.3. If $G_{\Delta_{i}}^{\Delta_{i}}$ is almost simple then $G$ is quasiprimitive.
Proof. Suppose the contrary. Then there is a minimal normal subgroup of $G$ such that the $G$-invariant partition $\Sigma$ is the orbit decomposition of the point set of $\mathcal{D}$ under $N$ by Lemma 2.7. Then $N_{\Delta_{i}}^{\Delta_{i}}$ is a normal subgroup of $G_{\Delta_{i}}^{\Delta_{i}}$ acting transitively on $\Delta_{i}$ for each $i=1, \ldots, \frac{\lambda^{2}+4 \lambda-1}{4}$. Then $\operatorname{Soc}\left(G_{\Delta_{i}}^{\Delta_{i}}\right) \unlhd N_{\Delta_{i}}^{\Delta_{i}} \unlhd G_{\Delta_{i}}^{\Delta_{i}}$ by [13, Theorem 4.3B(iii)], since $\operatorname{Soc}\left(G_{\Delta_{i}}^{\Delta_{i}}\right)$ is non-abelian simple. Then $N_{\Delta_{i}}^{\Delta_{i}}$ acts point 2-transitively on $\mathcal{D}_{i}$ by Theorem [6.2, and hence $\mathcal{D}_{i}^{\prime}=\left(\Delta_{i},\left(B \cap \Delta_{i}\right)^{N_{\Delta_{i}}}\right)$, where $B$ is any block of $\mathcal{D}$ such that $B \cap \Delta_{i} \neq \varnothing$, is a flag-transitive, point 2-transitive $2-\left(\lambda+6,3, \lambda^{\prime}\right)$ subdesign of $\mathcal{D}_{i}$, with $\lambda^{\prime} \left\lvert\, \frac{\lambda}{\theta}\right.$. If $\mathcal{D}_{i}^{\prime}$ is symmetric, then $\lambda+6=7$ and $\lambda^{\prime}=\lambda=1$, since $b=\frac{(\lambda+6)(\lambda+5)}{6} \lambda^{\prime}$, whereas $\lambda \geqslant 3$ by Lemma [2.5. Thus $\mathcal{D}_{i}^{\prime}$ is non-symmetric and hence $\left|\left(B \cap \Delta_{i}\right)^{N_{\Delta_{i}}}\right|>\lambda+6$.

Since $N_{B} \leqslant N_{B \cap \Delta_{i}}$, being $\Delta_{i}$ a $N$-orbit, it follows that $\frac{\left|N_{B \cap \Delta_{i}}\right|}{\left|N_{B}\right|}$ is an integer, and hence

$$
\left|B^{N}\right|=\frac{|N|}{\left|N_{B}\right|}=\frac{\left|N_{\Delta_{i}}\right|}{\left|N_{B \cap \Delta_{i}}\right|} \cdot \frac{\left|N_{B \cap \Delta_{i}}\right|}{\left|N_{B}\right|}=\frac{\left|N_{\Delta_{i}}^{\Delta_{i}}\right|}{\left|\left(N_{\Delta_{i}}^{\Delta_{i}}\right)_{B \cap \Delta_{i}}\right|} \cdot \frac{\left|N_{B \cap \Delta_{i}}\right|}{\left|N_{B}\right|}>(\lambda+6) \frac{\left|N_{B \cap \Delta_{i}}\right|}{\left|N_{B}\right|} .
$$

Therefore $\left|B^{N}\right|>\lambda+6$. Since $N \unlhd G$ and $G$ acts block-transitively, the block set of $\mathcal{D}$ is partitioned into $N$-orbits of equal length greater than $\lambda+6$. Then the number of block- $N$-orbits is strictly less than $\frac{\lambda^{2}+4 \lambda-1}{4}$, as $b=v=(\lambda+6) \cdot \frac{\lambda^{2}+4 \lambda-1}{4}$, but this contradicts [27, Theorem 3.3], since the number of point- $N$-orbits is $\frac{\lambda^{2}+4 \lambda-1}{4}$. Thus the lemma's statement holds.

Proposition 6.4. $\mathcal{D}_{i} \cong A G_{h}(3), h \geqslant 2, G_{\Delta_{i}}^{\Delta_{i}}$ is of affine type and $\lambda=\theta=3^{h}-6$.
Proof. Assume that $\operatorname{Soc}\left(G_{\Delta_{i}}^{\Delta_{i}}\right)$ is non-abelian simple and let $N$ be any minimal normal subgroup of $G$. The transitivity of $G$ on $\Sigma$ implies that $\operatorname{Soc}\left(G_{\Delta_{1}}^{\Delta_{1}}\right) \cong \operatorname{Soc}\left(G_{\Delta_{i}}^{\Delta_{i}}\right)$ for each $i=1, \ldots, d$, where $d=\frac{\lambda^{2}+4 \lambda-1}{4}$. Also, $\operatorname{Soc}\left(G_{\Delta_{i}}^{\Delta_{i}}\right) \unlhd N_{\Delta_{i}}^{\Delta_{i}} \unlhd G_{\Delta_{i}}^{\Delta_{i}}$ by Lemma 2.6 and by [13, Theorem 4.3B(iii)], since $N$ acts point-transitively on $\mathcal{D}$ by Lemma 6.3. Thus $N \cong \operatorname{Soc}\left(G_{\Delta_{1}}^{\Delta_{1}}\right)^{e}$ for some $e \geqslant 1$, since $N$ is a minimal normal subgroup of $G$. Moreover, $\operatorname{Soc}\left(G_{\Delta_{1}}^{\Delta_{1}}\right) \cong P S L_{h}(q)$ with $q$ even, by Theorem 6.2, since $d||N|$ by Lemma 6.3.

Let $K$ be a normal subgroup of $N$ isomorphic to $P S L_{h}(q)$. Then $\Sigma$ is partitioned into $K$-orbits of the equal length, say $\mu$, as $N$ is transitive on $\Sigma$. Note that $d=$ $\frac{\lambda^{2}-1}{4}+\lambda$ is odd, hence $K_{\Delta_{i}}$ contains a Sylow 2-subgroup of $K$. Moreover, $K_{\Delta_{i}} \neq K$ by Lemma6.3. Then $K_{\Delta_{i}}$ lies in a maximal parabolic subgroup of $K$ by Tits'Lemma (see [45, Theorem 1.6]). Thus $\left[\begin{array}{l}h \\ t\end{array}\right]_{q}$, with $1 \leqslant t \leqslant h / 2$, divides $d$ and hence

$$
\left[\begin{array}{l}
h  \tag{6.1}\\
t
\end{array}\right]_{q} \left\lvert\,\left(\frac{q^{h}-1}{q-1}\right)^{2}-8\left(\frac{q^{h}-1}{q-1}\right)+11 .\right.
$$

Assume that $q^{h}-1$ contains a $p$-primitive divisor $u$. Then $u$ divides $\left[\begin{array}{l}h \\ t\end{array}\right]_{q}$ and hence $u=11$. Then $f h \mid 10$ by [26, Proposition 5.2.15(ii)], where $q=p^{f}$. Then $(q, h)=(2,10)$ or $(4,5)$ again by Theorem 6.2. However, none of these pairs fulfills (6.1). So $q^{h}-1$ does not have primitive prime divisors and hence $(q, h)=(2,6)$ by Zsigmondy's Theorem, since $q$ is even, $h \geqslant 2$ and $(q, h) \neq(2,2)$. However, $(q, h)=(2,6)$ does not fulfill (6.1). Thus $\mathcal{D}_{i} \cong A G_{h}(3), h \geqslant 2, G_{\Delta_{i}}^{\Delta_{i}}$ is of affine type and $\lambda=\theta=3^{h}-6$ by Theorem 6.2.

Proof of Theorem 6.1. $\mathcal{D}_{i} \cong A G_{h}(3), h \geqslant 2, G_{\Delta_{i}}^{\Delta_{i}}$ is of affine type and $\lambda=\theta=3^{h}-6$ by Proposition 6.4. Let $x_{i} \in \Delta_{i}$ and $x_{j} \in \Delta_{j}$, with $i \neq j$. Then $x_{i} \neq x_{j}$ and hence there are $\lambda$ distinct blocks, say $B_{1}, \ldots, B_{\lambda}$, incident with them. For each $t=1, \ldots, \lambda$, let $B_{t}^{(s)}$, where $s=1, \ldots, \lambda$, be the distinct blocks of $\mathcal{D}$ overlapping with $B_{t}$ on $\Delta_{i}$ including $B_{t}$, since $\theta=\lambda$. It is clear that $B_{t_{1}}^{\left(s_{1}\right)}=B_{t_{2}}^{\left(s_{2}\right)}$ if, and only if, $t_{1}=t_{2}$ and $s_{1}=s_{2}$. Then $B_{t}^{(s)}$, where $t, s=1, \ldots, \lambda$, are $\lambda^{2}$ distinct blocks of $\mathcal{D}$ incident with
$x_{i}$. Thus $\lambda^{2} \leqslant r$ and hence $3 \leqslant \lambda \leqslant \frac{\lambda+5}{2}$. Therefore, $\lambda=\theta=3$ and $h=2$, as $\lambda=\theta=3^{h}-6$ and $h \geqslant 2$. The assertion now follows from [38, Corollary 1.2].

Now, Theorem 1.1 follows from Theorems 3.1 and 6.1

## 7. Appendix

The aim of this section is to prove the following classification theorem for flagtransitive $2-(v, 3, \lambda)$ designs with $v \equiv 1,3(\bmod 6)$ and $\lambda \mid v-6$. An application of this result is Theorem 6.2, which is central in classifying symmetric 2-designs of type 2 .

Theorem 7.1. Let $\mathcal{D}$ be a $2-(v, 3, \lambda)$-design, with $v \equiv 1,3(\bmod 6)$ and $\lambda \mid v-6$, admitting a flag-transitive automorphism group $G$. Then $G$ acts point-2-transitively on $\mathcal{D}$, and one of the following holds:
(1) $\mathcal{D}$ is a $2-\left(\frac{q^{h}-1}{q-1}, 3, q-1\right)$ design, $q$ even, $\frac{q^{h}-1}{q-1} \equiv 0,1(\bmod 3), q-1 \mid h-6$, and one of he following holds:
(a) $P S L_{h}(q) \unlhd G \leqslant P \Gamma L_{h}(q)$.
(b) $G \cong A_{7}$ and $(h, q)=(4,2)$.
(2) $\mathcal{D}$ is a 2-(31,3,25) design and $P S L_{3}(5) \unlhd G \leqslant P G L_{3}(5)$.
(3) $\mathcal{D} \cong A G_{h}(3), h \geqslant 2$, and $G$ is of affine type.

As it can been deduced from the proof following propositions, the 2-designs in (1) and (2) do exist. Indeed, their point set is that of $P G_{h-1}(q)$, where $h=3$ in (2), and their block sets consist of all 3 -subsets of collinear points and non-collinear points of $P G_{h-1}(q)$ respectively.

Lemma 7.2. If $\mathcal{D}$ is a $2-(v, 3, \lambda)$ design, with $v \equiv 1,3(\bmod 6)$ and $\lambda \mid v-6$, admitting a flag-transitive automorphism group $G$, then one the following holds:
(1) $G$ acts point-2-transitively on $\mathcal{D}$.
(2) $G$ is a point-primitive rank 3 automorphism group of $\mathcal{D}$. For any point $x$ of $\mathcal{D}$ the set $\mathcal{P}-\{x\}$ is split into two $G_{x}$-orbits each of length $(v-1) / 2$. Moreover $r / \lambda=(v-1) / 2$.

Proof. Since $(v-1, k-1) \leqslant 2$, either (1) or the first part of (2) holds by [22, Corollary 4.6]. Hence, it remains to prove $r / \lambda=(v-1) / 2$.
Assume that the first part of (2) occurs. Let $y_{j}^{G_{x}}, j=1,2$, be the two $G_{x}$-orbits partitioning $\mathcal{P}-\{x\}$ and let $B$ any block of $\mathcal{D}$ incident with $x$. Then $\left|B \cap y_{j}^{G_{x}}\right|=1$ for each $j=1,2$, since $G$ is flag-transitive and $k=3$. On the other hand, $\left(y_{j}^{G_{x}}, B^{G_{x}}\right)$ is a tactical configuration for each $j=1,2$ by [10, 1.2.6]. Thus $\left|y_{j}^{G_{x}}\right| \lambda=r\left|B \cap y_{j}^{G_{x}}\right|$ and hence $r / \lambda=(v-1) / 2$, since $\left|y_{j}^{G_{x}}\right|=(v-1) / 2$ and $\left|B \cap y_{j}^{G_{x}}\right|=1$ for each $j=1,2$.

Proposition 7.3. $G$ acts point-2-transitively on $\mathcal{D}$.
Proof. Assume that (2) of Lemma 7.2 holds. By the O'nan-Scott Theorem (e.g. see [13]), one of the following holds:
(1) $S \times S \unlhd G \leqslant S \imath Z_{2}$, where $\operatorname{Soc}(S)$ is a 2-transitive non-abelian simple group of degree $n_{0}, n_{0} \geqslant 5$, and $v=n_{0}^{2}$.
(2) $\operatorname{Soc}(G)$ is non-abelian simple.
(3) $\operatorname{Soc}(G)$ is an elementary abelian $p$-group for some prime $p$.

The groups in (1) are classified in [6], those in (2) are determined in [2] when the socle is alternating, in [23] when the socle is classical, in 30] when the socle is an exceptional group of Lie type or a sporadic group. Finally, the groups in (3) are classified in [14, 17, 29].

In (1) the $G_{x}$-orbits on $\mathcal{P}-\{x\}$ have length $2\left(n_{0}-1\right)$ and $\left(n_{0}-1\right)^{2}$, and these are distinct as $n_{0} \geqslant 5$, so this case cannot occur. It is straightforward to check that $A_{7} \unlhd G \leqslant S_{7}$ and $v=21$ is the unique admissible case arising from (2) (see [2, 23, 30]. An overview of the subdegrees for $G$ is provided in [11]). Then $\mathcal{D}$ is a $2-(21,3, \lambda)$, with $\lambda \mid 15$. Actually $\lambda=3$, since $r=10 \lambda$ must divide the order of $G$, and since $\lambda=1$ is ruled out in [9]. By [8], if $x$ is any point of $\mathcal{D}$, either $G_{x} \cong S_{5}$ or $G_{x} \cong S_{5} \times Z_{2}$ according to whether $G \cong A_{7}$ or $S_{7}$ respectively. Hence either $\left|G_{x, B}\right|=4$ or $\left|G_{x, B}\right|=8$, respectively, where $B$ is any block of $\mathcal{D}$ incident with $x$. Moreover, $G_{x, B}=G(B)$, since $B$ contains exactly one point from each $G_{x}$-orbit. However, this is impossible, since $G_{x, y} \cong S_{3}$ or $S_{3} \times Z_{2}$ for any point of $y$ distinct from $x$ according to whether $G \cong A_{7}$ or $S_{7}$ respectively.

Finally, assume that $G$ is as in (3). Then the admissible groups listed below arise by [29, Tables 12-14], by [14, Theorem 1.1 and subsequent Remark] and by [17, Corollary 1.3 and Theorems 3.10 and 5.3]:
(i). $G_{0} \leqslant \Gamma L_{1}\left(p^{d}\right)$;
(ii). $G_{0} \leqslant N_{G L_{2}(7)}\left(Q_{8}\right)$ and the non-trivial $G_{0}$-orbits have length 24 ;
(iii). $G_{0} \leqslant N_{G L_{2}(23)}\left(Q_{8}\right)$ and the non-trivial $G_{0}$-orbits have length 264 ;
(iv). $G_{0} \leqslant N_{G L_{2}(47)}\left(Q_{8}\right)$ and the non-trivial $G_{0}$-orbits have length 1104;
(v). $S L_{2}(5) \unlhd G_{0}$ acting on $V_{4}(3)$ and the non-trivial $G_{0}$-orbits have length 40.

Clearly, $-1 \in G_{0}$ in (v). Also in (ii)-(iv) $-1 \in G_{0}$, since $4\left|\left|G_{0} \cap S L_{h}(q)\right|\right.$ for $(h, q)=(2,7)$ or $(2,23)$, and since the Sylow 2-subgroups of $S L_{2}(q)$ for $q$ odd are generalized quaternion groups with -1 as their unique involution. Finally, if $G_{0}$ is as in (i), then $G_{0}=\left\langle\bar{\omega}^{t}, \bar{\omega}^{e} \bar{\alpha}^{s}\right\rangle$, where $\omega$ is a primitive element of $G F(q), \bar{\omega}: x \rightarrow \omega x$, $\bar{\alpha}: x \rightarrow x^{p}$, and where $t, e, s$ satisfy the constraints given in [17, Theorem 3.10]. Moreover $p$ is odd, as $v=p^{d}$ and $(v-1) / 2$ is an integer. Arguing as in [4, Lemma 63], we see that $-1 \in G_{0}$. Thus $-1 \in G_{0}$ in each case.
Let $x \in \mathcal{D}, x \neq 0$, then -1 preserves the $\lambda$ blocks of $\mathcal{D}$ incident with $\pm x$. Moreover, -1 preserves at least one of them, as $\lambda$ is odd. Therefore, $B=\{0, x,-x\}$ and hence $\left|G_{0, B}\right|=2\left|G_{0, x}\right|$. Thus $r=\left[G_{0}: G_{0, B}\right]=\frac{\left|G_{0}\right|}{2\left|G_{0, x}\right|}=\frac{p^{d}-1}{4}$, with $p^{d} \equiv 1(\bmod 4)$, whereas $r=\frac{p^{d}-1}{2} \lambda$. Thus (i)-(v) are excluded, and hence $G$ acts point- 2 -transitively on $\mathcal{D}$ by Lemma 7.2.

Theorem 7.4. If $G$ is almost simple, then one of the following holds:
(1) $\mathcal{D}$ is a $2-\left(\frac{q^{h}-1}{q-1}, 3, q-1\right)$ design, $q$ is even, $\frac{q^{h}-1}{q-1} \equiv 0,1(\bmod 3), q-1 \mid h-6$, and one of he following holds:
(a) $P S L_{h}(q) \unlhd G \leqslant P \Gamma L_{h}(q)$;
(b) $G \cong A_{7}$ and $(h, q)=(4,2)$.
(2) $\mathcal{D}$ is a 2- $(31,3,25)$ design and $P S L_{3}(5) \unlhd G \leqslant P G L_{3}(5)$.

Proof. Assume that $G$ is an almost simple, point-2-transitive automorphism group of $\mathcal{D}$. Then $G$ is listed in [24, Section 2 , (A)]. Moreover, $v \equiv 1,3(\bmod 6)$. Thus, one of the following holds:
(i). $\operatorname{Soc}(G) \cong A_{v}$ and $\lambda \mid v-6, v \equiv 1,3(\bmod 6)$;
(ii). $\operatorname{Soc}(G) \cong P S L_{h}(q), h \geqslant 2, \frac{q^{h}-1}{q-1} \equiv 1,3(\bmod 6)$ and $(h, q) \neq(2,2)$, and $\lambda \left\lvert\, \frac{q^{h}-1}{q-1}-6\right.$;
(iii). $\operatorname{Soc}(G) \cong P S U_{3}\left(2^{2 m+1}\right), m>0$, and $\lambda \mid 2^{6 m+3}-5$;
(iv). $S o c(G) \cong A_{7}$ and $\lambda \mid 9$.

If $G$ acts point-3-transitively on $\mathcal{D}$, then $v-2=\lambda \leqslant v-6$, and we reach a contradiction. Thus $G$ cannot act point-3-transitively on $\mathcal{D}$ and hence (i) is ruled out.

Assume that (ii) holds. If $h=2$, then the point-2-transitive actions of $G$ on $\mathcal{D}$ and on $P G_{1}(q)$ are equivalent. Hence, we may identify the point set of $\mathcal{D}$ with that of $P G_{1}(q)$. Also $q$ is even, since $v=q+1$ and $v \equiv 1,3(\bmod 6)$. Then $G$ acts point3 -transitively on $\mathcal{D}$, which is not the case. Thus $h>2$ and hence $\operatorname{Soc}(G)$ has two 2 -transitive permutation representations of degree $\frac{q^{h}-1}{q-1}$. These are the one on the set of points of $P G_{h-1}(q)$, and the other on the set of hyperplanes of $P G_{h-1}(q)$. The two conjugacy classes in $P S L_{h}(q)$ (resp. in $P \Gamma L_{h}(q)$ ) of the point-stabilizers and hyperplane-stabilizers are fused by a polarity of $P G_{h-1}(q)$. Thus, we may identify the point set of $\mathcal{D}$ with that of $P G_{h-1}(q)$.

Assume that $B=\{x, y, z\}$ is contained in a line $\ell$ of $P G_{h-1}(q)$. Then each block of $\mathcal{D}$ is contained in a unique line of $P G_{h-1}(q)$, being $G$ transitive one the block set of $\mathcal{D}$ as well as on the line set of $P G_{h-1}(q)$. Moreover, $\lambda=q-1$, since $G_{\ell}^{\ell} \cong P G L_{2}(q)$ acts 3 -transitively on $\ell$. Since $\lambda \mid v-6$ and since $v=\frac{q^{h}-1}{q-1}$, it follows that

$$
(q-1) \mid \sum_{i=0}^{h-1}\left(q^{i}-1\right)+h-6
$$

Therefore, $q-1 \mid h-6$. If $q$ is odd then $h$ is even, whereas $\frac{q^{h}-1}{q-1}$ is odd. Thus $q$ is even and (1a) follows.

Assume that $B=\{x, y, z\}$ consists of non-collinear points of $P G_{h-1}(q)$. Then there is a plane containing $B$, say $\pi$. Let $\ell^{\prime}$ be the line of $P G_{h-1}(q)$ containing $x$ and $y$, and let $\mathcal{F}$ be the plane pencil with axis $\ell^{\prime}$. Then the blocks of $\mathcal{D}$ containing $x, y$ are triangles of $P G_{h-1}(q)$ with the third vertex contained in a (unique) plane of $\mathcal{F}$. By [26, Proposition 4.1.17(II)], $\left[q^{2(h-2)}\right]: S L_{h-2}(q) \leqslant G_{x, y} \leqslant G_{\ell^{\prime}}$, where $\left[q^{2(h-2)}\right]$ fixes $\ell^{\prime}$ pointwise and induces the translation group on the affine plane $\pi^{\ell^{\prime}}$ for each $\pi \in \mathcal{F}$, and $S L_{h-2}(q)$ fixes $\ell^{\prime}$ pointwise and permutes transitively the elements of $\mathcal{F}$. Therefore $G_{x, y}$ acts transitively one the set of all triangles of $P G_{h-1}(q)$ having $x, y$ as two of the three vertices, hence

$$
\lambda=q^{2}\left[\begin{array}{l}
h-2 \\
3-2
\end{array}\right]_{q}=q^{2} \frac{q^{h-2}-1}{q-1}
$$

It follows from $\lambda \mid v-6$ that

$$
\left.q^{2} \frac{q^{h-2}-1}{q-1} \right\rvert\, \frac{q^{h}-1}{q-1}-6
$$

and hence $h=3$ and $q=5$. Thus we obtain (2).

Assume that (iii) holds. Then the action of $G$ on the point set of $\mathcal{D}$ and that on the point set of the Hermitian unital $\mathcal{H}\left(2^{2 m+1}\right)$ are equivalent. Thus we may identify the point set of $\mathcal{D}$ with that of $\mathcal{H}\left(2^{2 m+1}\right)$.
If $B=\{x, y, z\}$ is contained in a line $\ell^{\prime}$ of $\mathcal{H}\left(2^{2 m+1}\right)$, then each block of $\mathcal{D}$ is contained in a unique line of $\mathcal{H}\left(2^{2 m+1}\right)$, being $G$ transitive on the block set of $\mathcal{D}$ as well as on the line set of $\mathcal{H}\left(2^{2 m+1}\right)$. Thus $\lambda=2^{2 m+1}-1$, since $\operatorname{Soc}(G)_{\ell^{\prime}}^{\ell^{\prime}} \cong P G L_{2}(q)$ acts 3 -transitively on $\ell^{\prime}$. So $2^{2 m+1}-1 \mid 2^{6 m+3}-5$, as $\lambda \mid v-6$, which is a contradiction.

Assume that $B=\{x, y, z\}$ consists of points of $\mathcal{H}\left(2^{2 m+1}\right)$ in a triangular configuration. Note that $\operatorname{Soc}(G)_{x}=Q: C$, where $Q$ is a Sylow 2-subgroup of $\operatorname{Soc}(G)$ acting regularly on $\mathcal{H}\left(2^{2 m+1}\right) \backslash\{x\}$, and $C$ is a cyclic group of order $2^{2(2 m+1)}-1$. If $a$ is any line of $\mathcal{H}\left(2^{2 m+1}\right)$ incident with $x$, then $Z(Q)$ preserves $a$ and acts regularly on $a \backslash\{x\}$. Also, $Q / Z(Q): C$ is a Frobenius group of order $2^{2(2 m+1)}\left(2^{2(2 m+1)}-1\right)$ acting 2 -transitively on the set of lines of $\mathcal{H}\left(2^{2 m+1}\right)$ incident with $x$ (e.g. see [20, Satz II.10.12]). Thus $C=\operatorname{Soc}(G)_{x, y}$ acts semiregularly on $\mathcal{H}\left(2^{2 m+1}\right) \backslash s$, where $s$ is the line incident with $x, y$, and hence each $G_{x, y}$-orbit in $\mathcal{H}\left(2^{2 m+1}\right) \backslash s$ is of length a multiple $2^{4 m+2}-1$. It follows that the number of blocks of $\mathcal{D}$ incident with $x, y$ is a multiple of $2^{4 m+2}-1$. Therefore $2^{4 m+2}-1 \mid \lambda$, and hence $2^{4 m+2}-1 \mid 2^{6 m+3}-5$, as $\lambda \mid v-6$ and $v=2^{6 m+3}+1$, which is a contradiction. So, (iii) cannot occur.

In (iv) the action of $\operatorname{Soc}(G) \cong A_{7}$ on the point set of $\mathcal{D}$ is equivalent to one of the two 2-transitive permutation representations of degree 15 , namely the ones on the set of points and on the set of planes of $P G_{3}(2)$ respectively. Arguing as in (1), we may identify the points $\mathcal{D}$ with the points of $P G_{3}(2)$. By [47], $G \cong A_{7}, G_{x} \cong S L_{3}(2)$ and $G_{x, y} \cong A_{4}$. Thus $T \leqslant G(B)$, where $T \cong E_{4}$ and $B$ is a block of $\mathcal{D}$ incident with the points $x, y$, since $\lambda \mid 9$. Since $N_{G_{x}}(T) \cong S_{4}$ and $G_{x, y} \cong A_{4}$, it follows that $T$ fixes exactly two points on $P G_{3}(2) \backslash\{x\}$ and these are necessarily collinear with $x$ (clearly $y$ is one of these). Thus $B$ is a line of $P G_{3}(2)$ and hence $\mathcal{D} \cong P G_{3}(2)$, which is (1b).

Theorem 7.5. If $G$ is of affine type, then $\mathcal{D} \cong A G_{h}(3)$.
Proof. Assume that $\operatorname{Soc}(G)$ is an elementary abelian $p$-group for some prime $p$ and denote it by $T$. Since $G$ acts point-2-transitively on $\mathcal{D}$, we may identify the point set of $\mathcal{D}$ with a $h$-dimensional $G F(p)$-space $V$ in a way that $T$ is the translation group of $V$ and $G=T: G_{0}$, with $G_{0}$ acting irreducibly on $V$.
For each divisor $n$ of $h$ the group $\Gamma L_{n}\left(p^{h / n}\right)$ has a natural irreducible action on $V$. As $G_{0}$ acts irreducibly on $V$, we may choose $n$ to be minimal such that $G_{0} \leqslant \Gamma L_{n}\left(p^{h / n}\right)$ in this action and write $q=p^{h / n}$. Also $q$ is odd, since $v=q^{n}-6$ and $v \equiv 1,3$ $(\bmod 6)$.
Let $B$ be any block of $\mathcal{D}$ incident with 0 . Assume that $B$ is not contained in any 1-dimensional $G F(p)$-subspace of $V$. Suppose that $-1 \in G_{0}$. If $x$ is a point of $\mathcal{D}$ and $x \neq 0$, it follows that -1 preserves the $\lambda$ blocks incident with $\pm x$. Actually, -1 preserves at least one of them since $\lambda$ is odd. Thus $B=\{0, x,-x\} \subseteq\langle x\rangle_{G F(p)}$, as $k=3$, but this contradicts our assumption. Therefore $-1 \notin G_{0}$, and hence $S L_{n}(q) \unlhd G_{0}$, with $n$ odd and $n \geqslant 3$, by [24, Section 2, (B)] and by [3, Lemma 3.12].

Assume that $B \subseteq\langle u\rangle_{G F(q)}$ for some non-zero vector $u$ of $V$. Then any block of $\mathcal{D}$ is contained in a unique line of $A G_{n}(q)$, since $G$ acts block-transitively on $\mathcal{D}$ and transitively on the line set of $A G_{n}(q)$. In particular the $\lambda$ blocks of $\mathcal{D}$ incident with
$\pm u$ are contained in $\langle u\rangle_{G F(q)}$. Since $A G L_{1}(q) \unlhd G_{\langle u\rangle_{G F(q)}}^{\langle u\rangle_{G(q)}}$ and $q$ is odd, there is a 2-element $\phi$ in $G_{0,\langle u\rangle_{G F(q)}}$ inducing -1 on $\langle u\rangle_{G F(q)}$. Therefore, $\phi$ preserves at least one of the $\lambda$ blocks incident with $\pm u$, say $B^{\prime}$, since $\lambda$ is odd. Hence $B^{\prime}=\{0, u,-u\}$, as $B^{\prime} \subseteq\langle u\rangle_{G F(q)}$. So, $B$ is contained in a 1-dimensional $G F(p)$-subspace of $V$, since $G$ acts-flag-transitively on $\mathcal{D}$, which is contrary to our assumption.
Assume that $B$ is not contained in any 1-dimensional $G F(q)$-subspace of $V$. Nevertheless, $B \subset \pi$ where $\pi$ is a 2-dimensional $G F(q)$-subspace of $V$. Thus $r=\left[\begin{array}{c}n \\ 2\end{array}\right]_{q} \mu$, where $\mu$ denotes the number of blocks of $\mathcal{D}$ contained in any 2-dimensional $G F(q)$ subspace of $V$, since $G$ acts flag-transitively on $\mathcal{D}$ and since $S L_{n}(q) \unlhd G_{0}$ acts transitively on the set of 2-dimensional $G F(q)$-subspaces of $V$. Therefore

$$
\left[\begin{array}{l}
n  \tag{7.1}\\
2
\end{array}\right]_{q} \mu=\frac{q^{n}-1}{2} \lambda,
$$

and hence

$$
\left.\frac{\left(q^{n}-1\right)\left(q^{n-1}-1\right)}{\left(q^{2}-1\right)(q-1)} \right\rvert\, \frac{\left(q^{n}-1\right)\left(q^{n}-6\right)}{2},
$$

since $\lambda \mid q^{n}-6$. Thus $2\left(q^{n-1}-1\right) \mid\left(q^{2}-1\right)(q-1)(q-6)$ and hence $n=3$, since $n$ is odd and $n \geqslant 3$. Now substituting $n=3$ in (7.1), it results $\lambda=\frac{2 \mu}{q-1}$. So, $\mu$ is odd as $\lambda \mid q^{n}-6$ and $q$ is odd.
Lastly, $S L_{3}(q)$ contains an involution $\sigma$ inducing -1 on $\pi$. Then $\sigma$ preserves at least one of the $\mu$ blocks of $\mathcal{D}$ contained in $\pi$, say $B^{\prime \prime}$, since $\mu$ is odd. Then $B^{\prime \prime}=\{0, y,-y\}$ for some non-zero $y$ in $\pi$, since $k=3$ and $\sigma$ induces -1 on $\pi$. Hence $B=\left\{0, y^{\beta},-y^{\beta}\right\}$ for some $\beta \in G_{0}$, since $G$ is flag-transitive on $\mathcal{D}$, but this contradicts our assumption. Assume that $B \subseteq\langle u\rangle_{G F(p)}$ for some non-zero vector $u$ of $V$. Then $G_{B} \leqslant G_{\langle u\rangle}$ and hence $S_{3} \cong\left(G_{B}\right)^{\langle u\rangle} \leqslant G_{\langle u\rangle}^{\langle u\rangle} \cong A G L_{1}(p)$, since $G$ acts 2-transitively on $V$. Thus $p=3, B=\langle u\rangle_{G F(3)}$ and hence the assertion follows.

Now, Theorem 7.1 follows from Proposition 7.3 and Theorems 7.4 and 7.5 , Finally, Theorem 6.1 follows from Theorem 7.1 .
