A REMARK ON DEFORMATIONS OF 1**-CONVEX MANIFOLDS WITH EXCEPTIONAL CURVES**

SZ-SHENG WANG

ABSTRACT. A formula for the dimension of the smoothing component of a 3-dimensional isolated Cohen–Macaulay singularity is shown. We apply this formula for a 1-convex threefold with a connected exceptional curve which is blown down to a terminal Gorenstein singularity.

1. INTRODUCTION

An *n*-dimensional complex manifold *X* is called a 1*-convex* (or strongly pseudoconvex) *n*-fold if there is a proper surjective morphism *π* from *X* onto a Stein space *V* with $\pi_* \mathcal{O}_X \cong \mathcal{O}_V$ and a finite subset $\Sigma \subseteq V$ such that $X \setminus E \to V \setminus \Sigma$ is biholomorphic where $E = \pi^{-1}(\Sigma)$. We call *E* the *exceptional set* and π : $(X, E) \rightarrow (V, \Sigma)$ the *Remmert reduction*.

In [\[17,](#page-8-0) Theorem 2], Laufer proved that if *X* is a 1-convex manifold with a 1-dimensional exceptional set *E* then it has (the germ of) the miniversal deformation space $Def(X)$. It is a natural question to ask for a formula for the dimension of Def(*X*).

We may assume without loss of generality that the curve *E* is connected, i.e., $\Sigma = \{p\}$ and thus the germ (V, p) is an isolated singularity. In the case of surfaces, Stephen Yau gave a formula of dim Def(*X*) in [\[30,](#page-9-0) Theorem 3.1] for an isolated hypersurface singularity (*V*, *p*) and Wahl in [\[27,](#page-9-1) Theorem 3.13 (c)] for a smoothable, normal surface singularity.

In the present note, we will generalize the results of [\[27,](#page-9-1) [30\]](#page-9-0). The main result of this note is Theorem [3.1](#page-6-0) in Section [3](#page-6-1) for a 3-dimensional isolated Cohen–Macaulay singularity which is smoothable. As an application, we derive a formula of dim Def(*X*) for a certain 1-convex threefold *X*:

Theorem 1.1. *Let X be a* 1*-convex threefold with a connected exceptional curve E*, and π : $(X, E) \rightarrow (V, p)$ the Remmert reduction as above. If K_X is π -trivial, *then*

$$
\dim \text{Def}(X) = \tau - \frac{\mu + \sigma}{2}
$$

where μ (*resp.* τ) is the Milnor (*resp.* Tjurina) number of the singularity (V , p) *and* σ *is the rank of the local divisor class group* $Cl(\mathcal{O}_{V,p})$ *.*

Key words and phrases. Deformation of singularities, 1-convex manifolds, Small resolutions, Cohen–Macaulay singularities.

2 S.-S. WANG

Here the canonical divisor K_X is said to be π -trivial if the intersection number of *K^X* with every irreducible component of *E* is zero. In such a case, the exceptional curve *E* blows down to a terminal Gorenstein singularity, so to an isolated cDV (compound Du Val) singularity [\[22\]](#page-9-2). We remark that in general (*V*, *p*) need not even be Cohen–Macaulay (see for example [\[1,](#page-8-1) p.626 (1)-(4)] and [\[2,](#page-8-2) Example 3.2]).

We will relate dim $Def(X)$ to Du Bois invariants $b^{r,s}(V,p)$ of the rational isolated hypersurface singularity (V, p) , which were introduced in [\[24\]](#page-9-3) (see [§2.1\)](#page-2-0).

Corollary 1.2. *Under the hypotheses of Theorem [1.1,](#page-0-0) the dimension of* Def(*X*) *is equal to* $b^{2,1}(V, p)$ *. Moreover, the following are equivalent:*

- *(1) The* (*V*, *p*) *is an ordinary double point.*
- *(2)* dim $Def(V) = dim Def(X) + 1$ *.*
- (3) $b^{1,1}(V, p) = 0$.
- (4) $b^{2,1}(V, p) = 0$.

The conditions [\(2\)](#page-1-0) and [\(3\)](#page-1-1) occur in the deformation theory of singular Calabi–Yau threefolds (see [\[11,](#page-8-3) Lemma 3.6] and [\[20,](#page-8-4) Theorem 2.2]), and the condition [\(4\)](#page-1-2) was studied in [\[25,](#page-9-4) Theorem 5.4, Remark 5.12]. There are similar results in [\[8,](#page-8-5) §3] (see Remark [3.4\)](#page-8-6).

We close this introduction with a few remarks on the techniques used in this paper. We will compare the Euler characteristics on the smoothing and the resolution (see Proposition [2.8](#page-4-0) and [2.12\)](#page-5-0) by using a globalization property of smoothings, proved by Looijenga [\[19\]](#page-8-7). Then we derive a formula of dim Def(*X*) for a 1-convex *n*-fold with a connected exceptional curve (cf. Remark [2.9\)](#page-4-1). It can be computed in principle by the Riemann–Roch theorem.

The Riemann–Roch defect for isolated singularities has been studied in [\[19,](#page-8-7) §3]. However, the scissor relation (c) in the proof of [\[19,](#page-8-7) Theorem 3.3] only holds for certain singularities (see Remark [3.3\)](#page-7-0). Fortunately, the theorem of Riemann–Roch on threefolds is easy to compute (see Proposition [3.2\)](#page-6-2). Based on the method of Laufer, Wahl and Looijenga [\[19,](#page-8-7) [27\]](#page-9-1), we will apply the Riemann–Roch formula to prove our results (see [§3\)](#page-6-1).

Acknowledgements. The author is greatly indebted to Prof. E. Looijenga for answering the author's questions and Prof. Chen-Yu Chi for many useful discussions. The author thanks Shing-Tung Yau Center of Southeast University and Institute of Mathematics at Academia Sinica for providing support and a stimulating environment, and was supported by the Fundamental Research Funds for the Central Universities 2242020R10048 and partially supported by the Ministry of Science and Technology (MOST) grant 110-2811-M-001-530.

2. PRELIMINARIES

2.1. **Du Bois invariants.** We start by recalling the setup from [\[24\]](#page-9-3). Let $(Y, D) \rightarrow (V, p)$ be a good resolution of an isolated singularity (V, p) of pure dimension *n*, i.e., *D* is a divisor with simple normal crossings on *Y*. We fix a representative $Y \rightarrow V$ with *V* a contractible Stein space.

Steenbrink defined invariants *b ^r*,*^s* of (*V*, *p*), called the *Du Bois invariants* (see [\[24,](#page-9-3) §2]), by

$$
b^{r,s}(V,p) \coloneqq \dim H^s(Y,\Omega^r_Y(\log D)(-D))
$$

for $r \geq 0$ and $s \geq 1$. These invariants do not depend on the choice of the good resolution, as they can be defined in terms of the filtered de Rham complex ([\[5\]](#page-8-8), [\[23,](#page-9-5) (3.5)]).

There are another invariants of (V, p) , defined in [\[24,](#page-9-3) §3]. By [\[23,](#page-9-5) Theorem 1.9], there is a mixed Hodge structure on $H^k(V\setminus\{p\})\cong H^{k+1}_{\{p\}}$ $\binom{k+1}{\{p\}}(V)$. The Hodge filtration *F* on the local cohomology $H_{\ell,n}^{k+1}$ $\binom{k+1}{\{p\}}(V)$ arises from a spectral sequence

$$
(2.1) \tE_1^{pq} = H^q(D, \Omega_Y^p(\log D) \otimes \mathcal{O}_D) \Rightarrow H_{\{p\}}^{p+q+1}(V, \mathbb{C})
$$

which degenerates at the *E*1-term. Therefore its Hodge filtration defines invariants $l^{r,s}$ of the singularity (V, p) by $l^{r,s} := \dim E_1^{s,r}$ $\frac{s}{1}$.

The following proposition follows from Lemma 2, Theorem 4 and 6 in [\[24\]](#page-9-3). Note that the isolated rational singularity (V, p) is Du Bois, i.e., $b^{0,s} =$ 0 for $0 < s < n$ (see [\[23,](#page-9-5) (3.7)]).

Proposition 2.1. *Let* (*V*, *p*) *be a 3-dimensional, rational isolated hypersurface singularity. Then*

$$
\tau = b^{2,1} + b^{1,1} + l^{1,1}
$$
 and $\mu = 2b^{1,1} + l^{1,1}$.

We remark that the main results in [\[24\]](#page-9-3) express the Tjurina and Milnor numbers of certain isolated singularities in terms of Du Bois invariants *b r*,*s* and $l^{r,s}$. We state the proposition above considering such hypersurfaces for simplicity, which is all we need in the proof of Corollary [1.2.](#page-1-3)

Let $\sigma(V, p)$ denote the rank of the local divisor class group $Cl(\mathcal{O}_{V,p})$, i.e.,

$$
\sigma(V, p) = \text{rank}(\text{Weil}(V, p) / \text{Cart}(V, p)),
$$

where Weil(*V*, *p*) is the Abelian group of Weil (resp. Cartier) divisors of the singularity (V, p) . It is a finite number if (V, p) is a rational singularity (see [\[16,](#page-8-9) Lemma 1.12]).

Proposition 2.2. *If* (*V*, *p*) *is a 3-dimensional, rational isolated hypersurface singularity, then* $\sigma(V, p) = l^{1,1}(V, p)$ *.*

Proof. Recall that $l^{1,1}(V,p) = \dim \mathrm{Gr}_{F}^{1}H_{\{p\}}^{3}(V,\mathbb{C})$ is defined by the spectral sequence [\(2.1\)](#page-2-1). Since (V, p) is rational, we have $l^{0,i} = l^{i,0} = 0$ for all *i* by [\[24,](#page-9-3) Lemma 2] and in particular $E_{\infty}^{02} = E_{\infty}^{20} = 0$. Hence we get $H_{\{p\}}^3(V, \mathbb{C}) = 0$ $\mathrm{Gr}_{F}^{1}H_{\{p\}}^{3}(V,\mathbb{C}).$ Then the proposition follows from the fact that $\sigma(V,p)$ = dim $H^2(V \setminus \{p\}, \mathbb{C})$ (see [\[6,](#page-8-10) (6.1)] or the proof of [\[20,](#page-8-4) Proposition 3.10]). \Box

Remark 2.3. Let $\pi: X \to V$ be a resolution of a 3-dimensional rational isolated singularity (V, p) . If the exceptional set *E* of π has dimension 1, then the number of irreducible components of *E* equals $\sigma(V, p)$ (cf. [\[16,](#page-8-9) Lemma 3.4] and [\[28,](#page-9-6) Remark 2.8, 2.10]).

2.2. **The Riemann–Roch defect.** Let (V, p) be an isolated normal singularity of pure dimension $n \geq 2$ which is smoothable.

Let $f: \mathcal{V} \to \Delta \subseteq \mathbb{C}$ be a good representative of a smoothing of $V =$ *V*0. According to a globalization theorem of Looijenga [\[19,](#page-8-7) Appendix], it follows that *f* is a restriction of a projective flat family $F: \mathscr{Z} \to \Delta$ which is smooth outside the point $\{p\}$. We wirte *Z* for the fiber Z_0 and Z_t , $t \neq 0$, for non-singular fiber. Let *S* be the smoothing component on which the smoothing \tilde{f} : $\mathscr{V} \to \Delta$ takes place and $\beta_f \coloneqq \dim S$ (cf. [\[27,](#page-9-1) (4.1)]).

The following lemma is known in [\[27,](#page-9-1) (3.8)], and we recall the argument for the convenience of the reader.

Lemma 2.4. *With the above hypothesis and notation, for* $t \neq 0$ *we have*

$$
\chi(\Theta_Z) = \chi(\Theta_{Z_t}) + \beta_f.
$$

Proof. By a conjecture of Wahl proved by Greuel and Looijenga [\[10,](#page-8-11) (2.6)], we have

(2.2)
$$
\beta_f = \dim_{\mathbb{C}} \text{Coker}(\Theta_{\mathscr{Z}/\Delta,p} \otimes \mathcal{O}_{Z,p} \to \Theta_{Z,p}).
$$

Note that the natural morphism is injective because the sheaf of relative derivations $\Theta_{\mathscr{Z}/\Delta}$ has depth ≥ 2 . Since $\Theta_{\mathscr{Z}/\Delta}$ is flat over Δ and induces Θ_{Z_t} for $t \neq 0$, the lemma follows from the additivity of the Euler characteristic and the fact that the function $\chi(\Theta_{\mathscr{Z}/\Delta} \otimes \mathcal{O}_{Z_t})$ is constant on $t \in \Delta$ [\[3,](#page-8-12) III, Theorem 4.12].

Remark 2.5*.* If (*V*, *p*) is an isolated complete intersection singularity, then it is unobstructed. Hence $β_f$ is the Tjurina number $τ$ of (V, p) , which is independent of the smoothing *f* .

Notation 2.6. Let $\pi: X \to V$ be any resolution of the singularity (V, p) . By *gluing the resolution π and the identity map of Z* \ {*p*}*, we get a resolution* $\Pi: \widehat{Z} \to Z$.

The following lemma will be useful in the sequel.

Lemma 2.7. Let \hat{Z} and Π be as in Notation [2.6.](#page-3-0) For a coherent sheaf $\mathcal F$ on \hat{Z} , we *have*

$$
\chi(\mathscr{F}) = \chi(\Pi_*\mathscr{F}) + \sum_{1 \leq i \leq n-1} (-1)^i \dim(R^i \Pi_*\mathscr{F})_p.
$$

Proof. Notice that $R^i\Pi_*\mathscr{F}$ is supported on the point $\{p\}$ for $i > 0$. The lemma follows from the Leray spectral sequence for Π and \mathscr{F} .

We recall the notion of equivariant resolutions (in the sense of Hironaka). A resolution $\pi: X \to V$ is called *equivariant* if the natural injection $\pi_* \Theta_X \hookrightarrow$ Θ*^V* is an isomorphism. Note that such resolutions always exists (see [\[13\]](#page-8-13) or [\[15,](#page-8-14) p.14]).

Proposition 2.8. *With the above hypothesis and Notation [2.6,](#page-3-0) we assume that* π *is equivariant. Then, for* $t \neq 0$ *we have*

$$
\chi(\Theta_{Z_t}) - \chi(\Theta_{\widehat{Z}}) = \sum_{1 \leq i \leq n-1} (-1)^{i-1} h^i(\Theta_X) - \beta_f,
$$

 \mathcal{C} *and* $h^i(\Theta_\text{X})=0$ *for all* $i>r$ *if the resolution* π *has relative dimension* $\leqslant r.$

Here and subsequently, $h^i(\mathscr{F})$ denotes the dimension of $H^i(X,\mathscr{F})$ for a coherent sheaf $\mathscr F$ on *X*.

Proof. We apply Lemma [2.7](#page-3-1) to $\mathscr{F} = \Theta_{\widehat{Z}}$, and replace $(R^i \Pi_* \Theta_{\widehat{Z}})_p$ by $h^i(\Theta_X)$ because *V* is Stein. The first assertion follows from the fact that Π is equivariant and Lemma [2.4](#page-3-2) and the second assertion from the theorem on for-mal functions [\[3,](#page-8-12) III, Theorem 3.1]. \Box

Remark 2.9*.* Let *X* be a 1-convex *n*-fold with 1-dimensional exceptional set. By [\[17,](#page-8-0) Theorem 2], the miniversal deformation space Def(*X*) is smooth of \dim ension $h^1(\Theta_X)$. It is also known that the Remmert reduction $\pi\colon X\to V$ is equivariant (cf. [\[7,](#page-8-15) (3.1)]). If *V* has a smoothing $f: \mathcal{V} \to \Delta$, then by Proposition [2.8](#page-4-0) we get

$$
\dim \mathrm{Def}(X) = \chi(\Theta_{Z_t}) - \chi(\Theta_{\widehat{Z}}) + \beta_f.
$$

For $n = 2$, this was given in [\[27,](#page-9-1) (3.10.3)].

Let *F* be the Milnor fiber of the smoothing $f: \mathcal{V} \to \Delta$, i.e., it is the fiber of the topological fiber bundle $f: \mathcal{V} \setminus V \to \Delta \setminus \{0\}$. The middle Betti number $b_n(F)$ of *F* of the smoothing *f* is called the *Milnor number* μ_f of *f*. If we write *E* for the exceptional fiber $\Pi^{-1}(p)$, then the difference of topological Euler characteristics *χ*top of *E* and *F* equals the global topological defect (see [\[27,](#page-9-1) $(3.5.3)$]),

(2.3)
$$
\chi_{\text{top}}(F) - \chi_{\text{top}}(E) = \chi_{\text{top}}(Z_t) - \chi_{\text{top}}(\widehat{Z}).
$$

We remark that if the isolated singularity (V, p) is a complete intersection then μ_f depends only on the singularity. In this case, we denote it by $\mu(V, p)$. Moreover, the Milnor fiber *F* is $(n-1)$ -connected (see, e.g., [\[18,](#page-8-16) (5.8)]) and there are only two non-vanishing Betti numbers $b_0(F) = 1$ and $b_n(F)$, and thus

(2.4)
$$
\chi_{top}(F) = 1 + (-1)^n \mu(V, p).
$$

2.3. **Dual of dualizing sheaves.** Keep the notation as Section [2.2.](#page-3-3) We further assume that (V, p) is Cohen–Macaulay. Then there is a relative dualizing sheaf $\omega_{\mathscr{Z}/\Lambda}$ for the globalization $\mathscr{Z} \to \Delta$ of the smoothing *f*. It is flat over the 1-dimensional disk Δ . The dual $\omega_{\mathscr{Z}/\Delta}^{\vee}$ is still torsion-free and thus flat over Δ , and induces $\omega_{Z_t}^{\vee}$ for $t \neq 0$ and an inclusion $\omega_{\mathscr{Z}/\Delta}^{\vee} \otimes \mathcal{O}_Z \hookrightarrow \omega_Z^{\vee}$.

Wahl introduced the notion of *ω*∨*-constant deformations* [\[26,](#page-9-7) (1.4)], to which the dual of the dualizing differentials lifts, and an invariant of the smoothing *f* [\[27,](#page-9-1) (3.7)],

(2.5)
$$
\alpha_f := \dim_{\mathbb{C}} \mathrm{Coker}(\omega_{\mathscr{Z}/\Delta,p}^{\vee} \otimes \mathcal{O}_{Z,p} \hookrightarrow \omega_{Z,p}^{\vee}).
$$

Note that the smoothing *f* is ω^{\vee} -constant if and only if $\alpha_f = 0$ (automatic if (V, p) is Gorenstein). By semicontinuity [\[3,](#page-8-12) III, Theorem 4.12], we get for $t \neq 0$,

(2.6)
$$
\chi(\omega_{Z_t}^{\vee}) = \chi(\omega_{\mathscr{Z}/\Delta}^{\vee} \otimes \mathcal{O}_Z) = \chi(\omega_Z^{\vee}) - \alpha_f.
$$

Next we treat the case of resolutions.

Lemma 2.10. *Under the above hypotheses, for the resolution* $\Pi: \hat{Z} \rightarrow Z$ *as in Notation* [2.6,](#page-3-0) we have a natural inclusion $\Pi_*(\omega_2^\vee) \hookrightarrow \omega_2^\vee$. Furthermore, it is an *isomorphism if the exception set of* Π *has codimension* ≥ 2 *.*

Proof. Let $E = \Pi^{-1}(p)$, and let \hat{j} : $\hat{Z} \setminus E \hookrightarrow \hat{Z}$ be the natural inclusion. Consider the exact sequence of local cohomology sheaves [\[12,](#page-8-17) Corollary 1.9]

$$
(2.7) \t 0 \to \mathscr{H}_{E}^{0}(\omega_{\hat{Z}}^{\vee}) \to \omega_{\hat{Z}}^{\vee} \to \hat{j}_{*}(\hat{j}^{*}\omega_{\hat{Z}}^{\vee}) \to \mathscr{H}_{E}^{1}(\omega_{\hat{Z}}^{\vee}) \to 0
$$

and note that $\mathscr{H}_{E}^{0}(\omega_{\hat{Z}}^{\vee}) = 0$ by a depth argument (cf. [\[12,](#page-8-17) Theorem 3.8]). Furthermore, $\mathcal{H}_E^1(\omega_{\hat{Z}}^{\vee}) = 0$ if *E* has codimension ≥ 2 .

By [\(2.7\)](#page-5-1), we have $\Pi_*(\omega_{{\hat Z}}^{\vee}) \hookrightarrow \Pi_*\hat{j}_*(\hat{j}^*\omega_{{\hat Z}}^{\vee})$. Let $U := Z \setminus \{p\}$ be the smooth locus and *j*: $U \hookrightarrow Z$ the inclusion. Then, since depth $\omega_{Z,p}^{\vee} \geq 2$, we get $\omega_Z^{\vee} \xrightarrow{\sim} j_*(\omega_U^{\vee})$ by $\mathscr{H}^i_{\{p\}}(\omega_Z^{\vee}) = 0$ for $i = 0, 1$. Thus the proposition $\text{follows from } \Pi_* \hat{j}_*(\hat{j}^* \omega_2^\vee) = j_* \Pi_*(\hat{j}^* \omega_2^\vee) = j_*(\omega_U^\vee)$). $\qquad \qquad \Box$

Remark 2.11*.* If (V, p) has dimension two and $\Pi: \hat{Z} \rightarrow Z$ is the minimal resolution, then one always has $\Pi_*(\omega_{\widehat Z}^\vee) \xrightarrow{\sim} \omega_Z^\vee$ by [\[26,](#page-9-7) (3.5)].

Proposition 2.12. *Let X,* \hat{Z} *,* π *and* Π *be as in Notation [2.6.](#page-3-0) Then we have*

$$
\chi(\omega_{Z_t}^{\vee}) - \chi(\omega_{\hat{Z}}^{\vee}) = \sum_{1 \leq i \leq n-1} (-1)^{i-1} h^i(\omega_X^{\vee}) - \alpha_f + \gamma_{\pi}
$$

 ω *ith* $\gamma_{\pi} = \dim_{\mathbb{C}} \text{Coker}(\Pi_*(\omega_{\hat{Z}}^{\vee})_p \hookrightarrow \omega_{Z,p}^{\vee}).$

Proof. By Lemma [2.10](#page-5-2) and the additivity of the Euler characteristic, we get $\chi(\omega_Z^{\vee}) = \chi(\Pi_*\omega_Z^{\vee}) + \gamma_{\pi}$. Then the corollary follows from Lemma [2.7,](#page-3-1) [\(2.6\)](#page-5-3) and that *V* is Stein. *Remark* 2.13*.* Suppose that (*V*, *p*) is a rational Gorenstein singularity, i.e., it is a canonical singularity of index 1 (cf. [\[4,](#page-8-18) (6.4), (6.8)] or [\[11,](#page-8-3) (3.3)]). In the case $\omega_X \cong \pi^* \omega_V$, we have $h^i(\omega_X^{\vee}) = 0$ for $i > 0$. Such π is called a *crepant resolution*.

Indeed, we may assume that $\omega_V \cong \mathcal{O}_V$ for the Gorenstein singularity (V, p) . Then $(R^{i}\pi_{*}\omega_{X}^{\vee})_{p} \cong (R^{i}\pi_{*}\mathcal{O}_{X})_{p} = 0$ for $i > 0$ since (V, p) is rational.

3. MAIN RESULT

Suppose from now on that (V, p) is a 3-dimensional isolated normal Cohen–Macaulay singularity with a smoothing $f: \mathcal{V} \rightarrow \Delta$. Given a resolution $\pi: X \to V$, one can define the *geometric genus* $p_g(V, p)$ of (V, p) by $h^2({\mathcal O}_X).$ It is well known that the number is independent of the resolution.

In the previous section, we have seen the invariants α_f and β_f associated the smoothing *f* , defined as in [\(2.5\)](#page-5-4) and [\(2.2\)](#page-3-4) respectively. If the resolution π is equivariant, i.e., $\pi_* \Theta_X \cong \Theta_V$, then the following main result are going to relate these invariants $α_f$ and $β_f$ with certain numbers induced by $π$. This is a generalization of [\[27,](#page-9-1) Theorem 3.13 (c)].

Theorem 3.1. With the above hypothesis and notation, we assume that π is equi*variant. Then we have*

$$
\beta_f - \alpha_f = h^1(\Theta_X) - h^2(\Theta_X) - 22p_g(V, p) - \frac{1}{2}(\chi_{\text{top}}(F) - \chi_{\text{top}}(E))
$$

$$
- (h^1(\omega_X^{\vee}) - h^2(\omega_X^{\vee})) - \gamma_\pi
$$

where E is the exceptional set of the resolution π, F the Milnor fiber of the smoothing f and $\gamma_{\pi} = h^0(\omega_V^{\vee}/\pi_*(\omega_X^{\vee})).$

Before stating the result to be proved, we need the following proposition, which follows from Hirzebruch–Riemann–Roch theorem and the observation that $\omega_M^{\vee} = \det \Theta_M$ and $\det(\Theta_M) = (1/24)c_1(\Theta_M)c_2(\Theta_M)$ (cf. [\[9,](#page-8-19) Example 15.2.5]).

Proposition 3.2. *Let M be a* 3*-dimensional compact manifold. Then we have*

$$
\chi(\Theta_M) = \chi(\omega_M^{\vee}) - 22\chi(\mathcal{O}_M) + (1/2)\chi_{\text{top}}(M).
$$

We now obtain our main result:

Proof of Theorem [3.1.](#page-6-0) We shall use the same notation as in Section [2.2.](#page-3-3) By Proposition [2.8,](#page-4-0) for $t \neq 0$, we have

$$
\chi(\Theta_{Z_t}) - \chi(\Theta_{\widehat{Z}}) = h^1(\Theta_X) - h^2(\Theta_X) - \beta_f.
$$

Applying Proposition [3.2](#page-6-2) to the left hand side gives

$$
\begin{aligned} \chi(\Theta_{Z_t}) - \chi(\Theta_{\widehat{Z}}) = & \chi(\omega_{Z_t}^{\vee}) - \chi(\omega_{\widehat{Z}}^{\vee}) - 22(\chi(\mathcal{O}_{Z_t}) - \chi(\mathcal{O}_{\widehat{Z}})) \\ & + (1/2)(\chi_{top}(Z_t) - \chi_{top}(\widehat{Z})). \end{aligned}
$$

By [\(2.3\)](#page-4-2) and Proposition [2.12,](#page-5-0) it suffices to show that

(3.1)
$$
\chi(\mathcal{O}_{Z_t}) - \chi(\mathcal{O}_{\hat{Z}}) = -p_g(V, p).
$$

8 S.-S. WANG

To do this, we notice that only $h^2(\mathcal{O}_X)$ can be non-zero for the normal Cohen–Macaulay singularity (V, p) , and $\chi(\mathcal{O}_{Z_t}) = \chi(\mathcal{O}_Z)$ by semicontinuity [\[3,](#page-8-12) III, Theorem 4.12]. Then the equality [\(3.1\)](#page-6-3) follows from Lemma [2.7,](#page-3-1) and the proof is complete.

Remark 3.3*.* Let the hypotheses be as in Theorem [3.1](#page-6-0) and *S* the smoothing component on which the smoothing *f* takes place. Our result shows that

$$
\dim S + (1/2)\chi_{top}(F) - \alpha_f
$$

is independent of *S* (and depend only on $\pi: X \to V$). In particular, if one smoothing *f* is ω^{\vee} -constant (i.e., $\alpha_f = 0$), so are all smoothings on the same irreducible component *S* (cf. [\[27,](#page-9-1) (3.14.2)]).

As a consequence, the formula in [\[19,](#page-8-7) 4.4] is not correct in general.

Theorem [3.1](#page-6-0) allows us to treat the case of certain 1-convex threefolds.

Proof of Theorem [1.1.](#page-0-0) Recall that the exceptional set *E* of the Remmert reduction $\pi: X \to V$ has dimension 1 and K_X is π -trivial. Then (V, p) is a 3dimensional Gorenstein terminal singularity (see [\[22\]](#page-9-2) or [\[4,](#page-8-18) (16.2)]). In particular, it is a rational hypersurface singularity, and $p_g(V, p) = 0$ (cf. [\[14,](#page-8-20) Corollary 4.2]). According to [\(2.5\)](#page-5-4), Lemma [2.10](#page-5-2) and Remark [2.5,](#page-3-5) it follows that $\alpha_f = \gamma_{\pi} = 0$ and β_f equals the Tjurina number τ of (V, p) for any fixed smoothing *f* .

We note that *π* is crepant since the exceptional set *E* contains no divisors. By Remark [2.9,](#page-4-1) [2.13](#page-6-4) and Theorem [3.1,](#page-6-0) we find that

$$
\dim \mathrm{Def}(X) = \tau + (1/2)(\chi_{\text{top}}(F) - \chi_{\text{top}}(E)).
$$

It remains to prove that $\chi_{top}(F) - \chi_{top}(E)$ is equal to $-(\mu + \sigma)$ where μ is the Milnor number of (V, p) and σ is the rank of $Cl(\mathcal{O}_{V, p})$. Indeed, the irreducible components of *E* are smooth rational curves, meeting transversally with no cycles [\[21,](#page-8-21) Proposition 1]. By using the Mayer–Vietoris sequence, we get the number of the irreducible components of *E* equals $\chi_{top}(E) - 1$. Hence the desired formula follows from [\(2.4\)](#page-4-3) and Remark [2.3.](#page-3-6)

Proof of Corollary [1.2.](#page-1-3) First, under the hypotheses of Theorem [1.1,](#page-0-0) we have seen that (V, p) is an isolated cDV hypersurface singularity, and also have *σ* > 0 by Remark [2.3.](#page-3-6) Observe that it is an ordinary double point if and only if $\mu = 1$; in particular, $\tau = \sigma = 1$.

By Theorem [1.1](#page-0-0) and Proposition [2.1](#page-2-2) and [2.2,](#page-2-3) we get that the dimension of Def(*X*) equals the Du bois invariant $b^{2,1}$, and the condition [\(1\)](#page-1-4) clearly implies [\(2\)](#page-1-0), [\(3\)](#page-1-1) and [\(4\)](#page-1-2).

Conversely, we can rewrite [\(2\)](#page-1-0) as $\mu + \sigma = 2$ and thus this implies [\(1\)](#page-1-4). The condition [\(3\)](#page-1-1) implies [\(1\)](#page-1-4) by [\[20,](#page-8-4) Theorem 2.2] (see also [\[24,](#page-9-3) p.1374]).

Now suppose that (*V*, *p*) is not an ordinary double point. Notice that *V* can be considered as the total space of a deformation of a Du Val surface singularity. One can find a nontrivial small deformation of *X* under which *E* splits up into a finite disjoint union of smooth copies of **P** ¹ with normal

bundle $\mathcal{O}_{\mathbb{P}^1}(-1)^{\oplus 2}$ (see [\[29,](#page-9-8) Proposition 1.1] or [\[7,](#page-8-15) p.679]). Hence we get $dim Def(X) > 0$ and complete the proof of the equivalence of [\(1\)](#page-1-4) and [\(4\)](#page-1-2). \Box

Remark 3.4*.* In [\[8,](#page-8-5) §3], Friedman and Laza proved similar results as Theorem [1.1](#page-0-0) and Corollary [1.2](#page-1-3) with a different approach.
